Long-distance movement of copper across North America is often noted by archaeologists but little studied, with its provenance typically assumed to be the Great Lakes region. Such claims need to be tested, and recent studies have approached this problem using laser-ablation instrumentation to assess chemical and lead isotopic variability. Despite the renewed focus on this topic, minimal comparative data still exist, and solution-mode approaches yielding better precision and accuracy have not been explored. This study, therefore, breaks new ground and provides preliminary findings of a solution-mode lead isotopic study of native copper artifacts from the Mill Cove Complex, a St. Johns II (AD 940–1300) civic-ceremonial center in northeastern Florida. These results provide foundational data for future copper provenance research in North America.

“Picking at the Scabs of Ancient Wounds”: The Derry Excavations Collection

The “Derry Excavations Collection” (DEC) is a legacy collection recovered during a series of late 1970s salvage excavations conducted by archaeologist Brian Lacey in the city of Derry, Northern Ireland. This project focuses on a subset of artifacts associated with a seventeenth-century “town ditch” defensive feature used during the “Great Siege,” a pivotal episode in Derry’s history that has remained a social and historical lightning rod amid Protestant/Catholic and Unionist/Loyalist sectarian conflicts. Contemporary manifestations of these conflicts have also had a formative impact on the DEC itself, both in the circumstances surrounding its excavation as well as its subsequent management and storage. This project examines the layers of human activity and conflict in both the history reflected in the artifacts as well as the DEC’s tumultuous post-excavation “taphonomy.” Guided by the contents of the collection and a thorough documentary “excavation,” I interrogate how the improvisations demanded during emergency and conflict situations may produce atypical or “difficult” archaeological results that nonetheless reflect the complex web of social negotiations that guided their path from deposition to curation and may reveal a collection to be more than the sum of its material parts.

Refining Ecological Contexts of Animal Herding: Implications for Culture Process

Previous research that derived expectations from hunter-gatherer macroecology demonstrates that the combination of effective temperature zones and setting near coastlines or very large interior lakes display distinct patterns of resource intensification. These patterns allow researchers to predict the environmental zones of early plant and animal domestication and compare these expectations with archaeological site distributions. For plant domestication, the archaeological pattern is largely as expected, but it is clear that these variables alone are not sufficient to anticipate the timing/location of animal domestication. This comparative study seeks to refine our understanding of the environmental factors contributing to early animal domestication using geographic information systems (GIS) and spatial statistics to analyze measures of seasonality of plant growth, and other important variables while identifying regional and temporal patterns that may signal a shift in subsistence strategy to animal domestication. Clarifying which seasonality measures are most associated with the locales of early animal domestication will provide additional valuable insights for the development of formal models of relationships between innovation and population dynamics across multiple types of ecosystems.

Hurricane Salvage and Public Archaeology: Preliminary Results from Data Recovery Excavations in Kisatchie National Forest of Western Louisiana

Hurricanes Laura and Delta in 2020 caused extensive tree-fall damage to more than 100 sites throughout Kisatchie National Forest, including two large precontact sites (16VN3504 and 16VN3508). 16VN3504 and 16VN3508 are multicomponent sites measuring more than 100 acres and are eligible for listing on the National Register of Historic Places. In addition to storm damage, they have been heavily impacted by looting. Excavations were conducted at these sites last spring through an agreement between the US Forest Service and the University of Louisiana at Lafayette, Louisiana Public Archaeology Lab. The excavation of 55 m³ documented high densities of artifacts and cultural features, including a large number of projectile points, at least three post molds, and activity surfaces, with cultural material extending down more than 2 m in depth. Diagnostic artifacts indicate intermittent occupation of the Pleistocene terrace overlooking Drakes Creek from the Paleoindian period (ca. 13,500–10,000 years before present) through the early twentieth century. This presentation shares the preliminary results, including an analysis of more than 30,000 artifacts representing 13 millennia of Louisiana's deep history. Mitigating historic properties damaged by hurricanes and looting also presents an opportunity for advancing public archaeology and education.

Johnson, John (Santa Barbara Museum of Natural History)**[304]***Chumash Watercraft, Maritime Exchange, and Sociopolitical Complexity*

Jeanne Arnold explored the relationship between advanced boat technology and sociopolitical complexity in her research and in many publications. She investigated the origins of the Chumash *tomol* (plank canoe) and emphasized its key role in facilitating cross-channel trade between island and mainland coastal towns. She linked the importance of maritime exchange to the Chumash islanders coming to specialize in the manufacture of shell bead currency. Arnold advanced the study of these developments both theoretically and empirically through archaeological research. She engaged in vigorous, yet informative debates with others over theoretical issues and varying interpretations of evidence. The current study builds on Arnold's and others' contributions, calling attention to ethnographic and ethnohistoric observations that shed further light on the relationships between Chumash watercraft, exchange, and sociopolitical complexity.

The mortuary site Näsiri Kolat in the Lerik region of Azerbaijan was occupied from the Antik through the Middle Islamic periods (eleventh–sixteenth centuries), a fact further supported when the site is considered with the midden site Şəğolhoni. Ceramic analysis from these sites permit us to better understand how people in the Lerik region interacted with more distant communities. This project dates each site's occupation based on the style of Islamic ceramics found at Näsiri Kolat and Şəğolhoni and creates a stylistic database relevant to ceramics excavated in the region, with specific attention to decorative methods and designs. With images of Lerik ceramics, gray literature, and comparanda drawn from publications, we have built a database of the ceramics, analyzed the stylistic features in each sherd, researched the glazes present, and isolated a chronology of Islamic occupation in Näsiri Kolat and Şəğolhoni. Though these ceramics are often excavated from disturbed and comingled contexts, these analyses will better researchers' understanding of the chronology and the kinetic social movement of communities in Central Asia. This work contributes to the rich history of Islamic art in Azerbaijan and provides further context and texture regarding analysis of Islamic ceramics.

Johnson, Lucas (Far Western Anthropological Research Group Inc.) and Lisa Johnson (University of Nevada, Las Vegas)**[164]***Household Crafting in the Maya City of Palenque, Chiapas, Mexico*

Classic period (250–900 CE) Maya economic systems were diverse with most lowland cities revealing a combination of intensive surplus crafting workshops and more domestic household crafting. Some craft production may have been centralized and occurring under the supervision of the state and others appear to be operating independently at the household level yet still within city settlement. At Palenque, this appears to be the case with some crafting occurring in the central palace district and other crafting occurring in private homes within a neighborhood context. We are still learning the extent of diversity in the types of activities that occurred in Palenque's residential groups, however as compared to other residential groups that have

been excavated in the same neighborhood, one group stands apart as a multi-crafting household. The data includes many obsidian drills and nearly 100 chert drills recovered from discrete locations. This presentation will discuss recent excavations in a Palenque neighborhood and the broader implications following a preliminary analysis of chert and obsidian flaked stone.

Return to Yarinacocha: A pXRF and Petrographic Study of Ceramics Artifacts from the Tutishcainyo Site Series (1400 BCE–900 CE), Ucayali, Peru

When Donald Lathrap excavated a series of related archaeological sites on the shores of Yarinacocha, an oxbow lake of the Central Ucayali River in the Peruvian Amazon, the elaborately decorated pottery and long-occupied sites he uncovered contradicted the prevailing narrative of the Amazon as a “counterfeit paradise” impeding the development of cultural complexity. Instead, Yarinacocha’s six ceramic phases materialize a complex culture history. Prior stylistic analysis indicates the first three ceramic phases present a roughly continuous cultural sequence (1400–200 BCE), while the later three each embody significant stylistic departures, possibly related to regional Barrancoid (ca. 200 BCE) and Arawakan (ca. 100 CE) migrations. This study assesses diachronic ceramic craft production from a technological perspective and tests the hypothesis of local clay exploitation by combining portable X-ray fluorescence (pXRF) and thin-section petrography on a representative sample ($n = 37$) from the American Museum of Natural History’s Yarinacocha collection. These combined archaeometric techniques point to the continuous exploitation of multiple clay sources, as well as significant diachronic changes in Yarinacocha’s ceramic production related to the shifting social landscape.

Applying the Index of Care to Antemortem Cranial Trauma at Bab adh-Dhra’

The Early Bronze Age II-III (EBA) at Bab adh-Dhra’ represents a period of significant social change partially marked by the establishment of a fortified town at the site. This research examines the individual and

community-wide implications of antemortem cranial depression fractures (CDFs) during this shift in socioeconomic lifestyles and population density. The Index of Care, a progression of four analytical steps utilized in bioarchaeology of care studies, was applied in the case of two individuals to determine possible brain damage and assistance required from the community after their initial cranial trauma based on the location of the CDFs and the use of Brodmann areas, a regional/functional map of the brain. Possible biological and social consequences of the injuries were determined using a combination of clinical, neurological, and archaeological data. Results determined that both individuals would have required short-term care following the initial injury. Possible long-term care would have been necessary if neurological or motor function was affected. Despite these possible impairments, both survived their initial injuries and were eventually included in the A22 charnel house at the site. This suggests that cranial trauma was an understood and accepted experience within the community of Bab adh-Dhra' during the EBA II-III.

Continuity and Discontinuity: Ritual from the Iron Age to the Early Medieval Period in Ireland

While religion in Ireland is conventionally divided into the pre-Christian Iron Age and the Christian Early Medieval period, it seems obvious that the actual transition was far more complex. The details and focus of ritual shifted in certain ways to incorporate the new beliefs, and these can be seen in the archaeology of both periods. And yet, the break was not always as clear as it might seem. While ritual practice and its underlying context of meaning may have changed, the same landscapes continued to be used and sites which were important in the Iron Age continued to have a meaning in the Early Medieval period. These issues are explored in the context of Iron Age ritual, particularly focused on the ceremonial centers sometimes known as “royal sites”—Tara, Dún Ailinne, Cruachain, and Emain Macha. While these sites ceased being centers of ritual life, they continued to have significance in the context of an otherwise increasingly Christian culture, providing insight into the ways in which changes in belief and practice were experienced and expressed in Early Medieval Ireland.

A New Twist for Ancient Maya Yarns

Ethnographic, iconographic, and archaeological records attest to the sophisticated and sumptuous textiles produced by Maya peoples in ancient and contemporary times. However, historical neglect of cordage industries in archaeology, combined with poor organic preservation and gaps in the ethnographic record, complicate attempts at a fuller reconstruction of the significance of spun and twisted yarns in ancient Maya society beyond their recognized role in cloth production. In this paper, we offer a new perspective on the cultural significance of Maya yarn production informed by iconographic analysis and a broader cross-cultural anthropological context. Our observations contribute to a heretofore unacknowledged cultural understanding of the significance of yarn production among Maya peoples with pronounced ritual, cosmological, and elite symbolic implications.

Geochemical Analysis of Felsite Quarries at Pluvial Lake Mojave

This study geochemically documents the conveyance of felsite from quarries in the Soda Mountains adjacent to pluvial Lake Mojave, California to the archaeological sites along its terminal Pleistocene-Early Holocene (TP/EH) shorelines. Prior research suggests Paleoindians conveyed toolstone to Lake Mojave from the Coso Volcanic Field and Goldstone dacite outcrops to the northwest and Shoshone Mountain obsidian to the north, but little is known of the geochemical signatures or conveyance of the good quality, locally occurring felsite. I propose that a geochemically derived sourcing model using felsite artifacts from Lake Mojave's TP/EH shoreline sites will improve my understanding of procurement strategies around Lake Mojave and across the

region. To address this, I collected geologic samples from eight distinct felsite quarries and analyzed them with a pXRF instrument. Six quarries are in the Soda Mountains on the western edge of Lake Mojave (Soda Mountains West), another in the Soda Mountains to the north (Soda Mountains North), and one on the eastern shoreline of Lake Mojave. These three collection areas have geochemically distinct signatures, including some ability to identify artifacts to specific sources in Soda Mountains West, and together can be used to geochemically distinguish locally procured felsite artifacts around Lake Mojave.

There Is Much Else that May Be Told: Lessons in Navigating Nontraditional Career Paths in Anthropology, Archaeology, and Beyond

Throughout her career, Patricia B. Richards has held many prominent positions within and adjacent to conventional academic anthropology, among them senior scientist, adjunct curator, principal investigator, and associate director of an archaeological research laboratory. While these positions have traditionally been held in different regard from the professoriate, they allowed her to forge a successful nontraditional career path well before it was widely considered a viable option. Her experiences navigating this path and the work ethic she models have influenced the teaching, advice, and mentorship she provides to her many students, preparing them for equally successful careers in a variety of anthropological professions. By framing this mentorship and support as guiding principles, this paper defines in small part the positive and wide-ranging impact Dr. Richards has made on the discipline through the paths taken by her mentees. We share these dynamic principles (and their associated anecdotes) to demonstrate their continuing influence and inspire similarly impactful mentorship.

Unearthing Potential: Using Earth Rock Ovens as a High-Impact Practice in the Undergraduate Archaeology Course

High-impact practices (HIPs) using hands-on activities, experiential learning, and collaborative learning employ methods that educators in archaeology have already been using for decades. The pedagogical push to use HIPs recently involves widespread recognition that not only do these methods work to engage students, they rock! This paper explores the use of hot rock cookery as a high-impact practice and evidence-based example of experimental archaeology for undergraduate courses. The method involves heating rocks in a small pit to generate slow heat for cooking. A simple version of the oven and the materials needed for a smaller classroom project is described, as well as a longer module with a complementary lecture and readings. Students construct the oven and cook food using local materials, while learning about its significance and archaeological evidence of hot rock cookery in prehistory. Discussion includes (1) how students gain an understanding of archaeological concepts and ancient foodways through this method; and (2) how instructors can add this activity to their archaeology courses to increase student engagement beyond traditional assignments.

Jones, Emily Lena (University of New Mexico)**[260]***Across a Threshold: The Columbian Exchange in the Land of Tiguex*

In August 1540 Hernando de Alvarado, a member of the Coronado expedition, entered what he termed “the province of Tiguex” (today known as the Middle Rio Grande Valley of Central New Mexico), kicking off several centuries of socioeconomic transformation. As a case study in the impacts of the Columbian Exchange, this region is instructive. Today, it is home to Albuquerque, New Mexico’s largest city, and the associated urban sprawl of a twenty-first-century Western city. In contrast to the broad, braided river Alvarado observed, the Rio Grande is confined to a relatively narrow channel; many of the grasslands that were so tempting to Coronado’s army have been overgrazed. Native grasses have been joined (and often out-competed) by Eurasian plants, and introduced animals dominate both environments and the diets of the people who live here. Was this a gradual process, with each step having a cumulative impact? Or was the transition more of a threshold change—an abrupt change in environmental processes and/or species composition in a formerly resilient landscape? In this paper, I use the zooarchaeological record of central New Mexico to understand how this transformation occurred and the legacies with which it has left us.

Jones, Eric (University of Colorado, Boulder), Sharon DeWitte (University of Colorado, Boulder) and Catherine Livingston (University of South Carolina)**[44]***Health and Mortality during the Transition to Commercial Dairy Farming in Nineteenth-Century Upstate New York*

We examine the relationship between farm production and strategy and the health and mortality patterns of farm families during the late nineteenth century in upstate New York. This was a time when farmers were transitioning from subsistence to commercial farming and when dairy farming was becoming the preferred strategy to increase profits. Here, we focus specifically on the Town of Fenner in Madison County. The first part of this relationship is examined through an analysis of agricultural schedules in federal and state census records from 1850 to 1880. From these data, we apply an equation to calculate surplus and perform k-means cluster analysis to determine strategies based on livestock and crop production levels. We establish health and mortality using census mortality records and obituaries and death certificates when available. We conducted a multiscalar analysis by both cross-referencing individuals in the mortality schedule with their associated farm to examine specific households and analyzing general townwide health trends in comparison to farm production and strategy trends. The results suggest that there is a complex relationship between farm production level and strategy and mortality patterns that are not as simple as more household expendable income results in better health outcomes.

Jones, Gwendolyn (University of Texas, Austin)**[311]***Chair***Jones, Gwendolyn (University of Texas, Austin)****[311]***“Children Cry For It!” An Artifact-Centered Study of Children’s Health*

Children’s impact on material culture is often ignored in archaeology, and outside of mortuary analysis, archaeological studies of children almost exclusively focus on their toys. In this paper, I consider the procurement, use, and discard of medicines from a child-centered framework. Using archaeological context, archival documents, and oral histories to establish a life cycle for items such as an intact bottle of “Bumstead’s Worm Syrup,” I explore children’s health at the turn of the twentieth century. These artifacts from Eckley Miners’ Village, a coal company town in northeastern Pennsylvania, were unearthed during CRM

surveys and excavations in 1989 and the 1990s, and I have identified several using local drugstore catalogues from the 1880s. Contemporaneous diary entries from Eckley's company store clerk and oral histories collected there in the 1970s illuminate the community's perception of children's health. This research provides insight into the daily lives of working-class children, and how their health and wellnesses impacted their families and the community as a whole.

[22]

The Afterlife of a Desert Estate: The Qasr Complex at al-Ḥumayma, Southern Jordan at the Turn of the Second Millennium AD

From 1992 to 2002, the Humayma Excavation Project investigated a fairly modest palatial structure dubbed Field F103 at the site of al-Ḥumayma in southern Jordan. Early on, the excavators recognized that this structure should be identified as the qasr and mosque complex described in Arabic historical sources as having been built at the site by the 'Abbasid family. Since then, most discussion of F103 has focused, understandably, on its status as the location where the 'Abbasids planned the revolution that led to their mid-eighth-century AD ascent to the Caliphate. Occupation continued after the 'Abbasid family's departure, however, and recent analysis of the unpublished material from these excavations has revealed that the complex was remodeled in the tenth to eleventh century AD, generally seen as a period of collapse in the region. This paper will focus on this phase of occupation at the site to piece together the processes of political and economic fragmentation that took place in the southern Levant during this transitional period and the ways local minor elites, like those occupying al-Ḥumayma, adapted to this changing political-economic landscape.

Jones, Jennifer (University of Minnesota Duluth)

Applied Projects for Teaching Archaeology: Creating an Identification Guide for Trade Axes (1600–1900) in the Western Great Lakes Region

The University of Minnesota Duluth returned to in-person teaching as the pandemic emergency waned. Modifications to an upper division Archaeological Method and Theory course were made to accommodate students with serious demands on their time from outside employment as well as potential disruptions to instruction from COVID infections. The University of Minnesota Duluth partnered with a local avocational expert to design an applied project that would incorporate a variety of quantitative and qualitative skills and appeal to both anthropology and non-anthropology majors. Over the semester, the students created and tested a chronological identification guide for iron trade axes dating to 1600–1900 from the western Great Lakes Region. The Guide is based on 200 axes held in public institutions and is intended for use by museum curators and the general public. The students presented their work at a campus research fair and wrote a 94-page report which are available publicly on the University of Minnesota Digital Conservancy. Planning for COVID interruptions, accommodating disruptive student work schedules, while simultaneously doing an applied project, required adjustments to the course schedule and assignments.

Jones, Kara (UNLV)**[237]***Geospatial Analyses of Site Distributions at Ivanpah Dry Lake*

Ivanpah Dry Lake is an overlooked Holocene and paleolake located in the eastern Mojave Desert. Much of the archaeological work done in the area has centered around industry and development with data available in gray literature site reports and records. This research is a component of the author's Master's project relating to the geospatial distribution of sites and resources at Ivanpah Dry Lake. A 2018 geological study conducted by Spaulding and Sims revealed that Ivanpah is not a Holocene Lake as previously thought, but rather a paleolake. Geospatial analyses run on 59 sites within the paleolake Ivanpah boundary revealed land use trends related to resource targeting and adaptations over time in a changing environment. These tests show that Ivanpah was used persistently over time and had evidence of use by multiple cultural groups. These results have meaningful implications considering the overlap of the study area with the intersection of two important indigenous trails, the Salt Song Trail and Southern Fox Song trail. The conclusions drawn from this research creates an argument for increased protection and preservation of the entire Ivanpah Lake region and the value of nondestructive research methods by drawing on existing data.

Jones, Lauren**[272]***Should I Measure It or Should I BLAST It? A Case for the Regular Integration of Osteoarchaeology and Ancient DNA*

Osteoarchaeology, including bioarchaeology and zooarchaeology, has been a staple in our field for decades. Now, archaeogenetics (or aDNA) has also become a staple. But how do we decide when to use one approach or the other? What provides the best data for one's research questions? Here, I present data from a study of archaeological gophers from the Hall's Cave site in central Texas. Morphological and genetic results agree on the taxonomic identification for ~90% of the study sample, but ~10% of the individuals showed disagreement at the genus level between the two methods. Modern comparative ecological data suggests that this disagreement is a result of DNA inserts that can obscure accurate taxonomic identification from short genetic fragments. Thus, caution is warranted when using single-fragment aDNA to determine the taxonomy of archaeological faunal material. The use of both morphological and genetic identification methodologies can help to resolve this type of issue and is therefore an advantageous approach to questions of taxonomic identity in the archaeological record.

Jones, Mica (School of Archaeology, University of Oxford)**[190]***Reconsidering Cattle and Power at Great Zimbabwe*

Great Zimbabwe (GZ) is key for understanding precolonial African urban systems. Cattle bones are some of the most common materials recovered from GZ and have played a central role in interpreting the ways power was enacted at the site over time. Scholars use dental wear and eruption data from cattle molars and long bone epiphyseal fusion patterns to argue that elites on the site's hilltop regularly ate prime cuts from pre-breeding age cattle, while commoners away from the hill ate less beef and of lower quality. Although these foundational studies raise interesting social questions about animals and people at GZ, most rely on data from one poorly described context excavated in the 1970s. To build a more coherent picture of meat-eating and its relationship to inequality at the site, I apply updated age-at-death and body part representation methods to cattle remains from recently excavated midden contexts across the site. Analyses are ongoing but suggest that the slaughter and consumption of entire young cows was common throughout the site's use in both "elite" and "commoner" areas. This implies that links between food and power were more complex than originally thought and possibly involved feasting activities, perhaps on a seasonal basis.

Jones, Olivia and Megan Leight (West Virginia University)**[147]***Raising Appalachia: Promoting and Fostering Academic Spaces for Undergraduate Students to Engage with Archaeology at West Virginia University*

Students studying anthropology and art history at West Virginia University (WVU) have not always had access to experiential learning and laboratory training experiences. However, recent initiatives by early career faculty have boosted student engagement and prompted career success. In this presentation, we show that forming partnerships between university academic departments and state archaeology facilities provide crucial hands-on training and opportunities for students. The WVU Archaeology Lab was founded during the height of the pandemic in 2020 with one freshman student and a box of unwashed artifacts from the West Virginia Archaeological Research and Collections Management Facility. Since then, students working in the lab have processed thousands of artifacts, presented at conferences, completed field schools, and are publishing faculty-assisted research. These accomplishments have primarily been by Appalachian natives, and we have consciously prioritized first-generation, low-income students by hiring through the federal work-study program. The pedagogical changes were done with little funding but have had substantial effects on our undergraduates. These experiences increased students being awarded prestigious funding, such as the Gilman Scholarship, gaining admittance to graduate programs, graduate funding, or securing positions after graduation. This paper demonstrates how partnerships between academic institutions and collections facilities foster student engagement in Appalachia.

Jonsson, Emily (University of Arizona)**[167]***At the Intersection: Jicarilla Apache Values and Heritage Management*

Since the 1970s, tribal archaeology programs and Tribal Historic Preservation Offices (THPOs) have served a significant and positive role in supporting tribal sovereignty in heritage management. The increasing application of Indigenous and collaborative archaeologies has contributed toward both this goal and deepening our knowledge of past and present cultural traditions. This paper examines the application of tribal values in heritage management through the La Jara archaeological site, a Gallina phase (1100–1300 CE) cultural site on the Jicarilla Apache Reservation in northern New Mexico. The history of the management of La Jara, from its initial 1970s excavations by tribal and nontribal archaeologists up to more recent organization of its records and collections, offers insight into tensions around tribal sovereignty, cultural affiliation, NAGPRA, and the preservation of cultural heritage on Jicarilla Apache Nation.

Jorgeson, Ian (Southern Methodist University [SMU]) and Matthew Boulanger (SMU)**[84]***Obsidian Procurement in the Northern Tiwa Homeland*

We present results of a large-scale geochemical sourcing study of obsidian artifacts from Picuris Pueblo. We compare those results to obsidian-sourcing data from other sites on the Taos Plateau and in the Rio Chama basin. At Picuris Pueblo, almost all obsidian artifacts were produced on Valles Rhyolite or Cerro Toledo obsidian. Surprisingly, El Rechuelos obsidian is exceedingly rare. In contrast, assemblages from earlier sites on the Taos Plateau are predominantly El Rechuelos obsidian. We discuss the possibility that the arrival of Tewa-speaking migrants in the Rio Chama between the late thirteenth century and early fourteenth century effectively blocked access to El Rechuelos obsidian sources. This influx of immigrants into the Northern Rio Grande disrupted long-standing resource-procurement patterns and use of traditional landscapes for the people of Picuris Pueblo.

Unearthing the History of Mokil Atoll: A Fresh Perspective through Zooarchaeological Exploration

There has been a dearth of research on atolls in the central-eastern part of the Caroline Islands, especially from a zooarchaeological perspective. We present the first zooarchaeological analysis for Mokil atoll, which has been continuously inhabited since 1700–1500 cal BP. The material was excavated in 2013 on the islet of Kahlap. The majority of the zooarchaeological remains, over 67%, were mollusks, followed by fish, and a marginal quantity of birds and mammals. Use of bivalves largely decreases over time, while a slight increase in gastropods can be distinguished. The most prominent families represented are mesodesmatids, cone snails/true conch, and ceriths. Fish, especially parrotfish, wrasses, and groupers, were most intensively utilized between 910–1550 BP. Rats first appear in the archaeological record around 910–1550 BP, while evidence for chickens and dogs dates back as early as 1400–1700 BP. None of these appear in the oldest layers, suggesting that these species, often considered to be part of the “transported landscape,” were not introduced during the initial migrations to Mokil. This study sheds light on early migration strategies to atoll environments, as well as contributes to understanding human-environmental interactions through time, in one of the most remote areas of the world.

Reflections on DGR and RBR: David G. Anderson and the Richard B. Russell Reservoir Project

David Anderson’s archaeological career took root in the fields of cultural resource management and his research on the Richard B. Russell (RBR) Reservoir was integral to his intellectual development. Through three seasons of fieldwork and subsequent analysis and reporting, he directed archaeological excavations at seven sites for the RBR project including Rucker’s Bottom and the Abbeville and Bullard Site Groups. This work witnessed elements of his approach to archaeology, drawing from an ecological perspective and involving an extensive team of specialists. The RBR project itself is historically notable for the CRM collaboration between the National Park Service’s Interagency Archaeological Services Division and the US Army Corps of Engineers, Savannah District, and for the production and distribution of the Russell Papers as the final products of each investigation. Fittingly, David would serve as the lead and coauthor of the Russell Paper technical synthesis produced as the final technical Russell Paper. This presentation reflects on David’s work at RBR and the place of the project in the history of CRM.

Fluid Stone: Geological Materials in Process

Geological materials that constitute features in archaeological sites in Central America range from unfired clay and unmodified cobbles, to cut stone, and plasters produced by heating limestone. What these materials have in common is that from an archaeological perspective, they are often treated as inert, more stable than organic materials, less active, not agential. In this paper, drawing on theoretical frameworks from geoarchaeology, feminist new materialism, and the varieties of practice theory that have recently been advanced as “process archaeology,” I seek to rethink mineral matter as active, agential, dynamic, and in process. This involves considering how people in the Central American past engaged with clay and stone, under conditions that exposed the energy inherent in these materials, including flooding, volcanic eruptions,

and the emergence of stone from hot springs and cave formations. It also involves considering indigenous ontologies, for which I draw on ethnographic and historical documents from Lenca communities in Honduras. Building on observations by indigenous people who recognize sources of mineral matter such as mountains and volcanos as animate, and recognizing the ways people in the past intra-acted with durable formations of rock and clay allows us to define a new materialist geoarchaeology for this region.

Geoarchaeology of the Big Blue River Valley, NE Kansas: Implications for Paleoindian and Earlier Archaeology

The Central Plains of North America have yielded fewer stratified Paleoindian archaeological sites than other regions of the Great Plains. The dearth of recorded early sites is due to geologic filtering of the archaeological record; processes of erosion and deposition have removed or deeply buried early sites, respectively. At the Coffey site in the Big Blue River valley (BBRv) in NE Kansas, however, late Wisconsinan alluvium (Late Member of the Severance Formation; LMSF) containing a stratified Folsom component was documented 50 cm below surface. Given the presence of the LMSF at the Coffey site, alluvium of similar terminal Pleistocene to early Holocene age may occur elsewhere in the valley. We used soil stratigraphic data from seven localities and 38 radiocarbon dates spanning the last ~25,000 years to assess the temporal and spatial pattern of late-Quaternary landscape evolution in the lower BBRv, and to determine the potential for stratified Paleoindian and earlier cultural deposits. We conclude that terrace fills dating to or before ~10,000 cal BP are rare in the BBRv, but that alluvial fans along the valley margins consist of LMSF (ca. 12,000–25,000 cal BP) and are therefore targets for archaeological survey seeking stratified Paleoindian and older cultural deposits.

Perplexing Landscapes: The Role of Natural Landscape Features in Late Preclassic Site-Design of Noh K'uh in Chiapas, Mexico

The Late Preclassic (400 BC–AD 250) ceremonial center of Noh K'uh was designed in a quincunx pattern to commemorate the importance of cardinality and cosmological symbols. This kind of architectural design was commonplace in Preclassic Mesoamerica, as the earliest populations shaped their ceremonial spaces in reverence to natural phenomena, both terrestrial and celestial. Previous investigations at Noh K'uh have indicated that the quincunx pattern aligned to distant landmarks that surrounded the basin formation. A recent survey (2022) of these landmarks revealed a complex set of settlement patterns that blurred the line between the altered and unaltered environment. Ultimately, findings from the basin of Mensäbäk help redefine understandings of site boundaries, and ongoing survey work continues to reveal a site design that integrated massive construction projects together with natural landforms.

Navigating the Frontier of Colonial Diets: Domesticates and Wild Resource Use in the North America Fur Trade
European settlers in the Americas brought with them a familiar suite of domesticated plants and animals and frequently relied on them for subsistence. Between the seventeenth and nineteenth centuries, European colonial powers became involved in the fur trade, resulting in the development of numerous posts placed at varying distances from developed agricultural centers. Euro-American colonists had access to traditional Eurasian agricultural products; however, fort and trade post residents also incorporated local and wild resources into their diets. In this paper, we examine the role of Eurasian domesticates (e.g., pigs, cattle) in fur trade community subsistence. Specifically, what effect do regionality and geographic location have on the presence of domesticates at fort locations? Additionally, does the nationality of fort occupants affect dietary patterning? We assess zooarchaeological assemblages from 25 fur trade-era forts across four physiographic regions: Coastal Pacific, Great Lakes and East, Hudson Plain, and Inland North America. We use statistical analyses, including indexes, ANOVA, and clustering to assess the extent to which geography and nationality impact the assemblage. These data help shed light on how colonial interactions were shaped by the reliance on domesticate and wild resources during the fur trade in North America.

Home Is Where Your Boat Is: Movements within and around the Titicaca Basin (800 BC–AD 200)

The Titicaca Basin has long been home to communities of people who navigated their highland landscape effectively. Much research has been devoted to early developments in the southern lake basin (in modern-day Bolivia) as well as later communities on the northwestern side of the lake (in modern-day Peru). However, few studies have focused on movement throughout the region, which inevitably occurred given evidence for watercraft and reliance on lacustrine resources. This paper presents new strontium isotope evidence for both long-distance and circum-lacustrine movement of peoples between 800 BC and AD 200. We emphasize how these regular movements were likely tied to familial and ritual networks that facilitated trade throughout the region. We build on previous studies of archaeological and bioarchaeological remains to argue that these networks allowed communities to navigate environmental and social changes (such as a long-term drought and establishment of new territories and settlements) without the creation of social hierarchy or increased interpersonal violence. Additionally, this case study makes it clear that people were crossing modern boundaries with regularity in the past, emphasizing the need for transnational perspectives when interpreting the Andean past.

The Prevalence of Entomophagy in the Americas: A Meta-analysis of Human Coprolites

Ethnography demonstrates entomophagy, or consumption of insects, to be a relatively common practice around the world. Despite such prevalence, insect foods are discussed rarely in the archaeological literature, presumably due to Western biases, which may acknowledge the presence of edible insects but refrains from

considering them a viable food resource. To evaluate the extent to which past Indigenous communities of the Americas consumed insects, we conduct a literature-based meta-analysis of human coprolites. The analysis identifies over 9,150 specimens from 52 archaeological sites, comprising 57 distinct assemblages that span up to 14 millennia. Thirty-two percent of the assemblages contain one or more human coprolites with intentionally consumed edible insects, indicating that almost a third of past subsistence economies of the Americas incorporated insects into their diets. The samples containing edible insects also demonstrate that 4% of the average diet consisted of insects. These results reveal that insects were a common part of early subsistence economies in the Americas and were unlikely to have been the starvation food many Western scholars often assume.

Contexts and Meanings of Prehispanic Underwater Offerings Discovered in the Volcanic Lakes of Nevado de Toluca, Mexico

Nevado de Toluca is a volcano located in the central region of Mexico. At 4,200 m asl, there are two lakes inside its crater with evidence of rituals and prehispanic offerings. Archaeological evidence, recorded by both underwater and terrestrial archaeological practices, indicates a close symbolic relationship between water, meteorological forces, and the concept of the sacred Mesoamerican mountain. Due to the physical and chemical characteristics of the water, organic materials have been exceptionally preserved, like copal, maguey leaves, pine leaves, basketwork, and plant fibers. In this lecture, we present the context and meanings of these offerings to understand the ritual practices in their entirety considering ecological environment, prehispanic worldview, and the relationship of human groups with water.

Lifeways at the Onset of Urbanization in Central Mexico: Initial Findings from Ceramic Analysis and Residential Excavations at Middle Formative Tlalancaleca, Puebla.

Tlalancaleca is located in the western reaches of the Puebla-Tlaxcala Valley in Central Mexico and was one of the region's largest urban centers during its apogee in the Terminal Formative period (100 BC–AD 250). The pathway to this urban apogee is less well understood but a promising area of inquiry lies in the process of population aggregation that occurred at Tlalancaleca between 650 and 500 BC. In other world regions, archaeologists have hypothesized that population aggregation was a generative process that expanded inhabitants' consumption opportunities, social networks, and offered novel opportunities for ritual and social differentiation. In this paper, I evaluate to what extent these variables changed through the course of aggregation at Tlalancaleca using ceramic data from a Texoloc phase (650–500 BC) supra-household structure at Tlalancaleca. I compare ceramic types and vessel forms between Tlalancaleca and Tetel, a contemporaneous non-aggregated village in the region, as an additional avenue for evaluating changes at Tlalancaleca during aggregation. In doing so, I present preliminary interpretations on inhabitants' lifeways during the aggregation process and their implications for urbanism and conceptualizing the “urban” and “rural.”

Revisiting Eastern Morelos and Teotihuacan: Recent Research at San Ignacio, a Regional Center in Teotihuacan's Rural Countryside

San Ignacio is located in the Amatzinac Valley of Morelos, approximately 10 km south of the Formative site of Chalcatzingo, where it was the regional center and largest site in Eastern Morelos during the Classic period (300–600 CE). Previous studies argued based on regional settlement data that San Ignacio was a possible Teotihuacan administrative center. The Proyecto Arqueológico Mapeo y Prospección de San Ignacio

(PAMPSI) began in 2019 to investigate this hypothesis and the nature of San Ignacio's relationship with Teotihuacan. In this paper, we summarize initial findings from the first two seasons of fieldwork undertaken in 2019 and 2023, which entailed site mapping, surface collections, stratigraphic test excavations, and ceramic analysis. We present preliminary interpretations of San Ignacio's occupation, internal organization, and relationship with Teotihuacan. We propose directions for future research as long-term study of San Ignacio will be key for understanding Classic period societies outside of the Basin of Mexico, particularly those of Morelos, and Teotihuacan's local impact on social identities, ritual practices, and political-economic activities around Central Mexico. Initial findings and future research by PAMPSI will further discourse on Teotihuacan interaction and contribute new data to theories of Teotihuacan polity organization and urbanism.

Prehistoric Hunter-Gatherer Plant Food Use in the Northern Zagros: New Evidence from Carbonized Plant Macroremains

Research on plant remains over the past two decades increasingly point to the importance of plant foods in Paleolithic hunter-gatherer subsistence. In this paper I will present recent results of archaeobotanical research on carbonized plant macro-remains from late-Middle, Upper Paleolithic and Epipaleolithic sites located in the northern Zagros Mountains. The evidence to date supports a long-term reliance on wild pulses and nuts in this region. In addition, evidence from carbonized fragments of prepared food items indicate complexity and diversity of culinary practices, including the multistep preparation of plants with unpalatable and potentially toxic compounds. I will discuss this evidence in relation to plant resource choice in the context of hunter-gatherer occupations in Southwest Asia and the broader Eastern Mediterranean.

A Geospatial Analysis of Sacred Trees and Archaeological Sites in the Precontact Society Islands (French Polynesia)

Archaeological, anthropological, and historical sources speak to the importance of particular tree species for ceremonial and quotidian use in precontact Polynesian chiefdoms. Archaeological studies have largely discussed the spatial association of trees and archaeological sites in an ad hoc manner, thus more refined spatial analyses are needed. I fill this lacuna with an in-depth geospatial analysis of tree distribution and archaeological site distribution from the 'Opunohu Valley, Mo'orea, Society Islands. A full coverage survey recorded data on spatial relationships between 39 site complexes and over 1,800 trees. Here, I examine the spatial distribution of five native and Polynesian introduced tree species in relation to residential and ceremonial archaeological complexes. I question if ethnographically and ethnohistorically identified sacred tree species are more often associated with elite residential sites or elite ceremonial and ritual sites, are tree species with more general daily economic use more often associated with residential sites than ceremonial sites, and finally, are sacred trees more often associated with secondary elite political centers than more isolated ritual or specialized sites? The data point toward the complex ways in which the Mā'ohi intentionally planted symbolically charged tree species in or around secondary ritual centers and specialized ritual contexts.

Architecture and Hydrology: Defining the Sacred Landscape of the Tayasal Hinterland amid the Shores of Lake Petén Itzá, Guatemala

Recent lidar survey of the Tayasal Peninsula in the Petén region of Guatemala revealed a collection of residence groups, situated on ridges of higher ground and separated by possible waterways of lower elevation. These suburb-like communities stand 2 km from Tayasal's urban core. They include structure compounds arranged into a series of larger communities—perhaps neighborhoods, villages, or specialized activity areas. Some of these architectural groupings follow the contours of the terrain down toward lake edges, enhancing the hydrological context of the surrounding environment. In conjunction with the lidar survey, segments of this area and additional features like drainage areas and defensive walls have been ground-truthed, and support conceptions of the residential nature of these settlements. Further study of this area as a residential subset of the Tayasal architectural assemblage has great potential to contribute to the ongoing conversations regarding Maya spatial organization and corresponding geopolitics. The positioning of these settlements and their relationship to water is a key area of study, and further analysis will contribute to a more thorough understanding of resource management and its implications for the characterization of these outlying communities.

Northern Great Basin Cordage: A Regional Overview of Chronology, Technology, and Materials

Fiber technologies in the North American Great Basin have incredible antiquity and diversity, including fine cordage, rope, and braids spanning at least the last ~13,000 years. The Museum of Natural and Cultural History, University of Nevada, Reno, Nevada State Museum, and the Lakeview Bureau of Land Management have spent considerable effort in the past two decades compiling and obtaining new radiocarbon dates on fiber cordage from across the region with data on over 120 individual items. In this paper we discuss new radiocarbon dates in tandem with plant identifications and technological analyses from the Connley, Paisley, and Cougar Mountain Caves in central Oregon alongside existing data. This provides an updated regional and diachronic perspective of plant selection, new clues to the decision-making process in cordage technology, and novel insights into cultural change, adaptation, and innovation in the Great Basin.

Materialities of Boiling and Steaming: SEM Microscopic and Experimental archaeological Study on East and Southeast Asian Cooking Technologies

Archaeological and ethnographic data indicates that East and Southeast Asian cuisines have long been characterized by diverse boiling and steaming repertoires and techniques. These practices and resulting flavors and texture of foods are imbued with rich sociocultural meanings. This paper explores charred food remains as an “ecofactual artifact.” By applying a “life-history” approach, the transformation process of cooking and various food materialities can be compared and differentiated microscopically under SEM. Following the rising academic interest in the once-overlooked amorphous charred food remains from archaeobotanical flotation samples or ceramic food crust, this research focuses on the SEM microscopic approach to boiled and cooked cereal food,

aiming to provide a referential dataset to study past cooking technologies archaeologically. Based on existing ethnographic data and historical resources, a food categorization framework is formulated. Controlled cooking experiments of different boiling and steaming techniques were carried out at Butser Ancient Farm, followed by controlled carbonization. The resulting cooked cereal products were described through SEM observation to differentiate modes of boiling and steaming of East/Southeast Asian prehistoric cereals, such as rice (*Oryza sativa*), foxtail millet (*Setaria italica*) and broomcorn millet (*Panicum miliaceum*).

A More Sustainable and Ethical Foundation for CAREfully FAIR Data in Archaeology

Archaeologists generate vast amounts of data in the form of databases, media files, spreadsheets, GIS files, reports, articles, and other literature. However, despite years of advocacy and data management investments, archaeological information is still poorly curated, scattered, incompatible, and haphazardly preserved. Despite these challenges, David Anderson led projects that demonstrated the value of aggregating and reusing such data at scale. The Paleoindian Database of the Americas (PIDBA) and the Digital Index of North American Archaeology (DINAA) yield important outcomes in scientific understanding and cultural heritage conservation. Anderson's projects show how dedication can enable small teams and modest budgets to have big impacts. We need strategies to make these successes more routine, sustainable, and aligned to both the CARE and FAIR data principles. First, the widespread use of persistent identifiers will better maintain the provenance and contextual integrity of archaeological data. Second, new open-source software, especially the Arches Project (specifically designed to meet unique demands of the cultural heritage sector), can better sustain good practices while promoting autonomy, including data sovereignty for Tribal nations. These developments can support inclusive governance that protects and manages access controls to culturally sensitive data while selectively and strategically sharing information that advances shared goals.

Archaeological Legacy Data and Archaeological Data Legacies

Although digital repositories are well established, many researchers still use informal ways to share data, such as email. This type of sharing runs a great risk of information loss because data is often not well documented or formally described. One could argue, in fact, even new data is legacy data if it is shared in this way. That is, legacy data is not just the data in notebooks or in old file formats on hard drives; it's also any data we create that isn't easy for others to access or use. If we all agree that data sharing and access is important for our discipline, we need to stop creating legacy data and find ways to improve the intelligibility, interoperability, and longevity of the data we create. Rather than discuss technological solutions to this problem, this talk highlights the role that people play in improving data sharing and understanding. We use the publication of Richard Redding's zooarchaeological data from Giza to share step-by-step guidelines for data documentation, description, and cleaning as an example of working with archaeological legacy data to establish archaeological data legacies.

Kardulias, Drosos (University of Michigan)**[233]***From Enfilades to Medieval Caves: An In-Progress Report from the Medieval Roman Archaeological Survey of Kalymnos*

The Aegean island of Kalymnos was unsurprisingly transformed by conflict between Roman and Arab Caliphate forces through the early Middle Ages; atypically among its neighbors, the end of antiquity seems to have produced a more durable and connected Kalymnian community, compared to that which came before. This paper expands on earlier GIS analyses of the island's Roman remains through the recording of undocumented sites and external features of previously known locations. Substantial attention is paid to distinctive emerging tactical trends in fortification architecture, as well as the issue of transport through such a rugged coastal environment. Of special note is the network of previously unrecorded high ground lookout posts which facilitated contacts both among the communities of the island, and from Kalymnos to the broader empire. Operating in the restrictive Greek system, the Medieval Roman Archaeological Survey of Kalymnos project is also a case study in "agile archaeology," utilizing many vectors of analysis to build a picture of the past without excavation or remote sensing. Through the use of lay informants, consultation with museum personnel, and participation of Greek university students, the project aims to maximize involvement of the local community, while minimizing its impact on the archaeological record.

As part of the ethnoarchaeological component of the Athienou Archaeological Project (AAP), a team has conducted a survey of the public drinking fountains built in the town of Athienou in central Cyprus during the British colonial period. The research accompanies other field investigations to create a holistic examination of the community situated at the southern end of the Mesaoria, a fertile agricultural plain in the heart of the island. The semiarid summer climate makes access to water a major concern of the residents of Athienou. A

number of public fountains scattered throughout the town are a remnant of the British colonial presence in the twentieth century. Since 2016, an AAP team has recorded all of the extant fountains and several preserved ceramic water lines, and examined plans held by the director of the town's physical plant. The fountains reflect an effort to enhance a vital public service while simultaneously leaving an imperial imprint to clearly mark their origin. The features can be seen as the effort of a core to demonstrate the benefits of colonial status.

Death and the City: Funerary Practices and Social Transformations during the Archaic Period in Greek Poleis and Beyond

The abundance in textual sources and richness of its archaeological record make Athens one of the most studied Greek cities during Classical Antiquity. However, research has focused principally on Athens, leaving much of the periphery of the Classical world largely unexplored. Scholars have mostly focused in Classical period assemblages, while only little attention has been placed to the precedent period. Furthermore, studies concerning the Archaic period funerary record are rather scarce, both in Athens and elsewhere. Lastly, bioarchaeological studies of respective contexts are greatly absent. Humans are physical mediators of the interaction of cultural and natural phenomena, thus, by combining bioarchaeological data with the burial record, valuable insights can be gained regarding sociopolitical transformations diachronically. The present paper aims to offer a first synthesis of recent and older publications with regard to the funerary and demographic data in order to explore social transformations in Greek poleis at the advent of city-state formation. Emphasis is placed in data coming from the Attic peninsula and the Phaleron cemetery, which is the focus of the present theme session.

Between the Nile and the Desert: the Middle Stone Age of Kerma Region, Northern Sudan

The Nile valley, its associated drainage system, and the adjacent Sahara are thought to have been part of the Anatomically Modern Humans (AMH) dispersal routes out of Africa during the Middle and Late Pleistocene. Building on the pioneering prehistoric work of Marks and colleagues in the early 1960s in northern Sudan, we present the results of the 2019 and 2022 fieldwork of the DIASPORA project (Early Human Migrations and the Nile Valley: The Kerma Region during the MSA). This poster focuses on site location of the sites discovered in the eastern hinterland of the Kerma region near the Third Nile Cataract in northern Sudan. Archaeological data indicate that most sites are dated to the Middle Stone Age, including well-stratified rockshelters and quarry sites, as well as rare rock art locations and scattered cemeteries from more recent chronologies. Preliminary lithic finds reflect the presence of core reduction Nubian technology and typical Levallois. This study suggests greater techno-typological and raw material exploitation diversity during the MSA in the study area. This will contribute to the identification and possible tracing of the pathways of the spread of AMH in the Nile valley.

Kassabaum, Megan (University of Pennsylvania) and Alexandria Mitchem (Columbia University)**[140]***Looking Beyond Consumption: Archaeological and Ethnohistoric Approaches to Interpreting Sweetgum Use at Coles Creek Mound Centers*

The role of non-food plants in human history is a growing area of research for paleoethnobotanists. In this paper, we develop and present a multi-pronged method for exploring non-subsistence human-plant interactions in the archaeological record, using a case study from the American Southeast. The archaeological record of the Lower Mississippi Valley represents a long history of indigenous people making wide and variable use of the region's exceptionally rich ecosystem. Often, archaeological interpretations of these interactions focus on subsistence and do not take into consideration non-food uses of plants and animals. Our excavations at two Coles Creek (AD 750–1000) mound centers, Feltus and Smith Creek, yielded curious concentrations of sweetgum (*Liquidambar styraciflua*) in addition to the expected suite of plants. In this paper, we outline important advancements in our ability to recognize sweetgum in the archaeological record and synthesize pre- and postcontact ethnobotany to hypothesize about how and why Coles Creek people used this plant in ceremonial activities taking place at mound centers. We then reflect on the importance of such methodologies in allowing archaeologists to more fully explore non-food plant use in a variety of contexts.

Kassadjikova, Kalina (UC Santa Cruz), Mark Horton (Royal Agricultural University, Cirencester, UK), Cat Jarman (Royal Agricultural University, Cirencester, UK) and Lars Fehren-Schmitz (UCSC Paleogenomics)**[233]***A Paleogenomic Investigation of Historical Human Skeletal Remains from Rapparee Cove, North Devon, UK*

In 1997, human bones were discovered ashore at Rapparee Cove in North Devon, United Kingdom. Since then, much news coverage and public speculation has suggested that the remains belong either to French soldiers or enslaved African-descended rebels from St. Lucia who had drowned when the London had shipwrecked off the coast two centuries earlier in 1796. A decades-long international custody battle has ensued for their repatriation and reburial. We report the results of a genetic analysis of a sample of the remains. Results show mitochondrial haplotypes found predominantly in Europe. Population genetic analyses of nuclear genomes show that the individuals had unadmixed ancestry similar to local populations of Devon. These results suggest that the sampled individuals were of local descent, addressing the heated public debate. However, we note that the samples may not be representative of the numerous human remains that have been discovered or remain buried in the surrounding hillsides.

Kater, Thiago (University of São Paulo)**[54]***Chair***Kater, Thiago (University of São Paulo), Jennifer Watling (University of São Paulo), Fernando Almeida (Rio de Janeiro State University) and Eduardo Neves (University of São Paulo)****[54]***Ceramic and Starch Grain Evidence and the Social Factors Behind Pan-Amazonian Occupation Processes ca. 3500 BP*

Human agroforestry and landscaping practices in the Amazon Forest are now well-accepted phenomena among Amazonian archaeologists. Along the Amazon River, the oldest evidence of visible landscape modifications is largely associated with contexts in which pottery from the Pocó-Açutuba Tradition is identified, from 3500 years BP. This tradition, in accordance with the archaeological literature, also appears

to be the first material assemblage that was widely dispersed throughout different regions of the Amazon basin. For this presentation, we wish to consider and to reflect on some social factors that could have acted in this process. To achieve this aim, we share some results of techno-morphological analysis of Pocó-Açutuba ceramic assemblages excavated from archaeological sites on the Madeira River, as well as some starch grain evidence associated with pottery residues. The dataset informs us about a consistent vessel morphology and possible related feasting functions, which have several implications when considering the occupational processes that unfolded during the period.

Archaeology, a Historical Science of Multiplicities

During the Cold War of the twentieth century, the coterie of scientists at Los Alamos who had developed nuclear bombs continued their dominance through creating the National Science Foundation and the Santa Fe Institute. NSF science is laboratory-based physical sciences, manipulating “the tiny” as Derek Turner says. Its extreme form would be Hempel’s hypothetico-deductive procedure, which Lewis Binford advocated. Historical sciences (archaeology, paleontology, geology) are radically different: their data are truly “givens,” to be interpreted by analogies with ethnographically observed and historically described communities. Every dataset results from historical contingencies, an infinitude of multiplicities. This understanding of histories fits demands from non-Western nations for recognition of their historical knowledge; it is postcolonial. In this paper, I describe the method of historical sciences and make a distinction between “decolonization” (in which the usually White professional is the agent) and postcolonialism that recognizes the validity of the many realities resident in languages and cultural knowledge.

Redefining the “City” during a Time of Risk: The Site of Achanchi and the Chanka Heartland of Andahuaylas, Central Highland Peru (1000–1400 CE)

Traditional models of ancient cities have dominated archaeological discourse for nearly a century. This paper seeks to diversify definitions and assumptions regarding ancient cities, especially during periods of heightened

economic and social risk. Using the large Late Intermediate period (1000–1400 CE) ridgetop site of Achanchi in the Andahuaylas region of southern highland Peru, this paper presents a snapshot of “city” life, but contextualized within the highland Andean region during a period of dynamic change. This paper argues that the site of Achanchi encapsulated some, but not all characteristics and functions of a typical ancient city, yet played a critical, multifaceted role (e.g., refuge, economic center, burial ground) among local Chanka populations during a discrete time of overlapping risks linked to drought, warfare, and political factionalism.

Tectonic Origin of Desert Wetlands at Pozuelo, Peru

The Pozuelo site, one of the oldest in the region, is composed of four Formative period mounds (circa cal yr 1230 BCE) in southern, coastal Peru. Archaeological excavations at the site exposed both mound and pre-mound stratigraphy. Sediments beneath the mound showed a sharp transition from alluvial fan/eolian sediments to a thick (approx. 1 m) clay deposit containing evidence of freshwater plants. Discovery of this wetland environment was unexpected in what is now desert terrain and has implications for the pre-mound occupation of the area. Hypotheses for the formation of a standing water body include fault-induced topographical and hydrological changes, perhaps influencing a distributary channel, in this tectonically active region. In 2022, additional excavations revealed clastic dikes associated with earthquake-induced liquefaction cutting the clay layer in sediments beneath a mound. An electrical resistivity tomography (ERT) survey conducted in 2022, showed results consistent with faulting in the area immediately adjacent to and beneath the excavated mound. This information suggests the pre-mound wetlands may be the result of seismically controlled ground warping and water impoundment, followed by disruption by a large magnitude earthquake. Subsequent eolian activity created the sand dune which forms the base of the excavated mound.

Isotopic Data from Turkeys (Meleagris gallopavo) at Houck, Arizona (AD 800–1250)

As the only domesticated animal native to the North American continent, analysis of turkey husbandry in the prehistoric American Southwest is important to understand human-avian interaction, foddering techniques, and trade. Direct analysis of turkey remains provides information about their myriad functions. The Houck community of sites is located at 6,035 feet along the Puerco River Valley on the Colorado Plateau in northeastern Arizona (AD 800–1250). Houck was occupied during Chaco Canyon’s peak exhibiting a great house with Chacoan masonry. Previous zooarchaeological studies show that some Houck turkeys were used for gathering feathers. We combine dietary and geolocation isotopic data to analyze aspects of turkey husbandry at Houck from >35 turkeys found in various contexts. Houck turkeys consumed a strong C₄ diet, likely maize fodder (carbon: –8.5‰, nitrogen: 9.3‰). These dietary isotopic values indicate that Houck turkeys were fed maize from fertilized fields, more so than some North American prehistoric turkeys. Houck turkey average strontium value is 0.70965 and few turkeys are out of the range for soil samples near the site, suggesting local breeding. These results indicate a local practice of turkey husbandry at Houck communities during the peak of Chacoan influence. In honor of Jesse Alexander.

Kelly, Harold and Corinne Hofman (Leiden University)**[127]***Archaic Ingenuity through Continuous Change*

Archaic groups worldwide are often categorized as less technically and culturally developed. However, their deep understanding of nature and their environment and ability to translate this knowledge to adapt to new circumstances proves otherwise. Paleoclimatic research in the Caribbean has shown that the region endured significant climate variability throughout the Holocene. Alternating cycles of wet and dry conditions contributed to extreme weather events, which, together with relative sea-level rise, severely impacted the environment, available resources, and the ability of islanders to secure water, food, and shelter. In this paper, we look at Aruba, one of the driest islands in the region, and Saba, located in the hurricane belt of the northern Lesser Antilles. Our research shows that Archaic peoples on both islands were able to continuously adapt their lifeways to the natural hazards and climatic challenges they faced. Through the development of a deep understanding of nature and the building of social relationships, knowledge exchange, and intensive mainland-island and interisland mobility, early settlers introduced sustainable ways to construct their shelters, manage their water supplies, and produce foodstuffs that were adapted to the environmental conditions.

Kelly, John (Public Archaeology Laboratory Inc.)**[187]***Between the Shores and the Hills: Precontact Boundaries and Behavior along the Housatonic River in Southwestern Connecticut*

PAL's archaeological investigations along a natural gas pipeline right-of-way in southwestern Connecticut identified a cluster of precontact Native American sites in Newtown situated along Rodericks Brook, a tributary stream to the Housatonic River. The sites include the Canopy Site (97-101), the Alberts Hill Road Site (97-102), and the McLaughlin Vineyard Site (97-106). Rodericks Brook runs along a previously documented lithic watershed and inferred territorial boundary separating the coastal precontact peoples of the lower Housatonic drainage from the interior-oriented groups of the upper river drainage. While the assemblages from these sites contain stone raw materials typical of sites from similar periods in the Lower Housatonic valley, the large volume of burned and heat-treated vein quartz and the caching of bifacial cores is unusual and appears to be unique to the Rodericks Brook drainage. The unusual assemblages may be associated with boundary maintenance between distinct Native American populations along a shared frontier.

Kelly, Mary Kate (Mount Royal University), Caitlin Earley (University of Washington) and Brent Woodfill (Winthrop University)**[230]***Turtles, Faces, and Hieroglyphs: 3D Recording of Monuments from La Tortuga and San Isidro*

The adoption of 3D digital recording strategies at archaeological sites yields numerous benefits: detailed preservation of data while the original may be at risk of damage or erosion, increased visibility of small details, and precise tracking of change over time, to name a few. Additionally, there are nearly limitless possibilities for applications of 3D data, such as producing scale models and accessible virtual versions of artifacts. The Proyecto Arqueológico Sak B'alam has begun implementing digital recording techniques and is envisioning future research and collaborations around these data. Two archaeological sites were studied in the field season of 2023, La Tortuga and San Isidro. A total of nine monuments were photogrammetrically recorded between the two sites: an altar and a stela fragment from La Tortuga; and five hieroglyphic stairway blocks, one panel, and one column altar from San Isidro. In this paper, we discuss the process of digitally recording monuments at La Tortuga and San Isidro, as well as the preliminary results of epigraphic, iconographic, and contextual analyses of the monuments. We also discuss directions for future research, including the ways that digital data can support collaborations with the local communities at each of these sites.

Rapid Increase in Production of Symbolic Artifacts after 45,000 Years Ago Is Not a Consequence of Taphonomic Bias
Researchers have long been aware of an apparently rapid increase ca. 40,000–45,000 BP in the frequency of “symbolic” artifacts in the Old World paleolithic record. However, some hypothesize that if not for taphonomic loss the data would instead show a gradual increase in such artifacts’ frequency during the Middle Stone Age / Middle Paleolithic. We test this hypothesis by correcting the record for taphonomic bias. We find that even after correction, the ca. 40,000–45,000 BP peak remains with no prior gradual increase. However, research bias may explain much of the peak.

Restoring Relationships: Connecting Nunatsiavummiut to Their (In)tangible Cultural Heritage throughout the World
Settler colonialism is a disruption of Indigenous relationships. As a tool of settler colonialism, archaeology and collecting in particular have caused a disruption of relationships between Indigenous people, their land, their (in)tangible cultural heritage (Gray 2022), their Ancestors, and their pasts, presents, and futures. Over the last 500 years, many archaeologists, academics, tourists, missionaries, and government officials have collected Inuit (in)tangible heritage and Ancestors without Inuit consent. They are now housed in institutions all over the world without applying Inuit understandings of care, love, and respect. In this presentation we discuss how this violent practice has disrupted many different kinds of relationships, as well as projects we work on in collaboration with the Nunatsiavut Government and Nunatsiavummiut communities to work toward restoring those relationships.

Shaping Pots and Minds: Ceramic Experimental Archaeology in an Undergraduate Classroom

The study of archaeological ceramics has relied on a reconstruction of the techno-functional choices made by potters in the past through a *chaîne opératoire* approach. However, the insights gained through this analysis have largely confused or eluded our students due to a lack of practical experience with ceramic manufacture. In the fall of 2023, faculty in anthropology and art at Lyon College collaborated to create a course that

provided students with a hands-on experience in the ceramic production process from the gathering of raw materials to firing to vessel use. The expressed archaeological goal of the course was for students to be able to better understand the technological and functional decisions that potters made in the production process through experimentation. We also aimed to demystify the production of the material world by engaging in the complete chain of ceramic manufacture. This paper briefly presents the course structure and evaluates the efficacy of our experimental design in increasing technical and functional understanding of archaeological ceramic materials. More importantly, we highlight the lessons that we learned from our students in this shared experience.

The Impact of Fishing and Transportation Technologies on Nineteenth-Century Fisheries and Fish Supply in New Orleans, Louisiana

This paper examines fish supply in late nineteenth-century New Orleans to understand how new fishing and transportation technologies transformed fish trade networks in the Gulf of Mexico and beyond. Previous research has demonstrated temporal and geographic shifts in the city's fish supply, and we extend this work to late nineteenth-century contexts using zooarchaeological, ancient DNA, and stable isotope analyses. The identified species demonstrate rapid and extensive incorporation of multiple nonlocal fishes, especially snappers (family Luthjanidae), beginning in the 1860s. Although the relative abundance of these fishes in nineteenth-century New Orleans can be explained by rising urban populations and increased demand, this trade must also be understood as being enabled by the development and widespread adoption of new technologies including longline fishing equipment, railroad transport, and artificial ice production. These technologies not only allowed for the long-distance shipment of fresh fish at relatively low cost, they also underpinned the development of successive new fisheries such as those targeting Northern Red Snapper in Florida and White Hake in the northwest Atlantic Ocean. Ultimately, we argue that late nineteenth-century transportation technologies revolutionized the trade of fresh fish by enabling shipment of these commodities across continental and transnational scales in ways not previously possible.

Mining Datasets and Weaving Diverse Contexts: A Multisite Comparison of Indigenous Forced-Labor Compounds in Colonial Peru

The Spanish Empire drew on multiple forms of forced Indigenous labor in their American colonies during the sixteenth–eighteenth centuries. In the Andes, forced Indigenous labor was used to mine silver, craft textiles, grow sugar cane, and produce wine, among many other tasks critical to the colonial economy. Crucial to this

system was the ability to obtain (and retain) labor through various mechanisms, such as the mita draft, the encomienda, tribute levies, and slavery. Conditions at these compounds were often brutal, and many fled. While some compounds may have had heavy surveillance and control mechanisms, this has not been fully investigated on the ground. In this paper, we compare spatial and archaeological data from three colonial labor compounds to elucidate patterns and variations in their control, access, and surveillance. The three sites include (1) the Obraje de Chincheros, a textile mill (1670s–1820 CE, Ayacucho, Peru); (2) Pomacocha (1681–1821 CE, Ayacucho, Peru), and (3) Trapiche Itappalluni, a silver refinery (1650–1800 CE, Puno, Peru). By combining multiple datasets, a range of labor contexts, and intra- and intersite comparisons, we interrogate the classic Foucauldian ideal, highlighting the diversity of layouts, surveillance, and architectural choices throughout this time period.

Secrets in the Stones: Stones with Inclusions in the Passage Tomb Tradition

The passage tombs of Atlantic Europe are a lasting memorial to a society with a knowledge system encompassing aspects of engineering, astronomy, and stone-working. The stones used to build these monuments have been explored from a range of perspectives. It seems likely that stones were chosen based on criteria such as color, source, and texture, and some may have had symbolic meaning. This paper investigates the presence of stones with geological inclusions at these sites and asks whether such stones were socially significant. Stones with geological inclusions (SWI) can be defined as structural stones with fossils, mineral veins, or rock clasts embedded within them. Anthropological research demonstrates that unusual stones, such as these, are sometimes attached to origin myths and broader belief systems. This research considered whether the presence of SWI in Neolithic monuments indicates comparable beliefs in Neolithic communities. This paper draws primarily on fieldwork in Ireland, with smaller case studies in Britain, and Brittany. It demonstrates that SWI use is patterned, and sometimes used to reference geological features. Finally, this paper questions what SWI can tell us about Neolithic people and their worldviews.

Carnelian Beads from the Site of Kish, Iraq: Differentiating Indus and Non-Indus Carnelian Beads Using Technological, Morphological, and Chemical Analysis

Carnelian beads from the site of Kish, Iraq, include a wide range of bead types, including locally produced short cylindrical beads and long biconical beads that are thought to have been produced in the Indus region of South Asia. Beads from different excavation contexts can be dated to a wide range of time periods, between 2800 BCE and CE 200–600. Numerous different styles of beads were produced using multiple production processes that can be associated with both local workshops and workshops in South Asia, Egypt, and Iran. Using the scanning electron microscope (SEM) to study drill hole casts, it has been possible to differentiate some of the major drilling techniques associated with different regions. These techniques include percussion/pecking, tapered stone drilling, constricted stone drilling, and copper drilling with abrasives and diamond-tipped drills. Selected beads from different time periods were also analyzed chemically using LA-

ICP-MS at the Field Museum to determine the possible source areas that the raw carnelian was derived from. The results of these multiple analytical approaches will be presented to demonstrate that earlier assumptions regarding the distribution and sourcing of carnelian beads are much more complex than earlier scholars had proposed.

New Approaches in Buildings Archaeology: An Examination of Late Medieval Lodging Ranges

Buildings archaeology somewhat lags behind the broader discipline of archaeology in its adoption and creation of new theoretical propositions possibly due to the misconception that the built environment lies solely in the remit of architectural historians rather than archaeologists. It is not, however, sitting stagnant: a number of new approaches and key theories are influencing the study of buildings, such as the theory of space, phenomenology, and affect theory. This paper details the use of these methods in the examination of lodging ranges—the earliest examples of quasi-private spaces in the late medieval great house—to consider the buildings' form, function, use and meaning. These methods reveal varying sensory perceptions and the creation of illusory architecture and deepen our understanding of social distance and identities within the late medieval great house; this in turn provides an insight into the medieval lived experience.

Leaving a Calling Card: Why Is This Rock Art Here?

Plains warfare is well known for its “gamesmanship” aspect, but one of the less emphasized parts of that is the practice of leaving a “calling card” flouting your entry into an enemy’s territory and your success against him. Recent research has located more than a dozen “out of place” northern Plains rock art sites. These are best explained as calling cards, carved or painted by marauding raiders in enemy territory for the purpose of taunting their enemies.

Iconographic and Material Comparative Analysis of Ulúa Valley Polychromes

This thesis explores the relationship between iconography and material analysis of Ulúa polychromes in

Honduras between 450 and 1200 CE. From a dataset of 56 ceramic pieces, first analyzed iconographically, which has been the main form of analysis for these artifacts. Second, the 56 pieces were sampled for INAA and processed through a computer program. The purpose of using these two analyses is to see if past iconographic analysis holds firm in its assumptions of representing group identity as well as how these iconographic elements represent group dynamics among the Ulúa Valley. Chapter 1 details the historical context around the Ulúa Valley. Iconographic analysis of 56 samples is defined in Chapter 2. Chapter 3 introduces the instrumental neutron activation analysis process while Chapter 4 establishes the initial data findings. Chapter 5's discussion goes in depth to compare iconographic and material processes for samples and their corresponding groups. Chapter 6's concluding notes bring each group into a structural context of the Ulúa Valley and how the samples can tell us how these groups may present themselves in physical spaces. Through this research and the use of both analyses, there is a varied expression of samples even if composition is similar.

Identifying Ancient Intra-Monastic Pathways among Gandharan Buddhist Sites through GIS

This project focuses on identifying pathways between sites of the Gandharan Buddhist Civilization with the help of GIS technology to identify the locations of as-yet unfound Gandharan archaeological sites, which are under the threat of becoming permanently destroyed due to rapidly growing urbanism in the region. This project employed GIS principles and techniques for executing a least-cost analysis between the two major Gandharan Buddhist temple complexes of Mardan and Taxila. The project used ArcGIS Pro software to perform GIS analysis and produce maps. The project used 30 m Aster Global DEM data from the EARTHDATA database of NASA. The project used the metabolic cost of walking for humans to create least-cost paths between the two sites. The result of the project identified more than one possible route between these Gandharan sites for Buddhist monks and other people to travel by foot. This project provides the baseline for archaeologists to do Lidar or field surveys along the proposed paths to discover additional Gandharan Buddhist archaeological sites.

Four Thousand Years of Disaster, Vulnerability, and Resilience in the Lower Yellow River, China

For the past 4,000 years, humans have assaulted the environments of the lower Yellow River Valley. For millennia this region has been an entirely cultivated and (mis)managed anthropogenic landscape. Indeed, the lower Yellow River is called the "river of sorrow" and flows through a land of famine. At the same time, though, it is a land of remarkable resilience. Today this area is home to some of the densest populations on earth and is a self-evident human success story. How do we understand this paradox of vulnerability and resilience? The lower Yellow River valley provides an instructive case study for exploring long-term interactions of societies and their environments. Specifically, this region provides an opportunity to think about the nature of human adaptive capacity in the face of repeated natural disasters. Using archaeological and historical data on long-term human-environmental interactions from the end of the Neolithic into the Dynastic period, I document how shifting human and environmental fortunes are literally and metaphorically sedimented in the alluvial floodplain. This work illustrates how success and failure are contextual; these states are the outcome of human choices and transformations of social and environmental relations.

Kidder, Tristram (Washington University), Seth Grooms (Appalachian State University) and Maggie Spivey (University of Alberta)**[24]***Radical Cosmological Ritual Intervention at Poverty Point*

The Poverty Point site in northeast Louisiana is unique—in size, monumental architecture, artifact content, and history—and the site defies standard functional explanations for hunter-gatherer settlements. In contrast to existing concepts arguing that the site's monumental constructions were built over hundreds of years to express political and economic power by a limited group of people, our data suggests the earthworks were built rapidly over an exceptionally brief span of months to perhaps a year by a large voluntary labor force drawn from across eastern North America. We hypothesize that Poverty Point was a place of revelation; the construction of the earthworks was a radical, cosmological ritual intervention, spurred by perceptible climate and environmental changes across the Southeast after ca. 3300 cal BP. The earthworks at Poverty Point are among the materialized remains of ritual performances intentionally initiated by Indigenous people seeking to rebalance an unbalanced world.

Kidwell, Jasmine (Baylor University) and Julie Hoggarth (Baylor University)**[107]***Human Demographics, Paleoclimate, and Paleoecology of Far West Texas from the Late Pleistocene through Holocene*

The vast region of far west Texas remains understudied in terms of its cultural, climatic, and environmental past. Current paleoclimatological and environmental proxy datasets are few and inconsistent in time, resolution, and scope. Here, we summarize key proxy data while contextualizing human demographic variation within the cultural regions of far west Texas. Using radiocarbon dates spanning the earliest dated sites to the arrival of the Spanish, we present summed probability distributions and kernel density estimations of population variation across time and space. Current paleoclimatic and environmental proxy records such as pluvial paleolake levels, isotopic values derived from speleothems and cave sediments, packrat middens, and other proxy data are presented in conjunction with the demographic models. Together, these dataset the stage for contextualizing human behavior and demographic variability from the Late Pleistocene through the Holocene. Through a lens of earth's dynamic systems, we may better understand how the earliest occupants of far west Texas responded to long-term climatological and environmental change.

Kiker, Summer (Jacksonville State University), Douglas Bolender (University of Massachusetts, Boston) and Kathryn Catlin (Jacksonville State University)**[48]***How Many Bone Pins Is a Lot? Material Assemblages at Kotið, a Small Viking Age Dwelling in Iceland*

Icelandic Viking Age archaeological assemblages are notorious for their paucity and limited range of material types. Kotið, a small dwelling dating to the original Viking Age settlement of Iceland, is no exception. In two seasons of excavation, only a handful of artifacts have been recovered; however, three bone pins have been found, and several others have turned up at neighboring small dwelling sites. The abundance of bone pins is unexpected, as most Viking Age domestic sites from Iceland, including large and wealthy farms, have at most one or two. The pins are decorated in a variety of styles and show evidence of skilled production. This poster describes the designs and manufacture of the pins and explores the possible meaning of their relative abundance at Kotið and the neighboring small dwelling sites.

Kilby, David (Texas State University)**[332]***Chair***Kilby, David (Texas State University) and Marcus Hamilton (University of Texas, San Antonio)****[332]***New Perspectives on Bonfire Shelter, Texas*

Bonfire Shelter contains an extensive stratified record of human prehistory in the Lower Pecos Canyonlands of Southwest Texas, and a correspondingly long history of competing interpretations of that record. The initial investigations of the site in the 1960s led to the announcement of the earliest known bison jump in North America, attributed to Plainview and perhaps Folsom hunters. In addition, the shelter was found to contain a ca. 14,000-year-old faunal assemblage with potential human modifications, extensive deposits relating to a Late Archaic bison jump, as well as several intervening occupations. Subsequent investigators questioned some of the original conclusions, particularly regarding the Paleoindian-age deposits, and vigorous debates played out in the literature. Beginning in 2017, the Ancient Southwest Texas project has carried out detailed reexamination of the site, correlating the stratigraphy identified by previous researchers, obtaining new dates, and attempting to address the debates while also providing due attention to less contentious site components. This paper provides a general overview of the history of work at Bonfire shelter, including fieldwork and preservation carried out over the last seven years by ASWT, presents some tentative conclusions, and serves as a foundation for papers on Bonfire Shelter that follow in this session.

Picturing the Written, Read, and Spoken Prayers to Zell: Devotional Therapeutics for (In)Fertility and Motherhood at Mariazell

In the mountains of the Austrian province of Styria, the Catholic pilgrimage shrine of Mariazell claimed many healing miracles during the later Middle Ages (ca. 1200–1550). Notably, many of these miracles address ailments of fertility and parenthood, including infertility, miscarriage, stillbirth, and infant death. Early sixteenth-century visual culture of the Mariazell site not only visualizes the shrine's diverse range of intercessory capabilities, but also the desired method of intercession: verbal pleas to Our Lady of Zell. These formulas appear in brief inscriptions written below the painted and printed images of the shrine's miracles. The texts provide specific details of the ailment that prompted intercession followed by the solution of seeking aid from Our Lady of Zell and devotion to her shrine. By analyzing the iconography and language of Mariazell's devotional visual culture alongside contemporaneous treatises on medicine and health, this paper argues that the combination of devotional text and image function as an instructive form of healthcare for circumstances of reproductive affliction. I further argue that the Mariazell miracle images and their accompanying inscriptions reveal an expansive attitude toward the types of ailments affecting the reproductive body and appropriate methods of treatment in fifteenth- and sixteenth-century Europe.

Kim, Nam (University of Wisconsin, Madison)**[56]***Reimagining and Reengineering Political Complexity in Early Vietnam*

Archaeologists continue to be interested in the development of political complexity and early forms of “states.” There is compelling evidence that leadership strategies and political centralization in such polities involved modification and reengineering of both social and landscape topographies, making durable modifications that persist in respective regions. In recognizing the theoretical utility of the state concept, this paper reimagines it by focusing on the process of political centralization and how it can foment both societal change as well as physical alterations to surrounding landscapes. Thinking of the state as ongoing action allows us to better understand the role of centralization in the development of highly complex and large-scale collectives in the human past, and of their environmental footprints. Using a case study from early Vietnam, the paper highlights conditions that resulted in the emergence of the area’s earliest complex society, while also illustrating how the polity radically transformed landscapes as large-scale aggregations of people found new ways to perceive and interact with each other and their ecological surroundings. It explores how political mechanisms reengineered social organization, thus effectively marshaling resources and labor to effectuate permanent sociopolitical and environmental changes.

[256]*Experimental Study of Lentil Taphonomy in Gangetic Early Farming Period to Understand Culinary Practices*

Archaeological studies can uncover various foods associated with different cultures, where species selection holds ecological importance and preparation/consumption bear cultural significance. Regrettably, there is a shortage of research on food-related behaviors. This is especially true in the India Gangetic Early to Developed Farming periods, despite the excavation of numerous crops, native and exotic alike. Recent findings at the site of Sakas in Uttar Pradesh have uncovered diverse assemblages, including lentils which show taphonomic changes, yet our knowledge about how they were used in their dietary culture remains limited. To address this gap, we conducted an experiment aimed at reconstructing culinary behaviors. We evaluated how various cooking techniques influenced the structure of the seeds, comparing them with the archaeological material. Our results suggest that soaking in water or roasting methods closely align with the archaeological context, warranting further investigation. Considering that lentils in the Ganges were a non-native crop, it is likely they were unfamiliar to people at the time. By examining their preparation and change over time, we can gain insight into how people responded to a new ingredient. This sheds light on the cultural aspects of food preparation and offers a fresh perspective on understanding prehistoric subsistence economies.

Kimbell, Jennifer (Terracon Consultants Inc.), Catherine Jalbert (Terracon Consultants Inc.) and Victoria Pagano (Terracon Consultants Inc.)**[43]***Archaeological Investigations at Mission Concepción (41BX12) and the Historic St. John’s Seminary Campus, San Antonio, Texas*

In 1731, Mission Nuestra Señora de la Purísima Concepción de Acuña (Mission Concepción) was constructed along the San Antonio River as part of a larger mission system whereby Franciscan missionaries sought to expand Spanish Colonial influence in present-day Texas through processes of cultural assimilation. Many of Mission Concepción’s associated landscape features were lost following secularization and increased urbanization as the City of San Antonio expanded through the nineteenth and early twentieth centuries. From 2016 to 2019, Terracon Consultants Inc., performed archaeological investigations adjacent to the mission in support of the St. John’s Seminary Redevelopment Project. Terracon identified intact cultural deposits associated with the mission, including portions of the northern compound wall and several midden

deposits. Prior to Terracon's investigations, only small portions of this wall had been relocated and exposed archaeologically, and little was known about the potential for associated deposits. This poster presents preliminary analysis of archaeological materials recovered from contexts along and outside the north wall and discusses how these materials can be interpretively compared with extant archaeological collections from the other portions of the mission system.

Balché Consumption among the Ancient Maya: Bees, Honey, and Ritual Practice

In this paper we discuss our recent absorbed residue study of a marble Ulúa style vase found at the Pacbitun site in Belize. In that study, we detected evidence for the consumption of the ritual drink balché dating to Terminal Classic period (800–850 CE). Consumption of balché is discussed in historic text, recognized in modern practice, and hinted at in Classic period imagery, but ours is the first study to detect it from an archaeological context. Balché is a fermented drink whose two key ingredients are honey and the bark of the balché tree. Compounds in balché bark produce a heightened sense of euphoria and emotional awareness. In modern Mayan ritual practice, balché is consumed at ritual occasions that build community solidarity and contact deities. Christina Luke has argued the imagery on Ulúa vases references creation and are often found in contexts emphasizing placemaking. The consumption of balché from them would have served to contact deities whose approval was required for rituals that ensouled buildings, remade sacred landscapes, and legitimized rulers. Our identification of balché in an Ulúa vase recovered in Belize illustrates the key role that honey and Melipona bees played in ritual practices of the ancient Maya.

Exploring Prehispanic Maya Marketplaces in Northwestern Belize: NSF Project Overview and Preliminary MNAP Results

The 2023–2024 field seasons witnessed the beginning of an ambitious NSF-funded project to investigate the possible existence of marketplaces in the Three Rivers Region of northwestern Belize. This project is innovative in leveraging information from long-running, independent research programs, localized at different sites, to explore marketplaces using a collaborative, configurational approach. Because researchers had already investigated all the sites targeted by the project, specific techniques varied depending on the information that was missing from a particular site. All, however, used the same set of cross-culturally derived marketplace indicators, searching for those not yet explored by previous field research. Data on soils, botanical remains, and ceramics complemented the information obtained from current and previous survey and excavations. This paper presents an introductory overview of the NSF-sponsored research as well as the results from two sites explored by the Maax Na Archaeology Project (MNAP). One is the large site of Maax Na, the first in this region to reveal initial evidence of an ancient marketplace. There, excavations

further investigated several structures, preliminarily identified as stalls, a shrine, and a marketplace manager residence. The second is the small site of Bolsa Verde, where soil samples and excavations explored different possible marketplace areas.

Contract Archaeology and the Center for American Archeology

In 1953, Stuart McKee Struever (1931–2022) founded Archaeological Research Inc., the nonprofit organization that would develop into the Foundation for Illinois Archeology and ultimately the Center for American Archeology (CAA), as it is known today. As the institution grew, so too did Struever’s vision of its scope and mission—from a research-focused program into one that could engage all dimensions of archaeological research, education, and public engagement as it does today. One often underappreciated dimension of this expanding vision and suite of archaeological programs is the Contract Archeology Program that would embrace the then nascent discipline of cultural resource management (CRM). Spanning over two decades, “contract archaeology” at the CAA would contribute to the stewardship and preservation of archaeological resources in Illinois as well providing training for future archaeologists and new data for further research and knowledge production. In this paper, we explore the establishment and growth of the CAA’s Contract Archeology Program, its contributions to CRM archaeology, and its legacy, both in the past and present.

Meaningful Small Program Assessment: A Case Study with Dr. Goldentrowels

In smaller anthropology programs, assessing the major cannot be done through statistical comparisons alone. Archaeology in particular presents distinct challenges for efforts at authentic and meaningful assessment. This paper discusses a small anthropology program’s assessment strategy that leverages both quantitative and qualitative approaches. Our scenario-based instrument provides students with a real world proxy to grapple with via a “pop quiz” writing assignment in a senior capstone course. The learning objectives measured center on ethics, including the preservation of sites and working with descendant communities. To avoid giving students with more knowledge of specific archaeological sites an advantage, we elected to create a hypothetical scenario involving a fictional developing country. Meaningful assessment provides useful feedback to the faculty in what areas students are achieving or failing to meet expectations, which can then be used to improve the program and enhance student success. Analysis of assessment data from 2017 to 2023, including two pandemic years in which all anthropology instruction was conducted online, shows that most students are meeting or exceeding expectations, though there is some work to be done, especially with regard to engaging the local community.

Kingrey, Haden (Washington State University), Shannon Tushingam (California Academy of Sciences) and John Blong (Washington State University)**[133]***Evidence for Possible Digging Implements in the Southern Columbia Plateau: Microbotanical Analysis of Stone Tools from a Late Holocene Earth Oven, 45OK1722, WA*

Earthen ovens in the Southern Columbia Plateau are associated with the preparation and cooking of roots and tubers, with evidence dating back to the middle Holocene. Despite issues with the preservation of these plant elements in the archaeological record, researchers can use microbotanical analyses to identify microscopic remains that oftentimes preserve far longer than macrobotanical remains. Archaeologists have used microbotanical analyses to identify plant collection and processing from the residues of stones tools that would have been associated with those activities. We present the results of a multiproxy analysis of starch grains and phytoliths on bifacial flaked tools and ground stone tools excavated by Washington State University field school students at 45OK1722 in 2022. Based on our results, we hypothesize that these bifacial stone tools may be digging implements associated with the collection of roots for a late Holocene earthen oven. These results are significant because our multiproxy methods can identify ancient food collecting and preparation processes with direct botanical evidence from tool residues. These results also acknowledge that local, Tribal communities have collected these plant foods for time immemorial and continue to do so today despite issues with threatened access to these plants and the effects of climate change.

Kingsland, Kaitlyn (University of South Florida)**[14]***The Status of Roman Archaeogaming: Serious Games for Archaeological Education and Outreach of Ancient Rome*

The digital turn in archaeology sees an increased interest in combining gaming and archaeology. Integrating serious games with archaeology demonstrates benefits for the public of all ages and background to learn about the past in the classroom, at cultural heritage institutions, and at home. This paper seeks to establish the current understanding of serious games for education, research, and outreach in cultural heritage and archaeology. Looking specifically at the serious games for the ancient Mediterranean, the research is centered around archaeological games about ancient Rome. In a review of the scholarship and a survey of games, there is a distinct lack of accurate portrayals of Roman cultural heritage and archaeology. As such, the need for public archaeology initiatives that integrate modern knowledge of archaeological materials and analysis about the Romans via a serious digital is expressed. The emerging subfield of archaeogaming establishes that games created by archaeologists are “archaeogames.” The paper seeks to present a pipeline for how archaeogames can be generated through the reuse of digitized archaeological materials, both 2D and 3D, for the purposes of research, education, and outreach.

Kinsella, Larry and Steve Boles (Illinois State Archaeological Survey)**[154]***The Chip-a-Canoe Project: Stone Tools, 40 Volunteers, Over 400 Hours of Labor . . . and It Floats!*

In 2023, a large group of volunteers engaged in an experimental archaeology project to manufacture a dugout

canoe with stone tools. A large tulip poplar was felled with stone axes and the 8,600-pound tree was then transformed with stone axes and adzes into a 1,600-pound, 4 m long dugout. The tree felling and reduction process combined took over 450 hours of labor. Upon completion, the dugout was launched into the Illinois River and manned by several groups, comprised of four volunteers each, for its inaugural float. This process was well documented with numerous paper forms, stopwatches, and video. We provide highlights from this massive undertaking and insights gained on stone tool usage during the production process as well as its performance in the water. After the drying process is complete, it will be on display at the Center for American Archeology in Kampsville, Illinois.

Remote Sensing Methods to Locate Archaeological Sites through Vegetation Indices on the Florida Coast

Sea level rise is a growing threat to cultural heritage resources. Popular geospatial methods to identify at-risk sites work well for large-scale areas but are often overly laborious for the non-specialist to use and challenging to apply at a site-specific scale. Here, we create a Coastal Canopy Health Model, a method used to locate cultural resources in a nonhomogenous coastal environment using tree health as a proxy measurement for archaeological sites. On the northeastern Florida coast, archaeologists have casually identified a correlation between certain types of vegetation, such as live oak and cedar trees, with shell-bearing archaeological sites. Test sites at the Guana Tolomato Matanzas National Estuarine Research Reserve (GTMNERR) indicated a statistically significant correlation between vegetation health indices and canopy height derived from lidar to detect the locations of archaeological sites in a mixed canopy coastal forest. The Coastal Canopy Health Model performed statistically significantly better than a random sampling at accurately locating known archaeological sites, thus showing promise for locating archaeological resources at risk efficiently and effectively with no-cost data sources.

Climate Change and Archaeological Research: An Analysis of NSF-Funded Archaeological Research Projects

As the current climate crisis intensifies, requests for proposals of grant funding related to solutions addressing these issues have increased. For over a decade, there has been a push to integrate archaeology into conversations about climate change (Van de Noort 2011). In this poster, I analyze how archaeologists engage with questions related to climate change to determine the various ways in which archaeological research is applied to climate change. The corpus consists of abstracts from grants funded in the last 10 years by the Archaeology and Archaeometry Program at the National Science Foundation. I examine the frequency of climate change in funded abstract and then code the abstracts for key terms and phrases used to connect archaeological data to modern climate change. Main themes focus on what data methods are used, whether these topics are presented as part of intellectual merit or broader impacts, and the framing in which these topics are discussed (e.g., adaptation, vulnerability, resilience). Patterns within these abstracts determine

regional or sub-field-specific connections about how climate change is addressed. This research provides an initial exploration of how archaeologists engage with questions about climate change, which can be further expanded to include other funding agencies and interdisciplinary-focused programs.

Medieval Settlement atop Monte Bonifato: A Case Study in Function over Form

Defensive Settlement or late medieval escape for nobility? When it comes to castles and many of their associated settlements it seems the latter has been pushed in English language literature more than the former for a few decades now. In this paper, we present a case study that showcases the development of a stronghold and associated settlement atop Monte Bonifato, Western Sicily, in the context of political upheaval within the island of Sicily and the greater Mediterranean as a whole. We present data from three years of work atop Monte Bonifato, highlighting how its morphology fits more with earlier, Norman castles than the date usually ascribed to it, how the mountaintop was encircled by walls in a series of building events to make it ever more defensible, and how a spatial study of pottery types might yield more information on why the summit was used and why it was subsequently abandoned at a time when other castles and fortified settlements were being redeveloped.

Pleistocene Archaeology in the Formerly Glaciated Northeast: Why Bother?

Conducting archaeological research exploring the Pleistocene occupations of formerly glaciated northeastern North America is challenging. Obstacles include an absence of stratified sites, poor preservation of perishable materials and shallow, often disturbed, sites. Perhaps because of his experience confronting these challenges shortly after completing his PhD, Bob was skeptical of our dissertation proposals focused on this theme. To paraphrase, we were confronted with what we remember as something like “If you can do archaeology anywhere why would you want to do it there?” While initially blindsiding us both, in retrospect this simple question has profoundly shaped our research programs for the better. In only a few words Bob challenged us to think creatively about what is unique in the Northeast and how to bring this to bear on anthropological questions of continental or even global significance. Here we review the research that has grown from Bob’s challenge, how these findings relate to broader questions, and where this is propelling our future research programs, all while keeping in mind “if you can do archaeology anywhere why do it there?” We hope we now have a better answer to that question.

Birds, Circles, and Landscapes Enclosed with Soil: Geoarchaeology at the Eastern Edge of Pinson Mounds, Tennessee, USA

Pinson Mounds is a large Middle Woodland monument complex centrally located between two other mound centers in west Tennessee. Despite intermittent archaeological research, the Eastern Precinct of Pinson Mounds has remained understudied compared to earthen monuments situated throughout other parts of the site. Comprised of the 6.7 ha. Eastern Enclosure, a platform mound, and a possible bird effigy mound, this portion of Pinson exhibits the lowest known density of artifacts and other traditional objects of archaeological focus. Geoarchaeology provides a unique opportunity to better understand the deep history of landscape modification particular to the Eastern Precinct that other archaeological approaches have not. In this research, we explore how the landscape has been modified beyond just its visible earthworks, how its components relate spatially and temporally to one another and the rest of the site, and verify the original form of Mound 30. By integrating new radiocarbon dates, geophysical techniques like magnetometry and earthen conductivity, and bulk soil analyses such as particle size analysis, magnetic susceptibility, sequential loss-on-ignition, and micromorphology, we look to answer these questions to gain insight into the complex history of interaction between Indigenous societies and the landscapes they shape.

Sacrifice as Politics, Killing as Identity: Regional Synthesis and New Evidence of Late Prehispanic Human Sacrifice in the Lambayeque Valley Complex, Peru

Diverse new understandings involving human sacrifice on the north coast of Peru have surfaced since 1994. In the Lambayeque Valley Complex on the northern north coast of Peru, an extensive and diachronic record of human sacrifice from several sites spanning nearly 400 individuals have been documented beginning in 2002. This paper provides a current archaeological and bioarchaeological synthesis of ritual killing in Lambayeque, from Late Moche to Inka times (550–1532 CE). Special emphasis is placed on how sacrifice reveals extended political histories: how elites and non-elites both managed and manipulated power relationships, political economies, and systems of statecraft in the offerings of human lives to the supernatural. We also consider that among complex multiethnic late prehispanic cultures, victim and group identity was also key to structuring sacrificial programs. This paper includes new evidence from the sites of Pampa Grande and Santa Rosa de Pucará, illustrating for the first time regional Late Moche and intrusive Wari-associated ritual killings (550–850 CE), foreshadowing the development of large-scale sacrifice systems in the centuries to follow.

Also considered are a series of extremely puzzling Middle/Late Sicán contexts (1050–1300 CE) documented at Huaca Lercanlech which illustrate various challenges in the study of ancient sacrifice.

Digital Storytelling on African Urbanisms: Recommendations on Fostering Digitally Enabled Equitable Participation in Heritage Production

Fostering digitally enabled equitable participation in heritage production is a major component of democratizing heritage creation. While substantial progress has been made in ensuring that digital data and infrastructure complies with the principles of FAIR (findability, accessibility, interoperability, and reusability) and LOUD (linked open usable data), less progress is discernible where basic technological knowledge and accessibility are limited. The challenge is heightened when dealing with low-resourced environments, as is common in the Global South, and the associated logistical challenges including varying technical competencies, computer and internet speeds, and cultural understandings and language barriers. This paper presents the outcomes of the NEH/AHRC “Digital Storytelling on African Urbanisms: A Model to Empower Education Initiatives Across the Global South” project (<https://www.metsemegologolo.org.za/wordpress/digital-storytelling/>). “Digital Storytelling on African Urbanisms” focused on how to best empower secondary school and university educators in the Global South to explore cultural heritage about precolonial African urbanism through digital storytelling with spatial and nonspatial data. We will discuss especially the project’s recommendations about how marginalized voices and perspectives can be integrated into the digital storytelling process through self-directed, generative storytelling curations in museum and classroom settings.

The Osteobiography of Human Remains from the Seaview and Indian Town Trail Archaeological Sites

Climate change and privatization activities related to disaster capitalism threaten land ownership rights and landscape preservation in Barbuda. Barbuda is home to multigenerational residences, businesses, schools, and buildings of cultural significance. Also, on this land are dozens of archaeological sites, each representing intangible cultural significance and containing invaluable artifacts and human remains from early inhabitants of the island. Extensive site surveys and excavations have been conducted over the past five decades, each adding crucial insight about the archaeological sites and early residents of the island. The research presented here is an analysis of the human remains previously excavated from the archaeological sites of Seaview and Indian Town Trail, located on the eastern part of the island. These osteobiographical analyses include an inventory of the skeletal remains, determination of the minimum number of individuals (MNI), estimates of the biological profile, and observations of skeletal trauma and paleopathologies. Radiocarbon dating of selected samples will be utilized to determine the age of the skeletal remains and better understand site occupation in Barbuda. This research will be a comprehensive documentation of analyses conducted on the skeletal remains that were previously excavated from the sites of Seaview and Indian Town Trail.

Klokler, Daniela (Universidade Federal de Minas Gerais [UFMG])**[259]***Sharks and Rays and Sambaquieiros: A View from Piaçaguera*

Precolonial groups used various types of raw materials for manufacture of tools and adornments: rocks, clay, fibers, bones, and shells, among others. In general, lithic and ceramic assemblages gain more focus from researchers due to their ubiquity and better preservation. Shell mound sites, however, provide a context in which faunal remains are the main components of the matrix so the study of the social and symbolic meanings of faunal remains allows a special glimpse on the understanding of human societies' relationships with the animal world and with aquatic animals in particular. In this paper, I present findings about the shark and ray assemblages from Piaçaguera site, a shell midden (sambaqui) from Eastern Brazil. Bone points (gorges) and modified teeth (from sharks) are the most dominant types of artifacts at this site, and the majority of pieces are associated with burials. The results present a starting point for an examination of the relationship between these animals and coastal societies in the past.

Kmiec, Theodore (Texas State University)**[309]***Setting the Axis of the World: Investigations of World Tree Raising Ceremonies throughout the Chronology of Mesoamerica*

The ideological concept of the World Tree can be found in ancient and living cultures throughout the world. Many cultures located in Mexico and Mesoamerica have incorporated this tradition in their ancient indigenous art, ceremonies, and recorded oral histories. The ideology of a culture may evolve or transform due to internal and external factors over time; however, sacred principles can be hidden in plain sight or be kept secret by those who protect these ancient practices. Importantly, the concept of the World Tree is found in the iconography of Olmec material objects and monuments. Several peculiar stone cylinders were found at the three main Olmec sites of San Lorenzo, La Venta, and Tres Zapotes. This paper focuses on La Venta Monument 14, located within Mound A-3 in Complex A, at the Olmec site of La Venta. In this paper, I will explore tree or pole-raising ceremonies throughout the chronology of Mexico and Mesoamerica. Lastly, I will discuss the similarities and differences of these ceremonies found in Mesoamerica, and argue that a similar ceremony took place at Mound A-3 in La Venta Complex A.

Knab, Timothy (Universidad de las Américas Puebla)**[302]***Mesoamerican Transitions: Social, Psychological, and Symbolic*

We use metaphors for the human mind just as we do for religious, mythic and symbolic systems. These metaphoric systems reproduce the same social phenomena in ritual process and social organization. It should thus be clear that we find reintegration of social, symbolic, and metaphoric systems as a society is transformed and that they should be reflected in a coherent manner. These cultural projections reflect universal norms found not only in the work of Jung, Freud, Campbell, and Frazer but the rise of Rabbinic Judaism, Tantric Buddhism, and the Vedic Scriptures. In Mesoamerica we have failed to account for such transitions which clearly indicate major social, behavioral, and symbolic transformations. This is the case with the vibrant polycultural symbolism of late Mesoamerican narrative ceramics that reveal a remarkable world of psychical complexity and sophistication. I will examine the social, ideological, and symbolic transitions that take place in early antiquity and what they imply for Mesoamerican social and political structures.

Knapp, Gregory [220] see Pratt, Will

Knappett, Carl (University of Toronto)**[56]***Beyond the Knossian State: Urban Economy and Society at the East Cretan Site of Palaikastro*

In scholarship on the Bronze Age Aegean, there is a robust conjunction of palace, town, and state. If we take the case of Knossos, then the presumed central authority represented by its palatial complex, and its surrounding town covering 100 ha, are generally thought to imply an associated territory under its control. The same is usually assumed for the other major palatial centers that emerge on the island of Crete ca. 2000 BCE, namely Phaistos and Malia. However, Crete has other urban agglomerations that do not conform quite so neatly. The town of Palaikastro, for example, has neither any sign of a palatial building, nor any indication of a territory that one might consider a state. Where previously scholars have assumed a high degree of institutional alignment from settlement to settlement within this island society, it is increasingly apparent that some sites may have taken quite different routes in their collective action. Here I explore the coastal urban settlement of Palaikastro as a possible instance of such divergence, examining the ways in which its local economy might have contributed to its distinctive sociopolitical status.

Distinct Types? A Geometric Morphometric Analysis of Paleoindian Age Mojave Desert Lake Mohave and Silver Lake Projectile Points

Prior univariate and multivariate morphometric analysis of Paleoindian age Lake Mohave and Silver Lake projectile points from the Mojave Desert, California, revealed these types are distinguishable 80% of the time. Building on the prior study, we use landmark-based geometric morphometric (LGM) analyses and complementary non-LGM variables to assess whether Lake Mohave and Silver Lake points are stylistically distinct or if repeated breakage and resharpening led to convergence (overlapping morphologies) between the types. Efforts to preserve stylistic separation are evident if the point types were resharpened in an isometric manner to maintain the original shape-size relationship through the reduction process and if the blade and stem modules strongly covary and are highly integrated. Conversely, an allometric point shape-size relationship coupled with a lack of covariation between the blade and stem modules (little integration between the modules) may indicate repeated resharpening resulted in the convergence of types rather than the maintenance of distinct styles. A continuum between these patterns is possible whereby the types are separate but, in many individual cases, converge due to extensive resharpening and reworking. We tested these propositions using a database of more than 200 Lake Mohave and Silver Lake points from sites across the Mojave Desert.

[86]

New Perspectives on Precolonial Trade in Eastern Africa

Discrepancies are emerging between historical and archaeological perspectives on the nature, scale, and chronology of precolonial and caravan exchange networks in the eastern African interior. For example, the caravan trade is thought to have emerged as coastal interests expanded inland around 1800, yet multiple archaeological sites contain evidence of exchange predating the nineteenth century. This paper presents elemental analyses of obsidian and glass beads recovered from the contemporary Sandawe homeland of north-central Tanzania. The Sandawe have been characterized as descendants of a forager population that remained isolated until recent centuries. Obsidian originating in central Kenya may have entered the study area as early as 750 BC. This represents a 30% increase in the distance over which obsidian is observed to have been transported in eastern Africa, and it is the second farthest known transport of obsidian on the continent, following ancient Egypt. Glass beads from diverse sources in Asia and Europe may have arrived by the late 1600s, continuing into the present. When considered alongside other forms of material culture, these studies demonstrate that the region's inhabitants have had time-deep connections to numerous exchange networks, ranging from the Rift Valley to the Indian Ocean World and beyond.

Knodell, Alex (Carleton College)**[26]***Discussant***[26]***Chair***Knodell, Alex (Carleton College)****[26]***The Materiality of Surveillance: Scale, Complexity, and Polity*

Textual and archaeological evidence make clear that most ancient polities were concerned with surveillance in some way. However, the scale of material investment in surveillance suggests different motivations in different contexts. This paper compares the material signatures of surveillance in Greek Bronze Age polities, Iron Age city-states, and Roman imperial territories, in order to elucidate different scales of and interests in surveillance. For example, inter-polity surveillance depends on human-derived information gathering; bureaucratic systems record information about land and subjects; monuments and fortifications demonstrate the capacity to observe just as much as they function to collect actual information. In the Greek world, these material interventions seem to be significant first in zones such as borderlands, where immediate territorial claims are at stake, along key land routes, and in productive hinterlands to monitor subjects or slaves. In Roman times such interventions are deployed as explicit, material extensions of imperial authority, especially in recently annexed cities and landscapes. A long-term view of surveillance in contexts from Mainland Greece, the Cyclades, and Jordan suggests that the spatial scale and organizational complexity of ancient polities are closely linked not only to their capacity to surveil, but to showing that they are doing it.

Ko, Jada (Brown University, Institute at Brown for Environment and Society)**[19]***Reevaluating the Concept of Sustainability in the Context of Animal Resource Utilization in Ancient China*

The extraction and utilization of natural resources often come with an underlying question of sustainability. At present, there are constant debates on and readjustments to how sustainability is measured. One of the biggest challenges is to establish suitable baselines to evaluate the balance between resource economies, resource availability, and ecological homeostasis. Archaeology provides not only deep-time data to push ecological baselines back chronologically, but also long-term perspectives on how humans have impacted and have been impacted by changes in natural resource distribution, abundance, and characteristics in the midst of sociocultural, ecological, and climatic fluctuations. This paper explores from a zooarchaeological perspective on how the relationships between human societies and animal resources in ancient China can allow us to examine practices that impact resource sustainability. The discussion focuses on animal husbandry and wildlife exploitation in Neolithic to Early Bronze Age societies in different ecological zones, and on the long-term ecological footprints these practices left at local and regional scales. While sustainability is a relative concept dependent on space, time, sociocultural, economic, and political needs, histories, regenerative characteristics of resources and various other factors, the practices that affect sustainability are accumulative and relevant to the discussion of biodiversity losses we experience today.

Koenig, Charles (Sul Ross State University)**[294]***Earth Oven Experiments in Texas and Wyoming*

The durable remains of earth oven construction—namely, fire-cracked rock (FCR)—lack the same tactile

connection to the past as lithic or ceramic artifacts. However, constructing experimental earth ovens provides an immersive experience where students, researchers, and the general public can gain a better understanding of FCR, earth ovens, and Indigenous cooking strategies more broadly. Providing this experiential window into earth ovens is critically important for archaeology because (1) Indigenous groups across the world continue to use earth ovens, and (2) FCR are frequently encountered in academic and contract archaeological projects. This paper summarizes my experiences using oven experiments as part of research, field schools, and public outreach projects in Texas and Wyoming. Due to the effort required to construct an earth oven, most oven experiments fall somewhere along the continuum from replicative public displays with limited or no quantitative data collection to meticulous recording of every input variable. However, even in instances where features are constructed for public engagement, researchers are still able to collect meaningful information from oven experiments—especially when working with descendant communities.

Not Afraid of Conflict: The Feisty Rulers, Communities, and Scholars of Ancient Southern Mesoamerica—Retrospective of a Lived Tradition of Rivalry

Can we compare the power, decline, and survival of Mesoamerican sociopolitical and religious systems with contemporary academic schools? Are there characteristic relationships between researchers and research subjects? Does this apply at least to the Mixteca-Puebla and Oaxaca regions? In other words, what do the Danzantes, Quetzalcoatl, and Eight Deers share with the Diego Durans, Alfonso Casos, John Pohls, and his contemporaries? This somewhat adventurous thesis is the introduction to John Pohl's field of operation. How does it differ from the better-known studies on Mesoamerica such as that of the Maya and Aztec? How did academic schools come to be? Is the criticism justified that important results for the overall Mesoamerican picture are being ignored outside the regional focus? Are we content with small-scale slice-and-dice research? Given the long history of studying Mixtec pictorial manuscripts, how should we deal with the fact that this graphic communication system is rarely mentioned in the general literature? What about the powerful interpretive sovereignties, even misleading attributions, that influence not only international research, but lull the communities concerned into false certainties? A critical balance sheet and a cautionary outlook.

Kohanski, Neil

[221]

Unearthing Maya Rituals: The Power of Ethnographic Analogy

This paper seeks to explore the pivotal role of ethnographic analogy in archaeological research, with a focus on the Maya ritual within subterranean spaces. While ethnographic analogy remains indispensable to the archaeological enterprise, it has faced significant resistance within the archaeological community. This presentation aims to illuminate the importance of ethnographic analogy, especially in the context of the archaeology of religion, a field marginalized since the 1960s with the rise of Processual Archaeology. The marginalization has led to the misapplication of Western models to non-Western societies, highlighting the need for reevaluation and the integration of ethnographic methods. This paper reviews the extent to which ethnographic models have been employed in the archaeological investigations and interpretations of caves. I examine where these analogies have been successfully applied and suggest ways to further integrate ethnographic analogy into archaeology. I aim to promote a deeper appreciation for ethnographic analogy within the archaeological community, emphasizing its critical role in understanding the archaeology of religion and beyond. Through collaboration and interdisciplinary approaches, we can enhance the rigor and cultural sensitivity of archaeological research elevating the knowledge of indigenous communities.

From Pukaras to Polities: Exploring Late Prehispanic Andean Hillforts through Large-Scale Network Analysis

This paper employs network analysis to explore the sociopolitical dynamics of the late prehispanic south-central Andes through the lens of 1,400 hilltop fortifications. Hilltop fortifications in the Andean highlands, known as pukaras, are emblematic of the Late Intermediate period (1000–1450 CE) and Late Horizon (1450–1532 CE). Focusing on defensive networks reveals patterns of interdependence that provide insights into the larger framework of sociopolitical organization during the late prehispanic era. Our study investigates relationships among these hillforts by combining spatial analysis and formal network analysis. Edges between hillforts were constructed and weighted based on intervisibility and walking cost to account for the influence of the mountainous Andean landscape on interactions and mutual aid. We identify significant sociopolitical units within this regional dataset using community detection measures, validated against archaeological and ethnohistoric sources. Analysis of the resulting networks reveals important regional diversity in community structure, highlighting interactions between local landscapes, levels of conflict, and sociopolitical organization. This paper highlights the potential of interregional scale network analysis to uncover patterns in large archaeological datasets and advances our understanding of how defensive networks shaped late prehispanic Andean polities.

Archaeoacoustics at Chavín de Huántar: New Evidence for Social Complexity via Sonic Communication Technologies

A dynamic, pervasive link between materiality and humans, sound remains an underestimated and deeply misunderstood domain for archaeological study. Archaeoacoustics fieldwork with broad community contributions at Chavín de Huántar since 2008 has enabled the development of new archaeological research methodologies to reveal, define, and explain communication affordances of site materials, structures, and settings. Sustained explorations of "what studying sound in archaeology could be" in fieldwork leveraged acoustics and auditory science to understand site infrastructural features in both archaeometric and experiential terms. Site-responsive acoustical measurement techniques and novel performance experiments with site-excavated *Strombus* marine shell horns resulted in unprecedented documentation of archaeological soundmakers and ground-truthing of their use-potential in site settings. Systematic auditory localization experiments further elucidated perceptual implications of Chavín's interior architectural design. Through identifying and exploring diverse evidence for human-environmental interactions at Chavín, site archaeoacoustics research has demonstrated key material-anthropological connections that challenge some long-held interpretations about social roles and spatial functionalities, while exemplifying innovations that mark Chavín as a nexus of social complexity in the Andean Formative period. Nuanced archaeoacoustical analyses, considered with respect to site and regional contexts, constitute a novel "archaeological possibility space" (Kolar 2020) that models a new way of conducting and interpreting multisensory archaeology.

The Piedras Rayadas of El Tigre, Honduras: Brokering Place and Cultural Memory

Grooved boulders seem to be an archaeological feature unique to El Tigre island in Honduras. Distributed around the small island, they are known locally as *pedras rayadas*, and feature in local oral histories. As durable traces, their meaning is everchanging, yet intimately bound to the locality of the island. In the most eastern point of the site of La Tigüilotada, 16 *pedras rayadas* line a promontory on the edge of a cliff, along with petroglyphs. Material and malacological evidence suggest the use of this promontory in communal feasting. While the material associated with feasting seems to date to the earlier phase of occupation of La Tigüilotada (800–1200 CE), the *pedras rayadas* seem to date to the last occupation of El Tigre prior to colonization (1300–1600 CE). As such, the meaning of this place seem to have persisted through time, and through different sets of cultural values. In this setting, we propose to examine the monumentality of the *pedras rayadas*, both as place-making devices and activators of cultural memory. Through this case study, we aim to engage with the concept of monumentality (1) in terms of (re)production of meaning and (2) as brokering past, present and future.

El Jovero: Investigating Political Frontiers on the Usumacinta River

The borders and frontiers of ancient communities provide a rich opportunity to examine the effects of social and political change. These interstitial spaces are often conceptualized as part of a polity body but may be better understood as spaces of continual change and reorganization, positioning these communities as active rather than passive elements in regional political dynamics. I deploy this perspective to examine polities in the Maya lowlands, where an array of competing political structures vied for control over the landscape. Investigating the interstices of Lacanja Tzeltal, Piedras Negras, and Yaxchilan along the Usumacinta River provides a unique opportunity to contrast the effects of political machinations among ancient Maya royal courts on the countryside, borders, and frontiers of their territories. Presented here are analysis and interpretation of two seasons of fieldwork, supported by lidar-based GIS analysis, focused on the archaeological site of El Jovero, Chiapas Mexico. This research aims to better understand how the ebb and flow of control projecting from major regional centers affects communities in their interstices. I examine the occupational trajectory of El Jovero as a community inhabiting a landscape affected by power struggles and conflict between ancient Maya royal courts.

Therapeutic Dentistry in Prehistoric Maryland: New Analyses from the Late Woodland Period Hughes (18MO1) Archaeological Site

Late Woodland period human remains were recovered from the Hughes site (18MO1) in the Maryland Piedmont during the 1930s. Among the remains are two mandibles and a maxillary right dental quadrant that contain carious teeth suspected of having undergone antemortem dental modification. Affected teeth representing two adult females and a child were analyzed utilizing radiography, scanning electron microscopy,

and visible alternate light source macro-photography. These teeth show signs of both radial and concentric tool marks in both the enamel and dentin borders of carious lesions. It is proposed that these modifications provide evidence of the practice of therapeutic dentistry during the Late Woodland period in the Middle Atlantic region. This presentation includes photographs of maxillae, mandibles, and affected dentition representing individuals unaffiliated with known Native American regional populations. In good faith, an amended version of this paper was submitted to the Maryland Commission on Indian Affairs for comment, as these findings contribute to extant, albeit infrequent, documentation of dental pathological intervention in the Middle Atlantic, Late Woodland period. Nonacademic venues for dissemination of findings include bioanthropology students and archaeological interest groups.

Evidence of Maritime Trade at the Bulgarian Black Sea Site of Apollonia Pontica (Seventh–Third Centuries BC)

This presentation will highlight the evidence for trade networks and the distribution of goods at the ancient port city of Apollonia Pontica along Bulgaria's Black Sea Coast. Founded in the seventh century BC by Milesians from western Ionia fleeing an incursion by their Lydian neighbors, Apollonia—with its two excellent ports and easy access to the Bosphorus—quickly developed into a major economic and trade center distributing goods from the Aegean, the Black Sea, and the Near East. It appears that Apollonia's proximity to the copper ore deposits of the Medni Rid mountains and its abundant local fisheries aided its expansion. This presentation will discuss how the presence of certain pottery types, such as South Ionian Archaic Ib–c Wild Goat Style, Attic black-figure, and imported wine amphorae indicate exchange relationships with areas such as Attica, western Ionia, Rhodes, and Chios. The presentation will also explore the evidence for certain types of imported glass, as well as specific kinds of exotic fruits and nuts such as pistachios, dates, olives and pine nuts, to understand what kind of information they can provide about trade relationships between Apollonia and the Aegean, Ionian, and Black Sea regions.

Collecting, Caching, and Cooking: The Agency of Women in Hunting-Gathering Societies

Decades of ethnographic and archaeological research has shown that women manage and perform many activities associated with food preparation and the manufacture of food processing implements in hunting-gathering societies around the world. This paper argues that dramatic shifts in Terminal Late Woodland (AD 1000–1600) subsistence strategies in the Northern Great Lakes region of North America were driven by the decision-making of women. Analysis of subterranean food storage containers (their construction and location), ceramic cookware (its construction and use), and evidence of associated foodstuffs supports the argument for a shift in focus to select abundant fall resources that could be collected in surplus, with minimal labor costs. The tasks of food collection, processing, and cooking, along with the manufacture of associated technologies, are traditionally accomplished by women, leading to the conclusion that these primary markers of subsistence change were controlled by women. The traditional division of labor, evidenced in ethnographic and ethnohistoric accounts, places women as agents of socioeconomic change.

Sourcing Obsidian in the Central Mesoamerican Region Using XRF Analysis

Obsidian tools and flakes are commonly examined in sourcing studies in areas with abundant volcanogenic

deposits. Obsidian provenance research in the central Mesoamerican region has shown extensive networks of obsidian trade during the Formative and Classic periods. In this study, we used portable XRF to analyze a previously unstudied collection of over 200 artifacts housed at the Museum of Anthropology (University of Missouri) from sites in the Basin of Mexico, Belize, and Guatemala including Tula, Teotihuacan, Uxatlan, Cotzumalguapa, and others. The resulting data from the artifact analysis were then compared to the obsidian source reference database at the Archaeometry Lab at the University of Missouri Research Reactor. The results show patterns of long-distance exchange of obsidian that are useful for understanding patterns of trade relationships.

The Hall of the Braided Serpents (La Sala de las Serpientes Trenzadas): New Discoveries on Pañamarca's Moche Plaza

Excavations in 2023 revealed a previously unexcavated structure in the southern corner of the Moche plaza at Pañamarca. Here we present our findings related to this building, which contains large, well-preserved pillars with anthropomorphized snakes on all facades and the life-sized painting of a Moche monster chasing a man. We also discuss multiple renewal events of the space that included various offerings—most notably textiles—burning events, the careful capping of floors, and the whitewashing of previously painted walls. The prominent position of this structure, perched above the plaza but also private, leads us to suggest it played an important role for privileged individuals overseeing the activities performed below.

The Place of Maguey at El Tajín and in North-Central Veracruz during the Classic Period

The presence of maguey in key iconographic programs at the major Classic Veracruz site of El Tajín has been explained largely through a hypothetical pulque cult at the site. This presentation will both extend and debate this interpretation of maguey iconography by exploring the locative nature of the maguey motif in a regional context.

Rock Art and Archaeology in the Mongolian Altai, Part 2

The ongoing Khoton Lake project documents several hundred archaeological sites and environmental conditions spanning the past 8,000 years. Forty excavated sites ranging from pre-Neolithic to the Bronze, Iron, Turkic, and medieval periods occur as dwellings, ritual, mortuary, ceremonial, and special-purpose places. In many cases, geophysical orientations, intentional landscape settings, and proximity to rock art panels or clusters are apparent. More than 12,000 individual petroglyphs have been recorded. Direct association of rock art and archaeology is found most conspicuously in Late Bronze Age khirigsuur mounds that include engraved deer stones and Mongolian deer imagery executed on nearby bedrock. Proximity indicates a close relationship between practical lifeways, ritual, and belief rarely found in archaeological settings. Experimental scientific dating shows promise for linking rock art to archaeological cultures. Graphic representations that begin in the Upper Paleolithic and explode during the Bronze Age and later periods yield information that cannot be retrieved from archaeological contexts alone. Combined, these data demonstrate human relationships, behavior, technologies, values, and beliefs in ways that enrich our understanding of Central Asian cultures and their developmental trajectories, traditions, and ecologies.

Punto de referencia en la movilización de los olmecas de la costa del Golfo de México

Dentro y fuera de Mesoamérica, se encuentran varios objetos portátiles con la iconografía olmeca. Pero ¿este fenómeno está mostrando la movilidad de los olmecas? Es difícil de responder esta pregunta porque los objetos pequeños se pueden trasladar de distintas maneras. Sin embargo, también hay otros objetos no portátiles con la iconografía olmeca para comprender la movilidad de los olmecas, como petrograbados representados en las rocas gigantes. Aunque algunos de ellos no muestran el auténtico estilo iconográfico olmeca, pero también existen algunos petrograbados con el estilo auténtico. En este estudio nos enfocaremos a la distribución geográfica de estos petrograbados fuera de zona nuclear olmeca, comenzando con la identificación de petrograbados con el auténtico estilo olmeca, ya que para elaborar este tipo de objeto con autenticidad se necesita una comprensión profunda de significados iconográficos. Anteriormente, el petrograbado olmeca encontrado más al sureste de Mesoamérica se encontraba en Chalchuapa, El Salvador. Pero recientemente hubo un hallazgo de un nuevo petrograbado olmeca en el sitio arqueológico Los Naranjos, Honduras. La aparición de este petrograbado nos muestra una posible dimensión máxima y ruta de la movilidad de los olmecas, ya que podemos considerarlos como puntos de referencia de su llegada.

Koutrafour, Vasiliki (University of Edinburgh), Scott Van Keuren (University of Vermont) and Jonah Steinberg (University of South Carolina)**[6]***Early Romani Archaeologies*

Roma people, whose ancestors and language come from India, form a major community in all countries of Europe and are often referred to as “Europe’s largest minority.” Greece is distinctly central in Romani history, as Greek profoundly impacted the Romani language, and it was in the thirteenth and fourteenth centuries that settlements in the Peloponnese, Crete, and Corfu are first identified in historical records. The traces of these communities—the Romani archaeological past—have been entirely ignored by modern scholars. In this paper, we introduce the Early Romani Archaeologies Project, envisioned as an “archaeological ethnography” that reconnects this past to the lives of contemporary Roma in the region. We report preliminary results of fieldwork, but more importantly, explore questions about how such a long-term project should be conceived and who it might involve and ultimately serve.

Kovacevich, Brigitte (University of Central Florida)**[122]***Chair***Kovacevich, Brigitte (University of Central Florida), Michael Callaghan (University of Central Florida), Karla Cardona (University of Central Florida) and Rodrigo Guzman (University of Central Florida)****[122]***An Introduction to Archaeology at Holtun, Guatemala*

The archaeological site of Holtun, Guatemala, has been documented as an intermediate-sized Maya center with occupation spanning the Middle Preclassic through Terminal Classic periods. The site is situated approximately 35 km southwest of Tikal and 12.3 km to the south of Yaxha. The formal site consists of a monumental epicenter built atop a karstic hill positioned along a northeast-southwest axis. According to the most recent mapping at the site, the epicenter consists of 14 groups and 86 structures, all showing evidence of stone construction with a significant outlying, rural population. Major monumental architecture consists of a Middle Preclassic E-Group, Late Preclassic Triadic Group, ballcourt, stone-enclosed causeway, and various elite residential groups of stone architecture. This paper will introduce the session and give background on investigations at the site including the Holtun Archaeological Project (HAP) which began in 2010, as well as investigations that preceded it. We will detail the major findings of HAP, especially those that have been previously published. These include methods for preservation and recording of monumental art and ceramic analysis. Findings that are not able to be presented in the session will also be discussed, including bioarchaeological data and possibilities for future investigations.

Kowalewski, Stephen (University of Georgia)**[301]***The Institutional Basis of Sustained Farming Systems*

For key agricultural resources, people form and refine social institutions of property tailored to biophysical constraints and affordances of the local environment. As known from indigenous texts and practices, and a large body of historical research, in Oaxaca—and by extension Mesoamerica and beyond—intensive terracing, irrigation, and rainfall-dependent farming, etc. are associated with different institutions of property and resource management, and varying patterns of labor and social inequality. The agroecosystems, and associated institutions, knowledge, and cultural practices forming the social means of production have

archaeological correlates that can often be traced back in time for several thousand years. Here, property regimes do not form an evolutionary sequence, they do not necessarily become more exploitive over time, nor are they responses to population pressure. In fact, the most land- and labor-intensive farming systems can make for relatively low wealth inequality and democratic local governance. Property regimes are created and maintained because they work in specific contexts, they provide for sustained use of resources.

Extant Shark Tooth Artifacts at Cahokia

Cahokia is one of the most important archaeological sites in North America and was populated from AD 1000 to 1300. It was mound-building center with exotic lithics, ceramics, marine shell beads, and shark teeth. Here, I present information on 21 Greater Cahokia extant shark teeth along with contextual and chronological information. None of the teeth are fossils but rather are from freshly caught animals, and as such they are considered trade goods. More than one-third of the teeth were drilled in the middle of the root indicating that they were hafted for pendants or for tools/weapons. Shark teeth are rare from Mississippian sites, making shark teeth at Greater Cahokia especially unique. I show that the teeth and/or jaws were extracted from extant, freshly caught sharks and probably acquired from the Gulf of Mexico or south Florida. Shark teeth were found in high-status contexts, and shark tooth replicas were made from chert. The intentional importation of shark teeth is another indication of the seminal nature and far-reaching trading relationships of Cahokian culture.

Shake, Rattle, and Roll: Continuity of Rattling Ceramic Vessels and Adornos in the Caribbean

Ceramic rattles and rattle vessel adornos have received little attention in current Caribbean archaeology literature. These rattles may be overlooked or misidentified in Caribbean ceramic collections due to their minimal audibility or “failure” during the construction process due to their technical complexity. Here, we evaluate existing reports of rattle ceramics and adornos in the Caribbean as well as report on the discovery of five rattle adornos within collections at the Florida Museum of Natural History. A detailed review of adorno rattles, including microscopic analysis, measurement of sound intensity, and a replication experiment is conducted. This study answers questions regarding their technological construction, potential function, geospatial and temporal spread, and cultural implications to Indigenous groups in the Caribbean. Despite difficulty in their construction, adorno rattles and ceramic rattles appeared in the Greater and Lesser Antilles throughout the Ceramic Age and likely functioned in ceremonial spaces. The importance of rattles to Indigenous groups in the Caribbean and their association with *cemísm* indicates their significance as a social valuable.

Kradin, Nikolay (Russian Academy of Sciences)**[17]***Inner Asian Nomads and World-System Analysis*

World-systems analysis was created to describe capitalism. However, in 1989, Abu-Lughod expanded the temporal boundaries. She described the world-system of the thirteenth century, and now it has become customary to talk about Mongolian globalization. After her, Gunder-Frank, Chase-Dunn, Hall, and Wilkinson showed that world-systems analysis is applicable to preindustrial states, archaic, and primitive societies. In Afro-Eurasia, the nomads have performed important intermediary functions between regional world-systems cores (civilizations). They occupied a place of semi-periphery and have provided the connection of the flows of goods, finances, and technological and cultural information. The imperial and “quasi-imperial” organization of the nomads in Inner Asia developed after the ending of the “axial age” at the time of the creation of the Ch’in empire in China. In comparative perspectives, it was in regions first, where there were available large spaces favorable to nomadic pastoralism (regions off the Black Sea, Volga steppes, Mongolia, etc.) and, secondly, where the nomads were forced into long and active contact with more highly organized agricultural urban societies (Scythians and Western Asian ancient states, Hunns and Roman—Byzantium Empires, nomads of Inner Asia and China from Xiongnu to medieval and premodern Mongols etc.).

Kratimenos, Panos**[59]***Anachronology in the Study of the Precolumbian Maya: Toward a Post-Postclassic*

All Mayanists, and Mesoamericanists in general, are familiar with tripartite chronologies. The periodization of time in precolumbian Mesoamerica between a “Preclassic”/“Formative,” “Classic,” and “Postclassic” has been baked into the conceptual framework of the discipline since its earliest days. However, in the more than a century since the terms were first used, subsequent discoveries have consistently served to undermine these demarcations, rendering them increasingly tenuous and arbitrary. Moreover, beyond the simple matter of accuracy, this traditional model is also increasingly problematic in the era of de- and neocolonialism. Focusing on the precolumbian Maya, this talk will explore the origins of the tripartite chronology, the assumptions and underpin it and that we tacitly perpetuate in our persistence with it, as well as propose an alternative interpretive model for the long-maligned “Postclassic” phase from ca. tenth century AD to the Spanish conquest.

Krause, Maya (Vanderbilt University) and Tiffany Tung (Vanderbilt University)**[246]***Childhood in the Wari World: A Bioarchaeological Investigation of Dietary Patterns in a Middle Horizon (600–1000 CE) Community*

This paper uses an anthropological bioarchaeological approach to examine stable isotope data to reconstruct juvenile diet and migration. Through the analysis of stable carbon and oxygen isotope data from dental enamel carbonates, this study builds a preliminary understanding of the process of childhood-making and enculturation of individuals from the site of Auquimarca, which was affiliated with the Wari Empire (600–1000 CE) in the prehispanic Andes. The site, located in the department of Junín, is composed of residential structures and 126 tombs. This study analyzes 339 enamel carbonate samples, which represent 80 individuals. Stable carbon and oxygen isotope data from enamel carbonates allow for a reconstruction of diet and migration from infancy to adolescence, as dental isotopic signatures offer a retrospective glance into an individual's childhood. Results show a mean of -5.39‰ (SD = 1.7) for $\delta^{13}\text{C}$ in enamel and -9.46‰ (SD = 1.0) for $\delta^{18}\text{O}$ in enamel. Preliminary results suggest that the community heavily subsisted on C4 plants, such as maize. Additionally, five individuals in the community spent their childhood, or part of their childhood, in a nonlocal region. These data are considered alongside stable isotope data from other Wari era sites and other sites in the region.

Chipped Stone Production, Scavenging, and Trade in Spanish Colonial New Mexico: New Evidence from San Antonio del Embudo

Chipped stone is often found in archaeological deposits at eighteenth- and nineteenth-century settler villages of northern New Mexico, though there has been little critical assessment of settler traditions of lithic production and use. In this poster, we discuss an assemblage of over 500 chipped stone artifacts recovered from the small plaza site of San Antonio del Embudo. We examine the sources, geographical availability, tool and flake morphology, patterns of breakage, and tool-to-flake ratios to illuminate chipped stone practices during the Spanish colonial, Mexican, and early American territorial periods. We argue that the chalcedony artifacts in the assemblage were likely scavenged from a nearby thirteenth-century site, while the obsidian points were obtained through colonial era trade networks. By contrast, the rhyolite and quartzite flakes indicate that Spanish settlers were engaging in limited on-site knapping, likely learned from their Indigenous neighbors.

Kressly, Douglas (Wichita State University)

[266]

Analysis of Lithic Material from the Boxed Springs Site (41UR30)

While the Boxed Springs site is primarily known for the elaborate Early Caddo ceramic assemblage from cemetery contexts, lithic material is also abundant at the site. This study describes the lithic assemblage recovered from Wichita State University's investigations in 2021 and 2022. Given the limited time frames allotted for excavations at Boxed Springs during these periods, lithic material recovered at the site was abundant. This analysis was conducted in order to: Identify and document the raw material within the site, attempt a better understanding of the stages of production that may be present, and to identify and document any diagnostic artifacts recovered. The procurement of raw materials, especially when examined alongside stages of production present at Boxed Springs has the potential to provide information concerning possible cultural spheres and areas of interaction for the people that once lived there. Further, the presence of diagnostic lithic artifacts may assist in providing clues as to Caddo lifeways, both at Boxed Springs and within the greater Caddo region.

Searching for Submerged Salmon Streams

Beringia is central (both physically and theoretically) to most out-of-Asia theories for how humans first came to the Americas. Understanding the chronology of the peopling of the Americas is complicated by the fact that roughly two million km² of Beringia (an area larger than the modern US state of Alaska) was submerged over the course of the late Pleistocene and Holocene. Because of the vast areas involved, and extreme difficulty of underwater excavation, a simplified strategy for identifying key landform types could be useful for locating submerged sites. Identifying potential salmon-bearing streams using GIS analysis is proposed as a single-factor modeling strategy. Studies of the distribution of genetic diversity among modern salmon populations indicate that the fish were present in Beringia (as well as refugia along the Pacific Northwest coast). Salmon are a vital source of marine-derived nutrients and enhance the productivity of landscapes in which they spawn, in addition to serving as an attractive and reliable magnet resource for human populations. Accurate regional-level drainage models are not currently possible with available data, but smaller-scale modeling could prove fruitful.

Prehistoric World Systems in the Age of the Genetic Revolution: The Eurasian Evidence

The third science revolution has reintroduced migration and mobility as major drivers of change throughout later prehistory in western Eurasia. However, it has also allowed us to revisit and redefine different types of migrations and their role in the transformation of prehistoric world systems in a broad sense. Here, I exemplify this by contrasting three types of migration from the arrival of farming to the end of the Bronze Age.

The Remains of the Transcontinental Air Mail System

The period in American history from 1924 to the 1940s represents a pivotal time for transcontinental aviation, making it possible for mail to travel from New York City to San Francisco in 30 hours. Transcontinental aviation is a feat that had not been possible prior to the establishment of a system of lighted beacons and concrete navigational arrows. The transcontinental air mail system is associated with a pioneering period in American history associated with travel and transportation that predates the invention of radar. The ability for pilots to travel from east coast to west coast in a day and a half transformed not only the way aviation was conceptualized in our country but the fundamental ways in which people communicated. The physical manifestations of this transformative shift remain on the landscape in the form of slowly deteriorating concrete arrows and beacon towers remnants. The route and beacon locations are well documented textually. Using remotely sensed data and historic maps, this poster documents the physical vestiges of this small chapter in history to understand and document what remains of the transcontinental air mail system with a particular focus on public lands.

The Benefits, Challenges, and Student Outcomes of an Academic-Governmental Collaboration for Local Undergraduate Field Training in Archaeology

In 2021 the City of Phoenix's Archaeology Office invited Arizona State University instructors and students to assist in the development of a management plan for a parcel of land within the S'edav Va'aki Museum and Archaeological Park lands via a field training program in archaeological site assessment. This invitation was well-timed as ASU had also been looking to develop lower cost local field training opportunities. A treatment plan and course outline were developed through periodic meetings among ASU, the City's Archaeology Office, and the Tribal Historic Preservation Offices of Gila River and Salt River Pima-Maricopa Indian Communities. The field program was designed to provide students broad training that included archaeological field and lab methods, as well as a background in tribal consultation, the cultural resource management sector, relevant legal and ethical frameworks, permitting, curation, archival research, and long-term preservation planning. This poster describes the benefits and challenges of the collaboration for student outcomes. Such a program, while certainly more administratively challenging than many alternative arrangements, provides students with a number of important protections, greater access to instruction,

additional training opportunities beyond the course, and chances for professional networking outside of academic archaeology.

Reviewing the 2023 Intensive NAGPRA Summer Training & Education Program (INSTEP)

The national need for NAGPRA and repatriation education is widely recognized in the museum and tribal communities. In July 2023, the authors co-facilitated the first Intensive NAGPRA Summer Training & Education Program (INSTEP), funded by the Wenner-Gren Foundation. This presentation reviews the design, implementation, evaluations, and applicant information from the 2023 program. Its first iteration welcomed a total of 38 participants from universities, museums, federal and state agencies, and tribal nations. The workshop lasted for five days and was hosted in Bloomington, Indiana, and was led by a variety of tribal speakers. In order to improve the accessibility of this program, accepted applicants were not charged to participate—tribal citizens received scholarship funding, and all other accepted applicants participated for free as long as they could make it to the workshop location. INSTEP training topics included understanding and implementing NAGPRA; best practices for curation and consultation; decolonization in museums; inadvertent discovery under NAGPRA; and best practices for repatriation and reburial, among others. This presentation emphasizes both the project design and the efficacy of the program based on participant evaluations.

A “Little Bang” at the Start of the Little Ice Age? Late Mississippian Mound Center Chronology in the Upper Tombigbee River Drainage

The Mississippian presence in the Upper Tombigbee River (UTR) drainage is represented by dispersed communities and single-mound centers with modest-sized occupations. The artifact sequence for the UTR closely mirrors that of the neighboring Moundville polity and the UTR traditionally has been viewed as having occupations that extended throughout the Mississippian period into the colonial era. Lubbub Creek and Butler Mound are the only Late Mississippian mound centers in the UTR that have been intensively investigated, with the latter having been subjected to excavations in 2022-2023 by Mississippi State University. We present a robust sample of new radiocarbon measurements that were modeled in Bayesian frameworks to estimate the timing of settlement, mound building, and abandonment at these two sites. The results suggest that both sites were established around the start of the fourteenth century AD as part of a “little bang” of Mississippian community formation. Both sites then underwent dynamic occupation histories that provide further insight into regional events involving Moundville, how Mississippian communities responded to climate change, and how the initial European exploration of the North American Southeast impacted communities in the UTR.

Kruse, Andrea (USDA Forest Service)**[262]***Public Lands, Lithic, and Gray Material: Laysan Cave*

Laysan Cave is one of the older sites within the Cascades, this precontact site is also one of the few open to the public and accessible within the Gifford Pinchot National Forest. It is a multicomponent precontact site with a range of lithic materials, fauna remains, marine shell, nonlocal materials, and burned huckleberries. Results from the excavations indicate use of the cave began approximately 700 years ago and ended by 400 BP. With only part of the assemblage studied, new research needs to happen because more material was recovered after looting to the site. This project looks at completing analysis of sites within FS collections, publishing more open gray material past and current, and how to share that information with the public. This can be completed by looking at the past lithic analysis, gray literature, and new research to see how new cultural material can be now be shared in a more open manner. At this time looking at the lithic material will be the first step in that process.

When we teach archaeology, we are actively creating the discipline and its norms that students may carry with them beyond the course. In this student-faculty co-creative poster we present ongoing results of a collaborative effort to ask questions about the nature and impact of teaching choices in archaeology courses and broader program curricula. Through course-based studies of student engagement and belonging, as well as in-progress evaluations of syllabi, assignments, and program requirements across campuses in the US, we seek to understand current trends in teaching archaeology and how those trends impact students and thus the discipline. We have found that teaching practices that draw from the tenets of antiracist and inclusive pedagogies, and that include active learning and principles of applied social science, are best positioned to increase student engagement and motivate participation in archaeology beyond introductory courses. Besides sharing the current results of this research, we will also share plans for future research and ask readers to participate in our co-creative efforts to reimagine the norms for teaching and learning in archaeology.

Kuhn, Steven (University of Arizona)**[58]***Discussant***Kuhn, Steven (University of Arizona), Dušan Mihailovic (University of Belgrade), Bojana Mihailovic (National Museum, Belgrade), Tamara Dogandžic (MONREPOS Archaeological Research Centre) and Senka Plavšić (University of Belgrade)****[247]***Human Occupation of the Central Balkans during the Last Glacial Maximum: Recent Results from Serbia*

The Last Glacial Maximum (LGM), or Marine Isotope Stage 2, produced some of the most extraordinary environmental challenges faced by *Homo sapiens* during the Pleistocene. Large parts of temperate and subarctic Eurasia were depopulated, as humans retreated to areas with relatively favorable conditions.

Although the Balkans have long been seen as a potential LGM human refugium, archaeological evidence for humans in the area during MIS 2 has been very sparse. Recent excavation and dating projects have identified a number of localities in Serbia dating to just before, during, and just after the LGM: these include Šalitrena Pećina, Bukovac, Velika Pećina, Hadži Prodanova Pećina, Pešturina, Meča Dupka, Dubočka-Kozja Pećina, Velika Vranovica, Pećina kod Stene, Petrovaradin Fortress and Potpeč). These sites show a number of similarities in form, location, and lithic assemblages. These common features enable us to define some basic features of LGM Upper Paleolithic traditions and adaptations in this part of the central Balkans. At the same time, they highlight apparent voids in the existing record of LUP land use during this period.

Exploring the Gray Zone between Archaeology, Historical Records, and Oral History: Developing a Residential Biography of Building 57, Inishark, Co. Galway, Ireland

How do historical archaeologists reconstruct the life-history of residential buildings, and to what extent can archaeology, ethnography, and oral history be combined to generate a life history? The concept of house and home is, of course, culturally, historically, and personally defined. Drawing on archaeological excavations and ethnoarchaeological and oral history research from Inishark, Ireland, we put forth a residential biography of building 57 excavated in 2018 by the Cultural Landscapes of the Irish Coast project. Situated on the western end of the historic village of Inishark, on an island located seven miles off the mainland, building 57 is dry-laid stone structure that was occupied for at least 100 years. Originally a residence, modified many times and lived in by several different families, in its later years the building was converted into a shed to store equipment and food. Based on archaeological excavations and interviews with islanders, we explore the process of homemaking in general, how islanders created social spaces, how they used inside and outside spaces, and how they repurposed the building. This research illustrates how the mobility of islanders between physical residences within islands, often linked to moments in life history, is far greater than previously believed.

Micromorphology of Earthen Architecture at Palaikastro, Crete

Recent geoarchaeological studies of earthen architecture have demonstrated the social and environmental information that may be gained from combined macroscopic, microscopic, and elemental analyses of mudbricks and degraded building materials. Micromorphology can elucidate construction and maintenance phases, identify technological changes, and differentiate and quantify manufacturing practices and techniques. Additionally, micromorphology can detect taphonomic and pedogenic processes impacting architectural preservation and other aspects of site activities. Earthen architecture and fragments of mudbrick have been found in various contexts among the Minoan structures at the Bronze Age town of Palaikastro, Crete. For example, mudbrick architecture from Building 5 (LM IB) has been extensively studied at the macroscopic level, yielding information on social aspects of mudbrick production practices at Palaikastro. Taking a new microscopic approach, this paper presents micromorphological analyses on mudbricks and degraded earthen architecture from recent excavations (2022; 2013–2015). The results demonstrate the additional socio-environmental data that micromorphology provides in identifying variations in manufacturing techniques, environmental resources, and abandonment and postdepositional processes.

Fragments of a Mogollon Ritual Landscape in South-Central New Mexico, USA

Recent fieldwork in the southern and southeastern foothills of the San Mateo Mountains of south-central New Mexico has identified caves, rockshelters, rock art, nonstandard settlements, and shrines and other ritual architecture located on hilltops. These finds reveal a landscape of rich cosmological significance to ancestral Pueblo Mimbres and Jornada Mogollon people during the period AD 1000–1400. However, this reconstructed cultural landscape is fragmented due to scattered survey coverage, our incomplete understanding of Mogollon cosmology, and lack of archaeological signifiers for all landscape elements of cosmological significance. Regardless, even this fragmentary reconstruction allows us to view the intersection and interdigitation of the ritual landscape with the landscape of interaction and settlement ecology in this region in a way that site-based approaches to ritual cannot.

Archaeology of the Nucor Steel Project, Meade County, Kentucky

Nucor Steel Corporation planned and built a major steel recycling facility on the south bank of Ohio River at a location that turned out to be loaded with prehistoric and historic archaeological sites. From 2019 through 2023, Burns & McDonnell undertook archaeological investigations there in the form of survey, test excavation, and site mitigation. This paper reviews those investigations, focusing on findings from two sites where full-scale archaeological excavations took place. Site 15Md458 contained numerous Wyandotte chert flintknapping workshops interspersed with buildings and middens of the historic Glen Fount Plantation. The Craven Crawdad Site (15Md475) was found buried 2 m below the floor of the Ohio River valley, and it contained two stratified Early Woodland components that represent short-term occupations focusing on the production of Adena point preforms. The Nucor Project provided the opportunity to evaluate the efficacy of deep testing as a site delineation method, and of techniques for working safely in deep block excavations. Archaeological conclusions address the locally overwhelming Early Woodland presence, the inscrutable lure of Wyandotte chert, and the Constricted Valley of the Ohio River as an archaeological subregion.

Kalunga! Identifying Afrodescendant Landscapes in Spanish Santo Domingo, 1502–1822

The first Afrodescendant peoples arrived in the Americas on Spanish ships to the island of Hispaniola in 1492, and by 1502 played an integral role in the development of the colony of Spanish Santo Domingo. Both free and enslaved Afrodescendants undertook most of the labor needed to construct the urban landscapes on the island, as well as the production of sugar and the extraction of metals in rural landscapes. By 1502, however, documents also record Afrodescendant runaway activity on the island. This dichotomy continues throughout the existence of Spanish Santo Domingo, evidenced in historical documents. Yet, few attempts have been made to identify these locations cartographically. This presentation will document attempts to create maps that can guide future Afrodescendant archaeological research in the Dominican Republic.

Negotiating Local Tastes in Trade Networks: Reflections on Ann Stahl's Contributions to West African Archaeology

My research on local tastes and embodied practices during the Afro-European trade in Ghana is greatly influenced by Ann Stahl's extensive theoretical work in West Africa. The nineteenth and early twentieth centuries in West Africa witnessed a surge in the demand and export of botanical commodities like palm oil. Nonetheless, historical accounts often overlooked the active participation and embodied practices of hinterland people who produced these commodities. In this talk, I suggest that local people and their embodied practices

were central to forming and maintaining trade networks. In Amedeka, southeastern Ghana, where this research is situated, local tastes and their related performances are conceptualized as *nkudzedze* (“pleasing to the eyes”). I draw on Indigenous and Black feminist archaeology perspectives, along with the local performances of *nkudzedze* as a radical framework to decentralize our methodologies and research questions from the Euro-Western gaze and colonial epistemologies that continue to “otherize” local and Indigenous communities. I pay tribute to the influence of Ann Stahl’s research on mine and underscore her efforts to advance theories about Africa’s positionality in regional and overseas trade. Stahl emphasized the significance of Indigenous embodied practices as channels to comprehend Africa’s experiences of global entanglements.

Settlement Patterns and Chronology in Calakmul and Its Surroundings

Calakmul is the largest site on the northern edge of the Bajo el Laberinto and has been investigated intensively since the 1980s. Previous research has produced valuable data regarding the general urban extent and the Late Preclassic monumental architecture surrounding the main plaza, as well as public, palatial, and some residential groups from the Classic period. Comparatively little has been said about the chronology of its larger urban sphere and peripheries, which is why we have recently started a broad reconnaissance and testing program in this extended area. The preliminary results of our mapping and excavation efforts suggest that Calakmul experienced accelerated urban growth between ca. 450 and 650 CE. The formal configurations of domestic compounds are heterogeneous, ranging from simple, low house mounds to extensive multi-patio complexes. Surprisingly, this development occurred before the major political shift marked by the establishment of the Kanu’l rulers at Calakmul around 635 CE. Another unexpected find was that of formal settlements dating to the Postclassic, a period poorly documented in previous works. This late occupation suggests that Calakmul and the Bajo el Laberinto remained an important locale well after the departure of the Kanu’l and the end of the Classic period.

“Toda la Gente”: Advocating an Intersectional Approach to Heritage Production

Collaborative archaeological approaches recognize that partnerships between archaeologists and members of descendant communities can potentially democratize heritage production and foster a more inclusive—and thus more accurate—understanding of the past. Nevertheless, descendant communities are often themselves hierarchical. Inequalities based on age, gender, ethnicity, and other aspects of identity pervade contemporary social groups, including those that have historically been marginalized. How then can archaeologists avoid perpetuating and reinforcing the inequalities present in their own and in their partner communities? By foregrounding one axis of difference—that between archaeologists and members of descendant communities—do scholars unintentionally minimize other axes of difference, such as those based on gender? This presentation argues that the democratization of heritage necessitates an intersectional approach. Put differently, archaeologists must consider how various aspects of identity combine to create different types of

inequities for different members of descendant communities. To make this argument, this presentation considers the Punta Laguna Archaeology Project, located in the Yucatán Peninsula of Mexico, and specifically a community meeting where the phrase “*toda la gente*,” or “all the people,” was used to refer only to men.

Climate Change, Disease, and the Collapse of Swahili Urbanism

Complex city-states arose on the East African Coast that were hubs of international trade networks. However, by the seventeenth century, most of these settlements had been abandoned. What were the causes of the Swahili state collapse? Historians and archaeologists have implicated climate change as one of the causal factors in the collapse of highly organized political and social systems. Climate change's effects on the resilience of populations, in particular on health, food security, and disease in East African Coastal societies over the last 1,000 years have not been fully explored. To what extent did water scarcity caused by the Little Ice Age instigate a health crisis? How and in what ways did climate fluctuations and droughts represent an existential threat to ancient societies and political formations in Eastern Africa? What were the effects of climate change on established and taken-for-granted practices around subsistence, settlement patterns, intra- and intercommunity interactions, and the health and well-being of individuals and communities? What archaeological and ecological signatures did these societies leave behind as they struggled to deal with prolonged drought, competition, hostility, and warfare over declining resources? This paper will report preliminary results gleaned from our ongoing research at Gede in Kenya.

Food Storage and Processing: A Cross-Cultural Study of the Neolithic/Formative Period of Central Europe and the USA

We introduce the start of an international project focusing on the interpretation of prehistoric food preparation and storage in cross-cultural perspective—both different prehistoric cultures and different traditions of archaeological research. We consider archaeological patterns in Central Europe (the European temperate zone) and in US Southwest, examining the period of early agricultural prehistory (primarily the Neolithic in Central Europe and the Formative in the United States). Although the research regions are geographically and environmentally distant, similar cultural and social adaptations developed: “Neolithic” societies dependent on agriculture, reduced-mobility settlements based on shared community management, limited social hierarchy but a degree of settlement centrality, and in both cases construction of communal/monumental architecture. In both areas, underground silos were used for food storage, and plant seeds were ground using “querns” or “metates.” American archaeologists have traditionally approached the specifics of food storage and processing among pre-state societies from a functional and cultural perspective, since researchers had local ethnographic data available; European approaches have more often focused on chronology and typology. This project builds on research in both regions to analyze the technology and spatial patterns of food processing and storage in this comparative context and perspective.

The Gila River Farm Site and Salado Coalescence during the Fourteenth Century in the Upper Gila, New Mexico
Archaeology Southwest and the University of Arizona's Upper Gila Preservation Archaeology (UGPA) Field School has conducted excavations for six field seasons (2016–2019; 2021–2022) at the Gila River Farm Site. This paper evaluates intrasite coalescence between a small migrant community with ancestry linked to the Kayenta-Tusayan area and local inhabitants of Mogollon ancestry within room blocks 3 and 4 of this Cliff-Phase (AD 1300–1450) Salado settlement using distributions of ceramics, ground stone tool attributes, and domestic installations as material culture markers of active and latent cultural identity indicators while also introducing a scalar element to the discussion of the Salado phenomenon in this area of southwestern New Mexico. Results from the Gila River Farm Site indicate a fully coalescent community within Room Block 4 by the time of depopulation.

Shaping Global History Narratives of the Southern Levant: Lessons Learned from Tall Hisban and the Madaba Plains Region in Jordan

The Southern Levant region is critical to our understanding of the nature of globalization and connectivity in prehistoric as well as historical era contexts. This presentation will explore the challenges in shaping WST and global history narratives of the past that bridge micro (local) and macro (global) perspectives. Drawing on his experience working at Tall Hisban and the Madaba Plains Region in Jordan, the author will share lessons learned in his quest to situate the long-term history of this particular historical site on a global canvas. Examples of approaches to bridging micro-macro-perspectives will be illustrated with reference to various methodological and interpretive lenses, such as zooarchaeology, food systems, environmental studies, connectivity, Great and Little Traditions, and the concepts of the Great Acceleration and Anthropocene. Ultimately, the author argues for the relevance of archaeology in not only advancing WST and global history but also understanding the accumulative impact of the human eco-engineering activities that have led to the planet's current climate crisis. The presentation aligns with themes discussed in the publication "Levantine Entanglements: Cultural Productions, Long-Term Changes, and Globalizations in the Eastern Mediterranean" (2021).

Maya Funerary Diversity: A Nonlinear Perspective from Palenque, Chiapas

Ancient Maya land is characterized by a great diversity of funerary practices. The settlement of Lakamha' (Palenque) sharply evidences such heterogeneity: pluralism is found in terms of places of inhumation, types of containers, number of people per grave, grave goods, postmortem treatments, positions, and orientations of the body. Nonetheless, a little more than half of the burials share a basic pattern: primary inhumation in a container (monumental to very simple) of one person extended on the back, arms alongside the body, head to the north, with clay pots. The vast majority of the burials present non-taphonomical movements that

demonstrate human activity taking place inside the graves after the first burying event. Funerary treatment does not seem to depend on sex, but age categories do demonstrate distinct practices and subadults are scarce. In archaeo-thanatology, such funerary diversity is usually interpreted as the presence of distinct populations in the same geographical area. The absence of various identifiable models suggests that Lakamha' could have been a sacred city where communities, family nuclei or corporative groups of similar cultural forms but different geographical origins congregated periodically. Other elements such as the type of agriculture practiced and Lakamha's topographic situation support such a perspective.

Mississippi River Folk: Dugout Canoe Form, Function, and Frequency in the Magnolia State

In 1986, Sam McGahey published the first compendium of Mississippi dugout canoes. He listed the attributes of eight watercraft including recovery location, date of manufacture, wood type, method of construction, and dimensions. McGahey also included a composite drawing to better facilitate comparison. While dugouts are only infrequently encountered, they reveal key information about the means and mechanics of transportation and encode information about identity, subsistence, trade, migration, and warfare otherwise invisible in the archaeological record. Further inhibiting our understanding of this important artifact type is the cost of preservation and inconsistency of documentation. When resources allow, dugouts are installed as the centerpieces of exhibits, such as the Swan Lake Canoe on display at the Museum of Mississippi History. In other instances, they are pulled from a riverbank or lake bed and left to quickly deteriorate. This paper updates McGahey's list of canoes and surveys the variation present within the Magnolia State. We seek to encourage local reporting of dugouts as they are recovered by fostering relationships with avocational communities, and explore expedient, standardized means of documenting form through the creation of high-quality models. We conclude by reflecting on the current state of dugout research and highlighting future avenues of study.

The Development and Application of Isoscapes for Archaeological Provenance Studies in the Neotropics: Recent Developments and Future Directions

Isotope studies have become a common and effective method for inferring the geographic origins of a wide range of materials in various research disciplines, including archaeology. In recent years, such isotope approaches have also become more rigorous and quantitative, and increasingly make use of isoscapes (isotope landscapes) = maps of spatial isotopic variation. This paper provides an overview of the development and use of isotope-based geographic assignment approaches in the archaeology of the New World Tropics. I critically review a wide range of issues involved with the application of such approaches to this area of the world including: the selection of regionally appropriate proxies, the conversion of isotope datasets into isoscapes, spatial modeling, multi-source mixing, missing data, interval versus probabilistic approaches, and integrating multiple isotope data. I conclude with a brief reflection on the recent advances, continuing challenges, and future directions of isotope provenance studies in the Neotropics.

Lagarde, Patricia (Walters Art Museum)**[27]***Faced Façade: New Interpretations of Chavín's Tenon Heads*

The sculptural figures at Chavín de Huántar have long been considered potent symbols of a unified religious tradition across the Andes mountains. Today, Chavín is recognized as a Formative period pilgrimage center located in the highlands of modern-day Peru. It is known for its extensive sculptural program, and particularly for the tenon heads that once embellished the exterior walls of the monument. The anthropomorphic heads feature elements such as fanged mouths, contorted expressions, and serpents slithering across the surface of stylized faces. Although previous studies have argued that the heads are representations of shamans undergoing hallucinogenic transformation, this paper reveals that they are one-of-a-kind figures at a pivotal state on a spectrum of containment and release. Metaphorical substitutions for the eyes, nose, and mouth of the figures were leveraged to distinguish Chavín as unique across an increasingly homogenizing landscape.

Lagos, Samantha (Southern Methodist University)**[172]***Storage Pit Prospection and Capacity Estimation in Aotearoa New Zealand: A Comparison of Surface Detection Methods*

Lidar has revolutionized the way we survey for surface-visible archaeological features. Our ability to relatively quickly capture and assess large landscapes for features enables us to understand human activity across large spatial scales with significantly less time and financial investment than pedestrian or other forms of remote survey alone. As these data become cheaper to collect and more readily available, surveyors have developed a number of computer processes to speed up feature prospection. Subterranean storage pits are one archaeological feature that has been subject to extensive survey in a number of different environmental and cultural contexts. Often visible from the surface as eroded, shallow depressions, accurate surface prospection methods are not only key to identifying these features across landscapes, but to understanding their distribution and sizes; this has clear implications for our understanding of their uses in the past. However, detection of surface features from remote data must balance concerns around accurate identification with time investment and spatial coverage. Storage pits, or *rua*, are one of the most commonly recorded archaeological features in Aotearoa New Zealand. This poster explores a number of lidar-based detection methods and compares pit count and dimensions against data from these, pedestrian survey, and archaeological site maps.

A New Perspective on the Ore Source Supply and Potential Provenience of Han Bronzes from the Broader Lingnan Region

Previous lead isotopic studies have noted significant shifts in the choice of ore sources for Western Han bronzes, coinciding with the expansion of the imperial network. While existing literature has highlighted the prevalence of ore sources from the Eastern Qinling region during this era, the importance of ore sources from the broader southern frontiers, notably the southern Hunan-Nanling mountain ranges, has been underexplored. Given the substantial role of these regions as suppliers of raw materials during the Eastern Zhou period, it is crucial to investigate whether local sources continued to be utilized during the Western Han period. This study presents novel results from lead isotopic analysis conducted on Han period artifacts from the broader Lingnan region. When combined with legacy lead isotopic data, our research indicates that the majority of vessels discovered in Hunan and Guangdong were made using ores from the Nanling mountain ranges (southern Hunan and northern Guangxi). However, other types of products exhibit a distinct pattern originating from nonlocal ore sources. This fresh dataset illuminates the sustained use of ore sources from the southern frontiers during the Han period, providing valuable insights into the diverse changes within the bronze industry during the consolidation of the Han state.

Community Archaeology in the Jemez

Over four weeks in the early summer of 2023, a community-based archaeological project was conducted to re-record Whan hang kya nu Pueblo in fulfillment of a master's project in public archaeology at the University of New Mexico. Whan hang kya nu Pueblo is a prehistoric site located in the Jemez District of Santa Fe National Forest and has been continuously monitored for decades. However, it is still subject to interest and visits from the general public and, as such, is vulnerable to looting and social trails. Volunteers drawn from the local community were able to record and assess these impacts over the course of the project through pedestrian survey. In this way, community members were exposed to a variety of archaeological methods and were able to experience the importance of archaeology and site protection first-hand. There were several key takeaways from this project, such as best practices for communicating archaeological significance to the general public and what is necessary to recruit and sustain volunteer involvement in a community-based project. Ultimately, the continued integrity of Whan hang kya nu Pueblo was confirmed after a decades-long break in recording.

Cookin' with Cezin: Experimental Archaeology and Traditional Anishinabe-Algonquin Foodways

Excavations carried out since 2016 on the shores of Grand Lac Nomingue, Quebec, Canada, have uncovered thousands of ceramic sherds in the ancestral territory of the Anishinabe-Algonquin First Nation. These discoveries demonstrate the use of pottery by a nomadic population and lipid analysis show that various products were prepared in these containers, whether game, fish or plants. As part of a collaborative project, internationally renowned chef Cezin Nottaway, assisted by her father Solomon Wawatay, joined our research team to re-create traditional recipes prepared in replicated vessels and cooked over open fires. These replicated vessels will be sampled and lipid analysis will be used to compare their chemical signatures with archaeological contexts. This contribution offers an overview of the results obtained during the first season of this culinary archaeology project.

Slowing Down the Archaeological Process in Dolores, Petén, Guatemala

Maya archaeology has always relied on the labor and expertise of field technicians hired from heritage communities across the modern nations of Guatemala, Mexico, Belize, Honduras, and El Salvador. Some of these communities, like Dolores, Guatemala, have been continuously engaged with archaeological projects for several decades, granting its members multi-generational expertise on both Maya civilization and archaeological practice. These field technicians—or as we prefer to call them, grassroots archaeologists—and academic archaeologists have fruitful episodic collaborations. Yet, a disjuncture exists between (1) grassroots archaeologists and the production of archaeological knowledge and (2) academic archaeologists and the heritage communities that are home to grassroots archaeologists. The Dolores Slow Archaeology Program aims to address these disjunctures by slowing down the archaeological process to adequately integrate grassroots archaeological professionals from the Dolores community as active agents in the design of a sustainable and collaborative project. Join us to hear about the results of our first season of work in Dolores.

Resilience and Adaptation to Drylands: Long-Term Knowledge as a Path to Sustainable Agricultural Practices in Drylands

The incorporation of time-tested practices, encompassing Traditional Knowledge (TK), Local Knowledge (LK), and Indigenous Knowledge (IK), into sustainable agrifood system development has gained substantial traction. These practices are designed to address challenges such as food sustainability, food sovereignty, and enhancements to agrosystems. TK is defined as “knowledge honed over centuries and adapted to local

cultural and environmental contexts.” Yet, while TK encapsulates millennia of experiential wisdom, the insights derived from Long-Term Knowledge (LTK) have yet to be fully harnessed. Many ancient systems demonstrated greater longevity than modern infrastructure and were often inherently more sustainable consuming less energy, being easier to operate and maintain, and having more communal governance structures. In this talk I will present the results of RAINDROPS, an interdisciplinary project that combines experimental cultivation, ethnoarchaeology, modeling, and archaeobotany to trace the time depth of cultivation of drought-tolerant crops in drylands. I present two case studies related to the Indus Civilization in Pakistan and the Askum Civilization in northern Ethiopia. The results show how traditional rainfed cultivation dates back several millennia and has remained active since the present, albeit in small, fast-disappearing pockets.

Seabirds as Proxies for Past El Niño Events in Coastal Peru: An Archaeo-ornithological Approach

This thesis sets an initial foundation for an archaeo-ornithological approach to understanding past El Niño events on the coast of Peru and the use of avifaunal remains as proxies for ecological conditions. Here I examine the extent to which El Niño phenomena could influence avifaunal resources and the effect this would have had on the subsistence practices of Andean coastal communities through time. Taking a human-ecodynamics approach, I also examine ethnohistoric records, including published oral histories, and early Peruvian visual culture (e.g., ceramics, geoglyphs, regalia, textiles) to further guide my understanding of the relationship between coastal societies and their local ecology. Based on the apparent human-Aves ecodynamics between coastal Peruvian societies and local avifauna, I propose that marine avifauna could have acted as sentinels for ecological conditions, offering coastal occupants a warning of impending change. In some cases, avian responses to El Niño (e.g., massive die off, mass migrations, nest abandonment) could have presented a boon to industrious hunter-gatherers, a topic I also explore. Further paleoenvironmental research potential lies in determining the effects that different varieties or “flavors” of El Niño Southern Oscillation (Central Pacific, Coastal) would have posed on early subsistence practices and adaptation strategies.

Past Water Futures: Rehabilitating Ancient Dams for Present Use

Water is essential for life on earth. In the twenty-first century, water scarcity is increasingly seen as the main threat to human world economies. This is especially true of the Peruvian Central Andean highlands where lack of water is understood by experts as the single most threatened natural resource in the face of climate change and ever-retreating tropical glaciers, a sentiment echoed by local governments and especially rural communities. The Past Water Futures project is engaged in the rehabilitation of ancient dams for modern use in the Ancash region of north-central Peru. Our project addresses the live issue of water security and community resilience in the rural Andes. Ancient dams represent a tried-and-tested answer to water scarcity in the region. Ancient dam rehabilitation is a community-led, low-carbon, low-cost, and low-maintenance alternative to modern cement micro-dams, providing clean water, local economy growth, and protection of the natural and heritage environment. We contend that modern engineering can only provide partial solutions to increasing water fragility in the Andes, and that the marriage between past and present knowledge and technology can deliver a better, locally informed answer to future water stress and climate change in the Cordillera Negra and further afield.

Lane, Kevin (CONICET, IDECU)

[242]

Chair

Lane, Kevin (CONICET, IDECU)**[242]***Water, Maps, and Mountains: Shifting Water Taskways in the Andes*

In the past as in the present water was and is a central material element of the communities of the highland Andes. Underpinning their relationship with water and the taskways this entails has been the constant negotiation and impact of human-human and human-ecology relationships. In this regard, these populations' relationship with water has changed through time, influenced by warfare, colonization, and social change. Here, I examine this shift from the late prehispanic period (AD 1000–1532), through the Spanish colonial period (AD 1532–1826), and down to the present in the Cordillera Negra, north-central Andes. I trace how water taskways and the hydraulic architecture that sustain canals, amunas, reservoirs, and dams have swung majorly from a cosmological-economic to a commodity-economic model. In this regard, a loss of religious resonance in regard to water in the past was supplanted by the historic and present-day critical need to secure scarce hydric resources in the face of, respectively, colonial-elite oppression and climate change. Nowadays, water fragility has further precipitated a shift from artisanal constructions of stone and clay toward a development-led agenda where cement is king, with a growing disavowal of ancestral knowledge and taskways. Attempts to counteract this trend often meets considerable resistance.

Langlitz, Meredith (Archaeological Institute of America)**[64]***Discussant***Langlois, Meghan (McMaster University) and Erin Riley (University of Colorado, Boulder)****[80]***Understanding Resource Allocation and Dietary Stress through the Presence of Scurvy in Nonadults from Gać and Dzwonowo, Poland (Fourteenth to Sixteenth Centuries)*

As a result of the energy requirements related to growth and development, nonadults are more susceptible to biocultural change than adults, making them ideal proxies to examine environmental stress within a population. The village of Gać and town of Dzwonowo (fourteenth to sixteenth centuries) in Greater Poland provide a unique opportunity to examine the impact of biocultural stress on populations for which there is little historical or archaeological data. Shifting sociopolitical structures and climatic change during the Late

Medieval period in Poland led to increasing social stratification and unequal access to resources. This study uses macroscopic lesions for scurvy to examine disease prevalence in juveniles and adolescents to compare socioeconomic status, access to resources, and dietary diversity between Gać and Dzwonowo. Nutritional status is not expected to differ substantially between sites, due to the generally undiversified medieval Polish diet based on grains and small amounts of meat and fish, with few fresh plant products. Preliminary findings suggest a scurvy prevalence rate of 10.4% for the village of Gać, a higher rate compared to contemporary Polish sites. This study aims to shed light on the biological consequences of social change in medieval Greater Poland. ***This presentation contains images of human remains.

Black Bodies and the Making of Race in Antebellum America

University and museum collections containing human remains belonging to members of the African diaspora have recently come under scrutiny and for valid reasons. The curation of the bodies of Black individuals continues to inflict violence and reinforces the notion that Black people are objects, not humans. During the winter of 2020/2021, it was revealed that the Peabody Museum of Archaeology and Ethnology at Harvard University, located in Cambridge, Massachusetts, housed the remains of 15 individuals of African descent who were likely to have been alive during the time of slavery in the United States. This paper focuses on three Black Ancestors whose skulls traveled with Dr. Jeffries Wyman (1814–1874) when he left Hampden Sydney Medical College in Richmond, Virginia, to return to his alma mater, Harvard. Two skulls belong to men who were executed by the state of Virginia, and one belongs to an unnamed woman. Uncovering these Ancestors' itineraries and determining where they might be laid to rest requires an interdisciplinary collaboration between historians and bioarchaeologists. By combining archives of documents and bone, a case is made for the return of these individuals to a community that will mourn them.

Converting Monumental Landscapes to Human Dimensions: Ancient Community-Building Processes in Southern Honduras

A couple of years ago some good meaning citizens offered to donate complete ceramic pieces along with other objects they had “collected” from their properties to the regional campus of my university in southern Honduras. These same local citizens declared themselves a priori as descendants of the “Chorotega.” At

these locations, a fairly high number of sherds could be observed mixed with construction debris, but without the authorization of the IHAH, I declined to make a more thorough inspection of the sites, or an appraisal of the pieces. However, I was mystified by a massive, incised boulder in Orocuina's main plaza (Cholulteca), which was clearly out of place. My guides told me of other locations where massive boulders had engravings, and others could be found directly on cliffs bordering watercourses. I did a preliminary survey, to find the locations were impressive because of the very monumentality of the landscape. Beyond that, it seemed as if the engravings in boulders and cliffs were enhancing significant geographical features and natural borders. I am persuaded to side with Notroff, Dietrich, and Schmidt (2014), and venture to qualify these locations as monumental landmarks for the peoples involved in community buildings processes and group cooperation.

Ritualidad acuática en Media Luna y su relación con el juego de pelota

El análisis del contexto arqueológico sumergido, Media Luna, localizado en San Luis Potosí, México, ha permitido profundizar en los ritos mortuorios y en los actos de oblación que las comunidades de Río Verde realizaban en torno al agua durante el periodo Clásico y Posclásico Temprano (500-1000 dC). Sin embargo, recientes trabajos de arqueología subacuática, además de estudios iconográficos y contextuales, han identificado objetos arqueológicos relacionados con el juego de pelota, los cuales también fueron depositados al interior del manantial. La presencia de figurillas que posiblemente representan jugadores, fragmentos de yugos, así como la sacralidad acuática del espacio donde se localizan, aunados a la abundante presencia de canchas en la región, ha permitido proponer una posible relación entre algunos de los elementos rituales del juego de pelota y los ritos acuáticos llevados a cabo en Media Luna, ambos vinculados al inframundo en su aspecto mortuario y de fertilidad.

Excavations of Early Postclassic Commoner Households at Jalieza, Valley of Oaxaca, Mexico

This paper summarizes the results of two seasons of excavations at Cerro Tecolote, the Early Postclassic (AD 750–1000) settlement at Jalieza in the southern Valley of Oaxaca, Mexico. While the Valley of Oaxaca has been the focus of intensive and seminal archaeological research for over a century, the Early Postclassic is poorly understood in this region. The Early Postclassic has been referred to by scholars as a time of “changing politics.” It marks the transition from a highly centralized state-level society to a decentralized society governed by small competing kingdoms. The excavations summarized in this paper targeted domestic terraces at Cerro Jalieza to explore how non-elite households were affected by the collapse of the Zapotec state. Furthermore, this project presents one of the first attempts to investigate the scale of these “changing politics.”

Diversifying Heritage: A Foundation for Democratizing Heritage Production

Archaeological practice has benefited from including diverse stakeholders in the production of narratives around heritage, which can result in democratizing heritage creation. If done well, it can lead to a more democratic production of knowledge around heritage. Democratization heritage production involves shifting power dynamics in who “rules” over the creation of narratives and investing authority in the related “people”

or descendant communities. Because of archaeology's roots in colonialism, democratizing the discipline is no easy task. This can be especially difficult to accomplish in compliance-based work and few archaeologists are trained in how to do this work. Here, we situate these ideas theoretically, in practice, and offer background on the topic.

Environmental Personhood and the Management of Cultural Resources

Over the past two decades, there has been a renewed interest in the concept of Environmental Personhood, which grants particular natural entities with legal personhood with the intent of reorganizing anthropocentric hierarchies and better protecting the environment. These features, including Te Awa Tupua in New Zealand and Mutesheku Shipu in Canada, have been granted and maintained legal designation. Of course, though under different names, concepts of Environmental Personhood have long been deeply integrated with many Tribal experiences of the world. Many Indigenous ontologies understand the co-constitution of living and nonliving entities—that no material entity is unhinged from material and immaterial intrusions. Just as Karen Barad notes, “Existence is not an individual affair” (2007:ix). The co-constitution of the human and nonhuman and of living and nonliving should be considered in the interpretation and management of cultural resources. This paper explores how considering archaeological things and spaces in the context of movements of Environmental Personhood pulls those landscapes from the past, through the present, and into the future.

New Dendrochronological and Radiocarbon Dates for Northwest Mexican Cliff Dwellings

Over the years, several thousand archaeological wood samples have been collected across Northwest Mexico, but dating them has proven problematic because of short tree-ring sequences, poor sample quality, and complex growth patterns. A majority of these originated in cliff dwelling sites, which form a central part of an interregional network of relatively dated archaeological phases. An estimated 200 cliff-dwelling sites have been identified in Chihuahua (Gamboa and Baca 2013) and a smaller yet still significant number in Sonora. Only a handful of approximate dates for a subset of the sites have been published, and these are characterized by wide ranges of uncertainty. In this study, we present preliminary results of a new program of research combining tree-ring dating and high-resolution radiocarbon dating in an attempt to overcome these issues and present a comprehensive chronological framework for the region. This framework will assist in not only refining cultural chronologies but also prove useful in facilitating paleoclimatic reconstruction of seasonal precipitation and drought periods several centuries earlier than previously possible. Preliminary results indicate a pattern of occupation between approximately AD 1100 and 1250, corresponding to the Viejo and Early Medio periods per Whalen and Minnis (2009).

[171]

Viewshed and Network Analysis of Late Formative (600 BCE–200 CE) Chit'apampa Cuzco, Peru

Cuzco, Peru, has long been recognized as an important archaeological area in the Andes. Despite this recognition, earlier periods prior to the emergence of the Inka state remain under-researched, especially regarding pre-Inka political organization. In particular, the Late Formative (600 BCE–200 CE) is a period in which several important political transformations were hypothesized to occur. These transformations include increasing inequality, potential emergence of hereditary status positions, differing defense strategies, and the rise and fall of several important polities throughout the Cuzco region. One such area where these changes occurred is in the Chit'apampa Basin—just north of Cuzco. This poster utilizes the Hanan-Cuzco survey data as well as excavation data from a hypothesized center in Chit'apampa, Muyumoqo, to reevaluate existing hypotheses generated from the original survey data. Our work demonstrates that the site of Muyumoqo was

likely more important in regional political development than previously thought and provides promising lines of research to reassess other areas of Late Formative Cuzco.

Reassessing Herd Management Strategies in the Early Bronze Age of Southern Israel-Palestine: Preliminary Insights from Tell el-Hesi

Current discussions of herd management strategies employed in the Early Bronze Age III (EB III) in southern Israel-Palestine are often painted with a generalized brush. However, emergent data from the early urban EB III site of Tell el-Hesi, Israel, suggests a site-level perspective is required, particularly during periods of social stress and urban development. Previous excavations at Tell el-Hesi in the 1970s revealed a portion of the EB IIIA fortification wall and a workshop/market quarter, and renewed excavations in 2023 uncovered a portion of an EB IIIA domestic neighborhood. This paper combines faunal data and new carbon and oxygen isotopic faunal data from the workshop/market quarter and new faunal data from the domestic neighborhood excavations to form a comprehensive understanding of herd management strategies employed at EB IIIA Tell el-Hesi. In comparison to other sites in the region, results indicate that a site-level perspective reveals a more diverse range of herd management strategies in the face of newly emergent urban living in southern Israel-Palestine than previously suggested. This paper is inspired by Richard Redding's models of sheep/goat management, his repertoire of work on domesticated faunal remains, and the rise of social complexity in the Ancient Near East.

Ground-Penetrating Radar and Photogrammetry Survey of Laurel Hill Cemetery: An African American Cemetery in Western Pennsylvania

The Laurel Hill Settlement was a small, mountaintop African American settlement that was located in what is now Laurel Ridge State Park west of Johnstown, Pennsylvania. The settlement was formed sometime before 1825 and may date back as far as the late 1700s. It is unclear how large the settlement was and how many families lived there at any given time during its occupation. One of the only remaining above ground signs of the community who once lived at the site is a small cemetery. The cemetery has only a few remaining grave markers and likely contains a large number of unmarked burials. This poster presents the preliminary results of ground-penetrating radar (GPR) and photogrammetry surveys of the cemetery as well as historical research about individuals known to be interred at the site. The goal of this project is to understand the extent and layout of the cemetery and to discover what information the cemetery can provide on community size and the individuals who once lived in this community.

Lassen, Robert (AmaTerra Environmental, an ERG Company)**[335]***Chair***Lassen, Robert (AmaTerra Environmental, an ERG Company)****[335]***A Lithic Cache from the Crane Dune Site (41CR61), Crane County, Texas*

AmaTerra Environmental, an ERG Company, initially recorded site 41CR61 during a survey of a proposed highway expansion for the Texas Department of Transportation in 2019. The site was situated on a stabilized sand dune, and the presence of a buried dark earth anthrosol bearing multiple cooking features prompted data recovery excavations. During those excavations, an intact lithic cache containing 65 Edwards chert flake blanks and one Marshall dart point was recovered. The artifacts were stacked in seven layers of decreasing diameter, indicating they were buried in a pit. Analyses included minimum analytical nodule (MAN) analysis, platform/bulb descriptions and measurements, cortex percentage, dorsal scar counts and orientations, overall measurements, number of modifications, low-power use wear, attempted refitting, and general descriptions. The results indicate that one MAN type dominated the assemblage with three others present, that flakes were removed from large cores with hammerstone percussion mostly in one preferred orientation, and a lack of refits indicates selective removal of blanks from the procurement location. Overall, the assemblage appears to have been an insurance cache of nonlocal, high-quality lithic material that was stored for future usage. The Crane cache provides a glimpse of procurement and/or trade patterns in an understudied region of western Texas.

Lattanzi, Gregory (New Jersey State Museum)**[8]***I'm Only Human: A Case Study in the Problems and Progress in Achieving the Intent of NAGPRA*

In April 2023, one of the largest and most complex NAGPRA repatriations occurred in the northeastern United States. The Abbott Farm NHL repatriation included major museums, three federally recognized tribes, and the reburial of around 200 ancestors and over 10,000 associated funerary objects. As such, issues surfaced associated with the understanding of artifacts, chronology, context, interpreting the archaeological record, all of which can restrict interpretations of assigning cultural affiliation. Additionally, working with multiple museums, federally recognized tribes, and understanding different state burial laws and reburial across state lines were problems where solutions needed to be quickly sought. This presentation lays out those problems, discusses the solutions, and how to go about them. NAGPRA is a continual process of learning, understanding and growing; it is all about what it is to be human.

Lau, George (Sainsbury Research Unit, University of East Anglia)**[81]***Chair***Lau, George (Sainsbury Research Unit, University of East Anglia) and Milton Luján Dávila (PIARP)****[81]***Before the Cults of the Condor and Catequil: The Pre-Recuay Occupation at Pashash, Ancash, Peru (ca. 500 BCE–100 CE)*

Recent field investigations at the hilltop site of Pashash clarify key diachronic changes during the rise of segmentary lordships in the Pallasca highlands of northern Ancash, Peru. Ceramic, radiocarbon, architectural, and ancillary contextual evidence help to reveal local cultural patterns tracking the Pashash settlement from a small, unassuming agropastoral community during the Early Horizon to a seat of regional and cultic power for

Recuay groups by about AD 100. “Formative” period wares disappeared, and new polychrome styles appeared with a dramatic uptake of fancy prestige objects. Interestingly, great intensification of camelid use predated political consolidation, while new forms of monumental architecture and Recuay’s distinctive imagery on pottery and stone sculpture appear to have emerged *sui generis* as part of an innovative ideology of authority.

Local Organization in Imperial Settings: Evidence from Late Antique and Middle Islamic Dhiban, Jordan

One of the many intellectual legacies of Richard Redding’s work is his exploration of how local communities made provisioning decisions to meet both their own local needs and demands by political authorities. This paper examines these themes among inhabitants of ancient Dhiban, Jordan during the Late Antique (ca. 600 CE) and Middle Islamic (ca. thirteenth–fourteenth centuries CE) periods. During the Late Antique period, Jordan was under the nominal control of the Byzantine Empire and taxation burdens were organized and met at a local level. In the later Middle Islamic period, Dhiban was part of the Balqa region of the Mamluk Empire. Using zooarchaeological and paleoethnobotanical data from contexts dating to each period we explore the choices inhabitants made in agropastoral production and their integration in regional systems that brought crops and animal products from other areas of southwest Asia into their larders. These provide evidence of regional integration, predicated on both taxation demands and the exchange networks facilitated by these imperial entities.

Basket Pedagogies and Other Object Lessons

How can we learn from an object? How is that different from learning about an object? In a class project, I asked students to undo institutionalized silences and challenge dominant narratives with museum objects that appear to be mute. We studied three O’odham baskets housed at the Syracuse University Art Museum that have scant associated provenience and provenance. Like many museum objects, they have spent much of their tenure in storage, propped up with tissue and foam and the ideals of Western heritage conservation. But these conditions, while good for the longevity of the fragile fibers, hasten the erosion of the object as a vibrant source of knowledge. I asked students to seriously consider what lessons the baskets held, and for whom. I challenged students to resituate the baskets as nodes in a larger network of relationships, yet to be acknowledged. The baskets defied student attempts to access the lessons they thought they were entitled to. Instead, lessons reached students according to what they were ready to take responsibility for. They offered the students tangible clues about socioecological networks of gatherers, willows, and rivers; and settler colonial interruptions, and wove these narratives together in ways that surprised us all.

The Fall of Vicksburg: Approaches to Landslide Archaeology in a National Cemetery

In May 2020, NPS archaeologists initiated an emergency response at Vicksburg National Cemetery, where a massive landslide affected numerous Civil War—era graves, primarily those of the first US Colored Troops (USCT). Working on a partially collapsed terrace, the archaeologists deployed innovative strategies and methodological approaches to recover disturbed human remains, before further subsidence could occur, all while navigating the unprecedented challenges of the initial weeks of the COVID-19 shutdown. The methodology developed and utilized in this unique situation would subsequently inform future work at Vicksburg and elsewhere.

Traditional Lifeways as Knowledge of the Past and for the Future

Traditional farming, cooking, and craft production provided a stable and integrated set of taskscapes to citizens of the Boveses for generations. As a result, the conflicts and challenges of living in a region of Italy that has long been neglected or exploited by whatever government was in power, residents see educating their children for professions outside their local environment as imperative and thus often select not to pass on cultural knowledge. Where attempts to conserve and celebrate the region's cultural heritage have been made competing factions and revenge have resulted in the destruction and loss of precious artifacts and papers. Many cultural traditions involve organic materials not preserved in the archaeological record, but which provide windows into activities that stretch throughout the post medieval era. This poster presents some of those activities and posits ways they can teach us about the past and provide insights for the future.

(Im)Proper Relations: Heritage Sustainability in Oaxaca

This paper is a call to expand our definitions of sustainability, troubling what has become the bedrock of community archaeology and heritage projects. In Oaxaca, the question of sustainability is pursued alongside a fixed imagining of how an ideal heritage site operates. A “successful heritage project,” institutional actors assert, is not what they term a “ghost building”—a dead and empty space. Yet, the paradox of sustainable practice seems to do exactly this, often turning spaces into sterile museums or frozen repositories designed for touristic consumption. Drawing on ethnographic and archival research conducted in Mitla, Oaxaca, and UNESCO, I think through the ways sustainability discourse is part of a moral project predicated on aligning communal and institutional relations to history. I query what is at stake in the ways heritage governance

currently operates, and explore how the emphasis on such a narrow rendering of what is sustainable and “alive” winds up positioning institutions as those whom regulate the distinction between life and nonlife, and, subsequently, both what proper relationality entails (Povinelli 2017) and what is worth preserving. In so doing, I hope to better sketch out the conceptual architecture of patrimonio and open discussions into its ontological boundaries and cosmological significance.

Measurement Variability in a Collection of Modern Gazelle (Gazella gazella) Skeletons and Its Archaeological Implications

Linear skeletal measurements have long been harnessed by zooarchaeologists to differentiate animals by taxon, breed, age, and sex, to investigate domestication and animal management strategies and the impact of factors such as climate change and anthropogenic activity. However, due to equifinality, interpreting archaeological body size data remains challenging. In this study, we investigate the degree and relative impact of different factors such as sex, age, and environmental variables (temperature and precipitation) on mountain gazelle (*Gazella gazella*) morphology. We explore measurement variability in five commonly preserved skeletal elements: the humerus, tibia, scapula, astragalus, and the second phalanx. Our analysis demonstrates that sex is the primary determinant of gazelle body size, and that age has minimal impact once elements have fused. For some elements, size is also impacted by temperature, while for others, the relationship is less clear. This connection may be obscured by human activities that disrupt the scheduling of resources used by gazelles, such as agriculture and landscape modification. Finally, we explore the potential of computerized procedures to improve the accuracy, precision, and repeatability of measurement data and show that 3D measuring protocols produce higher quality data than that obtained by traditional caliper methods.

The Tacahuay Landscape: Land Use and Environmental Change on the South Coast of Peru

The Tacahuay Quebrada on the far southern coast of Peru was shaped by a combination of human and environmental forces. Within its watershed, there is a system of channels that have provided resources for humans and other living beings throughout its anthropogenic history. Excavations within these channels revealed use of the Tacahuay landscape between 1000 BCE and 500 CE. This period coincides with flood deposits found within the main Tacahuay quebrada. While a permanent settlement was not found during my investigations, material analyzed from Tacahuay revealed that people were taking advantage of the quebrada channels in addition to accessing resources from the nearby coast. Tacahuay presents a case study of a mixed subsistence strategy approach to thriving in an arid desert region prone to natural disasters. These peoples continued a legacy of maritime resource collections and supplemented these resources with the terrestrial resources found on the Tacahuay landscape. Similar to the environment in which they live, the people of Tacahuay were influenced by the intersection of the desert and the sea. This paper unites environmental data, including sediment and pollen records, and material culture, to understand the relationship between populations at Tacahuay and the landscape in which they lived.

Where Have All the Red Elderberries Gone? A Collaborative Macrobotanical Analysis of Settler-Colonial Impacts on a Vital Coast Salish First Food

In 2019, Willamette Cultural Resources Associates identified a diffuse and deeply buried archaeological site on the Green River, south of Seattle, Washington, during construction monitoring of a large levee replacement project. The site is in close proximity to *ácabctac*, or “red elderberry place.” Macrobotanical analysis indicates that the site was used for mass processing of red elderberry (*scábt*; *Sambucus racemosa*) prior to intense settler appropriation of the area beginning in the 1850s. Yet by the early 1870s, red elderberry is absent from the vicinity according to General Land Ordinance cadastral surveyor notes. Ethnobotanical and ethnohistoric documentation are clear that settlers were well aware that red elderberry was highly prized by Coast Salish people, although they themselves thought the fruit “insipid.” We offer multiple lines of evidence, including consultation with Tribal knowledge-keepers; review of historic maps and other archival, ethnohistoric, and ethnographic sources; and our macrobotanical analysis to argue that settlers may have intentionally destroyed red elderberry to drive Native peoples away from this vital node in a carefully maintained network of traditional native foods.

Where Are the Women Warriors? The Evidence for Gender Equality on the Mongolian Steppe

Women in pastoral nomadic steppe cultures had a higher social status and fluid gender roles than their counterparts in sedentary agricultural regions. Central Asian women (Mongol and Qidan) are historically documented to have made diplomatic, economic, and military decisions in proxy for male relatives. Mortuary evidence for women warriors is inferred from burial status and grave goods dating back to 1000 BC. This study searched for evidence of women warriors using bioarchaeological methods on their own bodies. Fifty-seven burials (36 males, 19 females, 2 adolescents) were analyzed, dating from 700 BC to AD 1100. Potential warriorhood was defined as evidence of prolonged horseback riding, archery, and trauma patterns (interpersonal and warfare). Extensive horseback riding was common for men (92%) and women (89%) through all time periods. Adolescents had musculature diagnostic of horseback riding since childhood. Archery was practiced by men (75%), women (79%), and adolescents (50%) through all time periods. Warfare-related trauma was present but rare (males 17%, females 10%, adolescents 0%). This study shows that a portion of women throughout all time periods performed similar duties to men.

Ice Coring Archaeoecological Adventures with Dr. Robert (Bob) Kelly

The release of cultural and biological materials from melting snow and ice is the foundation for the field of ice patch archaeology, a sub-field of cryospheric archaeology—the archaeology of the frozen world. To better understand the nature and potential of the ice patch record in the mid-latitude Rocky Mountains, ice patches in the Greater Yellowstone Area and in Glacier National Park were cored to recover accumulations of

organic materials (lags) that form debris-covered surfaces during melt periods. Radiocarbon dating of the recovered lags demonstrate the presence of thousands of years of preserved material in these locations. This paper shares the methods used to obtain the cores and examines the ages of the lags recovered from three different cores for contemporaneity. The paper also examines the ages of the lags (melt surfaces) relative to the ages of directly dated organic artifacts recovered at ice patches. Indigenous partners participated in the planning and execution of these projects and the species/plant communities identified in the lags were shared with interested Indigenous and scientific communities, e.g., botanists.

Disaster Survey and Documentation of Southwest Florida Archaeological Site Damage from Hurricane Ian
Accelerating shifts in climate and extreme weather events such as hurricanes threaten archaeological sites, especially in coastal regions which contain some of the most vulnerable forms of cultural heritage. As such, coastal archaeological sites provide exemplary locations for (1) the rapid study of storm impacts to archaeological site stability, preservation, and resilience planning; (2) understanding how site managers balance disaster response with post-storm public education and outreach; and (3) the role of archaeological cultural heritage preservation in community recovery. Here we share the results of a disaster survey of four well-preserved Calusa archaeological cultural heritage sites (e.g., Pineland, Mound Key, Estero Island, and Calusa Island) in southwest Florida following Hurricane Ian (2022). Working directly with site managers and local community members, we documented and assessed damage from high winds, tree falls, and storm surge, as well as post-storm looting. Moreover, we documented heritage stakeholder values regarding the role of each site in supporting recovery and (re)defining community resilience following Hurricane Ian. Our results indicate variable types of damage across different sites, management concerns related to recovery and long-term resilience planning, and great value placed on sites as places for community coalescence and reflection in the wake of disaster.

Material Wealth and Herding Power: A Pastoralist Perspective on Divine Lordship from Pashash, Peru

Fluctuating political allegiances during the Early Intermediate period (200 BCE–600 CE) were coopted by competing leaders throughout the central Peruvian highlands and more broadly in the south-central Andes. The relationships and conflicts that resulted from socioeconomic negotiations among local networks; alongside the vacuum of power left by the collapse of Chavín influence several centuries before, provide an ideal opportunity to examine the way that pastoral practices enabled and inhibited the ascension of divine lords. In this paper, we examine the heterogeneity of camelid (llama and alpaca) herds from the site of Pashash (200–400 CE) to examine how material wealth as expressed in nonhuman capital shifted the balances of power in the region. Mobilizing osteometric datasets from camelid first phalanges and stable isotope results to trace dietary and mobility, our analyses attest that pastoralism holds a key set of practices that were both world-making and world-breaking. The ability to control nonhuman animal power was a cornerstone to defining divine lordship during the Recuay cultural phase of the central Peruvian Andes, and this left lasting consequences for the definition of power for centuries that followed.

A History of the Ancient Southwest Revisited

A History of the Ancient Southwest was published 15 years ago. How would I rewrite it today? After a brief review of that aging narrative, I'll revisit several key points, threads, and themes in light of new information and understandings. I will explore the importance of continental-scale contexts, hinted but not fully developed in the book. And I will assess the place of *History* in current and future Southwest archaeology.

Consumo de plantas psicoactivas en Chavín de Huántar: Primeras evidencias directas en tubos de hueso en contexto de la Galería 3

En 2018 el Programa de Investigación Arqueológico y Conservación en Chavín de Huántar excavó la nueva

Galería 3 del Atrio de la Plaza Circular, donde fueron reconocidos cuatro eventos deposicionales que consisten en concentraciones de cerámica, carbón, restos óseos y bienes suntuarios ofrendados antes y durante la clausura del espacio. Además de la cerámica identificada durante las excavaciones de la galería, se pudieron recuperar 22 artefactos óseos tubulares de los cuales 11 se encontraron en un mismo evento deposicional sobre el piso de esta galería. Se seleccionaron los tubos, más una cucharilla y una valva para análisis de contenido usando técnicas arqueobotánicas y químicas. Esto implicó el muestreo de los artefactos en un ambiente controlado, obteniendo muestras de sedimento del interior de los tubos y de las superficies de la cucharilla y valva. También se obtuvieron muestras de sedimento de la galería para control. Las muestras se analizaron mediante microscopía óptica y cromatografía de gases acoplada a espectrometría de masa. Ambos análisis coincidieron en señalar la presencia de residuos y moléculas asociadas a las mismas plantas psicoactivas en un sub grupo de tubos, sugiriendo su posible uso como inhaladores.

A Study of the Free-Backing Bow-and-Arrow System's Functions and Social Implications in Western Alaska (AD 600–Nineteenth Century) by the Use of a Morphometrical and Mechanical Methodology

Around AD 600, cultural dynamics and a technology shift emerge among coastal Alaska Neo-Inuit people. Archaeological sites show evidence of the adoption, in a unique and innovative way, of a recurved or reflex bow of highly probable Asian origin, reinforced with twisted sinew cables. Known as the “free-backing bow,” historically this innovation is documented by rich ethnographic collections from the Aleutians to Greenland and within the larger Bering Strait region. Yet many morphological variations regarding the bow's profile, sinew-backing type, arrow morphology, and subsequent functions remain poorly documented. In this paper, we present our analysis of some of the earliest remains of this bow technology from the Birnirk and Kugusugaruk sites near Utqiagvik, northern Alaska, with comparison to ethnographic collections. These bows and arrows are analyzed as intertwining systems looking at both their morphometrical and mechanical features while systematically recording their structural and materials components and conducting simulation of arrow shots using a 3D software. This systematic and system-oriented approach to ancient bow technology can be a valuable cultural marker in our quest to better understand the cultural interactions and means of technology adoption in the Bering Strait at a key moment in the cultural development of the region.

New Research on Andean Mummies at the Royal Museums of Art and History, Brussels, Belgium

The Royal Museums of Art and History preserves seven complete or partial Andean mummies. Three are still surrounded by textiles in the form of funerary bundles. Four others lacked textile remains but were probably also held up by ties and fabric. For the museum and for Belgium, one of them is very important because he was made famous thanks to the depiction by the Tintin illustrator Hergé in two of his comic albums as Rascar Capac (*The 7 Crystal Balls* and *The Temple of the Sun*). Recent advances in medical imaging (CT- and micro-CT scan) permitted us to obtain high-quality imaging and 3D modeling. The research demonstrated that the mummies were the object of specific treatments. We note, in fact, the ablation of viscera but also the presence of postmortem sutures. The insect analysis also gives us an indication of how long this process took.

Paleoenvironmental Studies at the Ancient Maya Center of Yaxnohcah based on Analyses of eDNA, Pollen, and Plant Macroremains

Yaxnohcah was a major civic-ceremonial center of the ancient Maya world, especially during the Preclassic period (1000 BCE–200 CE). Environmental data from excavations provided important insights into the interaction between the ancient inhabitants of the polity and the surrounding Neotropical forest, a subject area that previously has been poorly understood. Our research aimed to fill that knowledge void by employing traditional paleoethnobotanical approaches combined with a useful new technology, the analysis of environmental DNA. The results enabled us to characterize the vegetation associated with the principal structures and the artificial reservoirs that provided the city's water supply. Because the area is without access to permanent water sources, such as rivers or lakes, these reservoirs were key to the development and survival of the city. Our findings indicated that although there were large areas cleared for agricultural purposes, large patches of mature upland and bajo forest remained intact throughout the Maya occupation. In addition, our studies revealed that there were incursions of pine savanna into the area that may have been a reflection of prevailing edaphic conditions, or alternatively, the result of frequent burning.

Macrobotanical Evidence from Poverty Point

While it was initially assumed that the residents of Poverty Point relied on an agricultural subsistence base, it soon became apparent that there was no macrobotanical evidence supporting such an assumption. Instead, subsistence remains were found to be generally consistent with a Late Archaic hunting, fishing, and gathering economy. Macrobotanical remains recovered from multiple Poverty Point testing and excavation projects, and analyzed between 2014 and 2022, have yielded a wealth of information about the subsistence activities of Poverty Point's Late Archaic inhabitants. The diversity of plant taxa represented in the assemblages adds nuance to traditional paradigms of Late Archaic foodways in the region.

What Lies Beneath: Underwater Ground-Penetrating Radar Survey of the Inundated Liebman Site, an Early Paleoindian Site in Lebanon, Connecticut.

The Liebman Site (71-31) is an Early Paleoindian site preserved beneath Lake Williams, a ~270-acre lake initially created by nineteenth-century milling operations of Bartlett Brook in Lebanon, Connecticut. Originally discovered by John Parkos and excavated by John Pfeiffer in the 1990s when water levels were reduced, the site is generally inaccessible to traditional investigations. These excavations yielded 85 artifacts including 15 tools, comprising end scrapers, pièce esquillées, utilized flakes, and a fluted point base. The fluted point base is consistent with a Crowfield point type, indicative of an Early Paleoindian occupation of the site. To better contextualize the stratigraphy and environmental setting of the site, we surveyed the general site area via ground-penetrating radar (GPR) using a real-time kinematic (RTK) GPS encoded 350 MHz antenna and SIR-4000 with the antenna situated on a raft and surveyor on a paddleboard. Data were collected in transects perpendicular to relevant landforms, which revealed the presence of a stable floodplain and buried paleo-channel, as well as the nineteenth-century channel of Bartlett Brook. Our survey demonstrates the utility of underwater GPR survey, which provides a cost-effective method for assessing site stratigraphy of inundated archaeological sites in freshwater environments.

Exploring Psychiatry's History in Chile: A Material Perspective of the Dr. José Horwitz Barak Psychiatric Institute

This research aims to carry out an archaeological analysis of the current Dr. José Horwitz Barak Psychiatric Institute in Santiago de Chile, a place historically considered a total institution. Since its creation in 1858, this hospital has served as the main psychiatric center in Chile. The present investigation explores the historical use of space within the institute through the architectural record that includes historical buildings up to contemporary material evidence. The research delves into the material changes and continuities that have occurred over time. The study contributes to a broader understanding of the sociopolitical aspects and material implications of the history of psychiatry and of patients with psychiatric disorders, which have historically been neglected in Chile.

Reframing Heritage: Indigenous Views in the Forefront

In many parts of the world, it is assumed that the most important heritage are the ancient sites that are visible on the landscape. This is certainly true within the Maya region of Central America. Projects often start

out with the assumption that contemporary Maya communities are focused on local archaeological sites as primary heritage sites. Led by this assumption, archaeology projects become so-called community archaeology projects when Maya community members are hired to work together with the archaeologists. Archaeological sites might be important heritage sites to archaeologists, governments, and UNESCO—but are not necessarily of great importance to local communities. Real community heritage projects must start with a series of wide-ranging conversations about local areas and sites of cultural importance. Such conversations will help identify community heritage and the local histories and stories about that location. In addition, these conversations will also define the type of information and knowledge desired by local community members. These discussions provide a local framework for what is heritage, how to examine and work to define local heritage, and be considered a real community project. These concepts will be presented along with information from ongoing projects in both Mexico and Belize.

On Taro, Tridacna, and Turtles: Using a Multiproxy Method to Explore Food, Fishing, and Agriculture on Pingelap, a Micronesian Atoll

Pingelap Atoll, located in Pohnpei State, Federated States of Micronesia, has been home to humans for approximately 1,700 years. At 1.8 km² and 70 km from its nearest island neighbor, food procurement has traditionally relied on marine fishing and hunting as well as intensive management of the coral island landscape, centered on the cultivation of giant swamp taro (*Cyrtosperma merkusii*). In this paper, we explore patterns in Pingelapese food systems over the span of occupation, drawing on archaeobotanical (macroremain and phytolith) and zooarchaeological data (including land snails) from a large midden near the village, as well as interviews with modern farmers and fishers. We find evidence for notable shifts in marine food consumption as well as landscape improvements leading to the development of productive soils in this coralline environment. Modern practices still rely heavily on traditional land and sea foods, although environmental and economic patterns have led to significant dietary shifts.

The House of the Blademaker: Recent Excavations in the Urban Core of Late Postclassic Tututepec (Yucu Dzaa), Oaxaca

This paper presents the preliminary results of recent household excavations at the Late Postclassic (AD 1100–1522) capital of Tututepec (Yucu Dzaa), located on the Pacific coast of Oaxaca, Mexico. These excavations, carried out in 2022, are the first to target a residential area within the ancient capital's urban core. Among the most significant findings so far is compelling evidence for household production of obsidian blades. Furthermore, preliminary analysis indicates that the obsidian was imported in the form of well-prepared cores, with over 90% sourced from either Pachuca or Pico de Orizaba. The blademaker who lived at this household appears to have produced blades to exchange directly with other citizens or via Tututepec's central marketplace. This paper will also compare residential data from the "house of the blademaker" with that of households excavated previously in a neighborhood on the northeastern outskirts of Tututepec.

The Animal Provisioning System for a Late Bronze Age Temple at Hazor, Israel

The tel site of Hazor, Israel, is one of the largest such occupational mounds in the southern Levant. Excavated in the 1950s, 1960s, and continuously since the 1990s, archaeologists have uncovered monumental public buildings. One such building, now identified as one of several Late Bronze Age temples, contains

evidence of divination and animal sacrifice and/or feasts. So documented, the question remains: how was this temple provisioned with animals to supply sacrifices, feasts, and the meals of temple workers? Did this societal segment have direct access to animal herds of its own? Were they tithed from the city's population or purchased from nomadic pastoralists? To arrive at a possible explanation, I study zooarchaeological evidence in the form of sheep, goat, and cattle relative abundance, metric measurements, and kill-off profiles. I also draw on cuneiform tablets that record herd management practices at other cities. The questions posed, and approach taken, draw direct and indirect inspiration from Richard Redding's work on feeding pyramid builders in Egypt, as well as Melinda Zeder's more general efforts to untangle ancient food supply chains in ancient Iran.

Collaborative Indigenous Archaeology at Mohegan

This poster showcases collaborative archaeological approaches to research and teaching on the Mohegan Reservation in southeastern Connecticut. It describes the Mohegan Archaeology Project, a long-running collaboration that records and studies the textures of eighteenth- and nineteenth-century reservation life. The project has two main forms, an archaeological field school and a tribal archaeology workshop. These two forms of collaborative research and teaching act together to (1) shed new light on an understudied and poorly documented era of Mohegan history, (2) bear witness to the material realities of settler colonialism, and (3) “remake” the discipline. It accomplishes the third goal by opening new interpretive spaces—including voices and forms of knowledge that have been traditionally overlooked and even disregarded in the discipline—in which to train the next generation of archaeologists.

Monkey Business: Examining the Significance of Monkey Imagery in Maya Caves and Ideology

Monkeys are prominently featured in Maya creation narratives, in Maya art, and more rarely in burial contexts. Despite their apparent importance in Maya ideology, however, previous research on monkeys in the Maya world has primarily focused on their primatological, and linguistic significance. In contrast to those studies, this research investigates the archaeological significance of monkey imagery in Maya caves and ideology by examining monkey representations in cave art, on cultural remains in caves, in Maya hieroglyphs, and their depictions in Maya iconography in general. By conducting qualitative ethnographic research with participants at revitalized traditional deer and monkey dances, this research also explores data on the physical representation of monkeys as characters and figures in a postcolonial context. With reference to creation narratives and collected archaeological data associated with the depositional, chronological, and iconographical evidence of monkeys in art and burial contexts, this study also bridges the gap between archaeological and modern interpretations of the significance of monkeys in Maya cosmology and religion.

Supplying Life and Death: General Goods Stores in Nineteenth-Century Upstate New York

In the nineteenth century, residents of the Towns of Cazenovia, Fenner, and Nelson, NY were able to purchase a variety of necessary goods at general stores. These establishments provided items from furniture, to mourning wear, to ceramics, to coffins, and many things in between. Today, the idea of buying dinner plates alongside grave goods seems almost unbelievable: this poster explores the overlap in consumer spaces between the realms of the living and dead in nineteenth-century New York state. Through archival and

geospatial analysis, I examine the situation of general goods stores on the landscape, the kinds of advertisements they circulated, and the larger role these venues played in social and economic networks of the region. Understanding the role of general goods stores in this context draws connections between two often-separated aspects of historical archaeology: dead spaces and living ones. By studying these stores in their composite, taking the ceramics alongside the coffins, we gain a more complete picture of life in nineteenth-century rural America and the constraints, needs, and values that made such sites necessary for people in the past.

Nossa Senhora do Freixo, Portugal: A Late Antiquity Roman Basilica and the Continued Reuse of Sacred Space Excavations at the Late Antiquity Roman Basilica of Nossa Senhora do Freixo, Portugal, provide insight into the surprising significance of this hinterland community within the southern Iberian Peninsula. Recent excavations have revealed architectural components and compositional trappings associated with a center of regional affluence. Imported utilitarian items and associated wealth goods suggest critical involvement within the overarching sociopolitical and ideological landscape of the Roman Empire. Germane to our interest in the organization and maintenance of Christianity throughout the Iberian Peninsula is the symbolic and ideological reuse of sacred space. Detailed investigation of the Freixo Basilica and especially the eastern transept has provided uncommon insight into the continued practice of Christianity following the collapse of the Roman Empire. Carbon-14 analyses firmly associate Christian inhumations with periods of Germanic and Visigoth occupation.

Lens into History: Burial Recovery at Vicksburg National Cemetery

Following a landslide at Vicksburg National Cemetery in 2020, a portion of the collapsed terrace within the cemetery was subject to emergency excavations to recover burials that had fallen from the Section T terrace. In addition, the landslide covered a portion of the Section J terrace. These impacted areas contain burials of some of the first United States Colored Troops (USCT) who were part of the Vicksburg Campaign. Additional mitigative measures were determined necessary to exhume burials on the intact but endangered Section T terrace as well as those covered by the landslide on the Section J terrace. Manual and mechanical excavation techniques were implemented during the recovery process, but exhumations along the scarp face required more unique and situationally appropriate methodologies. Additional and ongoing erosion necessitated the re-excavation of units dug in 2020 during the initial recovery efforts and the attempted reassociation of more recently recovered human remains to the previously exposed burials. Results of this project have implications for the interpretation of burials of “unknown” individuals and the narrative of the USCT experience, both at Vicksburg National Cemetery and within the broader National Cemetery System.

[99]

Food for Thought, Smoke for Diplomacy

Food surrounds politics, economics, ideology, and cosmology. Food experiences go beyond the dishes. The scale of consumption varies from small daily meals to large ritual feasts. Intoxicants are used in conjunction with eating events. These substances are often paired with foods to enhance the eating experience and are used symbolically during special occasions. Tobacco was integral to all precontact people's lives in Eastern North America. Use of tobacco during eating events varied based on site and setting. Tobacco served as a medium for political and social negotiations. Exchanges of tobacco often initiated discourse. This poster will explore the relationship between food and tobacco within the Algonquin-speaking Lenape, ranging from common to special use, by evaluating ethnohistorical records and analysis of smoking pipes.

Intensive Regionalism among Hunter-Gatherer Groups in Eastern Oklahoma

Across the southeastern United States, the Woodland period is marked as a time by processes of increased cultural distinction known as regionalism. In Eastern Oklahoma, the Fourche Maline archaeological culture (ca. 2300–1100 cal BP) demonstrates a strategy of limited mobility and high intensities of regionalism prior to the Woodland period. These cultural attributes are examined through the analysis of the lithic assemblage from the Troy Adams (34LF33) site. The results of this analysis are compared to lithic assemblages from several other midden mound sites that indicate regionalist practices through time among Fourche Maline people.

Applying Indigenous Methodologies to Create an Indigenous Research Agenda Model

Indigenous methodologies are methods of research that are guided by Indigenous knowledge systems and worldviews. Indigenous methodologies include (1) doing research for, by or with indigenous communities, (2) incorporating indigenous worldviews, (3) incorporating traditional knowledge, (4) incorporating tribal ethics and protocols, (5) applying decolonizing aims, and (6) securing cultural information. Applying these methods to our research, the research process and the writings produced from them can change the course in how we present knowledge and educate the world. Using these methods will help us, as researchers, to understand how research directly impacts culture as well as tribal sovereignty. A research agenda model promotes tribal sovereignty by having researchers engage with the community, develop relations, and seek permission and approval of their projects from tribal committees and/or leadership officials. In this paper, we explore Indigenous research methods as well as observe how the Agua Caliente Band of Cahuilla Indian tribe came together to help create a research agenda model that can be used in further research studies on their culture.

Burning the Record in Order to Save It: Cultural Fire as Archaeological Survey Method

Global heating is increasing the size and frequency of catastrophic wildfires in the American West, with the 2020 wildfires burning nearly 2% of the area of Oregon. In the year following, hundreds of new archaeological sites within the Ceded Lands of the Confederated Tribes of Grand Ronde (CTGR) were recorded. Despite decades of archaeological surveys of these areas, relatively few sites per acre were identified before the 2020 fires, in contrast to the site densities identified post-fire in smaller survey areas. This apparent difference in site visibility in pre- and post-fire landscapes has implications for the CTGR's cultural resource responsibilities when implementing cultural burning and during consultation with federal and state agencies. This study was designed to characterize how fire application changes the visibility of archaeological sites during pedestrian survey by quantifying the detection rate of 250 identical small (<3 cm) objects distributed over 80 acres in pre- and post-burn settings. Key successes and challenges in collaboration between tribal, federal, state, and academic participants are reflected on and implications for future archaeological investigations and landscape level analysis and management are discussed.

Rediscovering the Revolutionary War on the Francis Marion and Sumter National Forests

The Francis Marion and Sumter National Forests in South Carolina include over 11,000 archaeological sites spanning major events throughout history. The Revolutionary War is no exception but represents an understudied portion of the forests' history despite its namesakes. As part of the forests' efforts to further site stewardship and a better understanding of the Southern Campaign of the American Revolution, a metal detection survey will take place on the Francis Marion Ranger District in the winter of 2023 to identify and delineate Revolutionary War period sites. Results of this investigation will be used to develop future management strategies and protection measures for these sites. These results will be detailed and presented as part of a pilot study for additional investigations across the Forest in anticipation of the 250th anniversary of the Revolutionary War.

Cheng and the Question of Large Walled Settlements in Neolithic China

Large Neolithic settlements (approximately 1–4 km² in size) surrounded by rammed earth walls or moat enclosures are frequently referred to as *cheng* (often translated as “the walled city”) in Chinese archaeology and analyzed as proto-urban centers through Childe’s notion of urban revolution. As an emic concept in classical Chinese, however, the notion of *cheng* highlights the wall enclosure as a defense mechanism around the settlement without necessarily imply the presence of urban life within it. Instead of evoking an imagined vision of urbanization to fill in the social space within these wall enclosures, this paper presents a comparative study of the great Yangshao, Liangzhu, Qujialing-Shijiahe, and Longshan sites to understand the organizational plurality and diversity of the large walled settlements in Neolithic China. I will explore the different dynamics of large population aggregation, the significant variation in their population density, and the diverse social mechanism responsible for the constitution and maintenance of these settlements. Besides alternative control strategies and centralized political authority, I will focus on pilgrimage and other ritual activities potentially responsible for the emergence of these monumental sites.

[19]

Dinning at the Colonial Frontier: The Maintenance of Erligang Foodways at Panlongcheng

Located in the middle Yangtze region, the Panlongcheng site represents the southernmost extent of the Erligang civilization’s expansion during early Bronze Age China. While much scholarly work has concentrated on elucidating the site’s significance and its implications for understanding the unique cultural expansion in ancient China, there has been limited exploration into the daily lives of the Erligang settlers in this region. This study presents archaeobotanical evidence collected during the 2019–2020 and 2021–2022 field seasons at Panlongcheng. Although the identification and quantification of archaeobotanical remains are ongoing, preliminary findings indicate that the Erligang settlers retained their traditional northern foodways—specifically, millet—in an area known for originating rice agriculture. This practice is particularly noteworthy given the local geographical conditions, which make millet production seemingly unfeasible. Our research thus suggests that the settlers may have acquired millet through long-term trade or exchange networks, reinforcing their Erligang identity and maintaining consistent interactions with their northern counterparts.

A Comprehensive Analysis of Faunal Remains from Lovejoy Springs (CA-LAN-192)

Located in the western Mojave Desert community of Lake Los Angeles, Lovejoy Springs (CA-LAN-192) is a large village site with extensive occupation beginning as early as 4000 BP. Four cultural components have been identified at the site—Pinto, Gypsum, Rose Spring, and Late Prehistoric. This presentation utilizes a faunal assemblage excavated by Cerro Coso College in 1989. The collection sat unassuming in museum collections for decades prior to this project. Due to the state of the assemblage, which is heavily fragmented and fire-affected, identification posed a challenge. Despite this, numerous taxa were identified, including a variety of birds, mammals, reptiles, and rodents. The presence of cut marks and modified bone offers further insight into butchery practices and use of local fauna at the site. Variations in fauna were noted between levels, suggesting the influence of several factors such as changes in site occupation and environmental shifts

over time. Due to the lack of faunal analysis data available in this region, this project provides valuable insights to our understanding of Lovejoy Springs and the region's ecological and cultural history.

Whole Pots and Harvard Drops: Understanding the Pottery from Turpin

Many early professional archaeological investigations in the Ohio River Valley resulted in legacy collections lacking in a variety of ways. The Turpin site, excavated by Harvard University in the late nineteenth century, is an early Fort Ancient village located along the Little Miami River near the confluence with the Ohio River. This site is important because it represents one of the very earliest Fort Ancient occupations in the region. Today it is the locus of our ongoing project striving to work to provide data to better utilize such poor collections. Here we focus on one material class in the assemblage—pottery—through the lenses of both intrasite variation and differences between previous and current excavation practices at the site. We do so by focusing on differences in temper types, surface treatments, neck and rim decorations, and vessel morphology from the site within the context of how excavation strategies have shifted from the nineteenth-century practices to the methods currently being used in our ongoing excavations at the site.

Prospección arqueológica en la Ciudad de Mérida, Yucatán: Consecuencias y oportunidades de la colaboración entre el Laboratorio de Prospección Arqueológica, el Municipio de Mérida y la Universidad Autónoma de Yucatán

En nuestra ponencia presentaremos el fruto de años de relación entre el Laboratorio fundado por el doctor Luis Barba, que fue nuestro profesor en los años ochenta cursando la licenciatura en Arqueología en la ENAH de la Ciudad de México. Desde entonces, nos asomamos como arqueólogos al patrimonio invisible y/o abandonado mediante las técnicas de la prospección geofísica y el estudio de la topografía antigua. Uno de los antecedentes importantes que condujo a la formulación de la propuesta que describiremos más adelante, fue la firma, en 2016 del convenio de colaboración entre el IIA-UNAM y la FAUADY, para contribuir a la construcción de bases de datos del patrimonio arqueológico; compartir información geográfica y productos del trabajo conjunto, útiles para el desarrollo de proyectos de conservación del patrimonio arquitectónico en contextos urbanos y, realizar la prospección arqueológica en escenarios reales de la ciudad de Mérida. Ahora participamos en el Proyecto de investigación El Patrimonio Cultural-Natural en las Políticas y Gestión del Desarrollo Urbano-Territorial en Ciudades Mexicanas del Siglo XXI con el objetivo de estudiar la relación del patrimonio en contextos urbanos y su estructuración y operación en el territorio y dar cuenta de su historia y sus relaciones.

Unfreezing Archaeological Palimpsests: A View from the Iberian Peninsula during the Third and Second Millennia BCE
The Dawn of Everything is a deep well of insights, provocations, and information about the human condition and the human capacity for creativity, particularly with respect to social organization and inequality. The

fundamental question the authors ask is “how did we get stuck?” Answering that question requires archaeologists to engage with the implications of the palimpsestic nature of the archaeological record and with site microhistories. My paper approaches these issues from the perspective of the Iberian Peninsula between 3000 and 1500 BCE—during the periods known as the Copper Age and Early Bronze Age.

Nalaquq / “It is found”: Collaborative Heritage Landscape Survey and Spatial Technology with Alaska Native Communities

In the face of a rapidly changing climate, Alaska Native Yup'ik (pl. Yupiit) communities on the Bering Sea are increasingly empowered and motivated to protect their landscape heritage—facilitated in part by collaborative projects with outside institutions like the Quinhagak Archaeological Project (2009–present). In this paper we show how high density survey and measurement (HDSM) technologies, when used in conjunction with Yup'ik partners and their traditional wisdom, can be effectively deployed to manage and monitor at-risk cultural landscapes. HDSM techniques and ethnographic approaches generate dearth of spatial data that can be used to manage threats to infrastructure, heritage, and subsistence activity areas. Many years of collaborating in this manner has culminated in the formation of Nalaquq LLC, an Alaska Native community-owned CRM firm based in Quinhagak, which seeks to carry out landscape heritage research in the region and foster a new generation of Yupiit trained in geospatial techniques.

The Dietary Practices of the Ancient Inhabitants of the Chengdu Plain

The extent to which aquatic resources influenced the dietary patterns of the Chengdu Plain's inhabitants is poorly understood, despite the region's intricate network of river channels. This research examines the nitrogen isotope makeup of specific amino acids in collagen derived from human bone samples collected from three sites in Sichuan. The objective of this study is to gain insight into the subsistence practices on the Chengdu Plain, spanning from the late Neolithic to the middle Bronze Age. This period is notable for the introduction and growing significance of agriculture and animal domestication in the region. The nitrogen isotope ratios of phenylalanine ($\delta^{15}\text{N}$ Phe) and glutamic acid ($\delta^{15}\text{N}$ Glu) suggest that the individuals residing on the Chengdu Plain predominantly relied on terrestrial foods. The dietary reliance on aquatic resources was found to be restricted. One potential rationale for the limited reliance on water resources could be attributed to the advancement of agriculture and the domestication of animals, which provided an ample supply of food. This study additionally evaluates the importance of these subsistence economies in the social development of the Chengdu Plain.

Lin, Xin and Guopeng Chen (University of Oxford)**[21]***Demand or Control? Reconsidering the Production and Consumption of Maya Jade*

The procurement and consumption of jade are conventionally thought to have been under the control of Maya elites. Through cross-cultural comparison with ancient China as a representative jade-using culture, we argue that the multidimensional circulation of Maya jade created more flexible and complex social relations than “elite control.” In the Classic Maya, the production, distribution, and consumption of jade artifacts among different centers, as well as the quality, quantity, and extent of labor invested in jade craftsmanship, are not in alignment with the political hierarchy of each center. The tradition of using jade in caches and burials also exhibits distinct tendencies. Small jade beads functioned as commodities in circulation.

Commoners were extensively involved in jade production, even in the procedures that required complex craftsmanship. Once items of ideological and symbolic significance, like jade, possess economic value, they could introduce greater flexibility and dynamism in social mobility across different strata. In this case, “elite control” might not be the most effective analytical concept to understand jade utilization among different social actors of Classic Maya. We conclude by highlighting the concept of demand and reciprocity to interpret various forms of collective actions and cooperation in jade production and consumption.

Thirty years beyond enactment of the Native American Graves Protection and Repatriation Act (NAGPRA), there is still much to be done. The growing curation crisis and renewed efforts by Tribal Nations and archaeologists at the South Carolina Institute of Archaeology & Anthropology (SCIAA) created a training opportunity for undergraduate and graduate students pursuing careers in archaeology at the University of South Carolina (USC). By revisiting collections excavated during the Keowee-Toxaway Reservoir Survey (1967–1969), students learn to navigate the complex processes of the NAGPRA statute, curation practices for legacy collections, and identification of archaeological materials for federal documentation. Matching students’ unique skills with appropriate portions of projects is crucial training the next generation of archaeologists in NAGPRA protocols while respecting the sensitivity of potentially eligible collections. This poster reports preliminary results of the Keowee-Toxaway Re-curation Project including quantitative assessment of collections management progress and qualitative assessment of student learning outcomes.

Lindley, Tiffany (The Alamo, ATI) and Pamela Jary Rosser (The Alamo, ATI)**[192]***Preservation of Cultural Heritage at the Alamo: A Collaboration between Archaeology and Conservation*

Archaeology and conservation might appear to be contradictory disciplines. Archaeological methods are inherently destructive, and conservation strives to prevent loss. However, at some historic sites archaeology and conservation collaborate as integral partners to preserve the physical structures and cultural heritage, as well as recovering new data through archaeological investigations. This is true at the historic Alamo in San Antonio, Texas, which began as a Spanish mission in the eighteenth century and served many purposes over the past 300 years. Over the years, the original mission structures and venues intimately tied to Texas history have experienced extreme weathering and deterioration. Additionally, the surrounding urban landscape has grown around, and over, the historic footprint. This unique situation creates opportunities for archaeological investigations to support conservation work at the site. As the conservation team designs solutions to preserve the historic structures of the site, they must collaborate with archaeologists in order to protect buried cultural resources. Projects begin with archaeology in a supporting role but quickly morph into the recovery of critical archaeological data. This paper will discuss how recent investigations at the Alamo demonstrate the necessary and impactful collaboration of archaeology and conservation, with a shared goal of cultural preservation.

Lindquist, Shayna (University of Kentucky)**[163]***Shifting Patterns of Obsidian Procurement within a Distant Consumer Region*

By the Formative period, prehispanic societies in southern Veracruz primarily relied on obsidian for numerous daily activities. However, as the geological sources of obsidian that were exploited occur in central Mexico and the Guatemalan and Honduran highlands, southern Veracruz represents a distant consumer macroregion of obsidian. The Eastern Lower Papaloapan Basin (ELPB) exists within this macroregion, located to the west of the base of the Tuxtla Mountains. Local communities within the ELPB necessarily forged interregional relationships that can be found underpinning the long-distance exchange networks facilitating the movement of obsidian raw material. In this paper, I endeavor to identify these dynamic exchange networks present in the ELPB during the Formative and Classic periods through a diachronic analysis of shifting obsidian procurement patterns. This transitional period also represents a time of sociopolitical and economic change at the local scale, as well as regional and macroregional scales; thus, the patterns of obsidian procurement must further be situated within these broader contexts. To facilitate this discussion, I draw on data generated from portable X-ray fluorescence (pXRF) and technological analyses of 5,022 samples of obsidian collected during a regional archaeological survey that targeted the ELPB.

Lindsay, Ian (Purdue University), Khachatur Meliksetian (Armenian National Academy of Sciences), Hripsime Gevorgyan (Mining Academy of Freiberg), Laure Dussubieux (Field Museum of Natural History) and Erik Otárola-Castillo (Purdue University)**[50]***Investigating Geological Sources and Sociotechnical Dimensions of Mica Pottery Inclusions from Late Bronze Age (LBA, 1500–1100 BC) Fortresses in Northern Armenia*

For 25 years, the Archaeology and Geography of Ancient Transcaucasian Societies project (Project ArAGATS) has focused on the origins, regional-scale organization, and sociopolitical dynamics among LBA hillforts in northern Armenia. This paper presents preliminary results from a pilot study of mica samples based on petrographic and elemental analyses undertaken by Project ArAGATS, Armenia's Institute of Geological Sciences, and the EAF. The goals of research were to (1) establish the viability of LA-ICP-MS as a technique for identifying the source of mica pottery inclusions, and (2) study the sociotechnical context of mica's circulation and incorporation into LBA ceramics. A prior ceramic circulation study in Armenia's Tsaghkahovit Plain based on INAA revealed that the small LBA fortress of Gegharot, host to a suite of several religious shrines, benefited from asymmetrical flows of pottery (and other goods) from surrounding sites. This center of ritual practice also sits on a natural source of mica, whose signature sparkling flakes, our

data suggest, were transported and added to ceramics 12 km across the plain. We present LA-ICP-MS and optical petrography results from regional mica sources linked to different metamorphic and magmatic rocks and explore the sociotechnical implications of mica inclusions as materialization of ritual practice.

Shapes of Power: Rectangular Tombs and Societal Identities at Yaracachi Cemetery, Moquegua, Peru

Humans have a variety of means of coping with the inevitability of death that is expressed in material culture. To interpret burials as the material remains of ritualistic processes, multiple variables need to be assessed, such as the construction, location, spatial distribution of graves, and associated grave goods. Two types of tombs were uncovered at the Yaracachi cemetery in Moquegua, Peru; round tombs and rectangular tombs. Rectangular tombs were atypical in the Andes during the Late Intermediate period (1100–1400 CE). For this project, I plotted graves based on shape and elaboration to discern spatial patterns and assessed the types and numbers of associated cultural materials to consider ethnic affiliations and social status. I analyzed grave data from approximately 22% of the 1,300+ tombs. Rectangular-shaped graves account for 10% of the graves examined and have a higher average number of grave goods and metal artifacts than round tombs, which suggests that these graves display a higher socioeconomic status of the interred individuals. Rectangular graves occur in clusters, which may indicate an association between these individuals, perhaps based on social status or ethnicity. The rarity of rectangular graves at Yaracachi and throughout the Andes suggests that these are high-status graves.

La explotación industrial de cetáceos en Bahía Aguila, Estrecho de Magallanes

El presente trabajo informa las actividades de campo realizadas en el marco del proyecto FIC 5377 de 2018/2019, y las metodologías utilizadas para el registro y recolección de restos óseos de cetáceos sumergidos en bahía Águila (estrecho de Magallanes, Chile) donde funcionó la planta de la Sociedad Ballenera de Magallanes entre los años 1905-1916. En dichas actividades se desecharon las carcasas de los cetáceos sobre la bahía, depositándose en el fondo marino inmediato miles de huesos, testigos del primer experimento de caza y procesamiento de ballenas a la usanza moderna en Chile. Utilizando diferentes análisis se espera obtener información sobre el impacto de la caza de ballenas en las poblaciones del estrecho de Magallanes, como a su vez dar cuenta de la memoria histórica de la actividad ballenera en este sector. Así también, comparar estos resultados con los de las poblaciones actuales, para estimar si los animales faenados en Bahía Águila están emparentados con los grupos que con cada vez mayor frecuencia son avistados en los distintos puntos del corredor Atlántico Pacífico y sus intrincados canales.

El Juego de Pelota del valle de Maltrata y su contexto cultural

El juego de pelota es un tema que ha llamado la atención a numerosos investigadores, algunos se han centrado en el estudio arquitectónico, otros desarrollan enfoques iconográficos o propuestas de rituales basados en evidencias como en el Tajín. En otros lugares, solo se distinguen las estructuras paralelas que definen al juego y no siempre es posible excavarlos o estudiarlos más detalladamente para sustentar la propuesta que estuvieron relacionados con prácticas o rituales. Este es el caso del valle de Maltrata, localizado en la región montañosa al oeste del centro del estado de Veracruz, en el asentamiento denominado Rincón de Aquila. Aquí se han encontrado dos estructuras paralelas definidas como Juego de pelota. En una temporada de campo se excavaron cuatro pozos con la finalidad de identificar algún alineamiento o evidencia cultural que pudiera indicarnos alguna actividad relacionada con rituales u otra función, además de poder precisar su temporalidad. En esta ponencia se presentan los datos del trabajo de campo así como el análisis de los materiales culturales que se encontraron, para poder inferir temporalidad y posible uso, y en el mejor de los casos poder identificar algún tipo de ritual.

An Examination of Commingled Atlantoaxial Joints by Deviation Analysis

This study builds on previous research that incorporated deviation analyses into sorting commingled human remains. This presentation will analyze a relatively untested joint surface, the atlantoaxial joint, to exclude potential commingled joint pairs. Virtual models were created at the University of Tennessee-Knoxville Donated Skeletal Collection from 68 atlases and 69 axes using an EinScan-Pro 2x + Handheld Surface Scanner. The shape of the articular surfaces was analyzed in Geomagic Wrap 2017, and the congruency of the two facets was measured with a deviation analysis. ROC curves were performed on a reference sample composed of 200 commingled and non-commingled joint pairs to identify threshold values that could help

separate commingled remains. A validation sample of 225 pairs was subsequently examined to demonstrate the efficacy of this method on a sample of unknown individuals. Statistical analyses demonstrated that the deviation analysis values from commingled joints were significantly larger than those from non-commingled individuals ($p < 0.0001$). Based on the selected threshold values, 66%–71% of atlantoaxial joint pairs were correctly excluded. This objective technique improves on previously subjective strategies for rejecting commingled atlantoaxial joints and can assist bioarchaeologists in the interpretation of commingled assemblages.

The YEAR Centre: A Research-Driven Pedagogical Approach to Experimental Archaeology

In recent years, since the development of our outdoor experimental archaeology “lab” (York Experimental Archaeological Research “YEAR” Centre, University of York) we have designed a series of modules that place experiential learning at the center of pedagogical practice. Such is the success of these modules we now have a dedicated master’s program on Experimental Archaeology and Material Culture. The pedagogical pathway commences with an UG module interweaving theory and practice, focused on experiential learning, facilitating practical engagement with diverse archaeological materials. By UG year two, students undertake a practical skills module, enabling them to build firsthand experience with a range of analytical methods, linked to different archaeological materials, while learning to execute and report on their own research projects, working in a group. The journey continues with our postgraduate courses where the focus shifts, with students achieving intellectual independence through practice-based research related to real research questions involving report writing, with the results sometimes published. These modules constitute a learning framework that support students to develop the skills to design their own experiments, select the appropriate methodological tools to analyze the data, and feel confident in integrating theoretical approaches to fully interpret and write up the data generated.

A Trading Post or Craftspeople’s Village? A Ceramic Perspective of the Blihun Hanben Site in Eastern Taiwan

The Blihun Hanben (BHB) site in ancient Taiwan, dated between 2,000 and 1,200 years ago, contained a wide range of remains that indicate an iron crafting settlement. The excavation yielded over 9,000 kg of ceramics from two cultural layers, indicating a prolonged period of human occupation. This study employed technical typology, geophysical, and geochemical analyses to examine the ceramic assemblage. These analyses unveiled 16 subtypes in seven groups within the upper layer ceramics and 17 subtypes in seven groups within the lower layer ceramics. The specimens were discovered to have originated from four different areas, namely BHB local, northern Taiwan, Ilan Plain, and eastern Taiwan. The quantity and multiple sources of ceramics suggest that the BHB people had continuous and frequent interactions with communities from other regions. Notably, frequent long-distance and intensive interactions were relatively rare in Taiwan’s archaeological cases, particularly when nonlocal production represented most of the BHB lower-layer ceramics.

Metallurgy in the Arc: Technological Choice and Resource Management Strategy during the Late Shang Period

The concept of the Arc, proposed in 1980s by Tong Enzheng and further developed by J. Rawson in the last 10 years, refers to the vast landscape stretching from northeast to southwest China. Its unique geography

incorporates both pastoralism and agriculture, vital to the communication between the Eurasian Steppe to the Central Plains of China in Neolithic and Bronze Age. In this paper, we have recharacterized the key metal assemblages in the Arc (e.g., Sanxingdui, Hanzhong, Northern Shaanxi) and compared them with those of Anyang. It reveals that the northern part of the Arc shows a rather different metallurgical tradition, with greater emphasis on mixing and recycling, whereas the Yellow and Yangtze groups appear to be more centralized, with an abundant supply of raw metal and well-selected alloying technologies for different social hierarchies.

[215]

Modes of Labor Organization and Variations of Pastoral Economies across East Asia during the Second Millennium BCE

There has been considerable recent momentum in documenting pastoral communities in the past who engaged with multi-resource subsistence strategies, including both husbandry and cultivation. This paper explores the potential conceptual conflict between cultivation and pastoral activities in the context of labor budget and surplus accumulation. Pastoral economies often employ extensive labor approaches in which productivity is driven by the size of herds and the quality and expansiveness of pastures. Traditional farming systems, on the other hand, are often limited by land availability, and consequently, productivity is driven by intensive labor input per area unit. I shall use three case studies from Southern Tibet, Eastern Tianshan, and Inner Mongolia, respectively, to illustrate varying labor organizations underlying subsistence choices during the second millennium BCE. These case studies inform about the flexibility and ingenuity of ancient pastoral communities who practiced more than one subsistence mode and combined them in a number of innovative hybrids that coexisted over thousands of years.

If Walls Could Whisper: Tales from a Talus Room

Despite its remoteness and the restricted access, there are very few standing structures on the Pajarito Plateau where Los Alamos National Laboratory now resides. One notable exception is Nake'muu Pueblo which was first built during the Coalition period (AD 1225–1300). Pueblo de San Ildefonso oral history describes that Nake'muu was reoccupied following the events around the Pueblo Revolt and the Reconquest in the 1680s–1690s. Very little is known about Tewa descendants reoccupying other ancestral places during this early historic period. In this poster I examine LA 136699, an Ancestral Pueblo period cave with standing talus room masonry architecture that was presumably rebuilt sometime post-1600. Photos show walls at least 1.5 m tall with intact roof timbers. Who rebuilt and occupied the structure? Examination of associated diagnostic artifacts should elucidate when the ancestral site was reoccupied and by whom. If the outcome of this investigation suggests Tewa descendants reoccupied the site, it would add considerably to our understanding of the use of the Pajarito Plateau post-1600; when Ancestral Pueblo peoples relocated their year-round villages closer to the Rio Grande but never abandoned the Plateau.

From Concept to Interpretation: Trail Design and Signage Collaboration among CRM, Volunteers, and a City Preserve

Interpretation, an educational method for inspiring interest in a topic by connecting individuals with cultural and natural resources through experiences and illustrative media, is not commonly associated with cultural resources management (CRM). In the 2010s, a local CRM firm provided management recommendations and options for a city-owned preserve in Arizona, which resulted in the collaboration between the firm and volunteers for a Class II survey within a historic cattle ranch on the preserve. The current project is a follow-up to the work in the 2010s and includes the creation of an interpretive trail with associated signage, a National Register of Historic Places (NRHP) nomination, a trifold brochure for the trail, and archaeological monitoring during ground-disturbance activities within the historic ranch. This paper presents the challenges and successes for collaborating with volunteers and city's parks and recreation department to create and design an interpretive trail and signage within a historic site in the post-pandemic era.

LoBiondo, Matthew (UC Santa Barbara) and Emily Kracht (UC Santa Barbara)**[50]***Tracking Population Movement and Interaction in Southern Appalachia: Elemental Analysis of Early Mississippian Pottery from Etowah*

Migration, pilgrimage, and other forms of movement and culture contact have long been recognized as important forces of social change. Social interaction among culturally diverse groups has been demonstrated archaeologically as an important causal factor in Mississippian origins throughout the US Southeast and Midwest. Archaeologists have argued that interregional interactions during the eleventh and twelfth centuries CE established important relationships among Native American groups from Southern Appalachia. These far-flung connections are poorly understood but were instrumental in the spread of Mississippian practices and beliefs, eventually leading to the development of hierarchical regional polities such as Etowah in northwestern Georgia. Recent analyses support a scenario in which both local and nonlocal groups were synchronically present at Etowah, with profound changes on sociopolitical relationships across Southern Appalachia. However, it remains unclear if disparate populations permanently or periodically occupied the site. New elemental compositional analysis of Etowah pottery indicates that pottery was made both locally and nonlocally, suggesting that a portion of the population involved in the establishment of Etowah were periodically visiting the site to engage in ceremonial activities.

The Maya are a People of Movement: An Isotopic Assessment at Chactemal (Santa Rita Corozal), Northern Belize
 Located in Corozal District in northern Belize, the coastal Maya archaeological site of Santa Rita Corozal, hereafter Chactemal, was continuously occupied from the Middle Preclassic (BCE 800–300) through the Late Postclassic (CE 1250–1532). While many sites in the Southern Lowlands experienced decline and abandonment in the Terminal Classic (CE 800–900), Chactemal flourished, reaching its apex in the Late Postclassic when it took on a position of regional power. It is not well-understood how mobility influenced this population growth. We measured stable oxygen isotopes of dental enamel ($n = 108$ samples) and bone carbonate ($n = 96$ samples) from 100 Ancestors recovered from Chactemal to diachronically assess movement. Approval for isotopic research was granted by the Belize Institute of Archaeology. Additionally, we co-developed this work alongside local Maya organizations and villages in Corozal District. $\delta^{18}\text{O}$ values (mean = -4.0 ‰ VPDB, SD = 1.4, range = -7.6 ‰ to -0.8 ‰ VPDB) indicate nonlocal Ancestors are present within the burial population and suggest nonlocal Ancestors from the Preclassic came from different places than those in the Late Postclassic. Chactemal's geographic positioning on the coast, between two rivers, and within the border zone between the Northern and Southern Lowlands attracted people from other places throughout time.

Lockett-Harris, Joshua**[78]***Chair***Lockett-Harris, Joshua, Kathryn Reese-Taylor (University of Calgary), Felix Kupprat (Universidad Nacional Autónoma de México), Armando Anaya Hernández (Universidad Autónoma de Campeche) and Debra Walker (University of Florida)****[78]**

Continuities and Transformations: A Sociopolitical History of the Central E-Group of Yaxnohcah, Campeche, Mexico
 Archaeological investigations at the ancient Maya site of Yaxnohcah, located in the Bajo el Laberinto region of the Maya lowlands, have demonstrated that the construction, maintenance, and elaboration of its central E-

Group-style plaza-pyramid complex was integral to the multimillennial development of sociopolitical complexity and urbanism at this site. Often centrally located, E-Groups were generationally altered to meet the demands of increasingly complex lowland societies. Through this process they came to embody specific generational realities and sociopolitical necessities, often reflecting larger contemporary sociocultural trends. Our research indicates that the form, alignment and possibly the function of the Yaxnohcah E-Group changed substantially through time, exemplifying the dynamic agency of the peoples of Yaxnohcah and the flexible evolution of the mental and material schemata of lowland E-Groups. This paper synthesizes two-millennia-plus (800 BCE–1250 CE) of excavation data from the central E-Group of the ancient Maya site of Yaxnohcah to identify important moments of material and sociopolitical transformation. We then analyze this sociopolitical history in relation to larger contemporaneous sociopolitical dynamics in this important region, specifically in relation to the prominent neighboring site of Calakmul.

Experimental Earth Oven Agave Bakes with the Southern Paiute in Nevada

Beginning in 2018, I have been working with the Southern Paiute to host annual agave bakes using experimental earth ovens at the Desert National Wildlife Refuge in southern Nevada. Our events have gradually grown as we experiment with various aspects of earth oven cooking, including the use and quantity of different fuel types, introduction of modern materials, and processing methods. Once a commonly used technology as evidenced by hundreds of earth ovens documented throughout the refuge, access to traditional baking areas were restricted to Indigenous peoples following decades of emigration and the establishment of federal lands. As a result, the ability to practice traditional lifeways, such as baking agave in earth ovens, was irrevocably changed. We hope that as interest continues to grow, this event may be expanded to include the participation of additional southern Paiute bands, as well as opening the event up to the public to share this traditional cooking method.

Vapaki: Akimel O'odham Cultural Knowledge Regarding Classic Period Platform Mound Villages in the Phoenix Basin
Vapaki is plural in the O'odham language for Vah'ki, which is the name used to refer to what archaeologists now call Classic period (ca. 1250–1450) platform mound villages. Importantly, Vah'ki is specifically applied only to platform mound sites, and the term is not used to refer to any other older villages such as Snaketown. Because O'odham traditions regarding the Vah'ki are of great importance, they have been carefully passed down, and this knowledge has therefore been preserved. This history individually describes platform mounds, and each Vah'ki has a unique name. The leaders who ruled each mound are also still known by name, and events that occurred at the sites are still remembered. Furthermore, the O'odham history says that Elder Brother, their primary deity, defeated the Vapaki rulers one after the other. Unfortunately, some archaeologists have misinterpreted this to mean that the O'odham are a different ethnic group than the people who lived at the mounds, but the traditions are that the mound builders are direct ancestors who were also O'odham. Indeed, the creation narrative begins long before the Vapaki were destroyed, and it is impossible that the prior events describe the lives of a different people.

New Developments with the Shield-Bearing Warrior Motif in the Rocky Mountains

The shield-bearing warrior, a widely recognized rock art motif on the Northwestern Plains, has a more complex pedigree than archaeologists originally recognized. Examples in north-central Montana are radiocarbon dated to the Late Archaic while other sites in southwestern Montana may date to the same time. Adding to the complexity, a possible Fremont connection has been made to shield-bearing warrior pictographs in southern Montana. The research points to long-standing intergroup warfare in the region.

Updates from the Southeastern NAGPRA Community of Practice (SNACP): Successes and Challenges

Over 33 years have passed since the Native American Graves Protection and Repatriation Act of 1990 (NAGPRA) was ratified. As practitioners, we recognize the progress that has been made and acknowledge the vast amount of repatriation work that still must occur. The Southeastern NAGPRA Community of Practice (SNACP) group was created in 2020 as a means of enabling NAGPRA practitioners to connect and have conversations that focus on common issues, practical advice, potential solutions, and the everyday realities of implementing NAGPRA with a particular emphasis on the southeastern United States. This poster will share resources and ways to connect further and will discuss efforts regarding split and shared collections as well as how increased communication, collaboration, and partnerships are key to successful repatriations.

Logan, Amanda (Northwestern University)**[250]***From Making to Mobilizing History in Banda: Learning from Ann Stahl's Place-Based Approach to Archaeology*

Ann Stahl's career spans over 40 years, and for most of that time, she has focused on working in one small place in central Ghana known as Banda. Banda is different than most regions where archaeologists usually conduct sustained, long-term fieldwork: it was not a large, well-known urban site or the center of a large polity, but a place that has long been a peripheral frontier. In this paper, I reflect on how this context and Ann's commitment to place-based work has anchored her trajectory as a scholar and a mentor. Revisiting this place-based work showcases how engaged, community-based archaeology can be enacted across a wide range of contexts, but also how community work acts to change the questions of archaeology as a discipline. I also detail how many of her scholarly habits (interdisciplinarity, theoretical agility, empiricism, and openness to learning) provide a set of aspirational practices for archaeologists today.

Recent findings have come to light from previously reported but poorly known preceramic deposits from near the village of August Pine Ridge, Belize, Central America. Years of sand quarrying have led to the recovery of hundreds of artifacts representing the entire known preceramic sequence from Central America. Present are fluted bifaces as well as manufacturing failures representing South American stemmed Fishtail points, so-called waisted styles representing local traditions, and North American-influenced Clovis types. Newly defined Late Paleoindian styles represent continued connections from South America to Central Mexico and document shrinking cultural interaction spheres following the disappearance of fluted biface horizons after around 12,000 years ago. An array of stone bowls, mortars, and pestles likely documents the emergence of plant-focused subsistence practices. An industry based on macroblades and flakes characterizes Archaic occupations from perhaps around 5,500 years ago until the emergence of Maya villages, ca. 3000 BP. The presence of a few constricted adzes represents the final millennia of Archaic technology, until the increasing reliance on maize cultivation led inhabitants to relocate from the sandy pine ridge to more productive soils. This presentation places into hemispheric and regional context one of the most important preceramic sites in Central America.

Loiselle, Hope**[51]***Multiproxy Analysis of Sea Lion Hunting in the Northwestern Pacific*

Around the Pacific Rim sea lions have served as a valuable food source for coastal communities throughout the Holocene and as a globally valued product in the expanding Eurasian and American colonial and imperial

trade networks of the past few centuries. In this talk I discuss the hunting of both Japanese and Steller sea lions in the northwestern Pacific. The Japanese sea lion is an extinct pinniped while the Steller sea lion is an extant but threatened species in the region. To better understand human relationships with these species through time and what factors led to their current population statuses, I use a combination of ancient DNA, stable isotope, and archaeological datasets. Japanese sea lions from 11 archaeological sites around Hokkaido dating from the Early Jomon through the Okhotsk period were sampled. Steller sea lions from the Kuril Islands were sampled and include individuals dating to the Epi-Jomon, Okhotsk, 1800s, and modern period. Both sea lion species appear to have been resilient to millennia of hunting and climatic change up until the 1900s.

Diachronic Evolution of Raw Material Management and Technological Innovations along the Gran Dolina TD10 Sequence (Burgos, Spain)

During the second half of Middle Pleistocene in Europe significant changes occurred, including the emergence of Neanderthal anatomical features and behavioral shifts documented in the archaeological record, such as fire use, Levallois technology, and development of complex hunting strategies. These changes could reflect distinct economic and technological organization. However, prior studies have not quantified the diachronic evolution in raw material management through reduction intensity. This paper investigates core reduction intensity in the Gran Dolina (Spain) TD10 unit, covering a time span from approximately 450 to 220 ka. Results reveal distinct patterns of reduction intensity in which the oldest subunits (TD10.4–TD10.3) show a prevailing trend of low reduction, while the youngest TD10.2 and TD10.1 exhibit increased core reduction intensity. These changes in reduction intensity correspond to several technological shifts. TD10.4 and TD10.3, associated with the Acheulean, emphasize optimizing knapping sequences through specific blank morphologies, while TD10.2 and TD10.1 are considered transitional between Acheulean and Mousterian technocomplexes, showcasing greater core exhaustion, multipolar knapping strategies, and the use of small flakes to produce retouched tools, suggesting more intense management of lithological resources. The study's combination of technological analysis with quantitative reduction studies demonstrates its potential in understanding the dynamics of raw materials management.

Preliminary Study of Funerary Patterns at the site of CuzCuz, Huarmey Valley, Peru

The archaeological study of funerary practices provides important data concerning cultural traditions, belief systems, social inequalities, and sociopolitical alignment. The excavations conducted at a prehispanic cemetery at the site of CuzCuz highlights funerary practices used by coastal Andean groups during the Late Intermediate period (LIP; AD 1000–1400). In the Huarmey Valley, this cultural period—associated with the production of a local pottery style—emerged following the collapse of the Wari State. While most evidence recovered from CuzCuz is associated with the LIP occupation, there is a Middle Horizon occupation interpreted from polychrome ceramic fragments, textiles, and other recovered artifacts. The study of funerary patterns and changes in material culture at CuzCuz offers the opportunity to observe and understand the social transition from the Middle Horizon to the Late Intermediate period in the Huarmey Valley.

Long, Kali (Barnard College, Columbia University)**[268]***Faunal Chronicles: Unearthing Cultural Significance in San Antonio del Embudo's Eighteenth- to Nineteenth-Century Animal Remains*

In this poster, I report on the faunal remains recovered from eighteenth- and nineteenth-century midden deposits in San Antonio del Embudo, a small settler village in northern New Mexico. I analyze species choices, skeletal element distribution, age profiles, and processing marks (cut, burn, fragment) along with disposal patterns. These remains unveil the story of rural settler families navigating violent uncertainties, transcending mere sustenance to reveal the pastoral traditions and foodways of these resilient families. Amid relentless precarity, their cultural identities are etched onto these bones.

Long, Nick**[33]***Nat 20: Looking at Gaming Pieces and Gambling from the Haynie Site*

For the summer of 2023, I traveled to Cortez, Colorado, to participate in a lab internship at Crow Canyon Archaeological Center. I was given the opportunity to conduct a personal project dealing with a set type of artifacts of my own choosing. For my project, I decided to look at the gaming pieces from the Haynie site (5MT1905). My goal for this project was to contribute a better understanding of gaming and gambling related to the Ancestral Pueblo people for the Crow Canyon Archaeological Center, which could potentially help to better recognize these types of artifacts in future projects and analyses for Crow Canyon. In addition to research dealing with gaming and gambling in the Southwest region and analyzing the gaming pieces that were already identified in the collection, I was able to identify four additional gaming pieces that were previously categorized under different artifact types. This paper that I am presenting discusses the process and the results of this personal project.

The surfaces of lithic artifacts, namely of ground stone tools (GSTs), are a rich repository of structured use-related biogenic residues (SU-RBR) such as starch, revealing the mechanical processing of starch-rich organs, naturally biodegradable and therefore vulnerable. The recovery of SU-RBR on the surfaces of GSTs from a consistent number of MIS 3 sites across the Eurasian steppe reveals the emergence of the transformation of dietary carbohydrates that might have served as staple food by *Homo sapiens* (Hs). Examples from key sites will be discussed to support the reasoning on the complex interplay between biology, environment and technological strategies that brought the successful peopling of the Eurasian steppe. Hence, by approaching stone tools as bioarchives, it is possible to document perishable technologies highly informative of the foodscape(s) of early waves of *Homo sapiens* (Hs) when colonizing the Northern latitudes.

Classic Period Integration at Yaxnohcah: A “Bottom-Up” Perspective from Ximbal Che

Recent investigations at the Ximbal Che group at Yaxnohcah have documented intriguing new data with implications for understanding sociopolitical and economic integration in the Bajo el Laberinto region. These data include diverse cultural assemblages that show radical changes to the built environment of Ximbal Che, ritual activities associated with this construction program, and pronounced shifts in inhabitants' wealth, status, and economic practices. We directly link these patterns to broader sociopolitical transformations following the arrival of the Kanu'l kings at Calakmul in the seventh century CE. This paper argues that these material outcomes reflect the integration of the Ximbal Che Maya into the Kanu'l political and socioeconomic apparatus as intermediate elites who oversaw Yaxnohcah's Sakjol neighborhood marketplace. This was not, however, a unilateral process of subordination. Instead, our findings suggest this was a historically contingent and multifaceted process involving a complex and dynamic interplay between top-down forces and bottom-up strategies, including negotiation, cooperation, and, at times, resistance. The implications of this dataset are discussed, with emphasis on what it tells us about integrative processes in the Bajo el Laberinto region.

Ways of Death at Los Guachimontones

Los Guachimontones was the largest site of the Teuchitlan tradition that flourished during the Late Formative and Classic periods (ca. 300 BCE–500 CE) in Western Mexico. The site exemplified the monumental architecture of the region—circular pyramid complexes and ballcourts. Human burials have been excavated among these structures and at burial grounds used continuously throughout the site's occupation. The burials and their human remains were examined through a bioarchaeological and mortuary archaeology lens to determine their age, sex, health, and manner of death and burial. The human burials demonstrate the variety of mortuary practices within this society, representing both ceremonial practices associated with the symbolic power of the monuments and the quotidian lives of the general population of the site. Funerary and burial practices, particularly those associated with monumental architecture, legitimated power structures at the site through the command of spiritual forces, labor, violence, and public space. This presentation will include images and a discussion of human skeletal remains.

Las poblaciones arcaicas del Cabo Samaná, República Dominicana

El Monumento Natural Cabo Samaná, situado en la provincia de Samaná, en la República Dominicana, atesora

una serie de importantes sitios arqueológicos de época arcaica en las cuevas y abrigos que jalonan el farallón rocoso. El equipo de arqueólogos de Guahayona Institute ha realizado cinco campañas de excavaciones arqueológicas en el área protegida citada. Durante los trabajos de excavación arqueológica se ha localizado un cementerio con los restos de al menos 26 individuos fechados hace alrededor de 5.500 años. También se han hallado restos de ocupación en la Cueva Funeraria de Daniel que ofrecen fechas anteriores al 9000 BP. Uno de los hallazgos más interesantes realizados es la planta de una vivienda, fechada hacia mediados del cuarto milenio antes de Cristo en el denominado Abrigo de Dana. Asociados a ella, aparecieron varios pisos de uso y algunos fogones. En los sitios arqueológicos excavados, se ha constatado la presencia de una industria lítica fabricada con mármol y caliza, que incluye proyectiles, y asociados a esta se han extraído abundantes restos óseos de animales utilizados como fuente de alimentación, entre los que destacan perezosos (*Parocnus*), varias especies de roedores extintos, huesos y espinas de pescados y abundante malacofauna terrestre y marina.

Cabo Samaná Natural Monument, located in the Dominican Republic's Samaná Province, contains a number of important archaeological sites from the Lithic/Archaic period in the caves and rockshelters that dot its cliffside. The Guahayona Institute team of archaeologists has carried out five archaeological excavation campaigns in this protected area. Among their principal findings, located in the Abrigo de Daniel, is a ceremonial burial site with the remains of at least 26 individuals, some dated as far as 5,500 years ago. Remains of occupation were also found in the Cueva Funeraria de Daniel, including a burial dated more than 4,000 years ago, and some dates before 9000 BP that we believe may be anthropic, under current study. One of the most interesting findings, located in the Abrigo de Dana, is the floor plan of a house, marked by postholes, dated toward the mid-fourth millennium BC, with several use-floors and some hearths associated with it. The excavated sites revealed a lithic industry made of marble and limestone, including projectile points, and abundant faunal remains of animals used as food sources, including fish, much terrestrial and marine malacofauna, several species of extinct rodents, three species of extinct ground sloths, and a primate.

What Lies Beneath: The Significance of a Midden Burial in Exploring Differential Mortuary Treatment of the Maya at Palenque

The PREP: Urban Life at Palenque Project 2023 field season brought about unexpected findings regarding household mortuary practices. Two atypical burials were uncovered: (1) an isolated, articulated right arm boxed-in by large stones at the entrance of residential structure J37, and (2) a complete primary burial discovered on the south side of the same structure. During the excavation, it was evident that the individual found to the south presented with typical cultural skeletal modifications and was in the typical burial position for this site. Importantly, however, this burial was found within a midden feature and is one of only three similar burials from this site. This midden burial presents a unique instance of deviation from commonly known mortuary practices of the Maya of Palenque: the individual was interred directly in the soil, with material artifacts, but no stones deliberately placed on top or around them, such as was the case with the isolated arm burial. This presentation seeks to build on the discussion of differential burial treatment of individuals interred within midden contexts, broadly among the Maya lowlands, and locally at Palenque.

Fire Effects on Obsidian Landscapes: A Case Study

We know fire can affect obsidian hydration, but how do forest fires, and our management practices impact these sites and their potential for data contribution under Criterion D? Is there a different way of going about evaluating data contribution or management practices to work with management in our age of large, intense climate-change influenced fires? In this poster, a combination of X-ray fluorescence and obsidian hydration are used to evaluate the effects of wildfire, and specifically intense wildfires, on the chemical

signatures used in sourcing studies, and relative dating using obsidian hydration. The damages caused by intense heat on these oft-used analyses, and how we may rethink our interpretation of their results. We also explore how this can help us reframe traditional management techniques in our forests, alternatives, and new directions of inquiry and research when these more traditional data sources are deemed no longer reliable for our usual questions of age and transport.

Recent Research about the Chiapanec and the Central Depression of Chiapas, Mexico, during the Postclassic Period
Five years of survey and excavations are providing data regarding Postclassic and contact period Central Chiapas, allowing new proposals regarding the functioning of the Chiapanec polity. This study presents an analysis of the distribution of the population near ancient Chiapan, the capital of the Chiapanec polity at the time of the arrival of the Spaniards. To do this, we use a landscape perspective, which allows us to broadly compare the changes in the valleys of Terán, Suchiapa, and Tuxtla, the Copoya mesa, and the banks of the Grijalva river between the Postclassic period (AD 900–1524) and the present time. The identification of 50 archaeological sites belonging to four different classes suggests that the population was distributed according to the economic and political needs of the Postclassic period when the Chiapanec polity controlled a vast territory of the Central Depression. Surface and excavation materials also provide new perspectives regarding commerce and politics.

Resultados preliminares del Proyecto Arqueológico Entre Bajos: Ichkabal y su entorno

El Proyecto arqueológico Entre bajos: Ichkabal y su entorno ha realizado intervenciones arquitectónicas en siete estructuras del Grupo Principal y excavaciones extensivas en la Plaza Poniente. En el entorno se verificó la imagen lidar en campo. Ichkabal se encuentra en el sur de Quintana Roo, México, a 11 km al oriente de Dzibanché. Destaca la Plaza Principal de más de tres hectáreas, delimitada al oriente por dos complejos triádicos de 43 y 32 m de alto (Estructuras 4 y 5), al norte por dos templos y al norponiente por el basamento de un complejo tipo acrópolis encarado hacia sur (Estructura 1), al surponiente por el basamento de una plataforma alargada con cinco templos orientados hacia el poniente (Estructura 2). La última estructura forma un agrupamiento tipo E con la Estructura 3, ubicada en la Plaza Poniente. Una aguada cuadrada cierra la Plaza Principal al sur. Los resultados de las excavaciones sugieren que las estructuras fueron afectadas por actividades postocupacionales. La verificación terrestre indica que varios templos que se encuentran alrededor del Grupo Principal fueron situados en la traza urbano con una declinación cercana a los 12 grados respecto al norte verdadero. El entorno contempla calzadas, aguadas y campos levantados.

Coast and Lowlands: Zooarchaeology of La Esmeralda Shell Midden (Uruguayan Atlantic Coast, Late Holocene)
La Esmeralda is a set of three *Donax hanleyanus* shell midden (3000–1000 BP) in which they were capture, processing, and consumption of coastal vertebrates (pinnipeds, fish, and birds) and terrestrial (field deer, mulita, and *Rhea* egg) in an exploitation scheme that includes the coast and the continental lowlands. The use of the *Donax hanleyanus* bank is simultaneous with the hunting of field deer and mulita and the collection of *Rhea* eggs from the grasslands of Laguna Negra. Potrerillo site (3200–2400 BP), located (4 km) on a hill surrounded by floodplains is composed by two earth mounds. The archaeological record of the site shows the exploitation of the surrounding environment (cervids and rodents) but also of the Atlantic coast (sea lion and lithic raw materials). Both settlements show the use of the ecotonal zone that forms the Atlantic coast and the coastal lagoons, may be as part of a coastal-inland mobility circuit. The relations between the coastal and continental occupations have been the subject of discussion for more than 20 years. The discussion should focus on the relative weight of coastal vs. continental resources.

Analyses of Pastes and Polychromy of Chupícuaro Pottery: A Diachronic Comparison Using a Noninvasive Approach
Pottery is one of the hallmarks of the societies that emerged in the present-day Acámbaro Valley known as the Chupícuaro culture (ca. 600–100 BC). The aesthetic features of Chupícuaro ceramics range from complex forms of monochrome ware to polychrome varieties based on three main colors: red, black, and beige. This work examines the pottery and color technology of a broad collection of Chupícuaro vessels. The goal of the research has been to identify the raw materials used to manufacture the coloring materials as well as the pottery clays to address the technological characteristics of the vessels from the early and late periods. For this purpose, a noninvasive analysis protocol has been developed that includes a wide range of analytical techniques such as false color infrared imaging (FCIR), optical microscopy (MO), fiber optic reflectance spectroscopy (FORS), X-ray fluorescence (XRF), and infrared spectroscopy (FTIR). This approach has been applied to a collection of objects from the National Museum of Anthropology of Mexico and the

archaeological excavations of the CHUPICERAM project. The results show differences in the composition of beige colors and black colors. An evaluation of the paste composition is also presented and discussed.

Bridging Borders: Exploring Heritage Management Models in Mexico and the USA through a Conversation with Terry Majewski

In 2014, I had the honor of interviewing Terry Majewski, one of the most influential women in the CRM industry. The insightful dialogue was facilitated through meticulously crafted questions curated by female students participating in my BA course on Heritage Business and Marketing. This conversation delved into her transformative journey as a student who did fieldwork at the Olmec site of Chalcatzingo in Morelos, Mexico. This paper, summarizing the dialogue, introduces a compelling juxtaposition of viewpoints concerning the challenges and possibilities within heritage preservation in Mexico and the United States. A prevailing theme that emerges through the conversation is the necessity of stripping heritage preservation of political implications and advocating for a model that places the public at its core. The conversation traversed into her personal journey, introducing her stature as a woman, mother, scholar, and practitioner. This trajectory is characterized by her willingness to embrace challenges head-on and her unyielding desire to learn something new every day. Terry's journey serves as a beacon to the future female professional, as the conversation highlights the qualities and skills vital for success within archaeology.

Unearthing Earthen Architecture: A Geoarchaeological and Environmental Perspective

This presentation combines the findings of two distinct studies focusing on earthen building materials in different border regions, shedding light on the evolution of earthen architectural practices. The first study delves into the geoarchaeological analysis of earthen materials and environmental records from the site of Artashat in Armenia. This research seeks to uncover the dynamics of continuity and change in earthen architectural practices from the Urartian to the classical period in the Caucasus region. The second case study focuses on the geoarchaeological examination of public earthen structures found at two Levantine sites: Ashdod-Yam, linked to the Philistine Iron-Age Pentapolis in Israel, and Palaepaphos (Old Paphos), an ancient Iron Age city-state in Cyprus characterized by intricate multi-period earthen constructions. This contribution discusses the results of

SEM-EDS, FT-IR, XRF, LOI, and micromorphological analysis performed on both case studies and the inference we can make on human-environment interactions in the *longue durée*, the concept of craft specialization in architecture and the identification of communities of practice through the geoarchaeological record.

The Ecology and Physical Properties of Gathered Plants in Cordage and Textiles in Prehistoric Scotland

Within the last 30 years of ancient textile and cordage research, new and revisited archaeological evidence and ethnographic studies have shown that prehistoric people in Europe were using a wider range of plant species to produce cordage, netting, mats, and textiles than previously thought. This presentation will take a look at some of the preliminary data gathered on the use of gathered sedges, mosses, and riparian tree species as identified in Scottish non-woven textiles and cordage case studies. It will discuss the method of microscopic analysis and physical testing undertaken with comparative modern botanical samples that will be used to evaluate the inherent physical properties of flora present in prehistoric Scotland cordage and textiles. It is hoped that through delving deeper into the physical properties and ecological research of gathered materials, the relationship between these plants, their environmental context, their use as materials, and the people who worked with them will become clearer. Thus, broadening our understanding of what is and can be a textile or cordage plant in the prehistoric context.

The Ballgame and Sociopolitical Organization in the Eastern Lower Papaloapan Basin

Although ballgame paraphernalia and figurines depicting ballgame players have been reported from Tres Zapotes and other nearby sites since the 1930s, the identification of ballcourts in the Eastern Lower Papaloapan Basin (ELPB) has been elusive. At Tres Zapotes, the areas between mounds and in the hollows between parallel ridges of the Ranchito group and Lower Terrace could have served as ballcourts. However, no formal ballcourts had been reported in the region. Over the last decade, a large-scale regional survey, aided by Lidar mapping, of the area extending from south of Tres Zapotes to the Late Formative Center of El Mesón has changed this picture. While it is not clear if ballcourts were ever present at Tres Zapotes, a number of ballcourts were indicated by the lidar in Standard Plan architectural complexes that emerged in the region during the Protoclassic and Early Classic periods. Here, we examine the distribution of these complexes across the ELPB, the variation in their form and layout, and make some observations on the roles that these courts, and the ballgame itself, may have played in the sociopolitical dynamics of the Early Classic period in the ELPB.

Formative Period Mesoamerican Cities and Low Density Urbanism

Mesoamerica is one of only a handful of places in the ancient world where first-generation cities developed independently, and the lowland Maya cities of the Classic period are frequently cited as prime examples of low-density urbanism. Scholars now recognize that the Mesoamerican urban tradition began well before the Classic period, however, although its scale and extent are still underappreciated. We consider large, low occupation density settlements in Formative period Mesoamerica and their place in Mesoamerica's urban

tradition. Archaeological investigation of these early settlements has revealed the diverse mechanisms utilized by various communities to forge an identity, develop strategies of political integration and centralization, while also participating in broad and robust networks of economic and intellectual exchange. Rather than focus on definitional issues, or whether these settlements qualify as “urban” or “cities”, we explore the nature of these settlements and the trajectory of urbanization in the Formative period. Regardless of what qualifiers are attached to the term ‘urban’, our case studies illustrate how theories of urbanism and urbanization can be brought to bear in analyzing problems of aggregation, settlement growth, and trajectories of social change.

Changing Taste: An Investigation into the Importance of New York Coastal Marine Shells to Albany Foodways during the Nineteenth Century

An examination of the relationships between food and identity is explored among middle-class African Americans in Albany, New York through four periods (early to middle nineteenth century, middle nineteenth century, late nineteenth century, and late nineteenth to early twentieth century). This research synthesizes zooarchaeological data collected from the Stephen and Harriet Myers Residence and historical accounts to understand the foodways of Albany urban residents. This study seeks to consider marine shell use in Albany in a broader interpretive context, drawing parallels between consumer and trade patterns in Albany during the nineteenth century to those of other urban and rural historical communities in the region. The work presented here contributes to a deeper understanding of foodways in the mid-nineteenth century as well as situates the Myers family foodway, that of middle-class African Americans, into the larger context of middle-class consumer patterns.

Discoveries from the Fort St. Joseph Bead Collection (Past and Present)

As small as they are, beads can create a window into past cultures. Their many uses demonstrate the intricacies of people’s personal preferences, socioeconomic status, religious practices, and much more. There has been no shortage of beads found at Fort St. Joseph, an eighteenth-century mission, garrison, and trading post. Made of glass, ceramic, or bone, hundreds of necklace, rosary, and bracelet beads have been recovered through archaeological excavations at the fort, demonstrating their importance. Our analysis expands on previous research on beads identified at the site with three intentions: to identify newly recovered bead types; investigate their cultural significance; and compare the findings from the previous research with our own newly discovered conclusions.

An Appraisal of the Middle Preclassic Pyrite Mirrors from Tomb 1 of Chiapa de Corzo

Smith and Kidder were among the first to highlight pyrite prehispanic mirrors as “marvels of painstaking craftsmanship” (1951: 44). These mirrors presented a reflective surface consisting of 20–50 pyrite tesserae with beveled edges, perfectly cut, and average 2 mm in thickness. The first known examples of Mesoamerican

mirrors were the “Olmec” type, a concave mirror created from a single hematite piece, developed during the Middle Preclassic period; later, in the Classic period, pyrite mosaic mirrors replaced them. But, to date, we do not understand the changes from one type to the other. In this work, we present the description of two pyrite mirrors found as part of a funerary offering at the site of Chiapa de Corzo, Chiapas, Mexico, dated around 700–500 BC, as possible forerunners of Classic mirrors. Also, we will present traceological analysis of their manufacturing process using experimental archaeology and scanning electron microscopy. Based on these examinations, we identify likely materials and techniques employed in crafting them. We posit that production of these mirrors could have been the result of the development of specialized artisans at distinct workshops, increasing the complexity and labor investment in the lapidary objects as prestige goods.

Using Geophysics for Cemetery Delineation on DOD Installations: Practical Advice, Pitfalls, and Project Examples

Cemeteries and burial grounds are a common feature of the historic landscape, and mapping cemeteries is a consistent and pressing land management need for DOD cultural resource managers. When a cemetery is involved, stakeholders may be diverse and the results can be emotionally charged. Land managers and the public may consider geophysical methods as a straightforward method to identify unmarked graves because they seem to present a simple and noninvasive way to find answers. Geophysical survey results, however, are rarely clear-cut, and they require custom approaches, experienced practitioners, and intensive data processing. New South Associate’s geophysical archaeologists have surveyed over a hundred formal and informal cemeteries both on and off DOD installations. This paper outlines survey strategies for different cemeteries and discusses the evaluation of geophysical survey results. It highlights practical examples of large and small area surveys using multiple instruments including single channel GPR and multichannel GPR in a towed array.

Maya Pilgrimage to Interactive Places: Human Bones in Caves at Mensabak, Chiapas

This presentation focuses on the anthropology of pilgrimage as a journey to places outside of everyday realms. For Maya societies, pilgrimages are important for maintaining the relationships between people and nonhuman persons linked to the ritual landscape. In this context, the presence of human bones in caves around the lakes at Mensabak, Chiapas, Mexico, is related to perceptions of personhood and the dividual in ancient, historic, and contemporary Maya societies. We present research on rituals with human bone and artifacts in burial caves near water and rock art, which are shrines associated with various types of persons. We incorporate ethnographic insights from Lacandon Maya regarding the cave shrines, human burials, and nonhuman persons to shed light on these important otherworldly sites.

Chemical and Mineralogical Characterization of Ceramic Traditions on the Precolonial Colombian Middle Orinoco Archaeological Sites

The “Cotúa Reflexive Archaeology Project” (2015–2018) directed by José R. Oliver (UCL, UK) included a ceramic research analysis in the Venezuelan Middle Orinoco area, specifically in three archaeological sites of the Átures Rapids region, to identify trading and interaction process in precolonial ceramic materials. As a result of this study, a chronological occupation model was proposed, based on new radiocarbon data and the definition of new ceramic complexes in the area (Lozada-Mendieta 2020). Between 2021 and 2023, new archaeological sites in the Middle Orinoco area have been found on the Colombian side bank as part of the “Ancient Potters of the Upper and Middle Orinoco Project” funded by Universidad de Los Andes (Colombia). This poster will present the result of the analysis on new ceramic materials from a systematic surface on open area sites and rockshelters associated with rock art and burials. A sample from 15 sites was analyzed using macro trace, petrography, and portable X-ray fluorescence spectroscopy. The results were compared with the ceramic complexes developed for the Venezuelan side, revealing common ceramic fabrics and new paste recipes and vessel forms, most likely related to newly identified funerary traditions and postcontact communities.

[205]

From Flowers to Sin: Exploration of Sexuality and Gender in Ancient Mesoamerica

In modernity, sexuality manifests in a dynamic spectrum of expressions which centers on individual sexual awareness, contesting antiquated sentiments of traditional sexual hegemony. In this presentation, we will journey into ancient Mesoamerica in the attempt to conceptualize Maya and Aztec notions of sex and gender by examining various lines of information: archaeological, epigraphical, lexical, and historical sources to isolate and identify representations of sexuality. In addition to the recognition of practices and identity, we will locate, identify, and acknowledge Spanish colonial interpretations of Mesoamerican sexuality in the attempt to understand and counter its influence. In addition, I question modern western theories of sexuality and their ability to truly describe Mesoamerican ideologies of sexual identity.

[273]

The Presence of Maya Aquatic Imagery at Teotihuacan

Previous studies have illustrated the continuing relationship between the Maya area and the Basin of Mexico, especially with the presence of Maya iconography at the site of Teotihuacan. Maya imagery can be seen in diverse cultural materials such as ceramics and stucco-painted murals. For example, researchers have argued that the stucco-painted murals at the Atetelco apartment compound at Teotihuacan have strong connections to the Maya sites of Tikal and Copan. However, previous studies have not focused on the presence of Maya aquatic iconography found within Atetelco’s murals. Therefore, my study analyses the iconography in Atetelco’s stucco murals and suggests that Maya water bands appear but in Teotihuacan style. Maya water bands are seen combined and intertwined with Teotihuacan imagery that is strongly associated with water, such as the reticulated jaguar as well as with the Teotihuacan Tlaloc. In addition, I will highlight other Maya aquatic iconography, such as the Maya water serpent and the Maya water lily both presented in a Teotihuacan style. This new style of Maya aquatic iconography blended in a Teotihuacan style at the great metropolis could reflect the political atmosphere in the apartment compounds during the Early Classic period.

Lucas, Virginia (University of Nevada, Las Vegas; Lost City Museum)**[103]***Precontact Domestic Dogs in the Moapa Valley*

Since the domestication of the dog (*Canis familiaris*), they have been granted various roles within human society. Because of the often close relationship with people, domestic dogs were often given similar burial customs as people. Precontact dog burials have been recovered throughout many regions in North America. Although some of these were incidental burials, others were deliberately buried. While many of the known examples of dog burials in the American Southwest have been studied, to date, the dog burials of the Moapa Valley in Southern Nevada are largely unknown to the archaeological community. Dogs likely served as hunting companions as well as guardians of crops, and in several instances in the Moapa Valley, at least one dog was buried with a person. This poster explores the archaeological context and ethnographic studies in order to examine the relationship between the Lowland Virgin Puebloan peoples and the domestic dog.

Lucero, Lisa (University of Illinois, Urbana-Champaign) and Adrian Chase (University of Chicago)**[251]***House and City: Ancient Maya Water Management in Belize*

The rainfall-dependency of the ancestral Maya shaped their daily and seasonal existence in homes, communities, and cities. They adapted quite well to the annual wet and dry seasonal cycles—as well as extreme weather events like hurricanes, tropical storms and severe droughts, resulting in an enduring history in the tropical jungles of Belize. From farmer to royals, integral to their survival were diverse scales of water features to capture, store, move and drain water—especially for agriculture and a consistent supply of drinking water, as well as for construction (e.g., plaster production), manufacturing (e.g., ceramics), bathing, cooking, and so on. The Maya also treated water with the respect it was due resulting in sacred watery landscapes in addition to those shaped by subsistence water systems creating a complex relationship with water. Maintaining water features required long-term, sustainable management and skill that provided the means to withstand the elements for millennia and provide lessons for present and future water management.

Lucet, Genevieve (IIE-UNAM)**[214]***Epiclassic Palaces: Exploring Social Behavior from Spatial Design*

The built environment expresses the social values applied during architectural design, although these criteria are not always used consciously. Thus, the buildings constructed for the elite of a community show how this group conceives its relationship with the environment and with the other inhabitants, that is, its social behavior. I will compare the residential structures of Cacaxtla, Xochicalco and Teotenango (AD 650–1100). These elite living spaces were used for private, ritual, and governmental activities. The variations in shape, size, quantity, density, boundaries, visuality, and accessibility of the buildings, interior spaces, patios, and plazas testify to a subtle use of architectural language and the search for solutions to different spatial needs. Here, the characteristics of spatial language serve as a basis for the study of relationships between elites and other groups in the community. These, in turn, can also be extrapolated to present hypotheses about political organization of societies.

Luchsinger, Heidi (ERM), Juan Belardi (ICASUR, UNPA-UARG-CONICET), Luis Alberto Borrero (UBA-CONICET) and Flavia Carballo Marina (ICASUR, UNPA-UARG)**[281]***Geoarchaeology of the Southern American Frontier: The Late Quaternary Archaeological Landscapes of the Mack Aike Canyon, Santa Cruz, Patagonia, Argentina*

Geoarchaeological investigations in the Mack Aike Canyon were conducted in March 2023. Located in southernmost Patagonia, Mack Aike is ca. 13 miles (21 km) long and was repeatedly occupied by hunter-gatherer populations for at least 3300 years BP. Alluvial deposits and complex sequences of wetland and eolian deposits within the canyon boundaries were recorded. Three buried paleosols were identified as

marker horizons throughout the canyon. A buried peat deposit at 143 cmbs was also identified through augering and radiocarbon dated to the Middle Holocene. Distribution of the archaeological record throughout the canyon is fairly continuous although density varies likely due to behavioral and postdepositional formation processes. Mack Aike provides protection from a harsh climate and offers abundant resources from an extensive network of wetlands and channels, surrounded by a complex volcanic and glacial landscape. A combination of environmental and archaeological characteristics of Mack Aike facilitated its persistent use and its role in regional mobility until the contact period. In 2024, additional fieldwork and radiocarbon dating will be conducted to test subsurface locations for buried archaeological materials to continue building the chronology of the landscape history and archaeological record of Mack Aike during the Late Quaternary.

Reimagining the Castleton Medical College through 3D Imaging and Visualization

The Castleton campus of the new Vermont State University is one of the oldest institutions of higher education in the country, first opening its doors to students in 1787 and serving as one of New England's leading medical colleges from 1818 to 1867. Today, the few reminders of this early era in Castleton history are the former Castleton Medical College building, known locally as the "Old Chapel," and a poorly maintained collection of medicines and medical instruments in its entryway. The limited visibility of this collection and the building that houses it obscures the complex history of the medical college's relationship with the town and broader society, including both local graverobbing for medical dissections and participation in the Indian Boarding School movement. This poster imagines a more comprehensive and inclusive exhibit for the Castleton Medical College through 3D imaging of associated artifacts and a digital reconstruction of the medical college building.

Un taller de Spondylus dentro de un edificio ritual en Pachacamac, Costa Central del Perú (ca. 1470-1533 dC)

En la Costa Central del Perú, las investigaciones llevadas en el Edificio B15 de Pachacamac recuperaron materiales malacológicos que nos acercan a conocer las diferentes actividades realizadas tanto dentro de este edificio como de este prestigioso sitio durante los períodos tardíos. Los objetivos del análisis fueron identificar los especímenes malacológicos y recuperar la mayor información de fabricación de conchas a partir del análisis de la muestra. Los resultados aportan mucha información sobre el uso de los recursos marinos, con ello se puede conocer los recursos utilizados para la alimentación y aquellos utilizados para la fabricación de adornos, ofrendas y otros artefactos de probable uso ritual. Los recursos fabricados fueron la muestra más importante en el análisis, destacando el *Spondylus*. Se han identificado todos los pasos de elaboración de los artefactos, desde la acumulación de la materia prima y pasando por las diferentes etapas de fabricación hasta la obtención del objeto final. Las evidencias sugieren que este taller probablemente refleja la presencia de artesanos Chimú desplazados desde la Costa Norte en el marco de la política imperial inca.

A Queer Afterlife: Re-excavating the Halcyon House Collection

A rumored tie to LGBTQ history has drawn people to the Halcyon House archaeological collection across several decades. In this talk, I draw on Sara Ahmed's concept of queer phenomenology that conceptualizes queerness as an "orientation" toward certain objects and bodies. What does it mean to seek resonance in the past through queer ancestry? How does the tangibility of material culture prompt a queerly tactile relationship to the past? Located in the Georgetown neighborhood of Washington, DC, the Halcyon House mansion's grounds were excavated in 1985 but the project became embroiled in funding disputes and was never completed. Archaeologists had found many more artifacts than initially expected, many dating from the early twentieth century when the property was owned by Albert Adsit Clemons who was rumored to have lived with a male carpenter. The artifacts include makeup remains, alcohol bottles, and lingerie items marketed to women at the time. In 2018, after learning about the collection, I was drawn to study it through my own queer identity in relation to queer pasts. Drawing on engagement with LGBTQ-identified community members, I think through the meaning of "queer heritage" to frame the collection's connection to various actors throughout its tumultuous existence.

Persistence in Pastoralist Practices during the Uruk Period at Tepe Farukhabad

The Uruk period (4100–3100 BCE) was a transformative time in Southwest Asia, marked by the precursors of writing, the rise of urbanization, and an intensification in cross-cultural interactions. Subsistence strategies were shifting as well, as hunting declined relative to herding and animals such as sheep and goats became favored for both their primary and secondary products. Tepe Farukhabad, located on the Deh Luran plain on the fringes of Mesopotamia, offers an opportunity to study how these developments manifested in changes in herd management strategies. In this paper, stable isotope analysis is used to investigate the herding strategies utilized in the Middle and Late Uruk through the reconstruction of the diet and landscape use of herded ruminants from Tepe Farukhabad. Sequential sampling of sheep and goat teeth produced carbon and oxygen isotope values ($\delta^{13}\text{C}$ and $\delta^{18}\text{O}$), which showed a variety of herding strategies were implemented in both the Middle and Late Uruk. Some animals were foddered or herded seasonally to higher elevations in order to access better grazing pastures, while others were herded near

the site. The variety of strategies used at Tepe Farukhabad reflects resilience among pastoralists in the midst of the many changes of the Uruk period.

Soils, Water, and Agriculture in the Maya Lowlands: Lidar and Paleoproxies Reveal New Perspectives on Complexity and Resilience

Questions of human subsistence, impacts, and response to environmental change have driven decades of research on ancient life in the Maya Lowlands. While traditional geoarchaeology and paleoecology methods have already documented a rich variety of agricultural and subsistence options in the Maya Lowlands, the lidar mapping revolution of the last decade has deepened these questions and their answers in extent, scope, magnitude, and meaning. In this paper, we synthesize the results of our three-plus decades of research on Ancient Maya agriculture and resource use in Belize, Mexico, and Guatemala, including soil and water resources, and present the results of our latest lidar, field validation, and laboratory campaigns in the Maya Lowlands. Our first lidar collection was in 2016; our coalition group of several archaeological project partners in Northwestern Belize collected another set of lidar data in 2022, extending our 2016 aerial coverage. Meanwhile our teams conducted field seasons in Guatemala in 2022 and in Belize in 2023 to follow up on features identified in lidar for these respective regions through field survey and excavation. We present our recent field and lab validation results from Northwestern Belize in the context of our other studies across the region.

Undiscovered Country: The Ground Stone Tools Assemblage from Hell Gap National Historical Landmark

One of the most complete records of human activity on the North American Plains, between 13,000 and 8,500 years ago, is found at the Hell Gap National Historic Landmark in Wyoming. The area was inhabited continuously during this period as evidenced by the five main site localities. While we know a good deal about the activities on site from chipped stone tools and fauna, the ground stone has yet to be integrated into site interpretations. Our general assumptions about cultural practices during this time presume the exclusive use of ground stone as a means to create other types of tools, for instance, shaft abraders or for processing ochre. At Hell Gap there are more than 30 ground stone artifacts ranging from abraders and hammerstones, to palettes. They are found throughout the site's localities. The artifacts are associated with the Folsom, Hell Gap, Eden-Scottsbluff, and Agate Basin cultural components. In this presentation, we describe the materials found in close proximity to these ground stone tools to put the implements in context and build a picture of how they fit within our current knowledge of Hell Gap and Paleoindian material culture and to test our current assumptions about their function.

Investigating Beringian Hunting Toolkits from Experiential Perspectives

Experimental archaeology is an underutilized methodology for investigating variability in projectile point

technologies of Upper Paleolithic Siberia and Late Pleistocene/early Holocene eastern Beringia. This paper presents the results of a multifaceted experimental research project combining 1) actualistic testing of three Paleo-arctic projectile point styles and 2) use-wear analysis of a large sample of osseous and lithic tools from 11 eastern and western Beringian archaeological sites to test established hypotheses of projectile point variability in the north. A major component of this project was the 3) development of scaffolded and scalable student-centered learning activities tailored to engaging the general public, stakeholders, and Indigenous communities through hands-on experimental archaeology and object-based teaching. Understanding the functions of these important artifacts can inform on the significance of inter- and intrasite assemblage variability in Beringia and adaptive responses to shifting resources during the Pleistocene/Holocene transition across Beringia. Here we present developing behavioral models to explain the variable projectile technologies, including seasonality, site-specific or prey-specific activities, raw-material conservation, and ballistic performance of weapon systems as contributing variables.

[80]

Sociopolitical and Environmental Change and its Effect on the Biology of a Medieval Polish Population through Isotopic Analysis

The Late Medieval to Early Modern periods in Poland underwent a shift toward a feudal sociopolitical structure and experienced environmental changes leading to an increase in social stratification and an unequal distribution of power, opportunity, and resources (e.g., food). This project examines how a non-elite Polish population biologically responded during periods of significant sociopolitical change using molecular and skeletal analysis of human skeletal remains, correlated with historical documentation. Cemeteries from the Late Medieval village of Gać (fourteenth–sixteenth centuries) and Early Modern village of Pień (seventeenth–eighteenth centuries) comprise non-elite individuals. The proximity of these villages to nearby centers and the potential for involvement in complex economic exchange networks make the sites ideal to examine the complex interplay between biology and culture. Preliminary data investigates how serfdom and global cooling impacted dietary access to traditional food sources, including terrestrial/marine protein and C₃-based crops (e.g., wheat, barley). This study presents analyses of strontium and oxygen isotopes to distinguish between “migrants” and “residents” and carbon and nitrogen stable isotopes to assess diet. It is hypothesized that diet will differ between migrants and residents and there will be less access to traditional protein sources and an increase in C₄ (millet) consumption for residents.

Analyzing Highland and Coastal Ceramic Techniques of Production in the Middle Horizon Period

The relationship between coastal and highland cultural groups during the Middle Horizon remains widely debated and still not fully understood. Scholars have argued that “Coastal Cajamarca” plates found in Moche sites on the coast are local imitations of high-quality kaolin plates from the Cajamarca polity in the Highlands. My research examines the production techniques employed in the creation of “Coastal Cajamarca” plates with other Moche and Cajamarca ceramic styles retrieved from the Late Moche (AD 500–800) archaeological site, Huaca Colorada, in the Jequetepeque Valley along the North Coast of Peru. By comparing techniques of production, my investigation challenges the prevailing notion that “Coastal Cajamarca” vessels were imitations of foreign elite wares. Rather, they were not local creations but were introduced to the site alongside other highland Cajamarca ceramics, including the distinctive “Kaolin Plates” and utilitarian “Cajamarca Coarse Red” ceramics. Employing technological analysis, I illustrate the shared production techniques between “Coastal Cajamarca” ceramics and highland vessels, distinct from the methods used in crafting local Moche ceramics. This finding underscores that these ceramics signify more than the movement of elite goods or the copying of foreign elite styles by local Moche artisans.

Lyons, Scott**[186]***Burning Questions: The Ogata Archaeological Site and Kofun Period Ironworking*

The Ogata archaeological site in modern Osaka Prefecture, Japan, has come to be seen as representative of large-scale blacksmithing sites and technology of the Middle and Late Kofun period, and many artifacts related to ironworking have been unearthed from hearth features there. Accordingly, many of these hearth features are typically interpreted as remains of ironworking hearths. However, other pyrotechnologies were also practiced at and near Ogata, and so the tendency to view all pyrotechnological features as relating to ironworking has the potential to distort our understanding of Middle and Late Kofun period ironworking technologies. This presentation will reexamine the blacksmithing remains unearthed at Ogata, paying close attention to the variety of production activities conducted there, as well as its long-term trajectory as a place of technological and economic exchange in close proximity to the political center of the Japanese archipelago. This revised interpretation of the site clarifies not only the changes in ironworking technology seen at Ogata and in the Middle and Late Kofun period more broadly but also the ways in which “specialist” workshop sites in this period are integrated in exchange networks of varying sizes through both their specialist and peripheral production activities.

[70]*A Novel Application of $\delta^{15}\text{N}$ Values to Segregate Human and Nonhuman Remains*

Archaeologists are routinely tasked with sorting and identifying osseous remains in complex assemblages. When dealing with non-diagnostic fragments or significant taphonomic alterations, a straightforward determination of human or nonhuman based on osteological analysis is not always feasible. This study tests the use of nitrogen isotope delta values ($\delta^{15}\text{N}$) of bone collagen for determining if osseous remains are human or not. Previous research, using a large dataset of modern casework samples from the Defense POW/MIA Accounting Agency Laboratory, calculated lower limits for human bone collagen $\delta^{15}\text{N}$ values that can be used to assess whether osseous remains “are probably” nonhuman (7.50‰) or “are” nonhuman (6.35‰). This study builds on that previous work by testing the applicability of the limits in broader archaeological contexts. We applied them to bone collagen data for humans and nonhumans found in the published archaeological literature (>30 studies, sample size ~1,500). Our findings support the conclusion that $\delta^{15}\text{N}$ values can be useful for differentiating human and nonhuman osseous remains and have applications globally within archaeological contexts.

Mabry, Jonathan (Desert Laboratory, University of Arizona)**[75]***La Playa and the San Pedro Phase in the Sonoran Desert*

The origins of village lifeways foundational to more complex precontact societies in northwestern Mexico and the southwestern United States can be traced back to the independent development of irrigation and associated social changes in early irrigation communities at La Playa and sites in the Sonoran Desert during the San Pedro Phase between 1200 BC and AD 50. This presentation describes the regional and cultural contexts of agricultural intensification, changes in material culture, and inferred new social institutions at La Playa during the San Pedro Phase.

From Triangles to Rectangles: Exploring Change Over Time at the Epipaleolithic Site of Kharaneh IV, Jordan

The multicomponent Epipaleolithic site of Kharaneh IV, located in the Azraq Basin of eastern Jordan, documents ~1,000 years of occupation by hunter-gatherer groups late in the Last Glacial Maximum. Multiple lines of geomorphological, faunal, and archaeobotanical evidence indicate that the environs around the site were well-watered, lushly vegetated, and rich in a wide variety of animal species, clearly drawing human populations to the area. Early and Middle Epipaleolithic groups congregated repeatedly and for prolonged periods in this verdant landscape, perhaps even coming from the Mediterranean and Red Sea areas. This poster discusses changes in lithic technology at the site from the Early to the Middle Epipaleolithic. These changes will be examined through the conceptual framework of the *chaîne opératoire*; where the entire production, use, and discard sequence is considered integral to understanding how stone tools were developed and maintained at such an aggregation site. Changes in the *chaîne opératoire* from the Early to the Middle Epipaleolithic illuminate the different strategies employed by the inhabitants of Kharaneh IV, and when paired with other aspects of material culture, highlight changes in these communities over time and their adaptations to a dynamic landscape unlike that of today.

The Creation and Curation of Archaeological Data

The Arizona State Museum (ASM) Repository holds collections associated with thousands of archaeological excavations that span the advent of anthropologically oriented archaeology in the American Southwest. Encoded with these collections are various approaches to excavation and data management, which have dramatically changed over time. Repository personnel will standardize terminology as much as possible, for

internal institutional searchability purposes. The curation facility will also create metadata and add attribute information to the collections to meet their various legal and agency requirements, applying consistent data formatting and institutional ontologies to promote long-term usability of the collections. The idea is to ensure that the artifacts are findable for all stakeholders, including researchers interested in revisiting collections for reanalysis, and integrating artifacts into big picture research questions, but this is challenging to accomplish. Excavated materials and associated data from the Grasshopper Field School (1964–1992) are an illustrative example of the inherent impediments to reconstructing and integrating excavation datasets for a single, long-term excavation for collections management needs, while also considering the challenges associated with comparing complex excavation datasets for big picture research questions. This paper focuses on archaeological data as an aspect of the “curation crisis” and explores options for finding common ground.

Transitions in Past and Present: The Introduction of Huaca Dos Cruces and Huaca Tronco Prieto

The transition into the Late Intermediate period (LIP) (~1000 CE) held many changes for residents of the Cañoncillo region, but as of yet it is unclear why the prominent sites of Huaca Colorada and Tecapa were abandoned in favor of nearby mounds and architectural complexes. These shifts may result from a combination of social and environmental pressures including the introduction of new cultures like the Chimú and Lambayeque to the region, shifts in ideology, as well as dune encroachment. LIP sites in the southern Jequetepeque Valley exhibit ceramic markers of both cultural traditions, some of which are certainly produced on-site. This paper introduces the sites of Huaca Dos Cruces and Huaca Tronco Prieto where the Cañoncillo team will begin excavations in 2024. Covering an area of 5 km², the sites are composed of three prominent mounds surrounded by agricultural fields and small domestic enclaves. Preliminary survey in 2023 established distinct use areas including workshops, cemeteries, and possible ceremonial spaces with formal architecture. With the diversity of activities already visible at the sites, as well as evidence of multiple cultures interacting with them, these sites have the exciting potential to demonstrate a wide-ranging view of LIP society in the region.

Mack, Jennifer (University of Mississippi Medical Center) [312]

Ever True to Thee: Archaeo- and Osteobiographies from Asylum Hill

Founded in 1855, the Mississippi State Lunatic Asylum saw 30,000 patients pass through its doors before the institution moved to a new facility in 1935. Vital expansion of the University of Mississippi Medical Center (UMMC), located on the former asylum property, prompted historical and archaeological investigations of the now-unmarked Asylum Hill Cemetery, which holds the graves of 4,000–7,000 individuals who died as patients. In accordance with the wishes of potential descendants, identification of the dead is a primary goal of the project. Poor bone preservation in many graves limits the data that can be used to build osteobiographies, but intensive artifact analysis provides complementary information for comparison with family oral histories and surviving patient records. Though no identifications have been made among the first 335 individuals exhumed, the narratives revealed by their skeletal remains and associated coffin hardware, clothing remnants, and personal items foster a deeper understanding of the institution and its patients, contradicting the popular perception of asylum residents as “locked up and forgotten.” ***This presentation includes visual representations of excavated human remains, but not photographic images.

Mackie, Madeline (Weber State University)**[219]***Chair***Mackie, Madeline (Weber State University), Todd Surovell (University of Wyoming), Spencer Pelton (Office of the Wyoming State Archaeologist), Robert Kelly (University of Wyoming) and Matthew O'Brien (California State University, Chico)****[219]***Clovis-Folsom Overlap at the La Prele Mammoth Site*

The nature of the transition from Clovis to Folsom complexes has long been an area of interest for Pleistocene archaeologists in the West. While it has been hypothesized that Folsom was an innovation started during the Clovis time period there have been few clear cases of temporal overlap. A recent find at the La Prele Mammoth site in Converse County, Wyoming offers new evidence relevant to this enduring problem. Dating to approximately 12,950 years ago, the La Prele Mammoth site contains the remains of a Columbian mammoth alongside activity areas associated with butchery. The densest of these areas, Block D, also returned a diagnostically Folsom fluted point along with mammoth ivory, bone needles, ochre, and butchered mammal remains. Using geoarchaeology and spatial analysis we discuss the relationship between the Clovis and Folsom diagnostics at the site to better understand the relationship between these two complexes.

MacLellan, Jessica (Wake Forest University) and Daniela Triadan (University of Arizona)**[285]***Toying with Classic Maya Society: Ceramic Figurine Whistles and Children's Socialization at Ceibal, Guatemala*

We analyze 253 Late and Terminal Classic (ca. AD 600–950) Maya ceramic figurine whistles (*ocarinas*) and fragments excavated at Ceibal, Guatemala, as materials of socialization. The figurines are mold-made and represent repeating characters. Based on mortuary contexts and other evidence, we argue they were used in household performances and associated with women and children. Children could easily access and play with these everyday objects. As in the case of modern toys, like Barbie dolls, the cast of characters represented in the figurine whistles was determined by adults and tells us about dominant ideologies, including gender and beauty norms. For example, women were shown as active participants in both public and domestic life, while men were shown in public but not domestic roles. As agents of socialization, children could have reimagined or subverted narratives around these objects. However, the materiality of the figurines limited play and shaped social structures for centuries.

Macrae, Scott (University of Central Florida)**[289]***Chair***Macrae, Scott (University of Central Florida), Vo Thi Phuong Thuy (Vietnam Academy of Social Sciences), Ekaterina Menkina (University of Alabama) and Le Ngoc Han (Institute of Archaeology, Vietnam)****[289]***Searching for Settlement at the Dai Co Viet Capital of Hoa Lu, Vietnam*

Established in 968 CE the city of Hoa Lu was the first unified capital of the Dai Co Viet. This ancient capital is

found in the UNESCO World Heritage Site of the Trang An Scenic Landscape Complex, Vietnam. It was constructed of two enclosures bounded by a series of embankment walls adjoining steep cliff faces created by the karst mountains topography. While a clearly defined city, little archaeological research has identified the inhabitants and their subsequent settlement outside the royal echelon of the palace. In search of residential occupation outside the city embankment walls, within the sharply contrasting topography of soaring karst mountains and low-lying floodplains, the first systematic settlement survey was initiated by the IRAW@Hau Lu research project. This presentation will discuss the method employed, obstacles overcome, and ultimately results of the 2023 field season.

Agricultural Life and Socioeconomic Dependencies in the Western Andes of Southern Peru during the Second Half of the First Millennium BCE

The Formative Paracas archaeological culture has long been considered a coastal phenomenon in the southern Peruvian Andes. In this paper, we change this perspective and examine two Late Paracas and Initial Nasca (370 BCE–CE 90) highland settlements: Collanco (1,630 m asl) and Cutamalla (3,300 m asl) in the province of Lucanas, Ayacucho. Drawing on recent archaeological and geoscientific investigations—including large-scale excavations, archaeological and geomorphological surveys, photogrammetric documentation, soil testing, phytolith analysis, radiocarbon dating, and community-based research—we not only study these settlements in terms of their chronology, layout, and use but also pay special attention to their adjacent extensive agricultural terraces. We argue that such terrace-settlement systems must be understood as a single analytical unit in order to fully understand the organization, socioeconomic dependencies, and supraregional significance of these complexes. Collanco and Cutamalla formed part of a dense and continuous Paracas settlement pattern from the Pacific coast to the highland puna and were integrated into interregional exchange networks. Furthermore, our results reveal intensive and diverse agricultural strategies, complex dependencies both among people and on resources from multiple ecological zones, and changing climatic conditions that affected terrace cultivation, land use, and settlement on the western flank of the Andes.

Exploring Social and Economic Change at the Bronze Age–Iron Age Transition in Southern Britain: A Multi-isotope and Zooarchaeological Approach

The Late Bronze Age and Early Iron Age (ca. 800–400 BC) was a time of great transition in various parts of Europe, largely relating to climatic deterioration and the breakdown of networks surrounding the production and trade of Bronze. In southern Britain this saw the rise of a new site type, commonly termed a midden. These vast monumental mounds, some comprising millions of artifacts/ecofacts dominated by animal bone and ceramics, signal a societal refocus toward agricultural intensification and communal feasting on a grand scale. This suggests that feasts had a role in mediating new networks and husbandry regimes during this phase. This paper presents results from the FestNet project, which explores the scale and nature of the networks surrounding feasting events and new approaches to agricultural intensification at a time of climatic

deterioration. A program of strontium, oxygen, sulfur, carbon, and nitrogen isotope analysis on domestic animals from six sites demonstrates different catchments and variable husbandry regimes across both sites and species. Zooarchaeological research has enriched these interpretations, providing evidence for both extensive and specialized animal management strategies. These data provide new insights on the problematic issue of how the economy and patterns of connectivity changed during this transitional phase.

Artifacts of Motherhood: Revisiting the AUB Museum Collection

The AUB Museum collection of motherhood encompasses amulets, infant feeding bottles, and figurines. All these items are connected to the maternal body and specifically to motherhood. However, finding and identifying such artifacts is challenging as they might resemble ordinary objects: Infant feeding bottles could have been used as oil lamp fillers, droppers, or small pitchers. Additionally, figurines could have been used in rituals and as children's toys. As with most donated museum artifacts, we face several challenges related to their provenance and context (mortuary, domestic, etc.). This paper explores a collection of artifacts that could be identified as artifacts of motherhood and understand their function and use. Thus, this paper aims to widen our understanding of women and children's relationship with each other, health, and death.

The Mexica Tzompantli ("Skull Rack") as Life-Energy Battery Pack

The Mexica *tzompantli* ("skull rack") consisted of multiple, agricultural-style ordered rows of human skull-seeds. As such it constituted an enormous "battery pack," or milpa, that contained, stored, and radiated the life-energies and powers contained within the still animate skull-seeds placed on its rows. Its principal function was to actively rejuvenate, refortify, and renew Tenochtitlan, the Mexica lifeway, and the Mexica cosmos—not (as commonly averred) to intimidate functionaries visiting from other polities or intimidate the citizenry of Tenochtitlan, and not (as commonly averred) merely to symbolize or represent its fearsome power and efficiency at dispatching enemies.

Magoon, Dane (University of Leicester), Dale Hutchinson (University of North Carolina, Chapel Hill) and John Krigbaum (University of Florida)**[201]***From Maize Presence to Maize Incorporation: An Integrated Bioarchaeological Approach for Exploring Early Histories of Maize in the Eastern Woodlands*

Recent research has highlighted the difficulties with identifying the presence of early maize in the bioarchaeological and paleoethnobotanical records of the Eastern Woodlands. Simon et al. (2021) found that there is no hard evidence of Middle Woodland maize for the region, and the earliest verified maize is now synchronous with the chronological framework outlined by Larsen et al. (1991) based on dental caries data. This paper outlines an integrated exploratory approach using dental caries and carbonate-apatite carbon spacing ($\delta^{13}\text{Cca-co}$) data from archaeological bone for investigating early microhistories of maize, focused on the tidal fresh portion of the James River drainage in coastal Virginia.

Mahan, Samantha (Archaeometry Laboratory, University of Missouri Research Reactor Center), Alexandra Kuo (Archaeometry Laboratory, MURR), David Stalla (Electron Microscopy Core, University of Missouri), Gregor Bader (Senckenberg Center for Human Evolution and Palaeoenvironment) and Brandi MacDonald (Archaeometry Laboratory, MURR)**[42]***Microanalysis of Late Stone Age Rock Art Ochre Pigments in Eswatini*

Eswatini is home to several rock art sites of the Late Stone Age in Southern Africa. Ochres, iron-oxide rich pigments, are present in many of these sites but their compositions are yet unknown. Previous studies of ochres have shown the potential for the identification of trade, resource management, and other aspects of human behavior. The analysis of ochres in Eswatini rock art has implications for mineral selection in the Late Stone Age and could lead to future studies of ochre sourcing in Eswatini. Samples were taken from seven sites in northern (Sibebe, Nsangwini, Ntjoni, Mkhumbane, Nkamberi), southern (Nhlonhleni), and eastern (Muti Muti) Eswatini and were analyzed by SEM-EDS and Raman spectroscopy. The preliminary microanalysis is presented here and shows iron oxides, iron-rich clays, manganese oxides, and other mineral compounds.

Mahar, Ginessa (University of Florida) and Kenneth Sassaman (University of Florida)**[317]***Investigating the Sustainability of a Woodland Fish Trap on Florida's Northern Gulf Coast*

The increase in frequency and intensity of storm events in the twenty-first century has inspired communities worldwide to reconsider their investment and approach to coastal infrastructure. As often is the case, modern problems serve to inspire archaeological inquiry. In this paper we explore the advantages and drawbacks of permanent coastal infrastructure during a time of increased social complexity along the Florida Gulf Coast. Heightened gathering events tied to summer solstice ceremonialism required communities of the Woodland era to develop technologies to support seasonal increases in population. However, changes in sea level, storm events, and other environmental impacts may have affected the sustainability of such coastal infrastructure and potentially contributed to eventual site abandonment and a reconfiguration of social life. We bring together several lines of data in this paper to better understand the benefits and vulnerabilities that coastal fish traps would have provided these communities. Data presented are from Richard's Island Fish Trap, a shell-based construction situated to the immediate south of a Civic-Ceremonial Center known as Shell Mound (8LV42), and includes lidar, excavation, and coring, as well as comparative and experimental datasets.

Maher, Emma (Western Michigan University)**[284]***Revealing the Past through Ceramics*

Twenty-five years of excavation at Fort St. Joseph, an eighteenth-century mission, garrison, and trading post, have uncovered a large variety of artifacts, including hundreds of ceramic sherds. These ceramic pieces can

provide valuable information about individuals living at the post including their socioeconomic status and access to materials. Information about trade relations can also be revealed as ceramics were produced and shipped from Europe. This research will examine ceramic sherds recovered archaeologically from Fort St. Joseph in order to identify the types present at the site. Specifically, pieces of French faience will be analyzed in hopes of gaining insights on the varieties present and what they may indicate about the daily lives of those living on the edge of the French empire.

From Wetlands to Deserts: The Role of Water in the Prehistoric Occupation of Eastern Jordan

In the Azraq Basin of Jordan, dramatic landscape changes from wetlands to desert resulted in shifts in settlement and land use over time suggesting that, like today, water availability was crucial for past populations. Changing environmental conditions throughout the Pleistocene and Holocene had significant impacts on human population movements and land use. Recent work at the 20,000-year-old site of Kharaneh IV indicates settlement of this intensively used aggregation site around the end of the Last Glacial Maximum with abandonment by the start of a second drying period, Heinrich Stadial I. In contrast to narratives that associate aggregation and “settling in” during the Epipaleolithic with climatic amelioration, intensively occupied sites in eastern Jordan are also associated with shrinking wetlands. Drying at the onset of HI led the visitors and occupants of Kharaneh IV to reconsider their use of this location for large-scale settlement, and aggregation sites soon disappear entirely from the region—perhaps even the very practice of aggregation as a socioecological strategy. Epipaleolithic occupants of the Azraq Basin, and elsewhere, experienced similar situations to modern-day inhabitants of this region, where water is an increasingly dwindling and precious resource that continues to shape how people engage with the landscape.

“The Dead Do Not Leave”: LH Funerary Behaviors in Pueblo Viejo Pucara

Pueblo Viejo-Pucara, main settlement of mitmaqunas, Caringas de Huarochiri, is one of the emblematic cases of funerary behaviors involving the construction and use of open chambers. In most of the cases studied, the two-story structures of 1 m high each story, which fulfill the original function of storage rooms in each modular residential unit, are adapted for funerary purposes. The chambers of both floors are accessible through small square windows. The funerary structures directly adjoin the living spaces in use. The settlement, located on the hills of Manzano and Pucara, on the left bank of the Lurin River, was intensively excavated by the PUCP team between 1999 and 2012. The paper presents the results of the reconstruction of the funerary behaviors of burial, reburial, and complex taphonomic processes after burial.

Daily Life through Thousands of Artifacts: Revealing Patterns at French Fort St. Pierre (1719–1729) via Multivariate Statistics

As archaeologists revisit old collections, we strive to develop new, efficient ways to analyze complex datasets with thousands of artifacts. My own work attempts to do so through a reanalysis of the collection and architectural features of Fort St. Pierre (1719–1729). Almost wholly excavated in the 1970s, Fort St. Pierre, near present-day Vicksburg, Mississippi, was located between the Illinois Country and newly established New Orleans and Fort Rosalie in Natchez. The use of multivariate statistics updates Stanley South’s methods and allows for comparisons to contemporaneous French and Native settlements along the Mississippi River corridor. Statistical results combined with excavation and documentary evidence demonstrate the materiality of daily life as well as a looting event in the community’s final hours. Altogether this syncretic approach to the violent termination of the fort highlights early eighteenth-century French and Native sociopolitical struggles in the lower Mississippi River region.

WPA Murals as Historical Artifacts: What Is Archaeology’s Role in the Preservation, Protection, and Analysis of Early Twentieth-Century American Art?

When US President Franklin D. Roosevelt formed the Works Progress Administration (WPA) in 1935 as part of the New Deal, his goal of rescuing the United States from the Great Depression was predicated on

the creation of a flurry of new jobs that resulted in extensive public infrastructure as well as providing money for those skilled in the arts. One product of this investment was the production of thousands of artistic murals around the country. This paper argues that these WPA-era murals should be considered artifacts and studied within the discipline of archaeology and sub-discipline of historical archaeology. It questions why archaeology has not embraced WPA art as material culture worthy of study even though it falls within many established parameters of the field. Using examples of recently discovered and restored artwork at San Diego State University, we suggest that historical archaeologists are especially suited for complex issues of historic preservation and can be important interdisciplinary collaborators with art historians, museum curators, and others.

Why So Blue? The Great Island Tavern and Its Legacy

Archaeological collections and their perpetual care allow archaeologists an opportunity to right wrongs and revisit interpretations of site formation and identity. Looking at past methodologies through our twenty-first-century professional standards allows for a more objective review of both field and post-field practices. Over time, management decisions can have lasting effects on collections that archaeologists continue to spend time and money to unravel. We will present a case study of the Great Island Tavern collection from Cape Cod National Seashore that was excavated in 1969. The site lacks credible field documentation and an inherent bias led to a questionable interpretation of the site. The artifacts have suffered irreversible damage from ad hoc display techniques, experimental conservation, and manipulation of computer data. These well-intended attempts to rectify past mistakes further diluted the data that can prove the identity and function of this site. Both the initial field and legacy collection teams worked autonomously without any foresight for the long-term viability of this collection. The work that now remains can best be described as the archaeology of archaeology. The inherent bias assuming that “storage room” work and collection management are not actual archaeology hampers efforts to work toward higher standards.

Experimental Heat Treatment on Basalt Lithic Artifacts to Identify Wildfire Effects on Prehistoric Archaeological Sites

In recent years, the USDA Forest Service is increasing the pace and scale of fire and fuels management to mitigate the impacts of uncharacteristically severe wildfire. Due to the consequences of global climate change, wildfires are not going away. It is vital that we understand the effects that wildfires have on our cultural resources. Multiple studies have investigated the effects of fire on obsidian and chert artifacts; however, little research has been conducted on basalt lithic artifacts. In portions of the Plumas National Forest that were impacted by the catastrophic 2021 Dixie Fire, there are numerous of basalt lithic artifacts, but we cannot fully grasp the effect fire had on them due to the lack of research. For this study, we seek to enhance our understanding of fire effects on basalt artifacts by conducting a series of controlled heating experiments (temperature and dosage) to test the effects of heating on experimentally produced basalt flakes. From these results, we hope to set a baseline for fire effects on basalt artifact that can be applied to observations made in the field, as well as provide information to managers so they can better protect and manage cultural resources the event of a wildfire.

Building Island Futures with Heritage-Based Tools: Archival Records from Inishark and Inishbofin, Co. Galway, Ireland
Throughout the nineteenth and twentieth centuries under British rule, tax assessors, census takers, and Church personnel routinely recorded key aspects of the lives of Inishark and Inishbofin islanders. This research investigates house-by-house village histories through valuation records, historic maps, and baptism and wedding records. Using these documents, we seek to create village maps showing where families lived through time, and to share these findings with today's islanders. Our research uncovers many stories that are concealed in government archives. We seek to reunite these stories and records with the families whose descendants we work with today. In this ongoing process of reclaiming and mapping out local knowledge, we are working to establish a local archive of these records and our research results to be housed in the Inishbofin library. Ultimately, this research contributes toward islanders' efforts to connect with their pasts and build their futures.

Geoarchaeology and Paleoenvironmental Context of Magic Mountain (5JF223): A Stratified Site on the Front Range of the Southern Rocky Mountains, North-Central Colorado

The Magic Mountain site (5JF223) in Golden, Colorado, has long been recognized as one of the most important stratified archaeological sites on the Front Range of the Southern Rocky Mountains. Although Archaic artifacts have been recorded there, the site's richest and most extensive cultural deposits represent multiple Early Ceramic occupations dating to ca. 1800–800 cal BP. In this paper, the soil-stratigraphy of the site is described, and results of $\delta^{13}\text{C}$ analysis of soil organic matter (SOM) are used to infer bioclimatic change for the period of record. At 5JF223, a buried landscape marked by a prominent paleosol in alluvium occurs beneath nearly 2 m colluvium. Temporally undiagnostic artifacts occur on and within the paleosol. The paleosol was buried by colluvium soon after 9000 cal BP, and sedimentation ended soon after ca. 800 cal BP. The $\delta^{13}\text{C}$ record at 5JF223 indicates that C_4 grasses became an increasingly more significant component of the plant community from ca. 8900–6800 cal BP, suggesting that a warming trend (Altitheermal) occurred then, and peaked around 6800 cal BP. After 6800 cal BP, a mixed C_3/C_4 plant community was in place, though the amount of SOM contributed by C_3 plants increased during the Early Ceramic occupations.

Musket Ball Analysis at Fort St. Joseph

Firearms and ammunition were used by military officers, traders, European settlers, and Native Americans in hunting and warfare throughout New France. To better understand military forts, trading posts, and European

settlements, flintlock-related objects can be examined to determine the types of firearms being used at Fort St. Joseph, who was using them whether it was military personnel or civilians, and what country the firearms originated from. At the eighteenth-century site of Fort St. Joseph, an examination of flintlock components revealed the presence of more gun parts related to trade or civilian muskets than those of military weapons, confirming its important role as a trading post. However, several other components recovered from the site were badly rusted and unable to be assessed. To assist with this examination, an analysis of musket balls recovered from the site will be completed in hopes of determining the firearms used at the site and their country of origin. Through this research additional knowledge on the flintlocks available in the Great Lakes Region will be gained and can contribute to our understanding of military and trading operations in the area.

Colonial Archaeology and Deep Time Media: A Case Study from Hokkaido, Japan

As the study of past human activity through the analysis of artifactual data, archaeology involves the excavation of materials, digging deep into the earth to unveil pottery, house foundations, and animal remains. By excavating deep into the earth, the past time of human history is re-created, but only through the eyes of archaeologists and a public who concerns themselves with their work. Through the interpretation and display of archaeological artifacts and data, I argue that these artifacts constitute a form of deep time media, taken from the deep time of the earth and used for our own modern day purposes. By applying Krämer's (2015) media studies philosophy of messengers and traces to the archaeological record, I look at how archaeological materials are the result of traces being left behind that are then interpreted through the social and political context of the archaeologist, particularly within the context of the Indigenous Ainu of Hokkaido. This paper explores narratives used by the Japanese Empire concerning the Ainu to legitimize first their national and colonial projects.

Unearthing the Past: Tracing Settlement Continuity in Dutsen Kura Hill, Central Nigeria

This paper reports the possibility of the settlement continuity from the Later Stone Age (LSA) to the present in Dutsen Kura on the Jos Plateau, Central Nigeria. Archaeological survey and preliminary excavation at Dutsen Kura reveal fascinating results that suggest a continuous Later Stone Age occupation and a transition from stone working population to ceramic use. Our multidisciplinary approach combines systematic archaeological surveys, oral accounts, and excavations. Previous investigations have already unveiled critical insights into the rich history of this region. Evidence of early human habitation and a remarkable cultural transition during the LSA has emerged, shedding light on the complex dynamics of this ancient society. The excavation and analysis of artifacts, supported by GIS technology, have revealed settlement patterns and human-environment interactions that provide a deeper understanding of the region's past, enriching our understanding of the daily lives, beliefs, and traditions of the people who once inhabited Dutsen Kura Hill.

Early Animal Use in Rural New Spain: Comparing Trends and Practices in Sixteenth- to Seventeenth-Century Indigenous and Spanish Settlements from Michoacán, Northwestern Mexico

The massive introduction of European animals in what is today Mexico started in 1519 and historical documents attest for the rapid spread of livestock, in particular cattle, in the vast plains of the Altiplano that helped colonize the lands. Yet, there is a lack of material evidence to understand better the husbandry practices and the reactions of the local populations toward these new animals. So far, most of the

archaeological evidence has been obtained from urban centers, which tend to concentrate the Spanish population. But a recent archaeological project on the rural settlements of Northern Michoacán has allowed us to obtain new zooarchaeological data combined with fine-tuned cultural, social, and historical contexts. Here we compare two sites, only distant of ca. 50 km: Cuarum, an Indigenous village built on the northern shore of the lake of Zacapu, and an isolated Spanish building on the southern bank of the Lerma river registered as site PAI. Radiocarbon dating and ceramic typo-chronology indicate that both sites were occupied between 1560 and 1650. In Cuarum, local and introduced European fauna have been consumed in small quantities. In PAI, several thousands of bone remains suggest the large-scale processing of animal bodies.

French or British? Identifying the Eighteenth-Century Ceramics from a Minnesota Fur Trade Post

This paper reports on a recent project to reanalyze the European-made ceramics from archaeological site 21MO20, an eighteenth-century fur trade post near present-day Little Falls, Minnesota. The original interpretation of site 21MO20 as a French-era trading post, possibly associated with French trader Joseph Marin, was the result of Doug Birk's groundbreaking work at one of the few eighteenth-century fur trade post sites identified in Minnesota. The primary objective of this project was to determine if the tin-enameled ceramics recovered from 21MO20 are French faience or British delftware and hence to determine if the site dates to the pre-1763 French colonial era or the post-1763 British colonial era of Minnesota history. In order to determine the cultural origins of the tin-enameled ceramics recovered from site 21MO20, I conducted a comparative analysis of the tin-enameled ceramics recovered from other eighteenth-century sites in Minnesota and the Great Lakes region, including Grand Portage/Fort Charlotte, Fort St. Charles, Sandy Lake, and Fort Michilimackinac.

Remote Sensing Remote Islands: Error Analysis of Lidar-Based Archaeological Survey of the Small Cycladic Islands, Greece

The Cyclades, Greece, are islands with well-documented histories of human occupation and use. Among the larger islands in the archipelago there are many small, currently uninhabited islets with referenced land-use histories, including for agriculture and pasturage (goat islands). Despite these references, there have been few archaeological investigations into their individual use histories or into their role in broader Cycladic history. The Small Cycladic Islands Project (SCIP) seeks to understand the land-use history of these islets through lidar remote sensing and ground pedestrian survey. Using lidar, we model the entirety of each island to detect landscape features and create highly accurate digital elevation products useful for understanding the human relationship with the landscape over time. While proven to be useful for archaeological feature detection through dense forest cover, less attention has been given to lidar's archaeological utility in the maquis shrubland and jagged topography common in the Mediterranean. Here we report our analysis of

accuracy, error vectors, and utility of lidar survey conducted during the 2023 field season in the eastern Cycladic islets around Andros, Mykonos, Tinos, and Amorgos.

Inside and Out: Interdisciplinary Approaches to Injured Bodies in Industrializing London (1760–1901)

“Skin and Bone” examines the embodied experience of injury, accidents, and interpersonal violence of over 65,000 Londoners during the Industrial Revolution (1760–1901). Osteoarchaeological datasets from the Museum of London Centre for Human Bioarchaeology in combination with contemporary hospital (Middlesex, Royal London, Guy’s, St. Thomas’) and criminal justice records (England and Wales Criminal Registers, Millbank Prison Register, Home Office Prison Licenses, Metropolitan Police Habitual Criminal Register) from London, which note age, sex, and occupation alongside many bodily features (such as wounds and scars), provide a means of accessing and contextualizing embodied experiences. This project has generated an open-access multivariate database and innovative approaches to studying and visualizing the historic body. Uniting bioarchaeological, historical, and digital humanities datasets, this project explores the possibilities of studying the impact of industrialization and urbanization on the human body. This work is centered within the ecological model of violence, emphasizing the interconnections between individual, relationship, community, and society. Layering the osteoarchaeological and text-based data sources highlights how violence is literally embodied, as healed (e.g., remodeled fracture trauma; a fading scar) and unhealed (e.g., bones showing evidence of healing processes; fresh wounds requiring hospital treatment) injuries are considered within individual bodies and across the broader sample.

The Upper Marañón after Chavín and before the LIP: Glimpse into Poorly Documented Times

While the Late Intermediate period (LIP) in the upper Marañón region is well known for its unique surface stone architecture such as tall multistoried tombs, the periods immediately following the Early Horizon are still poorly documented and understood. Nonetheless, excavations at the site of Rapayán in Ancash and surface ceramics collected at a few heavily farmed settlements suggest a long and uninterrupted sequence of occupation spanning from the Formative to the LH. Furthermore, surface architecture in the upper Marañón, which has been mostly dated to the LIP, exhibits strong stylistic similarities with Early Intermediate/Middle Horizon architecture of Huamachuco (Marcahuamachuco) and the Callejones de Huaylas / Conchucos (Recuay). Combining the analysis of surface architectural stylistic variations and excavated data, I explore, through a comparative approach, the potential conservativeness of settlements in the region. I then discuss the possible implications of such findings to the understanding of social organization and political authority in the post-Chavín era of the upper Marañón.

Manzanilla, Linda (U Nacional Autónoma de México)**[152]***Introduction: What Happened after the Fall of Teotihuacan?*

The fall of the metropolis of Teotihuacan with the 570 CE great fire in the core of the settlement shook Mesoamerica. Demographic displacements, balkanization into small polities, military competition between sites, were all events of the so-called Epiclassic. This symposium will review data from my interdisciplinary project “The Study of Tunnels and Caves in Teotihuacan” (1987–1996),” behind the Pyramid of the Sun. The four tunnels excavated extensively were used by Epiclassic and Postclassic individuals, who lived inside, left traces of domestic and craft activities, and a vast array of ritual contexts, most of which involved Coyotlatelco and Mazapa burials. The use of different geophysical techniques (magnetometry, electrical resistivity, gravimetry, and ground-penetrating radar) was an important aspect. Different radiocarbon dates were compared with obsidian-hydration data. Chemical analyses of activity areas in one of these tunnels provided one of the different perspectives involving the study of activity areas, together with polished tools and obsidian objects. The presence of a substantial Coyotlatelco occupation, the transition between Coyotlatelco/Mazapa, another definitely Mazapa, and one involving Aztec occupants, gives us one of the most complete set of dates, as well as archaeobotanical, archaeozoological, osteological, ceramic, lithics, and other archaeological materials from post-Teotihuacan times.

Marciniak, Arkadiusz (Adam Mickiewicz University in Poznan)**[116]***Climate Change and Social Sustainability: The Case of the 8.2-ky BP Climate Event and the Demise of the Neolithic Community at Çatalhöyük in Anatolia*

The social strategy of imposed egalitarianism provided solid foundations for the unprecedented growth of the Neolithic community inhabiting the large settlement at Çatalhöyük for more than half a millennium. Its constituting elements comprised symmetry and balance among cross-cutting sodalities, as well as integration of domestic and ritual domains. However, the persistence of this social modus operandi started to disintegrate ca. 300 years before the ultimate abandonment of the settlement. This ongoing process was further strengthened by a significant deterioration of the local climate linked to the 8.2-ky BP event. In this paper, I intend to unpack the slow demise of the imposed egalitarian social system and the impact of climate-induced changes. In particular, I will outline the character of the resilience strategy adopted by these communities in wetter and drier climates. These processes are manifested in the reorganization of the settlement’s occupation, changes in architecture and burial practices, as well as in the economy and subsistence basis. They will be examined in the context of changes in the natural environment and the exploitation of its immediate environs.

A 10-Year Evaluation of El Guarco Project and Its Impacts in the Local Interactions at Cerro Azul, Peru

In the year 2014 as part of the Qhapaq Ñan project, a long-term intervention at the site of El Guarco in the coastal town of Cerro Azul was started. The project was thought from the beginning within the framework of collaborative archaeology and the relation with local people. This paper asks after 10 years of intervention in the site and permanent presences of the national project in the locality for the possible impacts—positive and negative—and how this project transformed or not the relation of the town with their heritage. We especially ask how the different actors like the state program, the local municipality, the association of fisherman, and others segments of Cerro Azul civil society adapt, transform, and create discourses around the Inka site, looking to their own necessities? We propose that although sometimes contradictory, these discourses were able to find an equilibrium that inspire a rebirth of the community's relationship with the archaeological site. While we believe that this relationship is positive, they are still in an embryonic stage, in part because the majority of initiatives are still top-down proposals with moderate local people participation given room for development of better co-creation initiative of heritage management.

Enriching Archaeological Interpretations with Tales from the Rez: Braiding Indigenous Knowledge into Archaeological Praxis

“In order to know yourself and find your way in this life, you need to know where you and your People come from and understand their relationship with the land.” This insight formed critical foundational knowledge that guides my Indigenous archaeological praxis. My experience and knowledge as a first-generation Indigenous woman archaeologist has created a difficult pathway to being an archaeologist. My experience and knowledge are often misunderstood by archaeologists and dismissed as being unimportant to understanding the past. This practice contributes to further marginalization of Indigenous archaeologists and Indigenous knowledge, it also pushes Indigenous archaeologists out of the discipline and creates a vacuum of information and pedagogy that has the potential to transform archaeological practice and pedagogy. The “tales from the Rez” that Indigenous archaeologists share with one another and their communities reflects a pedagogical shift in the need for braiding Indigenous knowledge into archaeological practice in order to shift the power that lies within archaeological interpretations to one that centers collaborations with, by, and for Indigenous Peoples and Communities. This process and shift creates pathways for archaeologists to learn how to work with Indigenous Communities to braid Indigenous knowledge into the stories they tell about our deep past.

Karst Landscapes and Uses of Caves among the Prehispanic Zoque People of Cerro Brujo, Ocozocoautla, Chiapas

Cerro Brujo is located in central Chiapas and is part of a mountain ridge that forms different karstic rockshelters, caverns, and caves. Early Zoque groups inhabited the area, took advantage of the resources, and developed symbolic activities in the interior of the cave system. Nearly a decade ago, the speleological “Grupo Jaguar” started expeditions to recognize the region. Recently, in collaboration with the INAH, a more systematic methodology has been developed to better understand interactions between Zoque groups and their terrain. Our research focuses on documenting the archaeological and geomorphological features in this region to add knowledge of geographical and cultural characteristics that define the human-landscape

relationships. The project also looks to create spaces for community engagement and outreach activities in closer modern towns. This paper discusses the joint efforts of a transdisciplinary study that directs to the enlightenment and preservation of the cave system and the archaeological material culture.

An Overview of Autosacrificial Instruments in Mesoamerica: Ethnohistory, Iconography, and Archaeology

It is well known that autosacrifice was a common practice among Mesoamerican societies since at least the Middle Formative period (ca. 900–300 BC). Iconography suggests that elites offered their blood and did penance to contact with the sacred realm. However, ethnohistoric evidence reveals that this practice was also carried out by non-elites with diverse objectives, using a variety of artifacts and in private spaces. While sacrifice has been recognized as a public act, autosacrifice seems to have been conceived as a personal and private ritual. For this reason, autosacrificial instruments are generally found in funerary contexts, accompanying their owners. Furthermore, archaeology has made it possible to identify autosacrificial tools in domestic contexts, showing the significance of this practice within different social levels. This presentation will offer an overview of the instruments used for autosacrifice in Mesoamerica through archaeological, iconographic, and ethnohistoric data to offer a cross-cultural approach to this fundamental ritual among Mesoamerican societies, stressing the variations through time and space.

Shift Success: A Field School Solution from the COVID Era

The archaeological field school is a critical experience for all students interested in pursuing archaeology. It is required to obtain employment in CRM and often to continue to graduate school. However, the traditional structure of a field school is inaccessible and unsustainable for numerous college students today. The COVID-19 pandemic and the restrictions placed by institutions and governments exacerbated the inaccessibility of field schools and forced professors and site directors to rethink how they were structured. The University of Akron and Summit Metro Parks, partnering organizations in the Community Archaeology Summer Program (CASP), were no exception to this problem. The result of their COVID-era problem-solving was simple and highly effective: shift-based scheduling. CASP has now permanently implemented this strategy for field schools, making it more accessible and sustainable for both CASP and students.

Markens, Robert (Instituto de Investigaciones Estéticas, Universidad Nacional Autónoma de México)**[252]***Reconsidering Tomb 7 at Monte Albán: Style, Ethnicity and Migration*

Monte Albán's Tomb 7 is the most famous prehispanic find in Oaxaca owing to its exquisite mortuary offering. Since 1932 when Dr. Alfonso Caso and his colleagues discovered the treasure, archaeologists have routinely ascribed the deposit to Mixtec migrants since the tomb's objects were rendered in the Mixteca-Puebla style. This ethnic ascription is the product of an essentialist perspective on style where the geographical extension of an ethnic group is believed to coincide with that of its style. When objects of a foreign style are found, they are explained by exchange or migration. On the contrary, the relationship between ethnicity, style, and territory is much more fluid. During the Postclassic period, the Mixteca-Puebla style was disseminated and adopted by different ethnic/linguistic groups throughout the Central and Southern highlands. One of the mechanisms responsible for its diffusion may have been the exchange of marital partners and sumptuary goods among the royal houses of the region in order to establish political alliances. In light of these considerations, I address several fundamental issues regarding Tomb 7. Who was buried in the tomb? What was their ethnicity? And why were they buried at Monte Albán 700 years after its abandonment?

The Namib Sand Sea (NSS) in Namibia is known to preserve a wide variety of Pleistocene-age archaeological sites. However, few Middle Stone Age (MSA) sites in this region have been systematically investigated and basic questions around chronology and technological organization remain open. Here we examine Narabeb Pan, an open air MSA surface site deep in the NSS first documented in the 1970s, and then reexamined in 2021 and 2022. Lithic technological analysis combined with geomorphological and optically stimulated luminescence (OSL) dates from Narabeb provide some of the first understandings of human-environmental interactions and preliminary estimates of chronology from the Late Pleistocene of the NSS. These data provide the foundation for larger, regional-scale analyses of early human adaptive strategies in this unique environment of Southern Africa.

Marks, Theodore [165] see Ostahowski, Brian

Marquardt, William (University of New Mexico, United States Forest Service)**[171]***Investigating Possible Hopi "Neighborhoods" at Pottery Mound (LA 416), New Mexico*

Hopi oral histories have a long tradition of migration and movement across the Greater Southwest and Mesoamerica. Archaeological evidence of the movement of Hopi people is well attested across the Middle Rio Grande Valley. Pottery Mound (LA 416) in the Lower Rio Puerco Valley has long been known to have connections with ancestral Hopi people through both oral traditions and archaeological evidence. This poster explores the possibility of discrete Hopi "neighborhoods" in Pottery Mound through spatial analysis of Sikyatki ware sherds located during the course of a 2014 surface survey of Pottery Mound. Kernel Density and Ripley's K-Function analysis tools in ArcGIS is employed to statistically analyze the spatial relationship of these surface finds in an attempt to locate stronger than expected occurrences of these distinctly Hopi vessels. These analyses revealed higher than expected concentrations of Sikyatki ware sherds in the western and southwestern portions of Pottery Mound. While these results alone do not confirm distinctive Hopi "neighborhoods," analyses point to strong spatial clustering of surface Hopi artifacts at Pottery Mound hinting at potential movements of a subset of the population possibly toward the Hopi Mesas or of a group from Hopi settling at Pottery Mound.

Marques, Sophia (University of Virginia)**[223]***The Valle de Mairana, Bolivia (ca. 1000–1532 CE): Elucidating the Everyday*

Sometime during the Late Intermediate period or the Late Horizon, the Valle de Mairana, Bolivia, became part of the farthest reaches of the Inka empire, which at its height spanned the Andean mountain range from Colombia to Argentina. However, relatively little is currently known about the people who lived in this valley during these centuries. How did the materiality of daily life respond to and shape people's lived experiences of and within larger scale transformations surrounding Inka imperialism in the valley? This paper addresses this question with data from pedestrian survey, subsurface testing, and excavation in the valley. A focus on the small-scale realities of lived experience centers the agency of past peoples in shaping their world. What was important to people? How was that negotiated materially? How can we better understand the relations and choices that contributed en masse to large-scale sociopolitical trends? From this, we begin to explore power and agency in imperial processes, epistemologies of the mundane, and the materiality of relational ontologies.

Márquez-Osuna, Angélica (Harvard University, Weatherhead Scholars Program)**[83]***Beekeeping in the Yucatán Hacienda: The Role of the Melipona beecheii in the Nineteenth-Century Rural Landscape from an Environmental History Approach*

This paper examines the role of the stingless bee *Melipona beecheii* in nineteenth-century Yucatán and shows how the rise of the hacienda system played a contingent role in reshaping beekeeping practices and human-bee relationships. Using primary sources such as beekeeping manuals and wills, this paper will reconstruct the way beekeeping became a central component of both the agricultural projects of the hacendados (or hacienda owners) and in the agro-urban economy that flourished in Yucatán as a response to food scarcity in times of war. Finally, it will show that at the end of the nineteenth century, the domestic hives' significance increased to the point of becoming a notable category recorded in the first economic census of domestic animals. How can we best understand the presence of the *Melipona* in the late nineteenth-century Yucatán Peninsula? I argue that during a period of upheaval, extraction of natural resources, environmental exploitation, *Melipona beecheii* continued to be the most important bee species used for beeswax and honey extraction in the entire peninsula in the nineteenth century.

Refining Comparative Metrics to Track the Cultural Transmission of Bow Technology in the Andes*

The appearance of new projectile technology can be among the most significant shifts in a region's history. To metrically distinguish dart and arrow projectile points, we present new data on hafted archaeological projectile points from museums in South America and compare them to published data from North America.

We suggest that using oversized ethnographic arrows as comparative data can lead us to misidentify small dart points as arrows. We recommend building comparative baselines only with archaeological points, which better reflect the metric impact of points' use-lives. Hence there seems to be no universally applicable comparative dataset or discriminant formula, but there are clear tendencies. We applied these to a database of lithic projectile points ($n = 422$) from 21 archaeological sites in the Andes (16° – 37° S). We carefully graded point integrity to eliminate retouched or recycled points. In our database, the earliest arrow-sized points are from ~ 1800 cal BP in the Lake Titicaca Basin (16° S), later than previously suggested for the earliest Andean bows. Farther south in Mendoza (34° S), similarly sized points appear later, ~ 1300 cal BP. Over this part of the Andes, our data suggest a southward trajectory of bows, which quickly replaced spear-throwers.

You Better Be-Leaf It: Microbotanical Remains Found in Dental Calculus of Individuals from Actun Kabul, Belize
Dental calculus (DC), the mineralized plaque or tartar on a tooth's surface, is formed and fossilized during life. Foodstuffs and medicinal plants that people interact with in life can be caught in the DC matrix. Because DC fossilizes during life, researchers can decalcify DC and analyze the microbotanicals, proteins, and aDNA trapped inside. Microbotanical analysis was conducted on multiple individuals from the site of Actun Kabul, Belize. Dietary isotopic data has previously been collected from these individuals. While the isotopic data provides information on the ratios of C_3 to C_4 plants and of terrestrial to marine protein for each individual, microbotanical remains provide a more nuanced view of what food and medicine an individual had access to and consumed. Because there are few microbotanical studies of DC in the Maya region, this study aims to demonstrate the feasibility of the method and discuss its applicability in Mesoamerican research.

[26]

A Mutual Gaze: Watching and Being Watched in the Unsettled Sociopolitical Landscape of Early Twentieth-Century Southwestern Tanzania

Archaeologists have long considered surveillance as a tool of control—for example, over enslaved or colonized peoples. But what of cases where the gaze goes both ways? The first two decades of the twentieth century were marked by seismic sociopolitical upheavals in what is now southwestern Tanzania: German colonialism and missionization, the anti-colonial Maji Maji War, the slow decline of the regional slave trade, and later British colonial conquest. Rashid bin Masoud, a slave and ivory trader, established Kikole as an entrepôt in the late 1890s. Residents there both negotiated and contributed to a predatory landscape through their participation in the slave trade. Bin Masoud's followers built a palisade around Kikole, dug wells inside its walls, and used massive termite mounds as reported watchtowers. These features, which enabled defense and surveillance, were also essential in 1905, when local Ngoni leaders attacked twice in retaliation for bin Masoud's support of German efforts to quash the Maji Maji rebellion. This paper considers mutual surveillance as a framework to understand how Kikole residents simultaneously inhabited the roles of watcher and watched. Such an approach may be of particular use to archaeologists studying surveillance in unstable sociopolitical contexts in which power was contested.

Archaeological Textiles in the American Museum of Natural History's Bandelier Collection

Between 1892 and 1903, Adolph Bandelier undertook an ethnographic and archaeological expedition to Peru and Bolivia, collecting materials on behalf of the American Museum of Natural History (AMNH). Bandelier sent four crates of materials back to the AMNH from Caleta Vitor, northern Chile, including mummies, grave goods, and other fiber and stone artifacts. This paper provides the first inventory and initial analysis of the materials in the Bandelier collection and outlines the potential for this material to shed light on the Late period at Caleta Vitor and the nature of Inka interaction at the site.

Martens, Vibeke (NIKU, Norwegian Institute for Cultural Heritage Research)

[71]

North Norwegian Heritage at Risk

Climate is changing now at an even higher rate than expected in some of the worst-case climate scenarios, with increasing temperatures, changes in precipitation, decreasing permafrost, more frequent and severe storms, sea-level rise, reduction of sea ice, floods, avalanches, and changing vegetation. In the Arctic, the temperature rise is already at 3°C—that is 2° more than the global average and beyond irreparable changes. These changes increase the risks of geo-hazards, e.g., erosion caused by wind, waves, and rivers; landslides; sea-level rise; and permafrost thaw. These changes particularly threaten coastal heritage sites, environments, and landscapes. The Arctic areas are more sensitive because they suffer more from combined threats and have previously been well protected by the aid of permafrost and sea ice. Environmental monitoring equipment installed at sites in the Arctic area through the CULTCOAST research project gives important data on the environmental site conditions and informs about possible threats to continued in situ site preservation. This data bridges archaeology and science and will be presented here.

New Excavations at Fell Cave, South Patagonia, Chile

The work of Junius Bird at Fell Cave played a crucial role in the acceptance of the association between early human populations and megafauna in South America. The evidence for behavioral association of cut-marked bones of American horse, camelids, and ground sloth with hearths, stone, and bone tools is still considered among the stronger proofs of Late Pleistocene arrival to the Magellan Strait area. We recently initiated new excavations at the site as part of a larger geoarchaeological and paleoecological project. This excavation is researching the possibility of previous human settlement at the cave and is concentrated on strata located below the lower occupations identified by Bird. Megafauna bones and a thick layer of a tephra, probably from

Reclús Volcano dated ca. 12,600 BP, were recovered. This possibility is reinforced because a certified tephra from that volcano was recovered on the alluvial plain of the Chico River in front of the cave. The geoarchaeological study of the deposits recovered at the cave together with the description of the local environment during the end of the Pleistocene will produce a new baseline to discuss the human use of the area.

Learning to Unlearn: Consulting and Working With and Not Dictating To a Community

The Delaware Department of Transportation has a project that will have an adverse effect on two National Register-eligible bridges in south Wilmington through their demolition. This location is within a disadvantaged and predominantly Black community with proud history, as one of the bridges is named for a state legislator from the community. The area has a past of immigrant waves who settled here and worked in the industries of Wilmington that have largely left. The development of an agreement document provides challenges of democratizing the heritage, its focus, recordation, and presentation. The consultation presented a learning opportunity on both sides. When the community was initially asked about their concerns and how the project could provide benefits, the response was largely silence. It was then realized that that approach was novel to them, as the standard practice was to dictate what the agencies thought was appropriate or necessary based on their knowledge and concerns. In addition to reaching an understanding that the community's opinions, experience, and knowledge matter, different consulting party elements also vie for predominance. It is taking time to build trust and understanding and balance the loud voices with input from all.

Cords of Restraint and Authority: Teotihuacan's Net Jaguars and Technologies of Ensnarement

Recent excavations at the Moon Pyramid in Teotihuacan, Mexico, have uncovered fierce predators—including eagles, pumas, wolves, and rattlesnakes—buried inside. Analysis indicates that many were alive at the time of sacrifice: some in cages, and others bound. Some show evidence of long captivity, including bone deformation from tethers. Many beasts were probably captured and controlled with cords: first hunted with remote-capture snares and nets, and then restrained with rope fetters. Though widely used globally, fiber restraints and string traps are often overlooked, because of their material perishability and physical mutability. Most snares collapse into a limp, amorphous bundle for storage or transport, but stretch into a taut openwork structure when deployed: one that must precisely match the dimensions and strength of the intended target. Western cultural bias favors “hard” weapons over “soft.” But at Teotihuacan, the archaeological record has preserved bindings on both human and animal sacrifice victims, and iconography features knots, interlinked cords, and webs in conjunction with apex predators and paramount figures, signaling the symbolic weight of fiber weapons as powerful instruments. One motif in particular, Teotihuacan's famous Net-Jaguar, faithfully depicts a corded snare, set to entrap this fearsome, exotic, and nocturnal feline.

Martine, Kristen and Emily Palus (US Department of the Interior Museum Program)**[305]***A Future for Archaeological Collections from Federal Policy Perspectives*

Federal archaeological collections acquisition and management practices are guided by decades-old law and policy, intended to uphold aspirational and perhaps unachievable expectations for preserving our nation's heritage. The resulting "curation crises," or, rather, the system that has become the status quo for collections management, is an unsustainable framework. After over a century of collecting with no end in sight, this system cannot persist. It strains limited capacities, finite resources, and dedicated staff, as well as relationships among parties with different objectives, values, and understandings of requirements and responsibilities. This paper explores modernization of collections management objectives and practices, emphasizing shared responsibility, co-stewardship, community partnerships, and increased use. This shift may bring new understanding to the interpretation of our collective history and changes in archaeological practice. Reorienting professional goals and practice and leaning into contemporary ethical standards and stakeholder interests warrants reexamination of why we preserve and how we use archaeological collections and may prompt reassessment of the federal regulations that guide collections management.

Martinet, Adrien (University of Bonn)**[118]***The Usulután Ceramics of Central America: Using Izalco-Usulután Wares to Understand Interregional Relationships and Local Social Complexity*

Usulután wares are ubiquitous throughout Central America during the Late Preclassic period. These ceramics likely originated in eastern El Salvador and quickly spread to neighboring regions of western Honduras, forming the so-called Uapala Ceramic Sphere. Recent investigations suggest that this Sphere covered a larger area than previously thought. It should extend as far as eastern Guatemala, northern Nicaragua, and northeastern Honduras. It also gained in complexity as sub-spheres were identified. Certain sub-spheres produced their own "Usulután-like" wares without much trade from other sub-spheres, suggesting that they were able to maintain stylistic and typological continuity through emulation. The Izalco-Usulután subtype is seen as the apex of Usulután wares. It required technological knowledge and specific qualities of raw materials to manufacture. This complexity lends itself as an indicator for high levels of interaction between communities and allows us to explore their sociopolitical relationships. Its typological focus on serving vessels also links it to feasting practices, which are central to public events and serve as mechanisms of social differentiation. Izalco-Usulután Ceramics are a great tool to further our understanding of the new regions added to the Uapala Ceramic Sphere, both on a local level and in relation to the "core" of the Sphere.

Bridging the Gulf: Reconnecting Belizeans to Their Precolonial Heritage through Enhanced Archaeological Education
Belize is rich in cultural diversity and history but has long faced a disconnect between its citizens' knowledge and the profound legacy of its precolonial past. Belize's ancient Maya remains attracts archaeologists from around the world. Despite this extraordinary heritage, some Belizeans are disconnected from this past, leading to a diminished sense of cultural identity and historical consciousness. This presentation investigates the causes of this detachment, revealing a multiplicity of factors, including colonial legacies, socioeconomic disparities, and a limited number of accessible educational resources within schools and communities. The existing curriculum often focuses on recent history, resulting in a generation less familiar with their nation's rich precolonial heritage. The consequences of this disconnect are multiple, encompassing the erosion of cultural identity, missed economic opportunities in heritage tourism, and the marginalization of Indigenous communities. We outline an archaeological education and public engagement plan to help overcome some of these issues and facilitate Belizeans in reclaiming their heritage and participating in safeguarding through education. The case of Belize underscores the global importance of preserving Indigenous heritage and fostering a sense of connection with the past, which, in turn, can contribute to a more cohesive and culturally enriched society.

Faunal Remains at the La Playa Archaeological site: Subsistence, Bone Artifacts, Dog Burials, and Bird Bundles

La Playa archaeological site is located at Boquillas Valley, Sonora, northwestern Mexico. Animal remains studied pertain to the Late Archaic / Early Agriculture period (1500/800 BC–AD 200). Their identification

revealed different uses for animals as subsistence, bone artifacts, dog burials, and bird bundles. Although agriculture was important for subsistence, hunting was still a crucial requirement for feeding. There were also some anatomical parts of hunted animals used as bone objects. The sample includes 25 artifacts, allowing the identification of manufacture techniques and possible functions as utilitarian or domestic (corn punches, perforators, smoother, and hammer), ornamental (pins), and votive (associated with a female burial). Dog burials (36 individuals) were also in the same areas but not directly associated with humans. Dogs certainly played an important role, since they received a differential burial treatment than other animals from the site. The estimated heights and body shapes of the La Playa and Arizona dogs are similar to characters known for common Indian dogs. Bird remains utilized for ritual purposes were also found, corroborating their use for several purposes. Ten red-tailed hawk individuals were deposited as bundles and employed for medical rituals. La Playa offered humans a wide range of resources without traveling very far.

Las urnas funerarias de la región noroccidental de Guatemala, en la colección del Museo Nacional de Arqueología y Etnología

El ser humano a través del tiempo, ha creado maneras de conmemorar la muerte y recordar a sus antepasados, algunos mediante rituales elaborados y otros por medio de la fabricación de bienes muebles que permiten el tratamiento mortuario de los individuos. En el caso de la región noroccidental de Guatemala, se han recuperado por diversos proyectos, decomisos y donaciones, urnas funerarias provenientes de diversos sitios de los departamentos de Quiché, las Verapaces y Huehuetenango, mismas que han pasado a formar parte de la colección permanente del Museo Nacional de Arqueología y Etnología y que muy rara vez han sido estudiados o publicados, por lo que en esta ocasión se presenta un análisis de iconográfico, estilístico y cronológico de los objetos depositados en la bodega del Museo. Diversos factores han influido en que las piezas en la colección no hayan sido estudiadas a cabalidad, tanto la falta de contexto de algunas de ellas, como la ausencia de los reportes científicos de donde provienen, es por ello que utilizando la iconografía, estudios comparativos y los elementos decorativos se establecerá un estilo característico de la región, aunado a los materiales constitutivos de las mismas.

Long-Term White-Tailed Deer and Human Relationships in Parita Bay, Panama

A long history of human groups interacting with white-tailed deer (*Odocoileus virginianus*) can be traced to Parita Bay in Panama. Archaeological evidence supports deer consumption since the Middle Holocene, and modern deer are continuously abundant on the Pacific side of the country where Parita Bay is located. When deer skeletal elements show evidence of a C₄ plant-based diet, it is considered a good indicator that maize crops or milpas were present, thus bone and tooth carbon isotopes are useful paleoenvironmental proxies. We sampled 120 δ¹³C carbonate bone and 23 enamel samples to capture environmental change over a long temporal range beginning with the early hamlet agriculture period marked by the introduction of agriculture (circa 6000 BCE) at Cerro Mangote and extending into the time of Spanish contact (1521 CE) at Cerro Juan Díaz. Our results indicate that the deer relied more heavily on C₄ plants, suggestive of extensive anthropogenic environmental alteration, at the beginning of agricultural introduction at Cerro Mangote than in later periods, where large agricultural villages such as Sitio Sierra and Cerro Juan Díaz have been documented. We also compared the δ¹³C carbonate of enamel and bone and found differences in the diet of juveniles and adults.

Revealing La Playa's Cultural Landscape during the Early Agriculture Period through Paleoethnobotanical Research

This paper presents a reconstruction of the cultural landscape of the La Playa Site in Sonora (SON F:10:3) during the Early Agriculture period (3450–1800 BP). We employ a paleoethnobotanical approach, analyzing 150 macrobotanical samples alongside ethnobotanical investigations, ethnographic data, and oral tradition from the O'odham and Comcaac Indigenous communities. Cultural landscapes represent the amalgamation of human activities, values, and knowledge intertwined with natural features that carry profound symbolic, historical, and social significance, reflecting the intricate relationship between communities and their environments. Our study yields a holistic understanding of past plant utilization for subsistence, aiding in landscape reconstruction and shedding light on archaeological feature functions. The Early Agriculture period in north Mexican archaeology represents the introduction of Mesoamerican crops, reshaping cultural landscapes, impacting diets, fostering interactions among diverse groups, and promoting innovative knowledge and technologies, sedentarism and population growth. Results highlight widespread maize adoption and utilization, along with over 30 different plant taxa, predominantly weedy plants, crucial for subsistence and offering insights into a modified cultural landscape with cultivated fields and irrigation canals. This research enriches our understanding of historical human-environment interactions, providing valuable insights into cultural and agricultural practices during this transformative period.

Territorial Strategies in Western Chiapas

This paper explores the different strategies used by a small polity to gain influence in long distance communication routes and access to resources and their changes through time. The research is based on spatial models and an archaeological survey conducted in the southern Mexican state of Chiapas. The survey was performed in an area in between two major archaeological sites, Mirador and Ocozocoautla, with occupations spanning from the Middle Formative (ca. 1000–250 BCE) to the Postclassic (ca. 900–1521 CE). The survey identified 53 archaeological sites in an area that was a border region between the two polities. I contrast four alternative strategies and link them to social processes at different scales, from the local to the macroregional, to understand the political organization of space in non-expansionist political units. The results suggest that prior to any attempt to influence long-distance communication routes the polities needed to exploit the resources in their immediate region.

Enigmatic Early Horizon Occupations: Las Pampas de Panecillo and the Alto Piura

The department of Piura includes a significant portion of the modern national border between Ecuador and Peru and remains understudied archaeologically. Pioneering studies of the Alto Piura in the final decades of the twentieth century introduced the site of Cerro Ñañañique to discussions of the border between the Central and Northern Andes. Beyond this site, however, our knowledge of occupations in this important potential corridor of interaction during the final two millennia BCE remains superficial. In this paper I will review the existing data on the Alto Piura and discuss new excavations at Las Pampas de Panecillo, a non-

monumental site located near the Yapatera River. I will consider evidence of interactions at various scales and explore phenomena that could have resulted in the enigmatic Early Horizon material record recovered including short-term occupations, mobility, and ritual.

Assessing Hominin Cognitive Evolution through Problem-Solution Distance Modeling: A Case Study Based on Acheulean Technology at Olduvai Gorge (Northern Tanzania)

Stone tool making has proven to be essential in human evolution and evolutionary cognitive archaeology studies (Herzlinger et al. 2017; Martín-Ramos 2022; Martín-Ramos and Steele 2023). In the case of the Acheulean technocomplex, concepts such as innovation, imposition of arbitrary form, and artifact variability have been linked to cognitive traits such as forward planning, spatial intelligence, self-recognition, or symmetry perception. In this sense, the research presented here explored the links between Acheulean tool production and use and hominins' Working Memory Capacity. The examination of the technological strategies employed in the manufacture of Acheulean Large Cutting Tools (LCTs) served as the basis of a problem-solution distance analysis (Haidle 2009; Muller et al. 2017) following Haidle's cognigram methodology (Haidle 2012). Ultimately, this research identified substantial diachronic changes in technological complexity across Olduvai Beds II, III, and IV, thought to have occurred as an adaptive response to the isotropy, shape, and size of the local raw material boulders. This analysis suggests that the cognitive skills of hominins within Bed III were similar to those at Bed II, but that a considerable and likely progressive increase in working memory capacity might have taken place throughout Bed IV.

Sustainable Visit to Rapa Nui: Global Perspectives

In this paper, I present some research results deriving from a collaborative and interdisciplinary research project called Sustainable Visits in Rapa Nui—Global Perspectives. The use of visits refers to tourism, colonization, and migrations in the long-term perspective, visits with colonial connotations, and research visits and Rapanui migrations, all of which have affected the society in social, economic, and ecological ways. The aim of the project is to explore the island from the perspective of island communities and on the terms of the islanders, the Rapanui. I use a lens of globality and problematize such concepts as remoteness, vulnerability, resilience, and survival to understand the effects of these visits. The aim is to learn something from the past to suggest regenerative actions to create social, economic, and ecological sustainable paths forward for this small island in a vast sea. Especially subsequent to European contact time, external interactions, slave raids, introduced diseases, and ethnographic, anthropological, and archaeological research placed the island in a global mindset that affected the local life. In this paper, I especially focus on presenting the results from interview projects on tourism, cultural heritage, and repatriation.

Ponderosa Pine Culturally Modified Trees (CMTs) at Great Sand Dunes National Park and Preserve, Colorado: What We Have Learned from 40 Years of Recording, Dating, Analyzing, and Consulting with Tribal Peoples

Ponderosa pine trees with cultural modifications, primarily bark peeling and wood removal, were first officially documented in Colorado at Great Sand Dunes in the late 1970s by the author for her master's thesis. At that time, CMTs were not recorded as cultural resources in Colorado. Since then, several hundred ponderosa pine CMTs have been documented within the park and many hundreds more have been recorded throughout the state. Advances in recordation techniques and dendrochronological analysis have resulted in more precise documenting and dating. The peeling dates for CMTs within the park range from the late eighteenth century through the early 1900s. Research goals have evolved from viewing the trees as individual resources to analyzing their distribution as indicators of how trees were utilized in larger historical landscapes over time. Tribal consultation suggests that numerous groups, including Ute, Apache, and Navajo, utilized these trees for food, medicine, building materials, tools, cradleboards, adhesives, and waterproofing. In partnership with tribal consultants, the park has created strategies to preserve and protect the CMTs and interpret these unique resources to visitors. A newly created visitor center exhibit includes a peeled tree with information about the tree peelers and how/why trees were modified.

The Indigenous Worldview of Water in the Isthmus of Panama

The rivers are natural limits to many cultures between the knowing and unknowing worlds. Also, they were the border between different territories and a fundamental element in establishing a settlement in a place or not. The names of the rivers are remains of these aspects. A historic-archaeological and ethnographic study of the river's toponymy provides an approach to the indigenous Panamanian worldview and deepens the colonialism process of the Isthmus.

Two Examples of Recent O'odham Participation in Archaeological Projects in Southwestern Arizona

The application of archaeological strategies in conjunction with traditional knowledge has produced unprecedented results from recent projects conducted in southwestern Arizona and northwestern Sonora, Mexico. The Hia C-ed O'odham have occupied this area since at least AD 1300/1400, and probably much earlier. This paper offers examples from two ongoing projects that have benefited from interaction with O'odham individuals and organizations. First, Hia C-ed O'odham elders have mentioned the use of traditional routes by tribal members between villages at Quitobaquito and Dome, Arizona. It is also known that rituals in the Sierra Pinacate were performed along the way. Unfortunately, both the nature of the rituals and the exact locations have been forgotten. However, based on interviews and archaeological surveys the location has probably been identified and awaits verification. The second example will involve an examination of the site of Hótunikat (Sunset Camp) in the Sierra Pinacate. This site was abandoned in 1850 because of yellow fever and the Vikita ceremony was moved to Quitovac, Sonora, Mexico, at that time. Different versions of this ceremony have been documented and are the focus of studies by Tohono O'odham tribal archaeologists who, in turn, are consulting with local archaeologists and knowledgeable tribal members.

Mascarenhas, Shannon (IAC, LLC) and Roxanne Pendleton (IAC, LLC)**[224]***Exploring Precontact Pithouse Features and Artifact Assemblage at the Amoskeag West Bank Site*

This paper presents the results of analysis conducted using lithic and ceramic artifacts from the Amoskeag West Bank site (27-HB-079) in Manchester, New Hampshire, focusing on the evidence for a pithouse feature uncommon in the regional archaeological record. A targeted data recovery by IAC in 2022 yielded an assemblage of 961 precontact Native American artifacts, including several diagnostic specimens.

Archaeologists also documented an array of hearths, post holes, and pits within and around a large downcutting feature consistent with a pithouse rarely seen in northern New England. Datable artifact types and organic material from several features indicate occupation during the Woodland and Archaic periods, with preliminary evidence for a Paleoindian component. This presentation focuses on the data that indicate the presence of a pithouse, the associated cultural features and artifacts, and how the current data can inform on human behavior at a site with temporally distinct cultural deposits from across the precontact era.

Mason, Austin (Carleton College)**[257]***Teaching Cultural Complexity through Experimental Archaeology of Composite Artifacts*

Experimental archaeology is an inherently interdisciplinary field that fills gaps in our knowledge about the past by practically testing the production and use of material culture through collaborations between academics, skilled craftspeople, museum curators, and public historians. Similarly, the material culture of most societies is “interdisciplinary” in that many things are produced not by a single craftspeople, but by communities of people who pass on production techniques, engage in trade, and work collaboratively to combine multiple materials and specialty skills into complex, composite artifacts. This paper discusses a pedagogical approach to teaching experimental archaeology as a series of linked units that deconstruct composite artifacts and processes in order to better understand the complexity of past lived experiences. The case study undergraduate course, taught in 2021, revolved around the central question: “How much (and what type of) work was required to make an English woman’s outfit ca. 550 CE?” To answer it, weekly lab experiments investigated spinning and vegetable-dyeing wool (for yarn), green woodworking (for building a loom), pottery formation and firing (for ceramic loom weights), weaving on a loom (for cloth) and tablets (for trim), and bronze casting (for brooches). The resulting historical understanding was greater than the sum of these parts.

Mason, Owen (INSTAAR University of Colorado)**[307]***Restructuring the Occupation of Near Ipiutak/Norton at Point Hope: Sedentism, Warfare, and Whaling at Point Hope?*

Archaeological discourse can remain in thrall to classificatory and theoretical constructs. “Near Ipiutak” was framed by Larsen and Rainey in 1948 within the penumbra of the hundreds of Ipiutak ruins, <1 km distant, that resulted from an aceramic, non-whaling habitus and aestheticized mortuary practice. In the monograph *Ipiutak and the Arctic Whale-Hunting Culture*, the two cultural matrices offered a contrast of “primitive” and inferentially evolved characteristics: Ipiutak, the presumed ur-kultur, had to precede its successor, Near Ipiutak, whose ceramic, slate use, and whaling were complexity-emergent properties. This view of Near Ipiutak is increasingly shopworn as recognized by Larsen in 1982, who relocated within Norton. Reanalyses of the legacy text further refine the sequence and calibrated ¹⁴C ages between 100 BC and AD 300 establish that Near Ipiutak preceded Ipiutak by more than 300 years. Revising the prior cursory discussion, Near Ipiutak at Point Hope is more significant: including a fifth of the graves, several houses, and extensive midden, providing well-contextualized, dated evidence for warfare, not previously emphasized. Whaling remains inferential, based on two whaling harpoon heads within graves, with middens lacking archaeofauna. Likely, Ipiutak developed in situ from Norton ancestry, reoriented toward the interior, forswearing pottery and whaling for caribou.

Monumental Architecture on the South Summit of Cerro Tajahuana, Ica Valley, Peru

Proyecto de Investigación Arqueológica Tajahuana conducted excavations at two unique buildings located on the south summit of the Paracas site of Cerro Tajahuana in the Ica Valley, Peru. The larger of the structures, often referred to as a fortress, was built along the edge of a steep ravine above two large groups of figurative geoglyphs and isolated figures corresponding to the Late Paracas-Initial Nasca occupation of the site.

Excavations do not support a defensive interpretation for the buildings. A distinctive pattern of closed architecture that includes walled patios and exterior spaces, interior rooms with tall walls connected by stairways and ramps was identified. It contrasts with the open, stepped platform mounds and plazas present on the north summit. The unusual configuration of these buildings and corresponding artifact assemblages suggests their use in private, closed rituals. Close proximity to large areas of complex figurative geoglyphs reinforces a ceremonial interpretation for the structures. AMS dates and associated pottery collections suggest they were in use between 500 and 200 BC, a period spanning the Middle and Late Paracas phases.

Ambivalence and Apostasy at the Sixteenth-Century Visita Town of Hunacti, Yucatán

Archaeological investigations of three Maya elite houses and a visita church at Hunacti reveal the mixed material signatures expected of a community deeply ambivalent to Spanish rule, strongly attracted to and at the same time repulsed by Spaniard house styles, Christian doctrine, and European goods. In a rural location at a distance from Franciscan centers of power in the mid-1500s, and near to the frontier (*montaña*) inhabited by free Maya people, Hunacti is renowned for acts of apostasy in historical accounts. Yet colonial Hunacti was grandly built, attesting to a wealth of masons and ambitious intentions of Maya lords and Franciscan parties. This paper examines the emulation and transformation of selected aspects of Spanish material culture by visita residents. Other institutions were rejected in favor of reproducing prehispanic institutions of everyday life and belief.

Life, Death, and Renewal: The Collective Experience of Performative Ritual at Huaca Colorada

Sector B, the principal monumental area of Huaca Colorada, has long been understood as the locus of rites of social and cosmic rebirth, ancestor veneration, and genealogical continuity. Excavation has revealed a ritual canon that included the construction of ceremonial platforms that staged elaborate mortuary rites, including feasts and the sacrifice of nonhuman plant and animal kin. In contrast, occupation areas found in Sector A to the northwest were previously considered to represent domestic and informal use spaces. Recent excavations of Sector A have revealed a surprising and deep palimpsest of architectural features including additional ceremonial platforms and a chamber-tomb with several impressive musical instruments. Dedicatory human offerings, primarily of pregnant women, infants, and children, were similarly followed by the ritual termination and destruction of these platforms. Furthermore, subsequent architectural renovation and social renewal in Sector A draws meaningful new parallels with Sector B for interpreting these rites. In this paper, we take a holistic approach to the consideration of Andean life cycles—birth, reproduction, and sacrifice of human and nonhuman kin, including the huaca itself—and the collective experience of acts of renewal in the maintenance of social and cosmic order.

Compositional Analysis of Obsidian Artifacts from the Great Temple of Tenochtitlan Using pXRF

Compositional analyses are fundamental in modern archaeological research. Recently, the introduction of portable X-ray fluorescence (pXRF) equipment has motivated an even greater interest in integrating chemical composition and provenance studies of raw materials as one of the primary objectives in archaeological projects. Obsidian is one of the most intriguing raw materials for provenance studies; its homogeneous composition and ubiquity in the archaeological context make it perfect for studying procurement processes and technological innovation in complex societies. In the case of the sacred precinct of Tenochtitlan (the capital of the Aztec Empire), there was no quantitative data about the different types of obsidian procured by this urban center. This study involves the analysis of 814 obsidian artifacts in two levels: a diachronic one, based on a sample that encompasses a long period of Aztec history (ca. AD 1375–1502), and a contextual one, based on the type of context where the artifacts were found (offerings and constructive fill). The data collected shows the frequencies and variations for specific kinds of obsidian through time and the preference for particular colors and qualities for the production of ritual and non-ritual objects.

Mathews, Jennifer (Trinity University, San Antonio)**[194]***From Food of the Gods to Avocado Toast: Bringing the Mesoamerican Avocado to California in the Nineteenth Century*

The earliest avocados of the Americas were so prized by the Olmec, Maya, and Aztec peoples for their rich caloric content and buttery flavor that they were portrayed in iconography on king's tombs and used as place-names for ancient cities. During the colonial period, the Spanish used the fruit as food for enslaved people on sugar plantations across their land holdings. However, in the early nineteenth century, the US Consul brought avocados from Campeche, Mexico, to Florida, and by the mid-1900s seedlings were transported from Nicaragua and Mexico to California. This started a trend of foreigners bringing avocados in various forms to California, although their popularity was hindered by their poor survival rate due to annual frosts. Using archival sources, family histories, and informant interviews, this paper will discuss the role that Southern California nurseries, "gentleman farmers," and amateur horticulturists played in ultimately establishing the crop in California in the nineteenth and early twentieth centuries, setting the stage for today's avocado obsession in the United States.

Mathieu, Elisa (University of Namur; Université Libre de Bruxelles)**[105]***Student Contributions to International Collaboration in MIA Cases: A Personal Case Study*

Investigating archaeological sites related to the recovery of MIAs from past conflicts requires international collaboration among various agencies and civilian volunteers. I graduated in 2023 as an art history and archaeology student at the University of Namur (Belgium). I served as an archaeologist and French translator on two different DPAA missions (Belgium and France), where I was able to apply theoretical knowledge and the fundamentals of archaeology that I learned during the course my degree. As a student volunteer, I benefited from those collaborative experiences and grew professionally through the practical application of historical and archaeological research and field methodologies (survey, mapping, excavation, life support equipment/material evidence processing, chain-of-custody documentation). As the site translator, I facilitated communication between the lead archaeologist and local stakeholders to ensure understanding between all parties. Students can contribute to the educational experience of both civilian and veteran volunteers on DPAA projects by bringing fresh perspectives and aiding in the use of technological innovations to help tell the stories of MIAs. Although this period of history may seem long ago to many students, we can all feel empathy, no matter our background, because these recovery efforts are all about our promises to people.

Mathiowetz, Michael (Getty Research Institute)**[11]***Discussant***Mathiowetz, Michael (Getty Research Institute)****[252]***The Aztatlán-Huasteca Network: A Model for the Acquisition and Dissemination of Scarlet Macaws from Mesoamerica to the US Southwest/Mexican Northwest*

In the long-running debate on the nature of interaction between societies in prehispanic Mesoamerica and the US Southwest/Northwest Mexico, the acquisition of scarlet macaws and their dissemination to the SW/NW has been perplexing. Questions abound as to how and why long-distance social networks were established and sustained to facilitate the northward movement of these tropical birds over thousands of kilometers between AD 900 and 1450. Who acquired scarlet macaws? How were they transported? What routes did these birds and their carriers traverse? Two decades ago, John Pohl proposed that an ideology of Seven Flower-Xochipilli—a solar deity linked to scarlet macaws, flowers, and maize-agricultural fertility—may have appealed to SW/NW people and spurred their interest in acquiring scarlet macaws, a hypothesis that

has been substantiated by the author in recent years. Mimbres (late AD 1100s) and Casas Grandes (AD 1200–1450) people bred scarlet macaws, and genetic studies indicate that these birds derived from wild populations around the broader Guatemala, Campeche, Chiapas, and Veracruz border region. I propose the existence of a ritually scheduled cross-continental route traversed by Aztatlán core-zone cargo holders that intersected with Huastecan networks, a corridor by which macaws and associated ideas were then transmitted northward via west Mexico.

Macrobotanical Analysis of Archaeological Excavations at the Moundville (1Tu500) Riverbank

This project looks at plant remains from an archaeological site, Moundville (1Tu500), in the Black Warrior River Valley of west central Alabama. Over centuries of occupation (AD 1020-1650), the people of the Black Warrior River Valley experienced profound changes in population size and social organization. Signatures of past peoples co-mediating demographic and political changes may be visible archaeologically in plant remains. For this research project, I analyzed macrobotanical remains, such as seeds, nuts, and other plant remains visible to the naked eye, collected during the 2017, 2018, and 2019 field seasons at the northernmost periphery of the site. Exploring changes in plant use over time helps disentangle plant-related activities and gain insight into the past lives of people at Moundville. I identified taxa presence, abundance, and density, and compared my work to previous work that was completed in the region during the 1980s and 1990s. New theoretical lenses and improved recovery techniques demand refreshed scholarship on the site's food systems and human-plant interactions.

Missions, Herds, and Habitat: Analyzing Livestock Dynamics in the Desert Pimería Alta

The Columbian Exchange reshaped ecosystems and societies across the Western Hemisphere, and the Pimería Alta (today Sonora and Arizona) was no exception. The establishment of Spanish colonial missions in the Pimería Alta region beginning in 1687 marked a pivotal moment, catalyzing the beginning of livestock ranching. This presentation delves into the rapidity of the spread of cattle, sheep, and horses in the Pimería Alta, highlighting their lasting influence. Focusing on zooarchaeological data derived from mission contexts, this presentation focuses on the temporal and demographic herd dynamics. Comparative analysis of precontact and postcontact faunal remains reveals the swift integration of Eurasian domesticates into local diets within a few decades of contact. These changes were never completely accepted, and historical records show how Indigenous resistance in the region impacted herd size and growth. Using agent-based modeling, we examine possible habitat impacts and scenarios to evaluate the effects of Indigenous raiding on herd growth. The transformation of landscapes through grazing practices and the permanent alteration of local dietary patterns are all legacies of these colonial-era animal introductions. Careful consideration of the dynamic relationship between herd and desert habitats helps reveal the impact and scope of the colonial introduction of livestock.

The Lambayeque Political System Viewed from the Lidar Map of Sicán Archaeological Complex

Lambayeque refers to the late prehispanic archaeological culture that emerged after the political demise of the preceding Moche Culture and reached its height of prosperity during the late tenth century, centering on a large city called Sicán on the Peruvian north coast. The Lambayeque Complex Archaeological Project (PIACL) has carried out research in and around the city since 2016. Previous research on this site, including ours, have focused primarily on its ceremonial core that consists of monumental mounds once called the “Batán Grande Group.” We have not paid equal attention to other miscellaneous mounds and residential zones that are thought to have extended further in all four directions. Thus, our view of the site, and inevitably of the society as whole, has relied heavily on research with an overemphasis on monuments. As the first step to solve this problem, in 2022 we carried out a 3D mapping of the site using the lidar SLAM and aimed to define the site extent and to clarify the architectural components, which have never been clear. We expect that the spatial configuration of the site revealed by this mapping project will provide important clues for examining the political system of the Lambayeque society.

Sacred Surfaces: Reed Mats in Classic Maya Writing

Archaeological, ethnohistorical, art historical, and ethnographic evidence attests to extensive use of reed mats over millennia across the Maya region. In addition to being used for sleeping or sitting atop benches or floors, mats partitioned space within the built environment, wrapped the bodies of the deceased for burial, or covered the thrones of queens and kings. Small segments of reed mat often adorn the accoutrements or bodies of members of dynastic courts. Mats were, in other words, ubiquitous in Classic Maya life, even if their physical remains are comparatively rare in archaeological excavations. This paper focuses on cross-media evidence of reed mats among the Classic Maya; namely, a small corpus of hieroglyphic texts arranged in an interwoven, mat-like format. This highly unusual layout was not only more sturdy than the reed original but highly restricted in time and place, in striking contrast to its quotidian counterpart. I argue that the practice of writing hieroglyphs in an interwoven format was a visually salient expression of the texts’ ritually activated surfaces. Woven writing, in other words, transmitted the ritual function associated with mats by replicating their structure in durable form.

Theory, Strategies, Objectives, and Preliminary Results of Transdisciplinary Studies of Ancient Consciousness on Time and Space out of Eurasia

Ancient consciousness may be a key concept to discern human biocultural evolutionary processes. We reassess how indigenous people out of Eurasia developed consciousness about time and space and created conceptual dividing apparatuses, like calendar systems. We begin with theoretical backgrounds to introduce our underlying triadic (ecological, neural, cognitive) niche construction model and present the specific objectives and strategies applied. The papers of this symposium derived from our ambitious five-year program “Integrative Human Historical Science Out of Eurasia: Exploring the Mechanisms of the Development of Civilization,” in 2019. After

the COVID-19 shutdown that delayed our field/laboratory work, one of our sub-programs, “Development of artificial niche construction and cognition of time and space,” began gathering original data of monuments, cityscape, landscape, and skyscape among the ancient societies established in the Mexican highlands, northern Peru, Micronesia, and Japan. We improved strategies to map materials of complex societies using total station, lidar, 3D scanners, or photogrammetric devices. We here present the preliminary consequences of the ongoing mapping projects and discuss our transdisciplinary studies. In some cases, we apply the data to an archaeoastronomy program we developed, to discuss how communities acquired cognitive mechanism to further develop their capacities and biocultural evolutionary processes.

After Monumentality: The Late Paracas Component at the Site of Campanayuc Rumi in the Peruvian South-Central Highlands

Campanayuc Rumi, located in the Peruvian south-central highlands, flourished as a major ceremonial center during the late Initial period and early Early Horizon (ca. 1000–500 BCE). While it ceased to function as a Chavin-related center and an important node of interregional interaction around 500 BCE, the ceremonial core was transformed as a domestic occupation and Middle/Late Paracas-related materials are associated with it. Considering that Campanayuc Rumi is located quite far from the core area of the Middle/Late Paracas Culture (ca. 500–250 BCE) in the south coast, the coexistence of local cultural traditions and Paracas material culture after the collapse of the Chavin Interaction sphere allow us to better understand the entanglements of local differences and widespread commonalities between the south coast and south-central highlands. This paper examines the nature of Middle/Late Paracas component at Campanayuc Rumi where the local style domestic constructions were placed on the ceremonial core ca. 500 BCE and new monumental construction project was not carried out though Paracas style pottery was continued to be utilized in the context of votive offerings.

“Fire and Be Damned”: An Analysis of Lead Bullets from Alamance Battleground State Historic Site (31MR397)

The Regulator Rebellion, a 14-year conflict between corrupt colonial powers and backcountry residents seeking governmental regulation, has been the subject of scholarly debate, the focus of numerous books and articles, and the inspiration for famous works of fiction. Despite academic and public intrigue, research on the Regulator Rebellion has been limited to the analysis of historical documents and accounts with little attention paid to the archaeological remains associated with events of the rebellion. The work presented in this poster seeks to rectify the lack of archaeological analysis surrounding the Regulator Rebellion through an artifact analysis of lead bullets recovered from Alamance Battleground. This poster seeks to answer the question: how can lead bullets found at Alamance Battleground provide new insights into the battle such as the location and emotional state of social actors?

Maurice-Hammond, Isabelle (University of Victoria) and Darcy Mathews (University of Victoria)**[133]***Getting to the Root*

Estuarine root gardens are poorly understood and under-researched sites of Indigenous plant cultivation on the Northwest Coast of North America. Combining archaeology, ecology, and pedology, and drawing from research conducted on 'Namgis and Ahousaht First Nations territories in British Columbia, Canada, this research proposes a novel method to aid in the identification of these gardens. Further, we provide an overview of how this method was successfully deployed to identify a root site that was no longer known by community in Songhees First Nations territory. Based on the success of this methodology, we argue that these sites, as important and often still functioning cultural landscapes, are in need of better recognition and protection by cultural heritage practitioners and legislation in coastal British Columbia. Further, this research highlights the ways in which archaeology remains complicit with colonial systems of power, which can only be rectified by centering Indigenous voices.

Mauricio, Ana (Pontificia Universidad Católica del Perú)**[243]***Comunidad y arqueología en el Valle de Chao: Conversando desde las escuelas*

Este trabajo presenta una revisión breve pero comprensiva de la historia prehispánica, colonial y republicana del valle y distrito de Chao (Costa norte de Perú) y discute la relación entre esta historia y el contexto social y económico actual del distrito. Este análisis busca entender la relación entre los pueblos asentados en este valle y el patrimonio arqueológico de esta región, es decir, su conocimiento, percepciones y expectativas. Este análisis ha sido la base para los trabajos que se han desarrollado con algunas escuelas del distrito buscando establecer una comunicación entre la investigación arqueológica y las comunidades. Esta presentación entonces, también analiza el impacto y resultados de este trabajo y el futuro del mismo en el contexto socioeconómico actual de este distrito.

Maxwell, David (Simon Fraser University)**[100]***Are Online Courses Less Engaging Than Traditional Lectures? A Comparison of Student Results from Different Presentation Formats*

ARCH 100 is a “breadth” course, providing a social sciences credit for students from across Simon Frazier University. Fall semester 2022, I taught sections of this course as both online asynchronous (OLA) and traditional in-class lectures. Both sections offered identical lectures and readings while employing identical multiple-choice exam formats, both written online drawing from the same question banks. Simultaneously teaching two versions of the same course provided the opportunity to compare student results using two different presentation methods, while holding most other variables constant. After teaching this course some 30 times, I expected mean class scores between 74% and 78%, typical for the class. Surprisingly, the in-person mean was 65.8%, compared to 73.5% in the OLA version. These unexpected results suggest at least three possible explanations: (1) online courses are more likely to appeal to students who are self-motivated, (2) my teaching methods were more different between the two classes than I anticipated, and (3) there was substantially more cheating involved in the OLA course than in the in-person course. I explore each of these potential (and not necessarily mutually exclusive) explanations.

May, J. (Schiele Museum of Natural History), Martha Gimson (University of North Carolina, Charlotte) and Robert Crisp (Schiele Museum of Natural History)**[44]***Holly Bend Plantation 2022: Search for the Kitchen Hearth, Ceif Cabin Site, and Dependencies*

Past documents describing the principal family residing at Holly Bend, the architecture, commerce, and social networks don't mention an African American component. That is until 2015 when identified colonowares

were linked with African American makers at other North Carolina plantations. Additionally, in 2017 ceramic tobacco pipe fragments were examined and associated with the separate kitchen where African Americans were preparing meals for Robert Davidson's family. Photographs from the early 1970s have been examined for specific locations of the kitchen and possible tenant/slave cabin. Reanalysis of brick fragments from earlier excavations are examined to more precisely locate the kitchen hearth and cabin site hearth and correlate with known African American artifact types.

Location, Location, Location: An Economic and Social Approach to Stone Houses in the Ancient Puuc District of Bolonchen, Yucatán, Mexico

Domestic architecture in the Puuc Hills shows an unusually high incidence of vaulted buildings, often considered to be the residences of higher status community members. The factors guiding their placement within communities are understudied, however. This is unfortunate since the siting of such expensive stone houses with respect to the built and natural environment is highly informative with regard to the social composition of settlement units and their main economic activities. This report summarizes our attempt to understand these factors in the southeastern Distrito de Bolonchen using a combination of intensive fieldwork and GIS analysis. Our ability to study domestic architecture in the eastern Puuc is now much improved thanks to lidar coverage of the region, coupled with extensive ground survey, permitting identification of a variety of domestic forms. Perhaps the most important factors dictating house location are the limestone outcrops or "altillos" and cone karst hills that provided construction surfaces, building materials as stone and sascab; besides, their contours can be used to define coresidential units. In addition, features related to the main economic activities performed by households, such as quarries and kilns, as well as nearby cultivable land, can also be used to differentiate larger settlement units.

Rock Art: A Biographical Perspective from Western Arnhem Land, Australia

In recent decades, studies of contact rock art have significantly contributed to rock art research globally. A key reason for this is that such artworks can represent a reverse gaze across cross-cultural encounters. Another reason is that contact rock art affords us neatly chronological points of time, before and after colonial engagements with First Nation societies. A common thread for such research is that it views contact rock art from a cultural-historical perspective but what happens if we move beyond such cultural perceptions and perceive contact rock art from a biographical perspective? In this presentation, we will use known rock art artists in western Arnhem Land, their lives, artworks, and biographies to explore how this is reflected in their rock art.

May Castillo, Manuel (Universidad Carlos III, Madrid)**[21]***Legally Nullius: How Colonial Discourses Underpinned Juridical Concepts Still Influencing Heritage Laws in Mexico*

In this presentation, I argue that paganism-barbarism not only amalgamated colonial propaganda to portray the Maya Peoples as enemies of the crown for the sake of colonization but also served to legally disable any Maya who dared to claim their rights before the Spanish Crown. Such legal disabling allowed the dispossession of their ancestral territories, the disruption of their spiritual relations with the land, and the imposition of a model of anthropocentric domination of land that impacts even the modern states' laws. This presentation aims to engage in a critical conversation about the influence of such colonial legal relics on heritage practice in Mexico.

Mayer, John [189] see Boudreaux, Sarah

Mayes, Arion (San Diego State University)**[69]***Bioarchaeological Evidence of Occupational Stress and Specialized Task Activity at Spiro Mounds, Oklahoma*

The archaeological site of Spiro Mounds was a ceremonial complex with an associated village of artisans and priests. Located on the Arkansas River, a tributary of the Mississippi River, the site is situated in a natural corridor between the Southeast, the Plains, and the southwestern United States. Long considered a quintessential Mississippian site (AD 1000–1450), this, one of the wealthiest of the Southeast complexes, was strategically placed as a cultural gateway. Through a detailed bioarchaeological analysis, individuals from Spiro Mounds are examined for evidence of occupational stress. Although there is an emphasis on high-status burials interred at Spiro Mounds, certain individuals exhibited osteological and dental changes due to activities exhibiting identifiable signatures of specific task-related processes. Here, the focus is on a suite of dental and skeletal changes that, elsewhere, have been attributed to basket weaving.

Mayfield, Tracie (University of Southern California)**[297]***Native Raizal Heritage: Landscape Utilization and Cultural Patrimony on Old Providence and Santa Catalina Islands, Colombia (1629–Present)*

The islands of Old Providence and Santa Catalina, located 130 miles off the coast of Nicaragua and around 8.5 square miles in size, have been a center of global trade, resource extraction, and military action since 1629, when the English Puritan venture capitalists of the Providence Island Company—whose shareholders also held stakes in the Virginia Company—financed the primary colonization of Old Providence and Santa Catalina in 1629, one year after the founding of the Massachusetts Bay Colony in what was to become the United States of America. Slaves were initially brought to the islands in 1633, and in 1638 those slaves, with the assistance of Maroons who were living on the southwest side of Old Providence Island, staged the first revolt in the English Americas. The islands are still occupied by descendants of the original English Puritan colonists, enslaved Africans, and self-emancipated Africans, who established a coterminous Maroon colony that included peoples of Indigenous and European descent fleeing the colonial industrial complex, and who now identify collectively as Raizal. In her presentation, Dr. Mayfield explores Native Raizal heritage—both tangible and intangible—through the lens of enduring forms of landscape utilization and discrete types of cultural patrimony.

Mayhew, Melanie (State Museum of Pennsylvania)**[317]***Where There's a Weir, There's a Way*

Pennsylvania has over 80,000 miles of streams and rivers. A project by the author to identify V-shaped stone fish weirs in this state has yielded over 280 structures using an array of data sources. Many of these weirs occur on the Susquehanna River and its tributaries, which drain into the Chesapeake Bay. This river is North America's longest non-commercially navigable waterway, and it supported a large fishing industry prior to the construction of hydroelectric dams during the early twentieth century. This presentation will focus on the identification of weirs in Pennsylvania using remotely sensed imagery and historic documentation. The author will discuss data sources, the development of naming conventions, structure attributes, and their strategy for recording resources in Pennsylvania's State Historic and Archaeological Resource Exchange (PA-SHARE). Data resulting from this research can help reveal archaeologically significant areas, support the locations of historically referenced settlements, inform fishery biologists in restoration efforts, and provide a visual reminder of our rivers' historic value.

Mayo, Carlos, Julia Torné Mayo (Fundación El Caño / SNI), Alfredo Campos (Universidad Tecnológica de Panamá), Eliecer Ching (Universidad Tecnológica de Panamá) and Hannah Fernández (Universidad Tecnológica de Panamá)**[42]***Long-Distance Exchange of Emeralds in the Isthmo-Colombian Area*

A group of translucent green stones have recently been found in the archaeological site of El Caño, Panama. It is not the first time that these types of stones have been found in the region. Stones with similar characteristics were found at Sitio Conte in the 1930s. The analyses carried out with pXRF in combination with spectroscopic techniques (FTIR, UV_Vis_NIR, photoluminescence) on the samples from El Caño confirm that the stones are emeralds, and their geochemical fingerprint suggests that they come from Colombia, probably from the Muzo region. In this paper, the type and possible exchange routes are evaluated with the help of written texts, archaeological contexts, and traceology. Three possible routes through exchange networks are proposed, through the Magdalena River, the Cauca River valley, or the Pacific coast from the chiefdoms of the La Tolita-Tumaco culture.

Mayo Torné, Julia**[42]***Preliminary Results of the Physico-Chemical Analysis and Manufacturing Traces of the Tesserae Mirrors from El Caño, Gran Coclé Archaeological Tradition (750–1020 CE)*

The study presented below aims to determine whether the mirrors of pyrite tesserae and iron ore tesserae not associated with bases, found at El Caño, are of local production or, on the contrary, came from Mesoamerica given their formal and material resemblance to those from that area. In order to achieve this objective, firstly, a formal typological classification of the mirrors according to their attributes, a characterization of their materials by means of optical microscopy techniques (thin slides and crossed nicols), X-ray fluorescence spectrometry (XRF) and energy dispersive spectrometry (EDS), and a characterization of the micro-traces or traces of manufacture present in the mirrors through refraction transformation imaging (RTI), secondary and electro-sprayed electron detection (SE/BSE), and digital microscopy. Preliminary analysis indicates that while some mirrors and tassels may be of foreign origin, most appear to be of local manufacture, suggesting that the people of El Caño produced their own mirrors inspired by Mesoamerican mirrors with which they share not only formal, but probably also conceptual aspects.

Beneath the Surface: Analyzing the Significance of Maya Cave Taphonomy in the Preservation of a Commingled, Fragmentary, Skeletal Assemblage

Cueva de Sangre is a 3.5 km cave that is a highly complex, multi-cave system in Dos Pilas, Petén, Guatemala, that includes riverine environments and seasonally inundated passages as well as dry areas. Use of the cave has been dated ceramically from the Late Preclassic to the Terminal Classic (400 BC–AD 800). This study examines the varied taphonomic processes of a fragmentary, commingled skeletal assemblage recovered within the cave. The taphonomy observed in Cueva de Sangre demonstrates the differences in the archaeological and geological context seen throughout this cave. The taphonomic alterations examined include a combination of manganese coating, calcium carbonate deposition, water erosion, and other taphonomic weathering processes such as longitudinal cracking and cortical flaking. The diverse taphonomy observed will aid in the interpretation of this skeletal assemblage. This study will deepen our knowledge of both the cave's environment and its role in protecting Maya heritage.

Precolumbian Art History at the University of California: Teaching, Mentorship, and Disciplinary Contention

In this presentation, I will recount my trajectory influenced by John Pohl during the formative undergraduate years of my art history training at UCLA, taking into account his teaching, the connections between the University of California (UC) and the California Community Colleges (CCC), and the disciplinary tensions in the study of the ancient American past (such as between art history, anthropology, and archaeology). My goal is to sketch a picture of continuity and conjunction that Pohl's mentorship and teaching have made possible. Moving from the CCC system to UCLA, I found that learning about Mesoamerican art history was a rarity, not a given, in a department that traditionally favored the study and scholarship around South America. Further, that an "anthropologist" taught in an art history department resonated with me both then and now, particularly after a recent issue in *21: Inquiries* takes as its central focus these very disciplinary divides. As I see it and have experienced, Pohl's main charge is to broaden and extend the study of the ancient American past to a wider audience; today, when the study of the humanities writ large is being critiqued—if not outright questioned entirely—I view this broadening as essential, integral, and vital.

[79]

The Tzotzopaztli as a Sacrificial Instrument in Religious Ceremonies of Prehispanic Nahuas

Sixteenth-century written sources, codices, and archaeological findings from the Templo Mayor Project have provided historians and archaeologists good tools for the study of instruments used for sacrifice and self-sacrifice among the ancient Nahuas. Frequently found among them are flint knives, maguey spines, and bone awls. However, there are other noteworthy instruments within the framework of the solar year ceremonies. We are referring here to the *tzotzopaztli* and to the flint-tipped arrows, which were used to sacrifice the *ixiptla* of *tzoalli*, made of amaranth paste, toasted corn, and honey. Regarding the *tzotzopaztli*, this was a wooden stick used as a beater to tighten the web while weaving. In the *Atemoztli veintena*, the *tzotzopaztli* was sunk into the chest of the Tepictoton, small edible effigies that represent the mountains, and with it the heart of the vegetable *ixiptla* was extracted. In this lecture, we will explore the symbolism of this instrument, in relation to the sacrifice of these aquatic entities and with the female half of the Mesoamerican cosmos. Likewise, we will use iconographic data from the codices as well as from ethnographic sources to strengthen our analysis.

McAnany, Patricia [254] see Slocum, Diane

McAuliffe, Richard (Texas State University)**[332]***Bonfire Shelter Archaic Occupations*

Bonfire Shelter in the Lower Pecos Canyonlands of southwest Texas provides evidence of sporadic human occupation of the site across the Archaic period. The deposits known as the Intermediate Horizon, bound by two bison bone beds dating to ca. 12,000 BP and 2500 BP, do not reflect the persistent site reuse seen at other rockshelters in Eagle Nest Canyon. Bonfire lacks features typical of those other rockshelters such as accumulation of burned rock midden deposits from repeated plant baking, bedrock mortars, rock art, and burials. Instead, only four isolated thermal features have been identified and recorded from the Intermediate Horizon. These features provide an opportunity to describe discrete events related to subsistence activities, how those may have changed across the Archaic, and differential use of rockshelters in the canyon. This paper presents the most recent interpretations of these Bonfire Archaic features and new radiocarbon dates placing them into the greater context of contemporaneous occupations of other Eagle Nest Canyon sites.

McCafferty, Sharisse (University of Kentucky) and Geoffrey McCafferty (University of Kentucky; University of Calgary)**[157]***Avian Imagery on Precolumbian Ceramics from Pacific Nicaragua*

Throughout human history people have been entranced by avians. Their ability to fly from earth to the sky, while displaying grace and beauty, as well as exhibiting a ferocity to protect their nests and hatchlings was revered. Birds were often seen as messengers between the sky and earth, communicating with other spirits, with the deceased, and transporting souls/spirits to other dimensions. Some cultural groups adopted special birds to represent their clan or area, or to act as an individual's guardian. Birds played an integral part in the animistic beliefs of the early inhabitants of Pacific Nicaragua and their importance was portrayed on clay vessels via techniques of modeling, incising, excising, and painting. This paper will discuss avian imagery on ceramic vessels from 600 to 1600 CE.

McCafferty, Sharisse (University of Calgary)**[157]***Chair***McCafferty, Sharisse (University of Calgary) and Jorge Zambrana (Independent)****[157]***The Rise of Social Complexity in Pacific Nicaragua*

Despite over 150 years of research, the archaeology of Nicaragua remains in its infancy. Projects have conducted settlement pattern surveys and rescue projects have recovered information from endangered sites, but very little problem-oriented research has ever been conducted. Consequently, "big question" interpretations such as the rise of social complexity are generally answered vaguely based on ambiguous data, often supplemented with interpretations adopted from surrounding regions. A basic chronology has been proposed with a refined ceramic sequence, satisfying some of the goals of a culture history for Pacific Nicaragua, but more complex questions are rarely addressed. Over the past decade, however, several rescue projects in the Managua area have recovered information on the La Arenera and Las Delicias periods (500 BCE–400 CE), with which some tentative insights on the rise of complexity can be offered. These data are contextualized with settlement pattern data from Granada, Rivas, and Masaya-Tisma.

McCaig, Haley, François Lanoë (University of Arizona), Joe Keeney (Bureau of Land Management Arctic District), Joshua Reuther (University of Alaska Museum of the North) and Ana Jepsen (University of Wyoming)**[174]***Northern Brooks Range Caribou Hunting Architecture*

Caribou hunting has shaped the cultural landscape of the Alaska Arctic interior. In many cases, this meant intentionally altering local landscapes to the direct advantage of caribou hunters. These engineered landscapes are visible today in various forms of hunting architecture, including stone drive lines, drift fences, cairns, and hunting blinds. Despite the prevalence of these features, caribou drive systems are often only noted peripherally to nearby habitation and processing sites. The lack of spatial analysis, dating, and exploration of the function of various hunting architectures in northern Alaska directly impedes our understanding of these features and how they relate to broader systems of land use through time. This poster outlines preliminary results from a recent spatiotemporal study of caribou hunting architecture in the northern foothills of the Brooks Range. The study area is situated along a significant caribou migration route of the Western Arctic Caribou Herd and was utilized over a long period by groups of North Alaska caribou hunters. The results are evaluated in the context of known local cultural traditions, including Ipiutak and late precontact / early contact Inupiaq and Dene Traditions.

Context for Petroglyphs: Recent Results from the Valley of Fire Archaeological Project

Famous for its striking natural landscapes, abundant petroglyphs and important prehistory, Nevada's Valley of Fire State Park is well known to the public, but our picture of the archaeological remains from here is piecemeal rather than comprehensive. A new joint project by College of Southern Nevada, Nevada State Parks, the State Historic Preservation Office and the University of Nevada, Las Vegas is reinvestigating important sites such as Atlatl Rock and its petroglyphs and conducting intensive and extensive surveys to put the rock art panels into context. Building on nearly a century of investigation, this project intends to provide an integrated view of the archaeology of well-known but understudied sites with the intention of establishing an archaeological district status as applicable. The project's continuing work has already resulted in substantial additions to our understanding of the archaeology in the some of the most heavily visited areas of the park and will ensure that these important cultural remains will be preserved in the future.

A Tale of Two Cemeteries: Learning to Listen to the Voices of African American Descendant Communities in New York and Philadelphia in the Context of Compliance Archaeology, ca. 1990

In the early 1990s I was a project manager at a regionally well-known consulting firm of archaeologists, architects, and planners. Through my involvement in the excavation of Philadelphia's 10th Street First African Baptist Church Cemetery and New York City's African Burial Ground, I learned how to listen to the voices of descendant communities and subsequently argued for a research paradigm based on open, honest, and respectful relationships with descendant communities as partners in the research process. This paper will summarize and compare those experiences to highlight early successes and lessons hard-learned toward community-engaged archaeological praxis.

Foxes in Retrospect: Unraveling Human-Fox Relationships through Fox Tooth Ornaments in the Swabian Jura

Personal ornaments play an important role in our understanding of human cultural and behavioral change during the Upper Paleolithic. Although small, ornaments are often well-preserved, occur in large quantities, vary across space and time, and can shed light on intangible aspects of human lifeways (e.g., identity, relationships, movement, status). However, some ornament forms are better studied than others, and fox tooth ornaments, despite their frequent occurrence and broad spatiotemporal span, are relatively under-addressed. Here we present the first comprehensive study of 40 perforated fox teeth from four cave sites in southwestern Germany. This region's rich symbolic record and evidence of long-standing human-fox relationships make the Swabian Jura an ideal case study. By applying a holistic approach, including geometric morphometrics and traceology coupled with experimental archaeology, we show that most teeth were perforated by bifacial scraping and grooving, and traces of polish and rounding indicate their use as ornaments. Ultimately, we discuss the role of foxes within human socio-symbolic and paleoenvironmental systems in the Swabian Jura and within the broader context of Upper Paleolithic ornamentation across Europe. Our study offers insight into the role of foxes during the Upper Paleolithic, especially regarding human subsistence, cultural expression, and ornament production.

[25]

The Ensouled Body: A Cross-Cultural Meta-analysis of Spiritual Beliefs about Human Bodily Parts and Substances

In many societies, human bodily parts and substances have been seen as symbolically significant and imbued with spiritual power. Over the years, several scholars have recognized the importance of these bodily parts and substances in various religious beliefs and behaviors. However, their research often focuses on specific regions or time periods. Therefore, the full global scope of these ideas is currently unclear. To address this issue, we conducted a meta-analysis of 25 scholarly works that discuss ethnographic and other firsthand accounts of symbolically powerful human bodily parts and substances. We organized the cultures presented in these works based on geography and language family. Thereafter, we coded which bodily parts or substances were viewed as symbolically powerful. Finally, we outlined the culturally held understandings about why these bodily parts and substances are believed to hold power. Through this analysis, we collated a global sample of cultures that held similar beliefs about the symbolic importance of bodily parts and substances. We propose that these beliefs are widely seen cross-culturally and are an important part of many religious beliefs and practices. This study suggests that researchers should consider these types of ideologically based explanations for archaeological remains of bodily parts and substances.

Regional Settlement, Subsistence, and Environment after the Demise of Teotihuacan

Significant changes in sociopolitical and economic organization following the collapse of the Teotihuacan state between the sixth and seventh centuries CE are evident in settlement patterns as well as archaeological materials including ceramics and lithics. The potential magnitude of this event and subsequent ramifications within the valley itself are only superficially understood as considerable research is focused on the urban center itself. In this presentation, the results of several lines of research are interwoven in order to construct a view of life after Teotihuacan: processes ranging from social/political fragmentation and partial abandonment, subsistence, environmental modification associated with less-intensive agricultural production, and climate fluctuations suggested by decreasing lake levels and reduced precipitation. The integration of results gathered over two decades of research in subsistence and landscape, in combination with earlier perspectives, offers insight into the challenges likely faced by inhabitants of the region as well as the ways in which they were able to adapt to shifting circumstances. The primary objective is to encourage new questions to guide future investigations and, hopefully, contribute to a broader understanding of the interplay of causal and subsidiary factors, treating the Teotihuacan Valley as a case study for long-term transformations.

[38]

Increasing Public Access to the Treasures of Edgar L. Hewett's American Southwest

The New Mexico History Museum is digitizing and making publicly available the manuscript and photograph collections of Edgar L. Hewett (1865–1946) thanks to a major grant from the National Historical Publications & Records Commission. An inescapable presence in early twentieth-century Southwest cultural life, Hewett earned his nickname of “El Toro.” Among his accomplishments, Hewett was at the forefront of modern Southwest archaeology. He trained a new generation of archaeologists, invited women into the field, and worked tirelessly for the United States Antiquities Act (1906). He led the Museum of New Mexico and the School of American Archaeology (today known as the School for Advanced Research) and preserved New Mexican cultural patrimony. He used his political skills and stubbornness to centralize cultural preservation

and promote and establish New Mexico as a hub for the “groundwork of American archaeology,” one of Hewett’s first publications. By making Hewett’s papers widely available, researchers can grapple with the history of Southwest archaeology and the methods and systems Hewett built as he elevated American archaeology on the world stage. These collections will be publicly accessible via a digital platform. The photographic materials will be available for the first time as an organized research collection.

Decision-Making in Subsistence Herding: A View from Mediterranean Europe

Richard Redding’s body of research pushed zooarchaeologists to think more deeply and creatively about human-animal interactions. His 1981 dissertation “Decision-making in Subsistence Herding of Sheep and Goats in the Middle East” set the stage for his impactful career, bringing together multiple disciplines to characterize the nature of subsistence herding. My own research was heavily inspired by Redding’s dissertation and subsequent publications. This paper presents a case study from Mediterranean Europe that demonstrates how Redding’s ideas continue to influence new generations of scholars. In particular, much recent research on sheep and goat herding among Neolithic farming populations in Mediterranean Europe is using multiple proxies to assess the nature and role of pastoralism, the impacts of introduced animals into new environments, and exploring the biological changes of small founder populations on ancient breed development.

[107]

Boom-and-Bust Population Dynamics: Climate Change, Resource Inequality, and Intergroup Conflict in the Prehistoric North American Southwest

With the transition to agricultural economies, human populations underwent profound changes including, in many regions, rapid growth accompanied by marked volatility. The Colorado Plateau in western North America offers unique insights into volatile population dynamics, as it represents one of the few known occurrences of near total population abandonment by sedentary agriculturalists and a reoccupation by mobile foragers. In this analysis, we investigate the drivers of local population growth and decline and suggest how multiple interactive socioecological conditions influenced the depopulation of the area. We leverage a newly developed archaeological database from the Bears Ears National Monument in Utah to model demographic variation as it relates to climate change, resource inequality, and human conflict, and compare modeled results to those observed in neighboring regions in the Southwest.

Ancient Oral Metagenomes from La Real: Insights into Health and Infectious Disease across the Middle Horizon Period

La Real is a site located in the Majes Valley of southern Peru associated with two chronologically distinct burial contexts dated to the early and late Middle Horizon periods. Previous analysis of these funerary assemblages has shown similarities in the demographic profiles and incidence of trauma between burials from the two periods. Documented increases in lethal violence in later burials and substantial changes in associated mortuary artifacts, however, have been interpreted in the context of increased Wari influence and associated reorganization of status and social structure in this region. Much is still unknown about how these political changes impacted health and infectious disease dynamics in this population. To this end, we present an

analysis of ancient oral metagenomes from dental calculus sampled from six individuals from La Real. In conjunction with ongoing bioarchaeological work, assessment of taxonomic diversity and metabolic function of the reconstructed oral microbiomes provides insights into diet, infectious disease burden, and oral health at this site. Additionally, this preliminary analysis identifies putative pathogens identified from these oral microbiomes, including members of the Red Complex of *Porphyromonas gingivalis*, *Treponema denticola*, *Tannerella forsythia*, and other periopathogens implicated in periodontal disease.

A Reassessment of Obsidian Procurement Networks on Guatemala's Pacific Slope

Networks of long-distance exchange in quotidian commodities are essential aspects of prehistoric economies. On the Pacific Slope of Guatemala, there was no more important commodity than obsidian, which accounts for almost all cutting edges found in archaeological contexts. Obsidian sourcing studies on the Pacific Slope have been limited, relied on very small sample sizes, and primarily on visual analysis. Furthermore, syntheses of Mesoamerican obsidian exchange have either avoided the Pacific Slope entirely or only included data from the Soconusco and Highland Guatemala. These analyses have led to models of three major exchange networks that remained static over millennia. However, a more careful scrutiny of the existing literature, unpublished data, and new geochemical evidence suggests a more complicated picture wherein networks of exchange overlap and shift over time. This paper reassesses the existing model to provide a more nuanced view of obsidian exchange on Guatemala's Pacific Slope from the Early Formative to the Late Classic.

Iconoclasm Island: New Research on the Destruction of Rapa Nui's Statues

Monuments are a critical window into people's values, beliefs, and social memories. The destruction of monuments is especially important since it can shed light on how these aspects of societies change over time. We describe new research aimed at understanding the destruction of *moai* (statues) on Rapa Nui (Easter Island). Our first goal is to build a chronology of statue toppling based on the exposure of the broken surfaces of statues to weathering. Exposure to rain and sea spray will over time damage statues in a way that can be measured nondestructively with a specialized handheld ultrasound instrument. To determine how long damage observed on statues took to accumulate, we are artificially weathering stone blocks as well as conducting other experiments. Our second objective is to assess how statues were toppled by looking for distinctive patterns in the timing and location of statue toppling that can be linked to purposeful destruction, neglect, or earthquakes. We utilize advances in archaeoseismology, specifically engineering computer simulations that predict how statues might behave in major earthquakes, coupled with recorded and synthetic earthquake waveforms. These data will help the local community to help make decisions about future conservation of statues.

McCray, Brian (Indiana University East), Jesse Stephen (DPAA) and Christopher Nicholson (Arizona State University)**[198]***Integrating Categorical Legacy Data in Spatial Models: A Unique Dataset from Southeast Asia*

Despite advances made in open-access publishing, significant archaeological information remains confined to the gray literature or to unpublished, internal reports in the possession of institutions. For at least 20 years, archaeologists have realized that digital archiving could make this material more accessible at a larger scale, but the tools to access these documents and convert them to be a legible part of a comparative dataset are still developing. This poster presents the results of an archival research project using natural language processing to make 159 legacy reports digitally accessible for incorporation in spatial models using generalized linear modeling and machine-learning approaches. These data were gathered from archaeological reports generated by the Defense POW/MIA Accounting Agency (DPAA) and its antecedents, in partnership with the center for Digital Antiquity at Arizona State University. Though challenging to implement, we found that context-specific categorical data, such as aircraft type, could be extracted from reports and used to refine generalized linear and machine-learning spatial models. The project shows how creative digital archaeology approaches can work with diverse datasets.

McCreary, Elizabeth (Indiana University of Pennsylvania)**[283]***Geophysical Survey of the Friendly Fire Incident, French and Indian War, Pennsylvania*

Fort Ligonier, constructed in 1758, was the advance post and the last in the line of supply forts constructed for Brigadier-General John Forbes' Expedition to take Fort Duquesne during the French and Indian War. A young George Washington was a colonel stationed at Fort Ligonier. On November 12, 1758, there was a small skirmish between a British Virginia regiment, which was led by Lt. Col. George Mercer, and the French Army and their Native American allies. Col. George Washington was sent with approximately 500 Virginians to aid Lt. Col. Mercer's men. However, during the skirmish, it was realized that the two Virginian regiments were firing on each other. By the end of the Friendly Fire Incident, there were approximately 20 Virginians dead on the battlefield. Washington notes that these men were to be buried the next morning, but it was not documented where they were buried. A noninvasive geophysical survey using both ground-penetrating radar and a gradiometer were conducted to find any potential burials or features associated with the friendly fire incident in addition to any other features on the landscape. Ground truthing was conducted to confirm the presence of some anomalies identified in the geophysical survey.

McCouston, Ashley (Colonial Williamsburg Foundation)**[16]***A Story of Soldiers and Surgeons: Excavating the Remains of Four Individuals and Three Amputated Limbs Interred at the Williamsburg Powder Magazine*

During recent archaeological excavations at the Colonial Williamsburg Powder Magazine, human remains were unexpectedly encountered and subsequently excavated to mitigate potential impacts from ongoing restoration work at the site. The excavation uncovered a mass grave containing three individuals, a single grave containing one individual, and a surgeon's pit containing three amputated limbs. All were identified as casualties of the Battle of Williamsburg in May of 1862. Archaeological and osteological analyses of these remains have provided rare insight into the lives, deaths, and medical practices of soldiers and surgeons during the American Civil War. Physical evidence uncovered during this excavation also directly contradicts many written accounts of the conflict and its aftermath, challenging researchers to rethink, reimagine, and reinterpret this complex chapter of Williamsburg's history. ***DISCLAIMER: Images of human remains will appear in this presentation.

McCuistion, Emily (University of Texas, Austin)**[332]***Radiocarbon Dating in the Lower Pecos Canyonlands*

This paper presents the historical and contemporary context of radiocarbon dating in the Lower Pecos Canyonlands (LPC) archaeological region of southwest Texas. It entwines discussions of early radiocarbon dating history, evolving dating technology and standards, regional infrastructure development, changing archaeological research interests, and land stewardship to understand the potential and limitations of the LPC radiocarbon record. This context, and its relevance, emerged while assembling a regional radiocarbon database, completed in 2019, which was subsequently vetted and used to address broad regional research questions.

McCulloch, Robert [174] see San Roman, Manuel

McCullough, Katelin [95] see Jazwa, Christopher

McCullough, Robert and Andrew White**[326]***Electromagnetic Induction as a Tool for Archaeological Research and Management: A New Manual*

Near-surface electromagnetic induction (EMI) instruments can complement gradiometry and other geophysical instruments for archaeological research and management. We discuss the Geonics EM38-MK2, an instrument that introduces a magnetic field into the ground and measures the electrical and magnetic responses of subsurface materials. The electrical conductivity (EC) of sediments is mainly related to the presence of moisture, while the magnetic susceptibility (MS) is related to the presence of iron oxides. EMI can thus be used to map the presence of human-made features that retain moisture differently than the surrounding soil (e.g., pit features, filled ditches, etc.) and/or have enhanced MS associated with organic and heated sediments. The EM38-MK2 collects EC and MS datasets simultaneously without ground contact (required by resistivity instruments) and with less sensitivity to ferrous metal than a gradiometer, and EMI is better than gradiometry for detecting thin deposits associated with single burning events. We introduce a new manual designed for novice users of the EM38-MK2, funded by the National Center for Preservation Technology and Training of the National Park Service. The manual covers the physics of EMI, instrument calibration, survey techniques, and data processing. Case studies and strengths and weaknesses of the EMI technique are also discussed.

McDaid, Christopher (US Air Force, Fort Eustis, VA)**[270]***African American Community Building on Mulberry Island, Virginia, during the "Jim Crow" Era*

In 1918 the US Army purchased all 3,238 ha (8,000 acres) of Mulberry Island, Virginia, to create Camp Eustis, now the Fort Eustis portion of Joint Base Langley-Eustis. English colonizers and enslaved African laborers had occupied Mulberry Island since the seventeenth century. At the time of the Army's purchase, a significant African American community lived on Mulberry Island. There were African American social and fraternal organizations, financial organizations, and a church founded in 1867. Most of the landowners who sold land to the Army were African American. The Fort Eustis Cultural Resources Management Program has been examining sites from the Reconstruction and Jim Crow eras to better understand the process involved in the creation of a free and vibrant community in the aftermath of enslavement and the increasingly restrictive Jim Crow era.

McDonald, Holli and Lacy Hazelwood (University of Montana)**[69]***Children of Casas Grandes: An Osteological Examination of Subadults at Convento and Paquimé*

Bioarchaeological research has played a significant role in understanding the Casas Grandes region of Northwest Mexico. Excavations at the archaeological sites of Convento and Paquimé recovered ~652 burials dating to AD 700–1450, providing a robust skeletal population for investigations, including research on population demographics, violence patterns, and social stratification. While there is extensive literature on these individuals, previous research focusing on subadults is nonexistent outside of our own. Integrating research on subadults with those of adults is necessary for a more comprehensive understanding of past societies and is particularly useful in understanding the prehispanic Casas Grandes perception of childhood. This study focuses on constructing biological profiles through osteological analyses to gain further understanding of experienced trauma, disease, and demographic information of the subadult population compared to their adult counterparts at Convento and Paquimé. Combined with molecular data, the resulting information is used to address key issues involving Casas Grandes population demographics. Newly constructed biological profiles will provide updated age-at-death and biological sex estimations, trends in physiological stress and trauma experienced by subadults, and any correlations between demographic factors, health, and violence. This will allow for a more comprehensive understanding of Casas Grandes society.

McDonald, Jo (University of Western Australia)**[156]***Dating the Murujuga Cultural Landscape*

The Dampier Archipelago (including Burrup Peninsula) is one of Australia's most significant rock art provinces. Recently nominated to the World Heritage List as the Murujuga Cultural Landscape, this talk describes efforts that are being made to directly date this deep-time rock art sequence, by innovative direct dating approaches. New efforts to understand desert varnish and experimental work with luminescence surface dating are being used alongside broader landscape focus on sand dunes and freshwater carbonate tufas. This project is contextualizing the human use and extensive modification of this land- and seascape through time.

McDonough, Katelyn (University of Oregon), Perry Chocktoot (Klamath Tribes), Geoffrey Smith (University of Nevada, Reno), Dennis Jenkins (University of Oregon Museum of Natural and Cultural History) and Richard Rosencrance (University of Nevada, Reno)**[87]***The Traditional Nutrition Project: A Collaborative Study of Plant Foods to Understand Indigenous Foodways and Health in the Northern Great Basin*

Foodways, culture, and health are closely intertwined. As such, food is a central aspect of Indigenous identity and the subject of much anthropological research. Traditional knowledge and archaeological records show that plants have always played important roles within Indigenous foodways in the Great Basin, yet nutritional information for those foods is scarce. This lack of dietary data is problematic for Indigenous communities seeking nutritional information, and for anthropologists who wish to consider nutritional perspectives. The Traditional Nutrition Project is a partnership developed between members of the Klamath Tribes, University of Oregon, and University of Nevada, Reno, to understand human diet and health in the past and present. The goal of the project is to develop a nutritional database for ancestral foods through biannual harvesting events that concurrently function to strengthen relationships between Tribal members and anthropologists while encouraging Indigenous perspectives and practices. This talk will introduce the project, highlight plants of interest, and share results of the first gathering events. We hope this project will support health and food sovereignty within Indigenous communities, contribute to theoretical frameworks in anthropology, and strengthen relationships between all involved.

McDowell, Alyssa (Arizona State University) and Cindy Hsin-yea Huang (Arizona State University)**[198]***Cutting Edge Technology: A Comparison of the Environmental Impact on the Emergence and Dispersal of Microblades in Siberia and Northern China*

During the Upper Paleolithic, microblade tools emerged in Siberia and northern China, representing a significant technological advancement in tool-making and tool use. It is hypothesized that microblades emerged early in Siberia as an adaptation to the cold high-altitude environments, and the intensification of forager mobility due to the harsh environments led to its dispersal in North Asia through migration and cultural diffusion. Crafting microblade tools was a complex process that required a high degree of skill and knowledge. The environmental conditions and available resources in each region likely influenced the emergence of these tools in specific ways. It has been argued that knowledge of blade production may have given foragers in Siberia the skills necessary to invent microblades and the environmental conditions may have necessitated it. The adaptive significance afforded to this highly mobile toolkit allowed for it to spread rapidly throughout North Asia. This study explores how the colder environments of these regions impacted the emergence and dispersal of microblade tools in North Asia through spatial and statistical analyses of microblade sites and Paleoenvironmental data.

McEnroe, Katherine (Colonial Williamsburg Foundation) and Sean Devlin (Colonial Williamsburg Foundation)**[16]***Curation and Conservation for Reburial: Balancing Respect and Discovery*

Over the last three decades, archaeological approaches to the excavation of human burials have radically shifted. These changes have demanded a large-scale reevaluation of the decision-making processes and research practices deployed not only during these excavations, but also in the approaches to curation and disposition after excavation is finished. From a collections' perspective, this shift highlighted the need for the development of practices centered on the ethical treatment of materials associated with burial contexts and in support of repatriation efforts. This paper explores the interaction of curation and conservation in handling, documenting, analyzing, treating, and returning the artifacts associated with the burials from two recent projects undertaken by the Colonial Williamsburg Foundation's Department of Archaeology. It focuses on the practical protocols implemented for the collections during these projects and reflects on the value of conservation and curatorial analysis while balancing the need for discovery of information with respect. ***Images of human remains may be shown.

[154]

Louisiana's Dugout Canoes: An Inventory and Assessment

Louisiana has 31 dugout and plank canoes spanning the last 2,000 years recorded in the archaeological site files. The collection reflects a diversity of shapes and sizes in both Indigenous and Euro-American assemblages, suggesting that beyond the required linear shape, individual preference and intended function significantly influenced form. This presentation will illustrate the variety of forms seen in both assemblages and how those appear to have changed over time and space.

Comparing Demographic Patterns of Archaeological and Modern Cemetery Data: A Novel Application of GPS Technology

Bioarchaeologists routinely generate demographic estimates of past populations from archaeological contexts across time and geography. Despite numerous ways that bioarchaeological data enhance demographic reconstructions of past populations, few contexts allow direct comparison between archaeological and modern demography of the same locale. This project presents a comparison of demographic data drawn from a Transylvanian archaeological cemetery and a modern cemetery directly adjacent to the archaeological site. The Papdomb site represents a medieval Szekler village church and churchyard that was in use for approximately 800 years. A modern cemetery utilized by the same village was established in the nineteenth century and is contiguous to the medieval cemetery. During our 2023 field season, the location of all visible tombstones was mapped using a cell phone and a GPS application. All observable names, birthdates, and death dates were recorded ($n = 319$ graves containing 522 individuals). Demographic patterns drawn from the tombstone data were compared to the site's bioarchaeological demography and several differences were observed, namely fewer nonadults and more older adults are present in the modern tombstone dataset. This novel use of GPS data demonstrates potential differences in demographic patterns across time and calls attention to the limits of age estimation in bioarchaeology.

Thinking about The Dawn of Everything in Black and Red

The Dawn of Everything urges us to rethink the most basic concepts of culture and cultural evolution. Waving the black flag of anarchism, Graeber and Wengrow question the widespread idea that inequality and exploitation were unavoidable consequences of human technological "advancement" and population growth. They maintain that humans do not have an inherent nature and that human actors make culture and cultural change. These actors are powerful and capable of choosing freedom. I applaud the authors for engaging a popular audience countering banal ideas of pop psychology (and academic evolutionary psychology) and media that sees human inequality as given. Waving the red flag of Marxism, I find much of value and much to agree with in these pages. Both the black and the red study history to show that humans created the modern social world. Since humans created it they can also transform it. But the key question must be how do we change it? Graeber and Wengrow emphasize the goal of emancipation and repeatedly show how people in the past chose to live free. Under the red flag, Marxists engage in a praxis that focuses on the relationships between material conditions, human consciousness (choice) and human action.

McGuire, Sara, Christine France (Museum Conservation Institute, Smithsonian) and Jared Beatrice (College of New Jersey)**[123]***“Young, Scrappy, and Hungry”: Social Upheaval and Changes in Food Resource Access in Colonial and Postcolonial America*

The Revolutionary War was a crucial turning point in American history, as the 13 British colonies broke with England and established themselves as an independent nation. This research takes a biocultural approach to explore the impact of these dynamic changes at the individual scale in terms of resource access and diet. Stable carbon and nitrogen isotope ratios from teeth, long bones, and rib samples were analyzed to explore diet throughout life for a subset of individuals ($n = 100$) interred at the historic First Baptist Church of Philadelphia (FBCP) cemetery during the colonial (pre-1775 AD) and post-colonial (post-1783) periods. The data reveal variation in stable nitrogen isotope values during infancy and childhood for both adults and subadults that indicate changes in feeding practices to incorporate more diverse proteins for site subadults, as compared to the childhood diets of adults. The data also reveal dietary patterns that align with different socioeconomic statuses when compared to contemporary populations. Overall, the data suggest increased dietary heterogeneity, similarity in diet for males and females, the prevalence of C_3 grains in the diet, and increased consumption of meat over time. As such, this research reveals insight into dietary stability and resilience among Revolutionary Era Americans in Philadelphia.

McIlvoy, Karen [227] see Proebsting, Eric

McKeeby, Zachary (University of Virginia)**[95]***Households, Community, and Crafting at Kanono: The Creation of an Early Second Millennium Village in Western Zambia*

The Machile River in Western Zambia formed a significant locus of Iron Age life in Zambia and served as a conduit for the localized movements of people, things, and ideas in south-central Africa for much of the last two millennia. Within this dynamic corridor, the early second millennium Kanono site represents a relatively short-lived but well-defined Middle/Late Iron Age farming community that integrated local crafting practices with global and regional orientations during a period of dramatic political and economic changes across southern, central, and eastern Africa. Combining high-resolution geophysical survey and the results of targeted excavations at Kanono, this paper traces the emergence, growth, and abandonment of the village between the mid-thirteenth and early fifteenth centuries CE. It is argued that changes seen in the village relate to the formation of a bounded co-residential community built around unilineal descent, who may have leveraged prestige in iron working into other forms of prestige—namely, wealth in people and access to exotic goods. Approaching the archaeological record at Kanono from the perspective of household archaeology and daily life allows for an evocative “peopling” of south-central African political economies.

McKellop, Robbyn (Wichita State University)**[285]***Assessment of the Boxed Springs (41UR30) Ceramic Assemblage*

Located in the east Texas Pineywoods, Boxed Springs (41UR30) is a lesser-known Early Caddo mound center characterized by a diverse and distinctive archaeological assemblage. Recently, Wichita State University has been granted permission to access the eastern portion of the site which was previously restricted. Excavation findings during the 2021 and 2022 field seasons are thus far consistent with prior assessments of the ceramic assemblages at Boxed Springs and other contemporaneous sites. To facilitate this research, the ceramic assemblage was assessed for attributes such as raw material use, temper, atmospheric firing, surface treatment, decoration, form, and ware type. These attributional features were then compared to previously known and established ceramic assemblages in the greater Caddo area. By identifying such features, we are able to further our understanding of the Early Caddo lifeways and technological adaptations.

Mountains of Manure: Assessing the Botanical Potential of South Indian Neolithic Ashmounds

The Neolithic of southern India is notable for features known as Ashmounds, large accumulations of fired and often vitrified cattle dung. First described in the late nineteenth century, the dung-based composition of these impressive features was clearly established by the mid-twentieth century. To date, however, no botanical analyses of Ashmounds have been carried out, notwithstanding their potential to reveal aspects of regional vegetation, livestock forage, and climatic conditions. We report here on preliminary assessment of the potential for pollen and phytolith analysis of ashmound material, using newly collected samples from the site of Brahmagiri, in northern Karnataka.

[286]

Design, Construction, and Evaluation of a Solar-Powered Mechanized Flotation System

Flotation remains one of the most important methods by which paleoethnobotanists recover botanical remains from archaeological contexts. However, logistics in the field can make supplying mechanized flotation machines with water (and subsequently powering motorized pumps) a challenge. This poster details the process by which we utilized bilge pumps, batteries, and solar panels to construct a mechanized flotation system that operated with a natural water source and the power of the sun. We describe the installation and operation of the system in the field during the Taraco Archaeological Project 2022 and 2023 field seasons and also examine the effectiveness of this system through an analysis of recovery rate and operation time compared to a gas-powered motor set up, operated during the same field seasons. Finally, we discuss the advantages and disadvantages of the system we used, and provide recommendations regarding the construction and operation of similar systems from this experience.

Coastal Trade: The Ancient Maya of Belize

The sea was important to the ancient Maya as a source of ritual paraphernalia and seafood, as a transportation and trade route, and as a desirable place of settlement. The coast of Belize includes hundreds of cays within the second longest barrier reef in the world and a coastline with navigable rivers connecting the sea to the heartland of Classic Maya civilization. However, sea-level rise flooded ancient coastal communities leaving them buried on land under mangroves or underwater, making them invisible in the modern landscape and diminished in view in the archaeological record. The known record of ancient coastal settlement in Belize extends from about 600 BC in the Middle Preclassic through the Postclassic. In this paper, we highlight coastal research by Maya archaeologists. We focus on research by the senior author on Wild Cane Cay and our ongoing research at the Paynes Creek Salt Works. The paper underscores the significance of coastal settlement and sea trade, the significance of salt and other marine resources from the Caribbean coast of Belize to the interior, and the endurance of the coastal Maya of Belize after the Classic Maya collapse.

Wetland Soils and Ancestral Menominee Maize Agriculture in Michigan's Upper Peninsula

Today, the dense forests of the northern Great Lakes seem an unlikely place for expansive ancestral Native American agricultural fields, especially ones dedicated to sun-loving crops, like maize. The short growing season in these northern climes, dense forest, alternative staples like wild rice, and past settlement history all would suggest a limited production of maize. However, our recent drone lidar survey documented expansive fields in Michigan's Upper Peninsula, challenging long standing conceptions of the intensity of maize agriculture. Here, we describe our ongoing efforts to document the expansive raised fields at the threatened Sixty Islands archaeological site in Michigan's Upper Peninsula. These fields were constructed with organic-rich wetland soils, illustrating the prowess of ancestral Menominee farmers to overcome the environmental challenges of these northern latitudes and the critical way that wetlands are utilized in intensive farming.

Digital Technologies in the Periphery of the Ancient Maya site of Lamanai, Belize

Threats to ancient Maya cultural heritage sites—from modern construction, looting, agricultural intensification, and burgeoning tourism—are an ongoing challenge in Belize. This is especially true of the northwest region of Belize, in the periphery of the well-known site of Lamanai, which has been hard-hit by looting and a growing community of farmers who clear parcels of land with heavy machinery. Recognizing that traditional paper-based recording methods are often slow with inconsistent results across multiple users, and therefore unsuitable for rapidly recording data from sites at immediate risk of damage and destruction, the Coco Chan Archaeological Research Project implemented a digital recording strategy during their investigations in Lamanai's periphery. This presentation will provide an overview of the different technologies used by the project, which included a digital software called STRATUM to record field information (developed by a team of researchers at the University of New Brunswick). iPad Pros with light detection and ranging (lidar) scanners were also used to create 3D models of excavation units and cultural features. Additionally, drone photography was captured using a DJI Mavic 3 and images were processed via photogrammetry into 3D and digital elevation models (DEM) of the landscape using Agisoft Metashape.

Plan de las Mesas, Copan, Honduras: Teotihuacan Is in the House

The Plan de las Mesas archaeological site rests high above the Copan Valley, 2.5 km northwest of the Acropolis. Inhabited by at least the Preclassic, evidence suggests that it functioned as a defensive fortress, or citadel, by the Early Classic period. This paper focuses on Group 1, Plaza B, and Group 12. Group 12 rests on a long platform with a direct view of the Copan Acropolis. Its structures were likely both domestic and defensive, housing warriors and their families. Nearly 8% of the obsidian found at this site is Pachuca from the Sierra las Navajas source, including Pachuca projectile points. Plaza B, created by filling in a space between two hills, rests up a steep incline from Group 12. It functioned as an important ritual space, a gateway to other parts of the site, and a repository for large volumes of ritual debris that cascaded down onto it from Plaza A. Structure 7, excavated in the 2023 field season, combines Maya practices found in Copan along with ritual behavior hailing from Teotihuacan. This archaeological site represents an unparalleled opportunity to learn about the processes of political interaction between Teotihuacan-backed Maya and the local population.

Trans-species Archaeologies and Ritual Bone Deposits: Respecting the Animal Ancestral Dead

Although created by people, marine mammal bone (e.g., whale, seal, dugong) ritual installations on land and in the sea are also expressions of marine mammal agency given that the sites are materializations of a social and moral contract centered on mutual respect and reciprocity. These sites are as much a part of the sentient, social, and spiritual world of the hunters as they are of the sentient, social, and spiritual world of the animals hunted. Hunters know that unless they treat marine mammal bones with respect and construct formalized and highly structured installations using the bones, especially skulls, of their prey, that their relationship with the marine mammals will break down and result in hunting failure. In other words, marine mammal bone installations were constructed by people for people but also, critically, for marine mammals. Marine mammal bone installations blur the boundary between the archaeology of humans and the archaeology of animals. These installations encompass a trans-species archaeology of human and animal agency that extends recent ideas on “multispecies ethnography.” They also require us to ask the radical ontological question of “What do marine animals think of the installations comprising the bones of their ancestral kin assembled by hunters?”

Blockade to Stockade: Blockade Runners, Globalization, and Confederate Supply

During the American Civil War, Glasgow-built blockade runners emerged as crucial supply conduits to the Confederacy, prolonging the conflict and sustaining chattel slavery by clandestinely running cargo into Confederate ports. This paper delves into the historical archaeology of blockade runner cargos, an area

relatively unexplored beyond shipwrecks. It investigates the material culture carried as cargo beyond munitions to explore luxury and mundane items that provided a sense of normality amid conflict. Through an analysis of archival records and material culture, market demands and choices were unveiled, shedding light on the role of these vessels in supplying non-combat necessities. By comparing artifacts recovered from Confederate and POW areas at Camp Lawton (9JSI), which held Union Prisoners of War outside of Millen, Georgia, the research establishes a direct link between supply lines and terrestrial sites in the South. And the flow of supplies into the interior of the Confederacy along rail lines from the open port of Wilmington, North Carolina, to Millen, where it passed into illicit markets utilized by guards and POWS inside the stockade. Ultimately, this research illustrates global connections between the Confederacy, Glasgow, and the 1860s economic boom rooted in enslaved labor, despite Britain's earlier abolition of slavery.

Bleeding in Limbo: Health, Tasks, and Ritual in the Liminal Spaces of Prehistoric Menstruants

The cycles of menstruating bodies have long been characterized in terms of impurity, pathology, and socio-spiritual threat both outside and within the field of archaeology. My research makes use of the archaeological record and existing literature to shed light on the experiences of women and menstruants in prehistory outside of these typically assumed conditions and illuminates archaeological sites where primary research may help further our understanding of women's health, experiences, and liminal spaces both in antiquity and contemporary society. Looking at physical spaces, material production and taskscapes, and the social impacts and functions associated with rituals of menarche, menses, and the stages of pregnancy, this work develops a preliminary understanding of women's liminal spaces in prehistoric Scandinavia, the Americas, and the Ancient Near East. Topics explored include the mitigation of perceived impurities associated with menstruation through forms of isolation, ritual purification, and behavior limitations; specific material production pursued in liminal periods and spaces related to menstruation and pregnancy, such as fiber arts and medicine; and dwelling structures specifically designed for women and menstruants' repeated isolation or temporary habitation.

Traditional Sports in the Sonoran Desert of Arizona

The O'odham of southern Arizona continue to participate in traditional sporting events, and a variety of organized competitions are still held today. Although they are one people, the O'odham are currently organized into four Communities, which are collectively known as the Four Southern Tribes. People in each of these communities still practice traditional sports, although the degree of participation varies, with women generally more active than men. We report the results of a questionnaire given to members of the Four

Southern Tribes regarding interest and participation in customary O'odham sporting events. These ongoing practices include games such as Toka, which is a highly competitive sport that is played with sticks, and is exclusively practiced by women. This information is then compared with ethnohistorical and ethnographic observations regarding athletic competitions in the southern Southwest. These data are in turn used to make inferences regarding prehistoric sports, which are difficult to infer based on archaeological information alone.

[198]

Reconstructing Utah's Indigenous Maize Farming Niche

Maize (*Zea mays*) was one of the most widespread domesticated plants in the Americas before European colonization. Despite its widespread distribution, explaining how and why ancient maize farming spread into Utah remains a central research question in Southwest archaeology. To understand how ancient maize spread, we need a comprehensive suitability model for maize agriculture using multiple ecological variables that accurately predict where maize farming was suitable and unsuitable. For this presentation, we have constructed a species distribution model (SDM) for maize, using a novel machine-learning approach called Random Forest, to produce a suitability model for Indigenous maize agriculture in Utah (ca. 3200–500 BP). Furthermore, this research builds on ecological theory recently applied to archaeological data by utilizing the ideal free distribution (IFD) model to explain the changes in behavior and settlement patterns observed in the archaeological record. Comparing locations best suited for maize agriculture, determined by the SDM, with well-dated Indigenous maize farming sites will test the predictions of the IFD model and help explain Indigenous maize farmer settlement patterns throughout the northwestern limit of maize agriculture.

Las reinas de la selva

El códice maya de Madrid, muestra aspectos de la vida cotidiana de los mayas, uno de ellos la meliponicultura, producción de las abejas sin aguijón. En el Puuc, la meliponicultura es una práctica desarrollada de manera secundaria después de la milpa maya, complementando el ingreso campesino; más recientemente la producción de abejas apis ha cobrado mayor espacio, por su alto rendimiento productivo y valor de mercado. Ambas, son una forma de conservar los recursos y las creencias. En la Reserva Biocultural Kaxil Kiuc, la meliponicultura se ha dado desde el asentamiento de los primeros pobladores, aprovechando las fuentes cercanas de agua como como jaltunoob y aktunoob, a la par que han mantenido la biodiversidad florística, logrando así al varias temporadas de miel. Actualmente la Junta Intermunicipal Biocultural del Puuc, ha promovido la profesionalización de esta actividad con grupos de mujeres mayas, desarrollando capacidades y la elaboración de subproductos, promoviendo el autoconsumo, acceso a mercado a con la marca Origen Puuc. La apicultura y en especial la melipoicultura, es una de las formas de resiliencia ante las crisis ambientales, económicas y sociales que se están dando en la Región Biocultura del Pucc, además de la conservación de la identidad y bioculturalidad.

Archaeology for Many More: A Necessarily Broad Approach to the Archaeology of Evergreen Plantation
 The Evergreen Plantation Archaeological Survey (EPAS) focuses on understanding Black life during contexts of enslavement and post-emancipation on Evergreen Plantation within Louisiana's Cancer Alley. In summer 2023, EPAS hosted its first interdisciplinary field school in which students not only learned archaeological methods but also undertook a diligent survey of Black culture and literature through two other organized courses. In this presentation, we lay out the ongoing and theoretically rich considerations in the making of this project that inherently encompasses more stakeholders, such as establishing the scale of analysis, defining descendant communities for plantation sites generally, and more.

End of the Line: Tikal's Final Ceramic Phase
 In the latter half of the nineteenth century the ruins of Tikal were briefly reoccupied. Refugees fleeing the Caste War of Yucatán cohabited with Lacandon Maya from the surrounding jungles and heavily Hispanized Itza Maya from the lakes of central Petén, Guatemala, to form a small multiethnic hamlet among the hulking ruins of the ancient Maya city. While the village was largely provisioned with cheap globally produced consumer goods from Great Britain and the United States, the most numerous artifact type discarded or abandoned by the historic villagers was a locally made ceramic ware. These ceramics were likely made in San Jose, on Lake Petén-Itza, where ceramic production continued well into the twentieth century. Tikal Project ceramicist Patrick Colbert assigned Tikal's final ceramic phase, the Caban ceramic sequence, to the Early Postclassic (AD 950–1200) but stated that it is "poorly defined," and it remains poorly understood today. This presentation explores Tikal's Caban ceramic phase and offers an introduction to the historic ceramics of Tikal, which potentially make up a large portion of the Caban ceramic assemblage. While focusing on Tikal's ceramics, this study begins a regional analysis of historic nineteenth-century ceramic traditions of the Petén and surrounding area.

Archaeological Evidence in the Caves and Cenotes of the Yucatán Peninsula, Mexico
 Since prehistoric times, the caves of the Yucatán Peninsula have been the locus of regular visits by animals but as well by the first humans populating the continent. Thousands of years later, the Maya culture would establish its cities around the cenotes and the few bodies of surface water. The Maya culture has developed over the centuries methods for the control and storage of water, and a system of rituals related to the underworld, where the caves and cenotes were the main scenarios. For more than seven decades, these paleontological, archaeological, and historical contexts have been identified and recorded. In this lecture, we will summarize and analyze these investigations by contrasting the archaeological evidence diachronically and linking them to the successive changes in climate occurring in the region.

The Pottery and the People of the Pethick Site in Schoharie County, New York
 In the summer of 2014, the New York State Museum Cultural Research Survey Program and the Anthropology Department at the University at Albany undertook the excavation of the Pethick Site. An archaeological field school was organized for the detection and study of the site's Native American features associated with an agricultural village. Through the efforts of students and professional archaeologists,

hundreds of Native American artifacts were found in addition to historical ceramics, glass, brick fragments, pipe stems, and metal nails. The Pethick Site produced about 58 sherds of pottery related to the time after the arrival of Europeans to the New World. The date ranges for these ceramics goes from the early 1700s to the mid-1900s. The countries that could have made these ceramics include the United States, Germany, the Netherlands, Scotland, and England. While this project was originally undertaken in the hopes of shedding some light on the first European occupation of the Pethick Site, it has become apparent that the ideal way of studying the development of nationality and identity in an archaeological context would be to look into regional history, economy, and consumption patterns.

Normalizing Culturally Informed Collections Stewardship

Culturally informed stewardship takes a holistic and culturally inclusive approach to the preservation, access, and use of cultural items, records, and images. It acknowledges that curation and care are political acts and that the stewards of cultural collections must do more than simply consider the autonomy, expectations, and requirements of originating communities, but work to privilege Indigenous perspectives. Museum, conservation, and originating community stakeholders have advocated for culturally informed collections stewardship for decades, but it has only recently emerged as best practice. This presentation offers an overview of the trajectory of cultural care, shares the challenges of implementation at a small academic anthropology museum, and highlights training needs and opportunities at the Center for Collections Care at Beloit College.

Scout's Honor: Archaeological Stewardship of Rural Spaces with the Boy Scouts of America

Archaeologists working in isolated rural locales continue to face the challenge of protecting archaeological sites from threats of looting and vandalism. Whether physically secluded beyond a watchful eye or simply located on private lands with few legal protections, sites in these rural spaces are at particular risk for damage or (un)intentional destruction. Nationwide scouting organizations such as the Boy Scouts of America (BSA) present a unique avenue to physically bring together disparate rural communities and build lasting relationships with an eager to learn audience. Scouting groups are powerful potential allies in promoting stewardship values and practices as archaeological ambassadors in their own rural communities. Based on recent fieldwork experiences in Monroe County, Illinois, this poster illustrates the Southern American Bottom Archaeological Project's (SABA) partnership with Camp Vandeventer to host an inaugural Archaeology Merit Badge Day in our 2023 field season. Here I discuss unique considerations, challenges, and potentials for such engagement in promoting enduring community partnerships and stewardship practices among rural youth and their guardians.

A Macroscopic Investigation and Analysis of Trauma among Late Post-Medieval Adult Male Individuals of St. Michael's Litten, Chelsea Old Church and St. Benet Sherehog

In post-medieval England (1500s–1800s), the rise in industrialization and urbanization provides an opportunity to analyze a potential glimpse of how adult male individuals lived daily life in England. This study looks at the potential etiological factors, types of trauma observed and found in the three selected dataset cemeteries of the Chichester Skeletal Assemblage, Chelsea Old Church, and St. Benet Sherehog. The results presented that the most common type of trauma among adult male individuals concluded being accidental trauma followed by intervertebral disc herniations (also known as Schmorl's nodes), with equal and proportionate amounts of the number of individuals from the cemeteries being greatly afflicted with work-related and accidental trauma. The least prevalent, yet present in all cemetery datasets of traumas was interpersonal violence, followed last by surgical interventions in which no individuals from the Chichester Assemblage that were selected from this set presented evidence of medical or therapeutic intervention. Overall, the results shed light on the effects of the impact that diverse work conditions, economies, and lifestyles had on adult males. This study can be further expanded to more geographical areas, cemetery populations, time periods, and demographic groups.

Assessing Variability in Refitted Lithic Reduction Sequences at Boker Tachtit (Israel)

Distinguishing cultural relatedness from independent convergence in lithic technological behavior requires high-resolution behavioral data. Arguably, the best source of such high-resolution data comes from refitted reduction sequences because these sequences illustrate the procedural steps taken by individuals to produce stone tools. But much remains to be understood about the degree of variability in production that is possible among individuals within a single population (i.e., shared cultural environment). Before one can assess the degree to which something is “culturally related,” one must identify the range of acceptable variability. Simply put, what is “different” enough to be considered culturally unrelated? This project first measures variability within a single occupation utilizing refitted lithic reduction sequences from the earliest occupation (Layer 1) at Boker Tachtit, an Initial Upper Paleolithic site in the Negev (Israel). Secondly, once a range of variability has been established for a single occupation, I assess the likelihood that subsequent occupations (Layers 2 and 4) produced tools in a culturally similar manner by an iterative comparison of individual nodular reductions (as proxies of an individual's learning environment) within and between occupations to produce a quantitative measure of variation that falls within/outside of the range observed within the first occupation.

Beans of Power: Phaseolus and Late Preclassic Rulership on the Pacific Coast

Rulership in Mesoamerican societies was inextricably tied to generative aspects of agriculture. Becoming a

focal point for the maintenance of cosmological order provided a pathway for asserting control of aspects of the natural world, like rainfall, that directly influenced agricultural productivity. Textual descriptions even associate the process of coming into power with sowing, and the maintenance of that power with cultivation and growth, including an aspect of verticality that is conspicuously vegetal. Discussion of this special relationship between royal power and agriculture has largely centered around maize and cacao. I introduce a time and place for which an early exercise in rulership coincided with a peculiar abundance of *Phaseolus* beans recovered archaeologically. In comparison to earlier and contemporary contexts from the Pacific coast, the bean assemblage from the Middle to Late Preclassic El Ujuxte site (ca. 600 cal BCE–200 cal CE) is unprecedented in its diversity, including all five domesticated bean species found in Mesoamerica—*Phaseolus acutifolius*, *P. coccineus*, *P. dumosus*, *P. lunatus*, and *P. vulgaris*. I situate this explosion in *Phaseolus* diversity in context with changes in ritual practices associated with the emergence of rulership to consider how these little legumes can enrich our understanding of major sociopolitical changes.

Shelf Life: Addressing the “Curation Crisis” through the Use and Reevaluation of Archival Collection Material

Compared to new archaeological data acquisition by traditional excavation and analysis, research and related funding associated with archival collections remains stagnant and is not proportional to the quantity of data present. This presentation highlights three cases of current research projects associated with the extant collections housed at the Cleveland Museum of Natural History, the Carnegie Museum of Natural History at Pittsburgh, and the Grave Creek Archaeological Complex, Moundsville, West Virginia. The first study leverages public archival records to fill in nationality data missing from the available demographic information for the Hamann-Todd Osteological collection, an essential step for reanalyzing the collection outside traditional racial categories. The second and third case studies showcase novel ceramic analysis techniques that are useful for large extant collections with poor documentation to demonstrate their viability as a reliable data source. The reanalysis in these cases shows that it is not only possible to add new results to existing excavation material, but previous outcomes can be reevaluated using new methods and theory. In all cases, the need for reevaluation of archival material is demonstrated through the discovery of misidentified material and underreported or missing data in published works.

Expedient Lithic Procurement at the Katterfeld Quarry-Workshop of Central-West Patagonia

The study of toolstone procurement in Patagonia is biased in favor of high-quality exotic materials—chiefly obsidian—often transported over large distances as heavily curated artifacts. Lesser-quality sources, however, may be important in the technological behavior at smaller scales (e.g., basin, subregion). The Katterfeld site is a ca. 73,000 m² siliceous shale quarry workshop located in the headwaters of the Ñirehuao River in central-west Patagonia. Its location above the tree line imposes seasonal access restriction. However, it stands as the largest and most intensely utilized site of this kind in the region. Our ongoing research includes the study of the geology of the area, understanding formation processes at a site level (mainly for addressing chronology), and the study of technology and taphonomy of the assemblage. Piece plotting over a 10,000 m² surface has revealed a total of 2,046 lithic artifacts showing the initial stages of lithic procurement, which occurred alongside other activities with short-lived tools. This paper discusses the Katterfeld workshop's record in terms of the expedient behavior represented at the site and

how it is different to other lithic assemblages in the basin/region, thereby highlighting the complementary nature of assemblages in central-west Patagonia.

Aguada Fénix and the Middle Usumacinta Region: An Introduction

Among the many Middle Preclassic sites in the Middle Usumacinta region, Aguada Fénix is, by far, the largest and possibly one of the oldest. A large, rectangular platform was built at its center, measuring 1,400 × 400 m. The construction of this artificial plateau follows the tradition of horizontal monumentality established at the Olmec site of San Lorenzo and contrasts with later forms of monumentality, which are characterized by elevated pyramidal structures. Social inequality at Aguada Fénix appears to have been less pronounced than at other major sites to the west, such as San Lorenzo and La Venta. Unlike those Olmec centers, Aguada Fénix does not exhibit clear indicators of marked social inequality, such as sculptures representing high-status individuals. If these interpretations are correct, they imply that the Gulf Coast Olmec region was not the only center of cultural development and that innovations did not always emanate from the most hierarchical polities.

Tree Resin in Mesoamerican Religion: Blurring Ontological Boundaries in Ceremony and Beyond

Copalli (copal) is an aromatic tree resin and a central figure in Mesoamerican ceremonies. Produced from various species of the *Bursera* genus, copalli is understood as the blood of trees and can be molded into figures or burned into thick clouds of smoke. Copalli is also portrayed as a food substance to be consumed by deities or a medicinal plant for human healing practices. At the Huey Teocalli (Templo Mayor) copalli is one of the most abundant materials in Mexica offering caches. In the Yucatán, hundreds of ceramic vessels of incense offerings were dredged from Chen K'u (Cenote Sagrado), pointing to the powerful presence of pom at Chichen Itza during the Postclassic period. Taking an interdisciplinary approach, this paper examines copalli and related materials (incense burners, altars, pictorial representations, etc.) to better understand the ecosystem of Mesoamerican religion. Specifically, I argue that the ritual consumption of copalli by humans, deities, fire, and water reveals its simultaneous durability and ephemerality while blurring ontological boundaries between plants, food, smoke, and blood. Attention to the presence of this resin in the archaeological record combined with analysis of divinatory codices offers insights into the nature of human and other-than-human relationships in Mesoamerica.

From Carnage to Credentials: An Amerindian Archaeologist's Journey from Child Laborer to Professor Emeritus

After nine months my mother “broke her water” on June 18, 1956. Because my father was away, my mother walked the two hours from Stockton through agricultural fields to the hospital in Frenchcamp where I was

born. Despite my father's herculean efforts, we were caught in a seemingly interminable poverty. Upon entering graduate school at the University of Arizona, I'd already lived in several dozen small towns throughout the Central San Joaquin Valley and had from age 7 through 21 worked as a farm laborer, and for many more years as a "Mexican" gardener in the blistering heat of Bakersfield. At age 12, I was introduced to the works of my Amerindian ancestors in and about Mexico City. From that moment onward, I was smitten by the allure of my Yaqui elders, Indigenous archaeology, and Teotihuacan. As such, this presentation confronts the intersection of my Indigenous and Mexican heritage, familial poverty, and the sense of alienation that largely shaped my career pathway and areas of research and service. This fact has long limited my peer relationships and prompted me to gravitate to the margins of the discipline through a life experience largely left invisible to those about me.

The Treasured Contribution of the Inner Ear to the Study of the Morphological Variation among Ancient Individuals from Brazil

Despite almost 200 years of debate, there are still crucial aspects that we do not fully understand in relation to the evolutionary history of South Americans. One of the major obstacles has been the limited number of available early Holocene skeletal samples with good preservation coming from the same region. In Brazil, there are two areas very rich in terms of the number of human burials from the early Holocene: Lagoa Santa (Minas Gerais) and Serra da Capivara (Piauí). Studies have been aiming at reconstructing the evolutionary history on two fronts: craniometric studies and aDNA analysis, but both have their limitations. In this presentation, we will share the preliminary results of the study of the morphological variation of a promising anatomical structure for reconstructing evolutionary history: the inner ear. We studied a sample of individuals spanning from the early to the late Holocene from different sites and localities in the northeast and central-east of Brazil (Serra da Capivara, Serra das Confusoes, Lagoa Santa, Pedra do Cachorro, Furna do Estrago; N-90). We will discuss the evolutionary implications of the biological affinities described here and propose an interdisciplinary framework for researchers working with human skeletons.

Solar Architecture and the Making of Inca Sacredness

Sunlight has long been curated within religious spaces to imbue them with a sense of sacredness and trigger a spiritual response among worshippers. The Coricancha was considered the most sacred temple in the Inca empire. Located in the capital of Cuzco and dedicated to the sun, this religious center exhibited a simple design in its form and layout. A unique sensorial experience was achieved through metal furnishings attached to the walls which resulted in light performances within the contained space. Made of gold, these reflective attachments not only redirected sunlight but, this material being associated with the sun, also served to summon sacredness, rendering visible the presence of the force to which Inca rulers attributed their ancestral origin. In this paper, I explore how Inca architects manipulated sunlight to center attention on the temple's courtyard and simultaneously impair visibility toward its perimeter. In contrast with the bright courtyard, the interior of the surrounding structures would have remained relatively dark therefore

constituting a more suitable setting to host private ceremonies. Thus, I analyze how the architectural management of sunlight as an ephemeral element played a critical role in the making of Inca sacredness.

Drone-Imagery Sub Project in Hoa Lu, Ancient Capital of Vietnam

The drone-imagery sub project uses drone-based aerial photography and photogrammetry to document the water gates, walls, enclosures, canals, and shrines of Hoa Lu, supplementary to the IRAW@HoaLu settlement and survey research. Amid the urban-landscape development, the cultural and natural features are subject to time. Observation of the valleys and topography beyond the royal city center provides an insight on how people strategically make use of space and boundaries today and in the tenth century CE. This paper presents methodology used to capture the three ring systems, and the postprocessing of large-scale photogrammetry models. The visual guidance of the features bridges technology and preservation in archaeology. Discussion addresses the usage of open-source 3D software, results, and the future research prospects using 3D technologies in northern Vietnam.

Wetlands and Woodland Period Settlement on the Florida Gulf Coast

Most prominent Woodland period ceremonial centers along the Gulf Coast are located near wetlands, which provided access to a wide variety of resources for the hunter-fisher-gatherer populations who built them. Researchers investigating these sites often suggest that these rich environments created the conditions for increasingly settled lifeways, complex social organization, and communal labor projects. In this presentation, I discuss the role that rich and expansive wetlands of the Gulf Coast played in reducing constraints on settlement and enabling a variety of developmental trajectories for Woodland period ceremonial centers.

Integrating GIS and QField for Enhanced Archaeological Surveys in the Maya Lowlands: A Methodological Approach for the El Tigre Project

Archaeological research in the Maya lowlands is marked by its rich cultural heritage and challenging landscapes. Conducting surveys amid dense vegetation presents unique difficulties, which have been exacerbated by remote sensing during fieldwork preparation. To improve our survey methodology, we integrated GIS and QField, an open-source mobile mapping application, for the El Tigre project. This paper outlines our innovative approach, emphasizing the fusion of GIS technology and QField for spatial data collection, analysis, and visualization in the complex Maya lowlands. The objective is to enhance survey, deepening our understanding of the ancient Maya civilization and their interactions with their environment. Our methodology, successfully implemented in the last field season, significantly improved survey efficiency near El Tigre. Key components include comprehensive GIS data preparation, real-time data collection with QField, spatial analysis tools, seamless data integration, and interdisciplinary collaboration. We aim to

contribute valuable insights into innovative survey techniques. Beyond streamlining data collection, our approach promotes archaeological site preservation through detailed digital records. The GIS and QField integration has the potential to transform surveys in challenging landscapes worldwide. Ultimately, this research deepens our understanding of Maya civilization, settlement patterns, and environmental impact while pioneering GIS and mobile mapping technologies in archaeology.

Minnesota's Dugout Canoes

Maritime Heritage Minnesota (MHM) has completed four Minnesota Dugout Canoe Projects that focused on 13 museum-held artifacts and one dugout canoe in situ in Lake Minnetonka. The artifacts were measured, photographed, drawn, and sampled for ¹⁴C dating. Two of the canoes underwent 3D analysis using a handheld scanner and underwater photogrammetry. MHM aligned the dugout canoes into a chronological series of Minnesota's oldest known watercraft, dating from AD 969; this process also determined one canoe dated to 1933. Probable cultural affiliations of the artifacts were determined using relative dating and construction attributes. The Dakota Unfinished Dugout Canoe Wreck in Lake Minnetonka (21-HE-557) was located by MHM volunteer Kelly Nehowig and recorded by video. MHM acquired a Minnesota Phase II Archaeology License to excavate the site in August and September 2021. When located, part of the site was protruding from a mix of silt, sand, gravel, stones, and weeds. MHM contends the exposed portion of the hull was uncovered by propellor washes that continue to put shallow wrecks at-risk. The dugout canoe is not finished and exhibits a variety of tool marks. MHM will present the findings of these projects including dugout canoe structural changes exhibited in the artifacts over time.

Los camélidos en el Ecuador: Estudio arqueológico faunístico y etnográfico

El tema zooarqueológico en el Ecuador sobre los camélidos es muy escaso especialmente en la región, solo algunos sitios reportan dicha especie, especialmente en la Sierra Norte, donde su presencia no es significativa, se presenta como un elemento especial o escaso. Nuestra investigación es entender el proceso de este animal en la prehistoria ecuatoriana, ya que existen muchos hiatos alrededor de presencia de las llamas en los diferentes periodos prehispánicos. Los enfoques para realizar en este trabajo estarán basados en una investigación comparativa de restos arqueológicos con actuales de diversos sitios. Donde a través de estudios básicos zooarqueológicos y posibles análisis de isotopos podremos entender como fue a la interacción entre esta fauna y los seres humanos.

Chavín de Huántar and the Chronology of the Andean Formative Period in Lima

This paper evaluates 113 radiocarbon dates of 11 Formative sites located in Lima and assesses them considering the existing Chavín chronological framework. All dates were modeled using Bayesian statistics through OxCal to reassess the chronological range of the Formative period in Lima, while special attention is put on the site of Ancon and the U-shaped building tradition. I conclude that this tradition was popular between 1500 and 1000 BC (calibrated) and entered a decline process between 1000 and 500 BC (calibrated), which coincided with janabarroid ceramic spread in the central Andes. While the U-shaped building tradition was in decline, sites such as Ancon and Curayacu experience an intense flourishing, represented in the abundance of local and janabarroid ceramics in their archaeological stratigraphies.

[283]

A Multi-instrument Geophysical Survey for the Identification of Preclassic Ritual Deposits at Cahal Pech, Belize

The Preclassic (~1000 BC–AD 300) marked the appearance of increased sociopolitical integration and the emergence of inequality in the Maya lowlands. Over the course of the Preclassic, emerging elites invested in monumental construction projects and consolidated their ritual authority with ceremonial events, which occurred in large public plazas. As one of the earliest sites in the Belize Valley, Cahal Pech has been the focus of archaeological research to understand Preclassic ritual behavior and the establishment of kingship. During the 2019 field season, researchers conducted a multi-instrument geophysical survey of the largest public plaza at Cahal Pech using gradiometry, electromagnetic conductivity, magnetic susceptibility, and ground-penetrating radar. Excavations in 2022 targeted features identified by the geophysics survey, revealing a dedicatory cache consisting of a dense layer of chert flakes and debitage. Radiocarbon dated to 780–400 cal BC, this feature represents one of the earliest examples of a ritual lithic deposit from the Belize Valley. Our results illustrate the success of geophysical methods in locating ritual features in Maya plazas. Additionally, excavation data suggest that placement of caches likely played an important role in the development of the leadership strategies that persisted through the Classic period.

Low-Tech in a High-Tech World: Teaching the Past to Shape the Future

For several million years our ancestors used tools to shape their world, and themselves. Some argue we have lost our way, as artificial intelligence and machine learning has reshaped the fabric of society. Our postindustrial, capitalist mode of production resulted in a nearly complete detachment from the sociocultural, environmental, political, and economic context in which things are produced. STEM-based solutions involve

greater investment in rare earth minerals and exploitative labor practices that have already driven the world into an anthropogenic doomscape we call the Anthropocene. Extinction rates are accelerating—not only of biota but also of lifeways. Included among these are the “traditional” skills and handcrafted technologies that offer a more balanced relationship between people and our world. Experimental archaeology and a craft-based pedagogy provides a mechanism to revitalize the low-tech lifeways that offer the potential for more sustainable futures. This presentation highlights the work currently being done at HEARTH—Hand-crafted, Experiential Archaeological Research and Teaching Hub. This unique public-facing facility, set within the SUNY system, not only prepares students for careers in archaeology and historic preservation but also encourages them to reconceptualize the relationships and systems that they want to be a part of.

Isotopic Investigations into Dietary Patterns of Early Medieval Communities in Thuringia, Germany

The Early Medieval period in Central Europe was a time of pronounced socioeconomic differences, as well as sociopolitical unrest. While the former Roman infrastructure was deteriorating, the costs of importing foods and other material goods into Thuringia increased, exacerbating differences in food availability between the various sectors of society, varying with individual and/or family wealth, and increasing the dependence on locally grown food for the general population. Using carbon and nitrogen isotopic ratios from long bone collagen (largely femoral or tibial diaphyses), we investigate the relationship between diet (animal protein consumption and reliance on C₃ vs. C₄ plants) and biocultural parameters: social status (indicated by burial goods and funerary practices), sex, and age in two Early Medieval communities from Thuringia. The sample consists of 79 individuals from Großvargula and Boilstädt, two nearby sites dating to the Merovingian period, and encompasses both males and females, as well as individuals of different ages. These cemetery sites show marked variation in the quality and quantity of burial goods among the interred individuals, suggesting a representation of different societal strata of the community, and allowing for a test of whether a higher or lower socioeconomic status affected dietary patterns within these communities.

Ending at the Beginning: Excavation of the Louis Beaudoin Site

In 2013 while conducting an archaeological survey for proposed interstate improvements, archaeologists with the Missouri Department of Transportation identified the remnants of an eighteenth-century French-style house. The identification of several post-in-earth wall trenches and a handful of period artifacts was monumental and changed the entire direction of the archaeological investigation. Over the subsequent years,

five additional French homes were identified and excavated, producing an ever-increasing amount of material and information. In 2018, during the final stages of the project and using lessons learned over the past five years, archaeologists returned to the Louis Beaudoin site to finish up where everything had started. A change in methods and approach not only produced a blizzard of late eighteenth- and early nineteenth-century artifacts but also identified the near-complete remains of the Beaudoin house. Prior conclusions concerning building construction and site use were set aside as new data demonstrated how the Beaudoin property differed from others in St. Louis and from comparable communities in Upper Louisiana.

Methods of Geophysical Testing

The Lockhart cemetery is located within the Missouri Army National Guard's Macon Training Site, Macon, Missouri. The cemetery is located within the eastern half of Site 23MC1586, a site recorded within the northwest section of the Macon Training Site. The western half of the site has foundation remains with historic deposits dating to the mid-nineteenth century. Utilizing archaeological surveys, historical records, and geophysical surveys, the project speculated that unmarked historic graves were located outside of the marked historic cemetery boundaries and that the marked graves had never been exhumed from the military property. This paper will discuss dual methodologies for geophysical surveys and its results for identifying marked and unmarked historic graves within the radius of the Lockhart Family historic cemetery.

Citizen Science and Paleolithic Art: Investigating the Visual Psychological Background to 15,800-Year-Old Engravings Online

We present findings from our Citizen Science-focused project that combines Pleistocene archaeology, traceology, and visual psychology experimentation to offer new perspectives on Ice Age art. Our project visually explores the content and wider context of the 15,800-year-old German Gönnersdorf/Andernach Upper Paleolithic engraved plaquettes (portable schist), which feature depictions such as female-like anthropomorphs, mammoths, and woolly rhinoceros. Here, we will showcase our Citizen Science project website, which engages the wider public in visual psychological experiments, including webcam eye-tracking when inspecting Upper Paleolithic art. One of our experiments tests participants' susceptibility to pareidolia, a phenomenon that makes our eyes (brains) see things that are not physically there. Another lets people place art onto a blank plaquette canvas at a place of their choosing, which is then compared against the corresponding archaeological record. Our overall data from these studies reveals how participants with different sets of backgrounds, such as total novices (no experience with UP art) and those that consider themselves Ice Age Art "experts," perceive and engage with artistic markings of the past. Collectively, they enable us to shed new light onto our perception and the holistic function of Ice Age art.

Economy of Production: A Theory of Household Labor Organization and Material Reuse

Although studies of household economies in archaeology are abundant, one area that has not been examined

is the economic use of materials, space, and labor and how this affects household economy and organization. Understanding how culture define thrift and waste would help us understand household economies more precisely. Related, many household domestic economies are managed by women. Examining how women within these economies adhere to cultural definitions of thrift and waste allows for a more complete understanding of gender relations in households and recognizes the importance of women's labor in household economies. In this paper I argue household economies need to be examined for economic uses of materials, space, and labor, and identification of such economic use in archaeological contexts is possible. I show that women engaged in a culturally defined economy within one particular household engaged in craft production at a southeastern Mississippian chiefdom. Through an economic use of materials, space, and labor, the inhabitants of this household increased their power over time. In examining material evidence of an economy of production archaeologists and anthropologists can more specifically identify the focus of household economies and cultures as a whole and the role of women in those households and cultures.

Forest Resources at Calakmul Based on Modern Forest Surveys and Lidar Assessment

Forest resources supported a sizeable population at the Maya city of Calakmul for centuries. This study addresses questions about maximum potential carrying capacity based on aboveground biomass (AGB) production and the diversity of ethnobotanically significant forest species. AGB of the modern forest was calculated by both modern vegetation surveys and lidar returns. Because sectors within the forest varied in AGB, a spectral classification of satellite images was used to determine distribution of vegetation communities. The forest resource extractive zone of Calakmul, the area where inhabitants would have collected wood for fuel, timber, and other essential resources, was defined by a Voronoi diagram based on archaeological settlement data. The Voronoi diagram was superimposed over satellite images to determine the total AGB for the resource extractive zone. Based on forest growth data, pollen profiles revealing ancient forest clearance and assuming sustainable wood consumption, AGB available for annual consumption was estimated. In addition to wood, inhabitants would have relied on the forest for food, medicine, and other essential needs. An assessment of species composition and prevalence of ethnobotanically significant woody species in the modern forest revealed a broad spectrum of non-timber forest products likely available to the ancient Maya.

Weaving a Complex Past—Longobards in Italy: A Population on the Move in the Early Medieval Times

The migration of the Longobards to Italy represents one of the most significant events of the Early Middle Ages regarding the sociopolitical unity of the peninsula. As reported in *Historia Langobardorum* by Paul the Deacon, in 568 CE, Longobards crossed the Italian boundary to occupy its territories. From this moment, the interaction with the inhabitants and land use began. The necropolis of Povegliano Veronese (northeastern Italy) dates to the first phases of the migration and the following one, namely between the sixth and the eighth centuries AD. The skeletal collection will be defined as a biological archive that registers the biological and cultural biography of a population. From this perspective, the bioarchaeological investigation examines levels of considerable complexity within our understanding of past societies. Following the methodologies

present in the literature, the social environment of Povegliano Veronese will be discussed based on the health status (paleopathological analyses; i.e., osteoarthritis, metabolic and oral diseases) and multi-isotopic analysis (diet and mobility). The results will point out the consequences of economic and social differences to the important role of economic inequality in defining disease and diet variability outcomes. The presentation will not contain images of human remains.

Multiple Clovis Occupations at the Belson Site: New Data for Testing Foraging Models from Southwest Michigan
Excavations at the Belson site in southwest Michigan have revealed at least two stratified Clovis occupations below the plowed deposit. These data provide a rare opportunity to test foraging models against data from each occupation. With lines of evidence such as chert sourcing, technological analysis, and proteomics, we can begin to understand how foraging behaviors may differ or remain consistent from year to year. Initial sourcing of chert via minerals and microfossils, indicates that people are procuring resources from as far as 600 km to the south; however, by far the most common chert in the Clovis deposits is from Attica, Indiana, about 280 km south. Initial study of ancient proteins from chert tools suggests a broad spectrum foraging behavior, with four different taxa identified on three tools, providing evidence against the traditional model of being megafauna specialists. Future analysis will focus on more rigorous model testing and formulation, including data from additional excavations.

A Sacrificial Graphic Pattern? Analysis of the “Curved Like Obsidian” Pattern in Images of Itztlacoliuhqui and Other Nahua Gods

The aim of this paper is to analyze the meaning encoded in the “curved like obsidian” graphic pattern present in the cap and face of Itztlacoliuhqui, the Nahua god of frost. Though supposedly it is a pattern that encodes “obsidian,” the sacrificial obsidian knives are painted in a different way. On the other hand, some more deities or beings have the same pattern painted on their faces, so, according to the rules of the construction of gods in prehispanic central Mexico, it indicates that they share common feature(s) or function(s), that in this case seems to be connected with sacrifice. Itztlacoliuhqui is also a sacrificed god, and one of his manifestations is in the form of a mortuary bundle. The meaning of the pattern and related subjects will be explored mainly on the basis of analysis of representations of gods in divinatory Central Mexican codices, particularly in the so-called Borgia Group.

NAGPRA 2.0? Comparing the Proposed Rule to the Law

On October 18, 2022, the Department of the Interior published the Proposed Rule (87 FR 63202) seeking to revise the Native American Graves Protection and Repatriation Act (43 CFR 10). Modifications include the introduction of clearer timelines and terminology, an emphasis on forthright and effective consultation with stakeholders, and addressing problems identified in the 1990 NAGPRA law (87 FR 63202). This poster will outline and compare the 1990 legislation and the 2022 Proposed Rule, while considering the potential outcomes of the changes. A clearer understanding of the major changes within the Proposed Rule on the implementation of NAGPRA is essential given the prevalence of NAGPRA cases across the US that remain unresolved for issues like, “culturally unidentifiable” objects. Finally, the presentation provides the opportunity to participate in student-led survey research focusing on real or perceived barriers in NAGPRA compliance. No human remains will be included in this presentation.

Choose Your Weapon: Material Selection for Middle Pleistocene Spears

The earliest archaeological weapons consist of one-piece wooden spears and throwing sticks from the Middle Pleistocene. These earliest weapons were made by late *H. heidelbergensis* and/or early *H. neanderthalensis* and were crafted from coniferous wood from at least 400,000 BP. They are typically associated to large prey, but the throwing sticks represent the technological capability to hunt smaller terrestrial and avian fauna.

Preserving only in exceptional contexts, they highlight the significance of organic materials for early weapons. In Africa, stone points were thought to be used to tip spears as early as 500,000 BP, while in Eurasia they appear as early as 230,000 BP. Yet, wooden spears are not replaced by stone-tipped weapons and continued to be used for hunting and violence. I will share preliminary results of an archaeological review of evidence of Middle Pleistocene weapons including stone points thought to tip spears, associating sites with data ecology, climate, and prey. The innovation of the use of inorganic materials for weapons, alongside persistence of organic materials pose not only “economic” questions but also those concerning social and ideological relationships between these early humans, their natural environments, materials, and prey.

Millán-Pascual, Rafael (Institute of Heritage Sciences [CSIC])**[28]***Landscaping against the People: An Archaeology of the Francoist Industrial Forestry in Spain*

In this contribution we combine landscape archaeology and the archaeology of the contemporary past to critically rethink the material, social, and ideological effects of the industrial forestry developed by the dictatorship in Spain. This case is a particularly relevant example to reflect on how the transformation of the landscape is one of the most durable and successful resources at hand for totalitarian regimes in order to modify the memory of their social, political and material consequences. The industrial forestry was part of large-scale operations developed by the Francoist regime in his quest for the material construction of his ideal Spain. That resulted in the transformation of extensive rural areas where the people was literally changed by trees. The progressive rising of the pines converted many villages into a forest, destroying its historical landscape and concealing its remains. Today, the forestation process reveals its strategic functionality for the dictatorship in the long term, since the forestry policy is one technique of “naturalization” of old peasants’ places and so of the political actions that changes those lands. We will see how the industrial forestry was here an agent of forced migrations, the abandonment of lands as much as one way of oblivion.

Miller, Bryan (University of Michigan)**[23]***Discussant***Miller, Bryan (University of Michigan)****[56]***States of Mobilities: Nomadic Institutions as the Foundations of Large-Scale Polities*

Theories surrounding the rise of complex polities have long hinged upon large urban centers, fixed infrastructure, and the centrality of agricultural economies, leaving any societies without these as incapable of creating stable large-scales collectives that one could call a state. Taking the case of the first steppe empire, the Xiongnu (ca. 200 BCE–100 CE), this paper argues (1) that pastoralism can be a stable economic basis for a political economy and can provide institutional foundations for intensification of production and the maintenance of surplus, and (2) that mobility, being a strategy for community adaptability in response to shifting ecological or political circumstances, was not the antithesis of governance but rather could foster large-scale communication, exchange, and mobilization of resources to adeptly overcome the purported tyranny of distance. I propose a concept of states of mobilities, in which the political economies that bolstered these regimes hinged on the control not so much of static territories of resources but more so of the movements of numerous and diverse resources, including raw materials, labor, products, soldiers, administrators, and knowledge.

Belongings as Archives: An Abundant Approach to Sugpiaq Archaeology

The historian Tiya Miles argues for an abundant approach to history, in which researchers learn to excavate absences in the historical record instead of allowing those silences to stand. *Belongings* (a.k.a. artifacts or objects) are additional archives that contain the stories, energies, and contexts in which they were made and used. As part of my work with the Old Harbor Archaeological History Project (OHHP), I use object-centered vignettes as an abundant approach to the recovery of Sugpiaq stories from the Russian colonial period in Alaska, which lacks documentation from a Sugpiaq perspective. OHHP is a community-based participatory research program exploring the strategies of persistence and survivance among Sugpiaq communities in the southeastern Kodiak Archipelago during the period of Russian colonialism. Here I present close examinations of ulus, beads, and a ceramic vessel alongside standard analyses of artifact assemblages from the Ing'yuuq site to interpret the lifeways of Sugpiaq ancestors during this tumultuous period of their history. While Sugpiaq ancestors faced immeasurable loss due to Russian colonization, these combined analyses of belongings show how they also leaned on each other for support, created well-crafted tools and adornments, made families, and maintained their relationships to land and sea.

Detection of Yellow Fever Virus in Human Remains Using Mass Spectrometry-Based Protein Analysis of Dental Pulp

The goal of this project was to determine if the yellow fever virus (YFV) could be detected in historic remains by analyzing the proteins found in the dental pulp of the remains. Typical YF diagnostic techniques rely on blood or liver tissue so when these tissues are not recoverable, YF detection is currently limited. In order to meet the objectives of the study, a retrograde collection method was used to extract dental pulp on modern teeth and will be used on teeth from a known yellow fever victim and teeth from a historical cemetery site. The three different populations serve as a negative control, positive control, and the unknown population for the purpose of yellow fever detection, respectively. Following the dental pulp extraction, the pulp was subject to a protein extraction methodology and was analyzed via liquid chromatography-mass spectrometry (LC-MS). The aim of using mass spectrometry technology is to detect both blood proteins (to validate the dental pulp extraction method) and to detect YF specific proteins (with the capsid protein being the primary protein of interest). If YF fever specific proteins are detectable in the dental pulp, this research could prove valuable for the fields of archaeology and paleomicrobiology.

[337]

A Low-Cost Method for Measuring Ridge Width on Lithic Artifacts for the Purpose of Evaluating Artifact Condition

To reconstruct the life history of an artifact one must understand how the tool was made, used, but also what happened to the artifact after it was discarded. For stone tool analysis, evaluating lithic artifact condition helps reconstruct this life history through insight into site exposure, assemblage integrity, and postdepositional processes. Multiple studies have used ridge width on lithic artifacts to determine artifact condition for several different raw materials. Presented here is a method for measuring lithic artifact ridge width using digital microscopy and Adobe Photoshop. This method is a cheap and quick way to evaluate artifact condition on single artifacts, and at an assemblage-level could prove useful to researchers traveling overseas or packing lightly for the field. It would also be useful for archaeological laboratory technicians, cultural resource management firms, students, and those who cannot afford more expensive research methods.

Riparian Protection and Restoration as a Necessary Mitigation Practice

When looking at the cultural landscape archaeological surveys often only consider the direct effects that construction projects have on observed cultural resources. Secondary effects such as erosion from construction activity, building usage, and waste deposition are often ignored. Disturbances to the seven aspects of site integrity often ignore effects that occur outside of the construction footprints. Consideration for the processual and causal elements of the construction process, as well as the overall alteration of the landscape by the additional and new usages caused by construction should be considered for proper protection of both observed and unobserved cultural resources, especially precontact resources. In this poster we address the unintended damages and changes wrought on cultural resources by the unplanned but inevitable degradation to the surrounding landscape by construction activities, and how to reduce and negate some of these effects through the protection, maintenance, and restoration of riparian areas focusing on landscapes in the Columbian Plateau.

Canaries in the Coal Mine: How Children Reveal the Embodied Realities of Colonialism

Childhood is paradoxically the most precarious yet vital period of a person's life. It is when children form their biological and social self, embodying everything around them. However, what surrounds them may not

be safe, stable, or congruent with a healthy, long life. Children are the first to embody and succumb to the effects of sociopolitical change, economic insecurity, or environmental disruption and this is particularly apparent in societies undergoing forced ideological or political transformation. Colonialism and imperialism have been shown to increase the morbidity and mortality of the communities being subjugated. This paper examines the embodiment of colonialism as seen in the remains of children recovered from the sixteenth-century colonial church cemetery in Xaltocan, Mexico. A contextualized bioarchaeological analysis reveals the stories of Xaltocameca children who were the canaries of the new society wrought by the long arms and nails of Spanish colonialism. Adolescents and adults who survived childhood still carry the scars of their lived, embodied experiences in youth. Social practices and cultural transmission were remade during colonial incursions into indigenous communities and the skeletal remains of the Xaltocameca reveal the realities of living in a colonized space. ***Images of human remains may appear in this presentation.

Fifty Shades of Gray . . . Obsidian: A Tale of Supply, Demand, and the Ties that Bind at Xaltocan, Mexico
In central Mexico, where obsidian was the primary toolstone used by Indigenous peoples, one can get a good sense of sources by separating green obsidian (from Pachuca) from gray obsidian (from Otumba, Ucareo, and several other sources). Compositional analysis can further clarify the gray sources. Over a decade ago, the Elemental Analysis Facility at the Field Museum began training archaeologists in the application of portable X-ray fluorescence spectrometry to source obsidian. In collaboration with the EAF, we conducted a small study of 103 obsidian artifacts from Xaltocan, Mexico, dating from about 900 to 1700 CE. About half of these artifacts were green and half were gray, black, red, or brown obsidian that could not be linked to a known source without compositional data. For the present study, we returned to Xaltocan with improved instrumentation, a better sense of chronology, and a more substantial sample of 898 additional obsidian artifacts of which 99% are gray or other uncommon colors. Our findings demonstrate the stability of supply networks and markets well into the colonial period as well as the homogenizing tendencies of the Aztec market system.

Mills, Barbara (University of Arizona) and Kelsey Hanson (University of Arizona)
[56]

Networks of Power in the Chaco World: Practices, Institutions, and Ideologies of Collective Action
In 2006, Lynne Sebastian synthesized political models used for Chaco society and argued that past interpretations were too heavily reliant on outdated models that stressed hierarchy and neo-evolutionary typologies. She especially drew on Susan McIntosh's (1999) book *Beyond Chiefdoms: Pathways to Complexity in Africa* and argued that power should be looked at in relational terms and that "wealth in people" rather than material wealth was more important in Chaco's development. We revisit Sebastian's argument and the models presented in McIntosh's volume to make the case for a historical-relational perspective on the Chaco World that includes the networks of practices, institutions, and ideologies through which power was created and used. We focus on three primary institutions: matrilineal households, ritual sodalities, and pan-village alliances or councils that contributed to Chaco's complex organization. Each of these groups drew on material and immaterial resources to accomplish their goals such as charismatic species, colorful pigments, and long-distance goods that we argue were essential for attracting people. Such an approach opens up the interpretive arena on Chaco governance to include a wider variety of ways in which decision-making and leadership was structured that accounts for large-scale collective action over multiple social and spatial scales.

Mills, Blair [174] see Kulisheck, Jeremy

Mills, Cassandra (HNTB) and Leo Demski (University of Nevada, Reno)**[140]***Contaminated Consumption: An Archaeological Examination of the Consequences of Adaptation in Industrial and Illicit Alcohol Production in the Southeastern United States*

The economic and communal importance of alcohol production across the southeastern United States can be traced from colonization to the present day. From colonists' advertisements for wives who could brew beer, to moonshiners outrunning revenueurs and Alcohol, Tobacco, and Firearms agents, to distillery-based tourism in the present day, alcohol production has sustained lives and livelihoods, becoming an embedded tradition throughout the region. Alcohol is the center of many community anxieties, constructed narratives, and targeted surveillance and policing. Archaeological investigations of alcohol production sites present colonists and homesteaders striving to survive in new landscapes, vast networks of illicit production and trade, and the adaptability of the alcohol industry during and after Prohibition. In this paper, we explore how the material culture of alcohol production and consumption in the southeastern United States both coincides with and contradicts historic narratives of these activities. We specifically focus on the transition periods into and out of Prohibition, examining how cultural narratives between legal and illicit alcohol display communal anxieties about race, gender, class, and health while erasing the diversity, agency, and contamination involved in production, distribution, and consumption of alcohol.

Mills, Conan (Louisiana State University)**[104]***Digital Archaeology at Sites 16VN3504 and 16VN3508 in Western Louisiana: Digital Preservation in the Face of Climate Change*

Digital archaeology provides opportunities to help safeguard and disseminate archaeological knowledge in the context of climate change. As environmental shifts intensify, archaeological sites are increasingly at risk, necessitating urgent measures to protect their invaluable information. Technologies such as 3D photogrammetry, lidar, and geographic information systems can be employed to digitally capture and archive site information, while being low cost and limiting field crew environmental exposure. Digital preservation not only conserves data but allows for remote access and mitigates physical exposure risks. Hurricanes cause a loss of information by damaging archaeological sites through flooding, erosion, and tree falls. Given the changing climate, it is vital to conserve and share archaeological information. Online repositories and interactive platforms democratize access, enabling researchers to engage with archaeological data regardless of geographic constraints. This poster shares a case study from two large multicomponent sites, 16VN3504 and 16VN3508, in the Kisatchie National Forest of western Louisiana. Digital archaeology techniques were used to document the sites, both impacted by tree falls from Hurricanes Laura and Delta, as well as ongoing looting. Stakeholders can leverage digital tools for public engagement, navigate the challenges of climate change, and foster preservation of our shared cultural heritage.

Milner, George (Pennsylvania State University)**[253]***Food, Conflict, and Mortality: Millennia-long Trends in the American Midcontinent*

There is nothing new about saying that the indigenous societies of the American midcontinent underwent significant changes during the several millennia prior to the arrival of Europeans. But lacking quantitative assessments of subsistence practices, intergroup conflict, and mortality patterns, among other topics, systematic evidence-based understandings of what took place and why it did so are greatly impoverished. Data assembled from numerous midcontinental sites clarify relationships among the intensification of subsistence practices (plant remains), differences in the intensity of intergroup conflict (human skeletons and defensive works), and changes in age-independent mortality (skeletons). During the Middle Woodland period two millennia ago, a time of impressive earthwork construction and the interregional exchange of symbolically charged objects, a stepwise shift in native plant cultivation accompanied declines in conflict and age-independent mortality. Less than a millennium later, and despite a further rapid shift to a heavy reliance on maize, both warfare and age-independent mortality increased. The mortality measure is an indication of

the effect on communities of changes in ways of life, in this instance subsistence practices and intergroup relations. Assembling such information is a fitting tribute to David Anderson because it is precisely what he has done so often and well.

Milosavljevic, Tania

A Paleoethnobotanical Comparison of Mortuary and Village Langford Tradition Sites in Northern Illinois

The last 40 years have seen increasing methodological sophistication providing for a relatively nuanced understanding of food technology and resource use. Paleoethnobotany is one way to observe the diversity of plant use among Langford site occupants. Using standard paleoethnobotanical practices, plant macroremains from the Robinson Reserve Site (11CK2) are analyzed. Results of the plant macroremain analysis are then compared to existing floral data from the Washington Irving site (11K52). This research investigates whether site functionality is distinguishable between Langford tradition mortuary and village sites.

[18]

Cave of Wonder: A Sacred Topos of Maritime Identities on Kalymnos

Caves often occupied prominent locations as visible landmarks or as nodal points in exchange networks and mobility routes. The paper discusses coastal sacred caves, which through the transportation of diverse material culture, provided the backdrop where maritime identities were played out. The study investigates the Late Minoan occupation phase of Daskalio Cave on Kalymnos Island to shed light on the use of coastal caves in connection to maritime travel in the prehistoric south-east Aegean. It is proposed that Daskalio Cave, which occupied a nodal position between the insular Aegean and the Anatolian mainland, was visited by maritime travelers. The evidence indicates the performance of ritual activities with clear references to Minoan cultural practices, which were emmeshed with local traditions, as attested by the presence of local pottery wares and shapes. The paper concludes that the coastal location of Daskalio Cave, its access by sea and the presence of imports, may suggest a close connection with maritime travel and seafarers for whom the cave may have marked a sacred landmark or a site of pilgrimage. It is also proposed that coastal caves that occupied liminal spaces, environmentally and symbolically, served as spaces where mobility and cultural exchanges created distinct maritime identities.

Minette, Ellie (University of West Florida)**[100]***Promoting Engagement and Interaction: How Local Museums Can Use Digital 3D Models*

With the increasing accessibility of digital technologies, photogrammetry and digital modeling have grown in popularity and applicability as archaeological tools. Recently, archaeologists have used digital models of sites and artifacts for various teaching and research purposes, with specific emphasis on 3D-printed replicas and augmented-reality content. Less attention has focused on how local museums can use digital models to enhance community engagement, education, and overall outreach efforts. Through the process of modeling sixteenth-century Spanish artifacts from the Pensacola Museum of History and the Archaeology Institute at the University of West Florida in collaboration with the Florida Public Archaeology Network, the goal of this research is to identify how local museums can integrate these artifact models into their preexisting infrastructure through museum websites or create new pathways for engagement and expression via social media platforms.

Mink, Kirsten (Idaho State University), Anna Novotny (Texas Tech University) and Gabriel Wrobel (Michigan State University)**[295]***Bona Fide: Advances in Ancient Maya Bioarchaeology from Belize*

Bioarchaeological studies have taken a central role in developing our current understanding of the sociopolitical and economic organization of the ancient Maya. This is in large part due to advances in methods and theory that allow a deeper contextualization of the biocultural processes in which human groups were enmeshed. Advancements in paleogenomics and biogeochemistry have drawn attention for the unprecedented interpretations they allow us to make about paleodemography, diet, and mobility (Ebert et al. 2021; Freiwald 2011; Green 2016). The bedrock of Belizean bioarchaeology, however, remains grounded in macroscopic analyses of human skeletal and dental remains. Contributions to biological profile estimation, paleopathology, body modification, complex mortuary contexts, and taphonomy from Belizean datasets shape our understanding of the biocultural aspect of the lived Maya experience. Bioarchaeological work in Belize also urges the field forward by incorporating unique theories such as identity creation (Geller 2014; Piehl 2006), life course and history (Wrobel and Cucina, in press), and queer theory (Nissen 2015). The growth within the field of bioarchaeology, spearheaded by work in Belize, will continue to allow researchers to better use the osteological and dental data to inform the social, economic, and political narrative of the Maya in Belize and broader Mesoamerica.

Mink, Philip (University of Kentucky, W.S. This poster presents the results of recent geochemical analysis of ceramics and other clay artifacts in the Upper Basin Region of the Baaj Nwaavjo I'tah Kukveni Grand Canyon National Monument. We will compare the geochemical composition of Tusayan Grayware and San Francisco Mountain Grayware sherds, acquired by portable X-ray fluorescence (pXRF), to the composition of daub collected from a nearby excavated masonry ruin. We also compare our recently collected pXRF data with benchtop XRF data collected on the same sherds over a decade ago. Finally, we explore the use of both scanning electron microscopy with energy dispersive spectroscopy and scanning micro-XRF to evaluate the effectiveness of these methods for future nondestructive geochemical analysis of ceramics.

Community Resilience and Connection on the Middle Nile: The Es-Selim R4 Archaeology Project in Sudan

The community archaeology project at the Kerma settlement site of Es-Selim R4 (ESR4) seeks to investigate how environmental, social, and political change intersect to affect a provincial population center over 1,000 years. The site is located in the Northern Dongola Reach, where the floodplain was braided with Nile paleochannels, supporting a network of settlements. Our initial community engagement in 2020 provided insight into how people living in the area relate to past remains of human activity in the landscape and what they want to better understand about past residents and environmental conditions. Community members identified questions about the ancient environment and subsistence strategies as a high priority, as our research results can inform their choices as they face climate change today. During 2021–2023, we continued to build relations with the residents through surveys disseminated with the assistance of the Sudanese National Corporation for Antiquities and Museum collaborators. Our initial findings and future goals presented here are based on the results of these surveys. They include insights into the level of public interest in the ancient Nubian past, how residents and tourists interact with ancient sites today, and how they hope to learn more in the future.

Exploring Roman Army Supply Networks on the British Frontiers: A Multi-isotope Approach

How did the Roman Empire supply its very large frontier garrisons? Maintaining provision was key to the success of Roman imperialism, but we still know remarkably little about how Romans soldiers on the frontiers were supplied and the impact this had on the provincial countryside and its population. This paper presents results from the project “Feeding the Roman Army in Britain,” funded by the Leverhulme Trust. A multi-isotope approach is applied to domestic fauna from 16 sites in three frontier regions of Britannia: South Wales, Hadrian’s Wall and the Antonine Wall, to explore the networks of supply and husbandry strategies that supported the army. Almost 500 animals have been analyzed for strontium, carbon, nitrogen, and sulfur isotopes. Preliminary results show species-specific landscape use and husbandry practices and suggest that, in some instances, resources were mobilized from a wide network. These results are embedded in the archaeological, historical, and environmental context to enrich our understanding of Roman supply strategies.

Archaeology and the Colorado River: Environment and Cultural Management

A rafting expedition covering a 17-mile stretch of the Colorado River in the McInnis Canyons Recreation Area revealed an invasive takeover of cheatgrass across adjacent canyons, once filled with bunchgrass and sagebrush during a previous survey conducted in the 1970s for cattle grazing. This presentation explores the dynamic relationship of environment, cattle grazing, fire, and its impacts to cultural materials. The resulting disturbance to the sites, as well as the overall landscapes, challenges archaeologists to reevaluate their role in land management practices and for preserving the integrity of both cultural resources and native ecosystems.

Refining the Chronology of Mortuary Deposits at La Consentida, Oaxaca, Mexico

In this paper, we present a refinement of the human burial sequence at the Early Formative period (2000–1000 BC) site of La Consentida, in Oaxaca, Mexico. Previously, the chronology of mortuary spaces at La Consentida has been supported by nine radiocarbon dates (2020–1510 cal BC) from secure contexts, including charcoal, carbonized material from pottery, and two human bone samples processed together using R_combine. Having only one direct date from human remains has necessitated the use of relative dating to place those mortuary deposits in the context of site occupation. The present study adds new dated bioapatite samples from nine sets of previously studied adult human remains found in the two mortuary contexts at La Consentida. Despite some challenges with dating bioapatite, securing new direct dates for these individuals enables our exploration of the mortuary spaces as they relate to the creation and maintenance of group identity and collective memory during the initial Early Formative period in Coastal Oaxaca. Finally, we compare the mortuary data from La Consentida to those from other sites in coastal Oaxaca, The Valley of Oaxaca, and Mesoamerica more broadly. Based on these comparisons, we discuss how La Consentida fits into local and regional mortuary traditions.

People, Plants, and Pests: Desiccated Macrobotanicals at Bartram's Botanical Garden

In recent years, archaeobotanists have explored the potential of desiccated assemblages cached by rodents in historic standing structures. This paper analyzes one such dataset from Bartram's Garden, established in 1728 in Philadelphia. The Bartram family, along with at least one enslaved and one indentured worker, cultivated over 2,000 native North American and imported plant species over 122 years. Examining the material traces of plants at the garden as collected by rodents provides an opportunity for grappling with both the global scale of plant migration, and the hyper-local scale of plant, animal, and human interactions in the garden. Considering these scales together is critical for understanding botanical gardens as a both loci and agents of environmental change in the eighteenth and nineteenth century Middle Atlantic. Despite the fact that gardens are known to have been vectors for invasive species during European settlement of North America, archaeologists have yet to study how they were a part of the changing environment of the American colonies and Early Republic. Exploring these questions is a critical step toward examining the material conditions of botanical gardens and understanding the new relationships that were made possible between species in those spaces.

Utility Lines Straddling State Boundaries: Cultural Resources Angle on Accumulated Knowledge and Knock-On Effects

In the regulatory side of archaeology we call cultural resource management, some of the utility line work

undertaken in the last several decades has created enormous repositories of information. The volume of excavated soil has been equally immense, in the process yielding critical data for present and future stakeholders. When utility work crosses state lines, it also meets particularities and legacy effects that are a function of individual states' processes of dealing with the accumulated data. This paper looks at several such projects and their ensuing maintenance, drawing attention to logistics and specific production of knowledge enabled by the scale of the undertakings.

From Buried Preclassic Villages to the Lexicon for Maya Architecture: The Impact of Architectural Studies in Belize on Maya Scholarship

In 1984, Stanley Loten and David Pendergast published *A Lexicon for Maya Architecture* based to a large degree on their observations during excavations at Lamanai and Altun Ha, both major Maya centers in Belize. At 16 brief pages of text and nine of figures, this much-coveted, difficult-to-find resource contains the essential vocabulary that scholars still use to describe Maya architecture. The lexicon provides a foundational platform on which architectural description and comparison across space and time can rest. While this work was critical to establishing a common language, it is perhaps the architectural heterogeneity of Belize across space and time that is most critical to our broader understanding of Maya society. While architectural studies in Belize have contributed to our understanding of Classic period (AD 250–800) trends in monumental architecture, the country has also been a key setting for research into domestic architecture, Preclassic (1100 BC–AD 250) architectural origins, and Terminal Classic (AD 800–1000) and Postclassic (AD 1000–1528) architectural transitions. In this paper, we review the major contributions Belizean archaeology has had on Maya archaeology scholarship while also pointing to some places where we believe architectural scholarship in Belize has been overlooked or misunderstood in the construction of broader narratives.

The Crop Fields of the Ramaditas: A Formative Site in the Atacama Desert

Ramaditas, a Formative village site dated to around 600 BC, is located in the driest section of the Atacama Desert. Surrounding the architectural structures is a large area of fields that were cultivated by the inhabitants of Ramaditas. Here we present aspects concerning the water system developed at Ramaditas based on an aerial study with drones and 3D digital reconstruction of the landscape, irrigation structures, and agricultural fields, which suggests the development of an efficient water system adapted to local environmental conditions.

Moeller, Nadine**[155]***Hierakonpolis: A Case Study for an Early, Large Low-Occupation-Density Settlement from Egypt*

Much attention has been drawn to the discovery of unusually large agglomerations, so-called “anomalous giants,” that appeared out of nothing at different times and in many parts of the world, suddenly and without any signs for a noticeable long-term trend that would have logically culminated in their existence. This paper will discuss a pertinent case study from ancient Egypt, the site of Hierakonpolis, which is an emerging urban center dating back to the Predynastic period (ca. 3800–3600 BCE). The site can be characterized as a multicomponent site with clusters of larger cemetery areas, loosely organized settlement remains in the low desert including distinct production and manufacturing areas, a sacred precinct or forerunner of an early sanctuary. This unusually large early Predynastic town did not persist in the landscape for long and seems to have disappeared as fast as it emerged. Given its retraction to a more dense and nucleated form of settlement, it constitutes a social experiment that probably faced several unsurmountable challenges; environmental change might have been the decisive one. This paper will address aspects on monumentality, group identity and economic considerations with the aim to shed new light on the inhabitants and their social hierarchies at this LLODS.

Moen, Marianne (Museum of Cultural Heritage, University of Oslo)**[246]***The Impacts of Absence and Displacement on Viking Age Childhood*

Childhood as a part of social and cultural frameworks is varied and fluid, and the space afforded to and occupied by children will vary in multiple ways according to intersecting lines of social identity. The Viking Age is generally recognized as a period of profound social divisions, with social status as a paramount defining line. Gender, ability, kin group, and age also acted to delineate how social personas were created and contained. Here, I wish to discuss the impact of travel on Viking Age childhood. Firstly, the impact that absence in the immediate family may have had on children when parents or other figures of authority were absent on long-distance expeditions. Secondly, the impact that distance may have had on children themselves who took part in travel. And thirdly, the impact that displacement may have had on children who were brought into slavery. This three-level approach to one influencing factor gives room to examine the definition of childhood in the Viking Age according to social status, as well as how external factors integral to Viking Age cultural realities shaped the experience of childhood.

Mofidi, Ethan (University of Oklahoma)**[266]***From Calf Creek to Reed: Understanding the Lithic Assemblage of School Land I (34DL64) Delaware County, Oklahoma*

Beginning in 1939, the Works Progress Association (WPA) led by David Baerreis excavated the School Land I site as a mitigation effort before the completion of the Pensacola Dam which consequently submerged the site and adjacent areas. Since that point, the materials collected by the WPA have been largely untouched for further analysis, save for the faunal analysis done by Lathel Duffield in 1969. This lithic analysis seeks to contribute a piece of the puzzle in understanding School Land I and its consequent relationships. Situated on the foothills of the Ozarks, it is clear that this site was a place of significant meaning for people living in the Northern Caddo area and their ancestors. It is the goal of this analysis to gain insight into stone tool typologies, raw material selection, and the processes behind biface failures which will in turn provide insight into the role of the site, its households, and the people that lived there through time.

Mogauro, Megan (Hamilton College), Hannah Lau (Hamilton College), Daniel Cusimano (University of Hawaii, Manoa), Alexis Boutin (Sonoma State University) and Benjamin Porter (University of California, Berkeley)**[199]***Zooarchaeological Analysis of Sar El-Jisr Faunal Assemblage*

This project analyzes zooarchaeological remains from the late third to early second millennium mortuary complex at Sar El-Jisr, Bahrain. The assemblage is a legacy collection and its analysis will expand on previous research of the Dilmun burial complex, and furthers our understanding of Dilmun as a sociopolitical entity. These implications are relevant at both a local level and beyond, with consideration to Dilmun's established role as a center of international trade. The primary goal of this analysis is to understand the influence of past humans in the formation of this faunal assemblage, which we relate to the larger relationship between humans and animals at Sar El-Jisr. Finally, this research will also highlight the importance and challenges of reporting and historically situating legacy collections, a pressing problem in modern archaeology.

Archaeology and the Politics of Erasure in the Middle East

As a discipline initially tasked with understanding non-Western histories and heritage, archaeology has functioned mainly as a technology of forgetting rather than remembering when it came to indigenous material cultures. The role of archaeology in colonizing African and South American cultures is widely explored, but its colonial impact in the Middle East is highly neglected. In the post-Ottoman era, for instance, archaeology was deployed to forge a raciolinguistic national identity for emerging Turkish nationalism at the expense of erasing indigenous nations such as Armenians and Kurds, among others, within the official history of the dominant ethnic group. In Iran, Persian-centric archaeological studies, informed by Aryanism, have been deployed as a powerful instrument for a selective remembering of the past, aligning with the Persianist primordial nationalism. This research addresses this gap by comparing archaeology's role in state-building across the Middle East with other regions of the world. Furthermore, the current conflicts in the region cannot be fully grasped by merely examining the actions of state and non-state actors. Instead, we need to unravel how the past has been narrated and how it has informed the present.

Archaeobotanical Evidence of Swahili Cuisine at Unguja Ukuu, Zanzibar

Food has an integral role in the formation of identity. Archaeobotanical techniques are an underutilized yet productive avenue through which we can understand African cuisines and identities, both past and present. This presentation will focus on the preliminary analysis of the archaeobotanical assemblage excavated from the site of Unguja Ukuu by the Urban Ecology and Transitions of the Zanzibar Archipelago project (UETZAP) in 2019. This research utilizes macro and microbotanical analyses to reconstruct Swahili cuisine(s) in the first millennium CE on the island of Unguja. Unguja Ukuu was one of the earliest and most influential cities on the medieval coast, presenting a compelling opportunity to discern what, why, and how everyday Swahili people were eating and how those habits may have changed. African cuisines have often been portrayed as simplistic or mere starvation foods, with popular conceptions conjuring the image of the "starving African." The goal of this presentation is not to erase the role of food insecurity in the suffering of African peoples. Rather, it will situate Swahili cuisine(s) and heritage within a deeper history, contribute to understanding the complexity of African cuisines and everyday life, and discuss the interplay between food and identity.

Playing the Game: An Analysis of Hohokam Ballcourt Structures

Despite nearly a hundred years of research, Hohokam Ballcourt Structures remain a conundrum for archaeologists. What they were used for, who could access the courts (or the events that occurred in them), or even if the communities that built them utilized them for activities besides ballgames all remain ambiguous.

This poster elucidates a performance theory-based analysis of Hohokam Ballcourt Structures from across Arizona. This framework was chosen as it has been successfully utilized to analyze architectural structures and practices in both large- and small-scale societies around the world. My analysis consisted of identifying sites with ballcourts and compiling feature maps for 67 different ballcourt structures. The feature maps were then digitized and analyzed using GIS to calculate two estimations for the number of observers for each court, representing two potential crowd densities. The number of observers was then compared to site population estimates to try and answer three questions: (1) Is ballcourt size influenced by the population size of the communities that built them? (2) What percentage of the community within the Hohokam Ballcourt world had prime viewing of activities occurring within ballcourts? (3) Was access to these structures open to the public or restricted?

[225]

Assessing Production Components of the Pre-Still Bay Lithic Assemblage from Sibhudu Cave, South Africa

At Sibhudu Cave, the Still Bay technocomplex is found ~71,000 years ago and its formal tool component is dominated by bifacial points, while the deposit below, which Wadley (2012) called the pre-Still Bay, has a low density of bifacial points. The Pre-Still Bay has many flakes with few bifacial points, and it dates to between about 74,000 and 80,000 years ago. Some archaeologists have argued that because some bifacial points are present, albeit rare, the 80–74 ka assemblages also belong to the Still Bay industry. If the pre-74 ka ago layers do represent a longer Still Bay technocomplex than previously thought, it has been suggested that perhaps the bifacial points were removed from the site or will appear outside of the Wadley excavation trench in another part of the cave. This paper presents preliminary data from a study which aims to identify whether there was indeed substantial bifacial tool production at this time period, through a technological core reduction study of the cores and various lithic products. The results of such a study would provide further questions about the technological progression of the Middle Stone Age, especially for the continuing work at Sibhudu Cave.

Reconsidering Kingship among the Gulf Olmec

For decades debate among Formative scholars has raged over whether to classify Gulf Olmec societies as archaic states or chiefdoms; yet scholars on both sides have assumed that these societies were governed by elites under the jurisdiction of a single hereditary ruler. Stone monuments in the form of altar-thrones, stelae, and—most particularly—colossal heads are cited as evidence of dynastic kingship at the primary sites of San Lorenzo, La Venta, and Tres Zapotes. This model of single-ruler governance is often used to ideologically unite Olmec kings with their presumed counterparts in the later courts of the Classic Maya, while simultaneously disassociating the Olmec from Classic Gulf societies reliant on corporate models of power-sharing. However, such an interpretation overlooks key contextual information that undermines the theory of single-ruler governance. This paper will reexamine the contextual, stylistic, and iconographic evidence associated with monumental sculpture to suggest a possible model of dual rulership among the Gulf Olmec of the Early (1500–850 BCE) and Middle (850–350 BCE) Formative periods. In doing so, I propose to align the discourse of Olmec governance with later examples of Indigenous political organization found both in and out of Mesoamerica's Gulf Coast.

Monaghan, Lee Ann, John Pohl (California State University, Los Angeles), Manuel Hermann (CIESAS) and John Monaghan (University of Illinois, Chicago)**[302]***Reconstructing the Codex Colombino-Becker*

Precolumbian manuscripts provide a view of indigenous life that is largely unmediated by Spanish colonialism. The Colombino-Becker is one of the masterpieces of the Mixtec Codices, but poor preservation, missing pages, and an effort to make the manuscript more palatable in a Christian context by erasing not only precolumbian rituals but also names and headdresses have limited the ease of understanding of what is written. A team, including John Pohl, has been working on the reconstruction of the manuscript. In this paper we will present two of the reconstructed pages and discuss the methods used to make the manuscript more accessible.

Monetti, Lisa**[123]***Arch Street Project: Sustainable Collaboration and Learning after Reburial Using Digitized Remains*

The highly collaborative nature of the Arch Street Project allowed for hands-on learning opportunities for university students. This was an especially valuable experience at universities that traditionally rely on replica human remains for teaching as it increased student access to taphonomic conditions, human variation, and discussions on ethics and reburial. The Arch Street Project also created an opportunity to reconsider the ways human remains can continue to be made accessible for teaching and learning after reburial. This presentation will share the methodology used to digitize the remains of several individuals from the Arch Street Project collection using a combination of 3D infrared light scanning and photogrammetry. The result is an immersive virtual laboratory in which students can practice osteological analysis. Pedagogically, this tool can be used for teaching and assessment and can be adjusted to different experience levels. This also creates an opportunity for collaborative learning across universities with different access to human remains in their teaching collections. It is incredibly important to consider and teach the ethical ramifications of digitizing human remains and to think carefully about ownership of data. For this reason, these scans have not been made publicly available and this presentation will also cover ethical recommendations.

Monge, Susan (University of Illinois, Chicago)**[118]***Poultry in Motion: The Translocation of Turkeys (*Meleagris* spp.) in Ancient Greater Nicoya, Costa Rica*

The trade and movement of animals and animal-derived artifacts was widespread and varied significantly throughout the ancient Americas, often requiring substantial efforts comparable to that employed in acquiring other material resources or prestige items. Originally native to parts of modern-day Mexico and the United States, turkeys (*Meleagris* spp.) represent an example of animals that were intentionally translocated or moved outside of their native environments in precolonial times. Preliminary data from the Greater Nicoya area of northwestern Costa Rica, the southernmost region where turkeys appear to have been translocated, suggests that these non-native birds may have been a restricted resource that served as indicators of social organization. Furthermore, turkeys may have been acquired through local participation in an elite-based regional interaction sphere. Their association with elite goods is also indicated by their representation in high quality ceramics accompanied by scenes and symbols of power and prestige. Using ancient DNA, stable isotope, and osteological data, my research aims to understand and address social aspects of turkey translocation and management practices within ancient Greater Nicoya societies during a period of important sociopolitical changes, increasing social inequality, and the arrival of foreign groups into the area.

Monroe, J. Cameron (University of California, Santa Cruz)**[250]***The Three Phases of Sans-Souci: An Architecture of Remembering and Forgetting in the Kingdom of Hayti*

Following three centuries of colonial rule, the Haitian Revolution ushered a period of political change, one in which ex-slaves, maroons, and free *hommes de couleur* united to forge new political institutions on the island of Saint Domingue. Henry Christophe was declared King Henry I of the Kingdom of Hayti in 1811.

Christophe was an avid builder, constructing royal palaces and fortresses and reclaiming plantations as rural seats of power. The largest palace was Sans-Souci in Milot, a 13 ha neoclassical complex remembered as one of the most magnificent edifices of the West Indies. Michel Rolphe Trouillot famously argued that the construction of Sans-Souci was a political act designed to silence the memory of a rival general of the same name. Recent excavations by the Milot Archaeological Project, however, have revealed the presence of at least three major construction phases, and documented clear continuities in the architectural plan extending back to the colonial period. I argue that these three phases of building, or architectonic mentions and silences, were intended both to “remember” and “forget” various classical, West African, and colonial pasts, providing a new perspective on how monumental architecture was used to shape public consciousness in the nascent Kingdom of Hayti.

Monroe, Shayla (Harvard University)**[85]***Chair***Monroe, Shayla (Harvard University) and Melina Seabrook (Harvard University)****[85]***Cattle Production and Strategic Meat Distribution in Egypt and Nubia*

Richard Reddings’s (1992) model developed at the site of Kom el-Hisn offered a means of understanding strategies by which ancient societies could strategically raise animals for the purpose of provisioning communities in multiple locations. This model proved useful for understanding meat provisioning strategies at the Egyptian fortress of Askut in Nubia (ca. 1850–1550 BC), in which local herders may have raised cattle for provisioning fortress residents while themselves consuming caprines.

Montenegro, Alvaro**[191]***Chair***Montenegro, Alvaro****[191]***Incorporating Knowledge about Future Weather Conditions on Navigational Decisions in an Agent-Based Seafaring Simulation: Comparison to Simpler Navigation Strategies*

The efficiency and safety of ocean travel is greatly dependent on along-trip environmental conditions. Agent-based simulations that optimize routes based on expected environmental conditions have been used by the shipping industry and the sailboat racing community for decades. Some recent efforts in archaeology have used the latter models. Here I describe what I believe is first agent-based seafaring model capable of route optimization designed specifically for archaeology, and with the distinguishing feature of defining how far into the future conditions are known by the vessel’s occupants. Simulations of the same trips with optimizing and non-optimizing versions of the model are conducted to provide insight into how and by how much knowledge about future weather influences trips performed under distinct settings (length of trip, oceanographic conditions, season, etc.). Under the widely accepted understanding that ancient seafarers possessed considerable knowledge about the ocean environment, including the ability to forecast future

conditions, I argue that the new version of the model allows for the adoption of more realistic navigational strategies in seafaring simulations. The experiments comparing optimized to non-optimized simulated trips will show under which settings knowledge of future conditions have the most and least impact on trip outcome.

Arqueología de transiciones: Enfoques teórico metodológicos para investigar el cambio desde la perspectiva de la cerámica Formativa y Clásica de Mazapa, La Sierra y El Escobillal, Veracruz

A lo largo de los años, la práctica arqueológica se ha dedicado a estudiar el cambio desde diversos enfoques, incluyendo procesos adaptativos, resiliencia, entre otros temas que guían nuestras investigaciones para comprender cómo vivieron las sociedades durante periodos transitorios. En esta ponencia, se realiza una reflexión sobre estos diversos enfoques y sobre la importancia del estudio de la continuidad para visualizar de una mejor manera qué fenómenos son realmente cambios y qué otros son más bien categorías de investigación arqueológica. La manera en la que navegamos entre estas dos realidades impacta de gran manera nuestro trabajo, por lo que es importante reconocer este tema como un reto para la práctica. Aquí, se toma como ejemplo el trabajo realizado con la cerámica del proyecto PAMLAS, en los sitios de Mazapa, El Escobillal y La Sierra, Veracruz. Se argumenta que, sobre todo en el sur de Veracruz, los estilos diagnósticos que indican el cambio se encuentran comúnmente dentro de un mayor contexto de continuidad, por lo menos en la práctica alfarera. Se exploran los posibles significados de este argumento, desde la transición entre el Formativo y el Clásico en dichos sitios.

Co-stewardship: Positive Impacts from Meaningful Consultation

S'edav Va'aki (formerly known as Pueblo Grande) is an ancestral O'odham (Hohokam) archaeological village site and the only National Historic Landmark in Phoenix, Arizona. For more than a decade, the S'edav Va'aki Museum (Museum) has consulted monthly with the Salt River Pima-Maricopa Indian Community (SRP-MIC) and Gila River Indian Community (GRIC) Tribal Historic Preservation Offices (THPOs). What began as a compliance-focused dialogue between the Phoenix City Archaeologist and SRP-MIC Cultural Resource Compliance Supervisor on citywide archaeology expanded to include Native American Graves Protection and Repatriation Act (NAGPRA) consultations with both GRIC and SRP-MIC THPOs. Ultimately, these compliance consultations expanded to meaningful collaborations on exhibits, signage, and collections management policies. Among the many positive impacts from this co-stewardship arrangement is renaming of the Museum from a Spanish name assigned in the 1920s—Pueblo Grande—to the O'odham name, S'edav Va'aki (meaning Central Platform Mound), which better describes the ancient village and represents the cultural continuity between its original inhabitants and the O'odham people. By collaborating with our tribal partners, the Museum has enhanced our interpretive programming to the public and has elevated the quality and cultural appropriateness of our collections care and archaeological compliance.

Practicing Indigenous Data Sovereignty On and Off Picuris Pueblo Lands

Over the past decade, a growing number of archaeological projects in North America have incorporated community-based participatory research (CBPR) methods. For Indigenous communities, this collaborative paradigm marks an extension of a more global body of anti-colonial activism and policymaking oriented around Indigenous sovereignty. In recognizing the inherent right of Native Nations to self-determination and governance, the framework of Indigenous data sovereignty offers a more radical reenvisioning of existing power dynamics around data collection, curation, and dissemination. In this talk, I situate the Picuris Pueblo Archaeological Research Project within a data sovereignty paradigm, drawing particular attention to the ways that our collaboration has shifted the locus of jurisdictional authority over archaeological data toward the Picuris Governor and Tribal Council. Throughout this discussion, I will highlight two major challenges in the application of the ethical principles of data sovereignty: differences in how sovereignty is enacted on and off-reservation lands and tensions around how to define benefits for a diverse group of community members and project participants.

Contextualizing the Ancient Cultivated Landscape of the Bajo el Laberinto Region, Campeche, Mexico

Ongoing archaeological investigations in the Bajo el Laberinto region, bolstered by advances in aerial laser scanning technology, have begun to offer a clearer indication of how the ancient Maya manipulated their environment to manage food, water, and soil insecurities. Multiple lidar campaigns have resulted in the acquisition of approximately 200 km² of high-resolution surface models of the area, revealing an intricate network of terracing, berms, and cultivated wetland modifications surrounding the extensive bajo. Densely populated during the Preclassic and Classic periods, the region provides a valuable setting for exploring the relationship between urban growth, long-term capital investment, and agricultural strategies in this portion of Mesoamerica. This presentation synthesizes remote sensing methods and data derived from archaeological excavations to examine the density, diversity, and complexity of terraforming features across the Bajo el

Laberinto landscape, including those associated with the major centers of Calakmul and Yaxnohcah. This research seeks to elucidate the sophistication of precolumbian food production in the Maya Lowlands, with a focus on agrarian engineering projects and land reclamation.

Interaction and Isolation in Manislan Mariñas: 1500 BC–AD 1769

This paper addresses long-term processes of inter- and intra-island interaction and isolation in the Manislan Mariñas (Mariana Islands), spanning their first occupation (ca. 1500 BC) to the end of the Jesuit colonial mission (AD 1769). I focus on mobility, ocean communication and networking, engagement with the sea, and social intersectionality. CHamoru DNA today can unite within a single person multiple ancestors from Europe, Asia, America, Africa, and Oceania. No doubt, this fact speaks of a long history of cultural interactions but may however reflect different realities when grounded to specific CHamoru communities. To understand these particularities, we need to intersect social position, gender, age, and ethnicity to better understand the role that ocean engagement, communication and networking had on the people of the Mariñas. This intersectional focus also enables us to examine how interaction and isolation may not be dichotomous but coexist together. This is clearly exemplified by modern Spanish colonialism that “connected” the Mariñas to the emergent global world while fomenting interisland disconnection and miscommunication.

Geophysical Survey at the Janis-Ziegler / Green Tree Tavern Site (23SG272), Ste. Geneviève National Historical Park, Missouri

The Midwest Archeological Center carried out multi-instrument geophysical surveys at four properties managed by Ste. Geneviève National Historical Park in 2022 to better understand archaeological resources within them. Ste. Geneviève is a French colonial town in southeast Missouri with vernacular architecture dating to the eighteenth century. Among these historic properties is the Janis-Ziegler / Green Tree Tavern site, which was constructed in 1790. The residence and business are associated with Nicolas Janis, a wealthy French Canadian, who moved with his family and at least 15 enslaved people to Ste. Geneviève from nearby Kaskaskia, Illinois, a year prior. Excavations conducted by Illinois State University from 2006 to 2009 revealed part of an outbuilding constructed in the poteaux-en-terre style. Based on recovered artifacts, it is thought to represent both a detached kitchen and quarters of enslaved people. Magnetometry, ground-penetrating radar, earth resistance, conductivity, and magnetic susceptibility survey results suggest that at least two outbuildings are present in the vicinity of the residence, including the structure tested previously, a pathway leading from the residence to this outbuilding, and a well located just to the side of the residence’s rear entrance. Limited test excavations are planned in 2024 to evaluate these finds.

Mooney, Dawn Elise (Museum of Archaeology, University of Stavanger)**[119]***From Staple to Shameful (and Back Again?): The Changing Fortunes of Seaweeds in the North Atlantic*

Seaweeds are in vogue: new initiatives tout seaweed farming as a solution to global problems of food insecurity that can simultaneously combat climate change through carbon sequestration and regenerate damaged marine environments. However, seaweed consumption is often presented as challenging for Western palates, requiring a significant cultural shift in order to become widely accepted. This presentation argues that seaweed exploitation was in fact widespread in the North Atlantic region until the twentieth century, and that the lack of seaweed consumption in the present day is less influenced by tradition than by industrialization, capitalism, and ideas of “modernity.” Archaeological finds of charred seaweed fragments will be interpreted in the light of ethnohistorical evidence to explore the importance of seaweeds in agriculture, diet, craft, and industry in the past, with particular reference to finds from Iceland and Norway. It is proposed that better understanding of past human relationships with seaweeds can make their use and consumption more appealing to modern consumers. However, this presentation also acknowledges the limitations of current archaeological practice and the consequent focus on finds of charred seaweed fragments and examines how we might gain a fuller understanding of past seaweed exploitation practices in regions with poor organic preservation.

Moore, Christopher (University of Indianapolis)**[331]***Places that Percolate: French Post Park and the Creation of a Hoosier Origin Story*

On the surface, French Post Park, a small, wooded picnic area and campground located on the south bank of the Wabash River in Carroll County, Indiana, may seem unremarkable. Covering about 5.4 acres, the park’s amenities consist of a small shelter, a few fire rings, a boat ramp, and a swing set. But, to the people of Carroll County, particularly those who live nearby in Adams and Rock Creek Townships, the park is a persistent place that cultivates their deep-seated feelings of patriotism, pride, and place. While we often associate persistent places with concentrations of resources, ancient traditions, or remarkable landforms, French Post Park reminds us that “place” is a quality, not a quantity, and that persistent places become such not because of the resources they provide but because of the relationships they foster and the feelings of belonging and connection they evoke.

Moore, Elizabeth**[70]***Linear Enamel Hypoplasia: An Analysis of Health Disparities between the Early Intermediate Period and Middle Horizon of Nasca, Peru*

There has been an abundance of research on the Nasca culture and linear enamel hypoplasia (LEH) separately. However, there is no literature specifically on Nasca and LEH analysis comparing the Early Intermediate period (EIP) and the Middle Horizon period (MH). The research detailed here shows there are evident disparities in LEH between Nasca individuals correlating to status, cranial vault modification (CVM), and trophy heads, between the EIP and MH. On the other hand, fluctuations in LEH severity are similar between sexes due to shared experiences of stress linked to changes in environmental conditions and in sociopolitical organization. I utilized macroscopic observations of LEH on 47 Nasca individuals from the Kroeber collection from the Field Museum in Chicago, Illinois. Through this project, I found statistical significance between sex and trophy heads, cranial modification and LEH presence, and LEH between Early and Late Nasca periods. I conclude that while not significant, but approaching significance, females tend to be more negatively impacted than males from similar stressors. Overall, health status deteriorated over time showing environmental changes and sociopolitical changes leading up to and during Wari imperial occupation had a negative effect on Nasca individuals, despite/regardless of status or sex.

Moore, Elizabeth A. (Virginia Department of Historic Resources)**[104]***“What Is Past Is Prologue”*: Climate Change, Predictive Models, Data Challenges, and Protecting Virginia’s Archaeological Resources

Like many other areas, Virginia is becoming increasingly impacted by the effects of climate change. Over the past several years, the Virginia Department of Historic Resources has taken efforts to model these impacts to identify vulnerable areas for cultural resources planning and mitigation purposes. Testing these models requires knowledge on the distribution, density, size, and integrity of sites across the landscape.

Archaeological survey varies significantly across the state and is primarily focused on the areas being impacted most by development pressures. VCRIS, the Virginia Cultural Resources Information System, contains locational and contextual information on over 50,000 archaeological sites. While many of these sites have been surveyed and have reliable integrity and boundary data, there is a significant number of older site records that include unconfirmed boundary estimates from surface observations or were map-projected with no ground-truthing. Our knowledge of the extent and conditions of submerged sites is even more limited. To begin to correct these issues, terrestrial and water-based survey is being conducted in a variety of physiographic settings across the Commonwealth. This baseline data will be used to assess and project site conditions and loss into the future and test various climate change impact models.

Moore, Elizabeth A. (Virginia Department of Historic Resources)**[274]***Discussant***Moore, Erik (University of New Brunswick) and Mike Meade (University of New Brunswick)****[197]***Embedding Librarians in Archaeological Field Schools*

For the past two summers, the Anthropology Librarian and the Digital Imaging Coordinator from the University of New Brunswick Libraries have embedded as experts and co-researchers in field schools led by archaeologists in the Department of Anthropology at UNB. The goals of this project are for those library specialists: (1) to gain deeper understanding of the complex data management and research needs of archaeologists, and especially of data and information praxis in the field, (2) to help students better understand the relationship between fieldwork, data, and dissemination within the broader research life cycle, and (3) to conceptualize and begin developing added areas of support from the Libraries in the form of research data management, dissemination of field-school work to disparate audiences, and expanded 2D and 3D imaging capabilities in the field and in the lab. Initial efforts have been very positive in both directions, and the project is moving from a pilot into a more formalized part of the field-school curriculum. Project archaeologists and librarians alike feel that this model is worth sharing, for others to explore in similar field-school contexts, where resources allow.

Moore, Jerry (CSU Dominguez Hills) and Carolina Maria Vilchez (Instituto Nacional de Cultura)**[161]***Una Frontera Permeable: Multiple Modes of Exchange in Prehispanic Tumbes, Peru*

Although the Tumbes region has been a frontier based on environmental differences, ethnolinguistic boundaries, and political divisions both in prehispanic and modern times, this frontier zone was neither rigid nor impermeable. Archaeological data dating from ca. 4700 BCE until ca. AD 1500 from Tumbes indicates exchange networks existing at multiple scales—regional, interregional, and long distance—and engaged various diverse settlements, and not solely principal centers. We propose that this long-standing, diverse, and non-centralized exchange was conducted by *vendedores ambulantes*, or peddlers, that complemented centralized market exchanges or political institutions. This decentralized economic exchange continues in the rural regions of Tumbes, where products such as fresh fish, furniture, and even gasoline are distributed through non-centralized networks. These less formal exchanges coexisted with state-organized production

and exchange such as the manufacture and exchange of *Spondylus* objects produced at the Taller de Conchales at the Inca provincial center of Cabeza de Vaca, networks of exchange and interaction that permeated the Tumbes frontier.

The Biological Baseline in Zooarchaeology: Unpacking the Domestication of South American Camelids

The domestication of llamas and alpacas in South America resulted in compelling similarities to sheep and goat pastoralism in Western Asia, but the underlying biology of the wild ancestors of camelids provided distinct challenges to human control and selection. The pastoral economies of South America are strongly affected by these factors even today; these factors also weaken attempts to use sheep or goats as a model for llama and alpaca domestication. The South American camelids have distinctive digestive systems; specialized adaptations to deal with aridity, hypoxia, and cold; and as induced ovulators camelids provide unique challenges to humans attempts to control reproduction. The archaeology of the ancestral guanaco and vicuna is compared with the assemblages that suggest early llamas and alpacas, tracing the morphological, demographic, and genetic evidence for a camelid-specific process of domestication. This paper gratefully acknowledges Richard Redding's fine-grained treatment of sheep and goat pastoralism that inspired a generation of scholarship.

The Sloppy Science of Ancient Maya E-Groups

Ancient Maya E-Groups have been a subject of archaeological fascination for nearly a century, resulting in extensive literature on E-Groups. However, consistency in that literature is hard to find. In this paper, we review some problems with E-Group research. This includes the lack of a consistent definition of the characteristics of E-Groups, the limited number of excavations that have taken place at E-Groups, and the lack of consensus on the functions and roles these assemblages played among the Maya. By highlighting these issues, we aim to show that our current understanding of E-Groups is mainly speculative, filled with academic baggage, and broad-stroke assumptions used on a range of architectural assemblages. Such assumptions are often treated as fact by virtue of repetition within the literature. We will end our paper with proposals on how to improve future academic discussions of E-Groups.

Negotiating Power? Explaining Dispersed Low-Density Mega-sites in Late Iron Age Europe

The mega-sites that emerged in the European Late Iron Age (ca. third century BCE–first century CE), often referred to as *oppida*, have struggled to be understood in the context of traditional concepts of urbanism. Comparative approaches to urbanism have, however, increasingly allowed them to be considered as part of a diverse range of alternatives to nucleated towns, as mega-sites, polyfocal complexes, or powerscapes. In this paper, I argue that European Late Iron Age mega-sites developed forms of dispersed, low-density occupation not simply due to reasons of sustainability but largely because of the social context in which they emerged. Through assessment of how these complexes operated as power centers, and through comparison with mega-sites around the world, the paper will explore how the development of Late Iron Age mega-sites charts these societies' negotiation of a transition from rural communities to larger social systems. These low-density centers reflect the varying ways in which these societies retained heterarchical social forms as power became increasingly centralized.

Cups for the King: Ajnumsaaj Chan K'inich of Naranjo and the Emergence of Regional Styles of Classic Maya Elite Serving Vessels

Distinct regional styles are a hallmark of Lowland Maya elite polychrome ceramic vessels during the Late Classic period (550–820 CE). However, our understanding of the phenomenon has not advanced beyond its mechanics—the presence of attached craft workshops at the courts of ancient Maya rulers. This paper attempts to fill the gap by considering one of the earliest styles associated with the royal court of Ajnumsaaj Chan K'inich of Naranjo. The presentation combines the analysis of the more technical properties of the style (vessel forms and decoration modes) with a survey of themes, texts, and paleography. It takes advantage of recent excavations at Naranjo and sites in its vicinity including Holmul that provided the first corpus of provenanced whole and partial vessels attributed to Ajnumsaaj Chan K'inich's artists. Finally, the paper considers the historical circumstances of the emergence of the Naranjo style of polychrome vessels. These multiple lines of inquiry offer insights into the reasons behind the rise of regional styles of Classic Maya elite pottery.

Participatory Mapping and Self-Management of Territory among the Kuikuro of the Upper Xingu, Amazonia

The use of cartography for land management is not new. However, the use of geotechnologies as instruments for strengthening indigenous communities, including the self-management of their territories, constitutes a new and wide-ranging possibility for the application of these tools. Participatory community mapping and territorial self-management are important resources for resistance against the threats posed to Brazil's indigenous and traditional peoples today, such as illegal invasions for logging and mining. Here, I present the experience with the Kuikuro peoples of the Upper Xingu (Southern Amazon) of using geographic information systems and new platforms based on cloud data. Now, lidar technology is also one of the key instruments that enlighten the past and strengthen the future of the Kuikuro people.

Reassessing a Postclassic Subterranean Ceremonial Complex at Teotihuacan

Life in the ancient city of Teotihuacan did not end with the collapse of Classic period society, but rather, until the constitution of the current zone of archaeological monuments, the area was a place of residence, rituals, and somewhat later, pastures and crops. We must remember that the period from AD 600 until 1521 occupies a broader chronological arc than the Classic period itself. However, although with some notable exceptions, it has received less interest. This contribution aims to update some of the ideas and interpretations derived from the partial excavation of one of the artificial cavities that were reused in the early Postclassic as a burial place.

Injecting Rationality into a Reevaluation of Chalchihuites Mining

As early as 1910, Manuel Gamio called attention to what he termed *cavernas* in the Chalchihuites area of Zacatecas. Later, in the 1960s, Charles Kelly and Philip Weigand labeled these features mines and proposed that they supplied Teotihuacan with turquoise. It has since been shown that the area is not a turquoise producing area. Nevertheless, the idea of the Chalchihuites as a mining area remains firmly entrenched even as proponents scramble to determine what may have been extracted. Logically, the mineral would have to be one that runs in veins in order to justify tunnel mining as opposed to pit or open-face mining. At no point has it been established what is being mined nor if the material runs in veins which would be consistent with tunnel mining. Even the most cursory examination of the proposed features suggests that the identification as mines is preposterous. Entrances are often tiny forcing entry and exit via crawling passage between chambers is similarly arduous. This paper proposes an alternative function for these supposed mines.

The Evolution of the Arch Street Project

In late 2016, the *Philadelphia Inquirer* reported that human remains were uncovered at a local construction site, 218 Arch Street, formerly the First Baptist Church of Philadelphia (FBCP) cemetery. Over the course of 2017 three phases of excavation ranging from extreme salvage to controlled CRM excavation took place resulting in the recovery of nearly 500 individuals. This presentation recounts the efforts of a multidisciplinary, multi-institutional collaborative of researchers, students, and professionals assembled to assist in the study and stewardship of the remains. Known as the Arch Street Project, this approach has led to new methods and scientific applications toward understanding the site of the cemetery and the lifeways of the individuals interred therein. Central to the story of the Arch Street Project are many legal and ethical challenges that continue to be navigated. The presentation explores what the Arch Street Project has accomplished since 2017 and the work to be done once all remains and associated artifacts are reburied.

Managing Teotlalpan: Resourcefulness and Socioecological Diversity during the Epiclassic Period in Central Mexico
 Studies on traditional ecological knowledge stress the importance of local resource management and autonomous governance. Resourcefulness constitutes an integral aspect of such bottom-up pathways. Dependent on knowledge, skills, and social capabilities, resourcefulness allows multiple organisms, materials, techniques, and places to be assembled into diverse ecological strategies and spaces. Resourcefulness is adaptive but also can buffer communities from a range of problems—environmental, social, and political. Recent investigations at the Epiclassic community of Los Mogotes, located between the northern Basin of Mexico and the Mezquital Valley, demonstrates a connection between ecological diversity and sociopolitical autonomy. Established on a defensible hilltop during a time of change, instability, and conflict, residents responded resourcefully to the environmental challenges of their local environment. They mobilized household and communal institutions to create a landscape of gardens, terraces, walls, canals, and reservoirs. They cultivated and collected a diverse assemblage of plants with unique and overlapping ecological requirements. Not only *Zea mays* but species of *Chenopodium*, *Amaranthus*, *Salvia*, *Phaseolus*, *Portulaca*, and other taxa were just as important, if not more so. This research suggests political autonomy, community persistence, and ecological resilience mutually depended on the resourceful management of a diverse suite of species, practices, and physical spaces.

Culinary Arts and Plant Residues of the Ancient Maya Lowlands: Botanical Ingredients beyond Maize and Cacao
 Foraging, home gardening, and large-scale cultivation yielded products consumed at every level of ancient Maya societies, albeit in varying proportions. For decades, researchers have carefully documented miniscule botanical residues, from chemical signatures to visible seeds, through a number of analyses. Some plants have proven more visible than others, and/or of more interest than others; specialized foodstuffs like cacao and annual crops like maize, beans, and squash have received the lion's share of attention. In this paper, I discuss how these better-known food plants were complemented by geophyte crops like manioc and sweet potato, home-garden resources like achiote and nance, and foraged foods like hoja santa and hackberry. Ancient Maya people across the Lowlands used these plants to great culinary effect, and sometimes in artistic representation and sacred ceremony. We find a wealth of plants with diverse flavors and aromas, contributing to the sacred and the singular as much as the quotidian and the mundane.

Techno-economic Approach to Early Lithic Industries of Fuego-Patagonia, Discussing Interactions among Culture, Society, and the Environment (50°–56° South Latitude)

In this paper, we discuss studies of the early lithic materials from Fell Cave and Cueva del Medio (ca. 13,000 cal BP) in comparison with Holocene industries from Punta Santa Ana I, Marazzi I, Cabo Monmouth 20, Pizzulic 2. Three main axes are assessed: first, transport and interactions related to nonlocal raw materials; second, elaborated core reduction methods and debitage with predetermination (for example Levallois, bifacial shaping, blade and blade tendency reductions) as the action modes that can be related to complex processes of knowledge sharing and transmission; and, third, functional analysis related to *chaîne opératoire* and toolkit behavior managements. Still, a large range of techno-economic strategies are observed and better understood within multiple scales and degrees of interaction among human groups and paleoenvironments. The results have a direct rapport with the key role of early marine nomads since ca. 7000 cal BP and dynamics related to biogeographic barrier notions related to the Strait of Magellan. This presentation is funded by grants: ANID/BASAL FB210018, FONDECYT 1211976, 1231691 & 1220219.

Spatial Distribution and Archaeological Characteristics of the Historical Record of Central-West Patagonia

The archaeological investigation of historical and recent periods in the Central West Patagonian region has garnered less attention than earlier records. Nonetheless, a diverse array of material evidence, primarily comprising rural architectural features, delineates a collection of sites and attributes that signify the relatively belated incorporation of this territory into Chilean colonization during the nineteenth–twentieth century. Leveraging prior research endeavors, we present a novel geographic information system (GIS)-based study encompassing a substantial portion of the region, incorporating records within continental basins as well across isolated inhabited islands of the western archipelago. This GIS-based approach facilitates the elucidation of spatial autocorrelation within historical records while examining their interrelation with pertinent variables like contemporary land utilization, topographical influences, and potential for mobility within this pristine territory. To ensure accessibility in presenting this amalgamation of temporal and spatial data, a user-friendly geo-portal has been developed and integrated into a dedicated website. Finally, this paper critically examines the historical and recent archaeological record through the lenses of functional, spatial, and temporal variability, underscoring the multifaceted utilization of space within Central West Patagonia.

From Controversy to Collaboration: NAGPRA Practice and Repatriation at Dickson Mounds Museum

Dickson Mounds Museum (DMM) in central Illinois has been ground zero for the intersection of archaeological practice, Native American rights, and the responsibilities of a state museum. For over 60 years, DMM presented viewing of an open excavation of over 250 Mississippian period (AD 1100–1300) burials left in situ. Additional burials were excavated and removed prior to construction of the current building, which opened in 1972. After a national-level controversy embroiled DMM, the burial display was closed in 1992 and sealed beneath a cedar floor. Nonetheless, the site remains an open wound for Native people and represents a critically unfinished historical baseline for Native American relations in Illinois and beyond. The Illinois State Museum (ISM) is practicing decolonizing methodology as it shapes its future and reenvision museum spaces in partnership with Native peoples. Building trust, and hopes of reconciliation, necessarily begins with repatriation of more than 1,100 Native American ancestors and 6,300 funerary objects from the Dickson Mounds site. Since 2020, the ISM and DMM have been working with a consortium of Tribal Nations to develop processes that facilitate respectful repatriation. This poster shares what we have learned as NAGPRA practitioners and museum professionals during this project.

The Radiocarbon Record and Precolonial California

Radiocarbon summed probability distributions (SPDs) have become increasingly popular as means to track demographic trends, and by association, any variety of explanations for changes in past behavior. This paper uses SPDs from across California to develop hypotheses as to the ostensible effects of climate, technological change, population movements, and demography itself on human behavior. These hypotheses are then critically reviewed per the method and theory behind using SPDs in archaeology and within the context of the limitations of the region's archaeological record.

[88]

O'odham Pottery: Prehistoric, Historic, and Contemporary Native American Ceramic Production in the Phoenix Basin of Southern Arizona

The Phoenix Basin in southern Arizona has some the earliest evidence of utilitarian plain ware pottery anywhere in the US Southwest, with associated radiocarbon dates as early as ca. 350 BC, and ceramic production has continued unabated since that time. Although researchers have extensively studied prehistoric pottery in the region, which has long been considered to be the heartland of the "Hohokam," less attention has been devoted to Native American ceramics that were made there in the historic period, and modern Indigenous potters remain largely overlooked. This paper presents recent research by analysts from the Gila River Indian Community Cultural Resource Management Program. This work has shown that while there are temporal and regional differences in ceramic production, including the red-on-buff pottery that the region is most famous for, there are also strong similarities in ceramic production through time and across much of southern Arizona. These similarities in ceramic traditions, including the use of the paddle and anvil construction technique, demonstrate the long-term continuity in cultural traditions from prehistory through today.

Scanning at the Artifact Roadshow: 3D Imaging as an Outreach Tool in Community Archaeology

Community outreach has played a major role in the Castleton Hidden History Project, which highlights a diverse and inclusive history of the Castleton, VT, area from the end of the Ice Age through the present day. Since 2023, a significant part of outreach programming has consisted of “Artifact Roadshows,” and 3D imaging is a central tool in these efforts. Hosted in Castleton and surrounding towns, community members of all ages are invited to bring artifacts found around their homes to the roadshow. Archaeology professors and students provide information about each item and document it in various ways, including 3D scanning. This work has multiple benefits: digital models are entered into the “Hidden History” online database, expanding our knowledge of local prehistory and history of the Castleton area. Taking 3D technology outside of the purview of museums and academic institutions, completed models are also shared with objects’ owners to provide a resource should the original become lost or broken. This mutual sharing of information builds community linkages and facilitates a deeper understanding of the Castleton area.

Capturing and Sharing Vermont’s Past: 3D Imaging as a Tool for Undergraduate Research and Community Engagement

Since 2019, the Vermont State University Digital Archaeology Project, in partnership with the Castleton Innovation Lab, has focused on documenting and sharing Vermont’s past through the use of diverse 3D technologies. Our activities have included documenting both archaeological and private artifact collections, collaborating with museums to create interactive and online content, and extensive outreach with K–12 school groups. 3D technologies have proven to be highly effective for digitally curating artifacts, reaching new online audiences, and connecting with younger students. The application of 3D imaging has also proven to be a remarkably effective tool for undergraduate research. Undergraduate archaeology, geography, and history students, trained in advanced 3D imaging and provided with open access to state-of-the-art 3D scanners, have engaged with Vermont’s past in new and innovative ways. Their work, in turn, has provided fresh opportunities to engage local communities. A review of ongoing work highlights the benefits of collaborative undergraduate research utilizing 3D imaging technologies to capture and share Vermont’s past with the public.

Mapping the Younger Dryas Landscape of the San Dieguito Paleochannel

Humans had established presence on California's Channel Islands by the Younger Dryas (YD) period (~12.9–11.7 ky BP), during which stable sea level was relatively stable for ~1 ky. No archaeological sites from this time have been identified on the nearby continental shelf, likely destroyed by subsequent rapid sea-level rise, but submerged paleochannels exhibiting landscape and sediment preservation could harbor archaeological materials. We mapped the paleochannel offshore the San Dieguito Lagoon in Del Mar, California to reconstruct the YD landscape. We imaged the subsurface by sub-bottom profiling and identified the YD paleoshoreline between 57–60 m depth, ~3 km from the current coastline, to delineate the subaerial portion of the landscape and constrain local sea level. Analysis of three sediment cores, one containing a transition from possible wetland to beach to terrestrial sediments dating between 12.9–11.7 ky cal BP, evidences landscape transitions near the beginning and end of the YD. The sub-bottom data revealed a layered channel which, combined with adjacent core dates, suggests preserved paleosurfaces from the YD or earlier. Such preservation demonstrates that the channel survived drowning enough to preserve information about southern California's early humans and the climate and sea level changes they experienced.

An Introduction to the Cultural Sequence of the Cañoncillo Archaeological Complex, Jequetepeque Valley, Peru

Intensive archaeological excavations of the Cañoncillo Archaeological Complex in the Jequetepeque Valley (north coast of Peru) have underlined the enduring importance of this region to a sequence of precolumbian communities over the past 2,500 years. Extensive investigations at the Late Formative period site of Jatunca (500 BCE–100 CE), the Late Moche site of Huaca Colorada (650–950 CE), and the Transitional and Late Intermediate period sites of Tecapa and Huaca Dos Cruces (ca. 800–1100 CE) have clarified the chronological limits of these occupations through a campaign of over 100 radiocarbon dates that project members collected between 2004 and 2023. This paper will outline the history of collaborative research in the region from 1997 to the present while also contextualizing the current state of collective scholarship of each distinct occupation area and phase. The availability of such a comprehensive sequence of dates from secure archaeological contexts offers a uniquely nuanced understanding of this important cultural landscape

to a degree seldom undertaken by current scholarship in this region. Ultimately, this presentation highlights the strength of long-term and ongoing collaborative research in a single locale by introducing and contextualizing a series of papers offered by project collaborators on their respective fields of examination.

Using Experimental Archaeology to Teach about Ancient Military Technology

This paper looks at addressing specific pedagogical questions in an experimental archaeology classroom using the case study of a lab with a group of 25 students from a variety of majors. The lab explores the development of three ancient Mediterranean military technologies that defeated and replaced each other over 350 years. The students first spend the two class periods preceding the lab reading and discussing ancient accounts of these military technologies and their attendant formations. As we are using proxy data—e.g., we are not using actual weapons but instead modify lengths of PVC tubing and plastic garbage cans and lids; we have small numbers; we are not in an actual conflict—the students are told to focus on three specific questions to see if we can address them: (1) How fast was the learning curve of each technology? (2) How does your personal feeling of safety differ between the three techniques? (3) Why did each formation replace the other? During the lab, group discussions are held after each formation on the research questions. In the class period following the lab we also discuss how proxy data be useful to learn about the past.

Multi-omic Analyses of Naturally Preserved Brains from a Philadelphia Cemetery: Insights from Molecular Taphonomy and Implications for Paleopathology

As one of the first organs to decompose postmortem, brains are far more numerous than they should be in the archaeological record. >4,400 preserved human brains dating back some 12,000 years have been reported in the last four centuries; yet archaeological nervous tissues remain little-studied, with <1% explored at the molecular level. During construction at the site of the eighteenth-century First Baptist Church of Philadelphia (FBCP) Cemetery, >60 brains were found within the cranial cavities of otherwise skeletonized individuals. These remains were examined as part of a comprehensive, systematic, and highly interdisciplinary investigation of 12 assemblages ($n > 150$) of archaeological nervous tissues from across North America and Europe, conducted to probe the chemical mechanisms underpinning spontaneous brain preservation. Proteomic and lipidomic analyses by ultrahigh performance liquid chromatography-tandem mass spectrometry have yielded a wealth of biomolecular data not only on the transformation of nervous tissues after death, but which also illuminates health and disease status in the once living. Resolving the processes by which the brain preserves at the FBCP site will ensure that we maximize recovery of the unique bioarchaeological information this most metabolically active organ harbors and enrich our interpretation of this historical community.

Artistic Currents in Late Paleolithic Times: An Approach from the Northwest of Iberia

Traditionally, the distribution of Paleolithic art was limited to the so-called “Franco-Cantabrian area,” but the distribution of this graphic phenomenon has enlarged with the identification of new sites in different parts of the Iberian Peninsula. Previously, the northwest of Iberia, roughly delimited by the valleys of the Nalón and Duero Rivers, was considered an area lacking in artistic evidence. This view changed from with new discoveries in the 1980s—both on parietal and portable supports—thenceforward integrating this territory into the graphic dynamics of the Iberian Peninsula. The Cova Eirós site is the only cave with rock art in NW Iberia, with some representations that—according to the dates obtained and their stylistic characteristics—date to the end of the Late Paleolithic (Finipaleolithic) stages. Based on the analysis of a group of painted and engraved zoomorphs from this cave, our aim is to investigate the similarities and differences with other images from the northwest and beyond. By means of this approach, both the common features and the particularities observed in several sites will be assessed and the possible existence of contacts among different Paleolithic communities suggested.

Contributions of Belize Cave Research to Ancient Maya Studies

Throughout the Maya area, caves are recognized as unambiguous ritual contexts that provide scholars with a glimpse into the ritual life of ancient people. Religious ritual was not epiphenomenal as some theoretical stances would argue, but was intertwined with the social and political fabric of ancient Maya society. Therefore, cave archaeology is in a privileged position to comment on many aspects of Maya studies from politics to poetics. Caves figured prominently in sacred geography, providing powerful venues for leaders to propitiate earth and underworld deities and to establish relationships with them that underpinned political power and helped to establish and maintain rights to rule. Caves were considered to be entrances into the earth as well as conduits to the underworld; the stone houses of deities and ancestors; and as living, breathing, entities themselves possessing life-force. From cave deposits we can infer relationships between socio/political and environmental stresses and ritual transformations. We can locate political maneuverings, understand differences in ritual practice among communities, and understand Maya aesthetics. Cave chronologies provide information about settlement and abandonment of a region, and help document of war events. Here, we review significant contributions of previous and ongoing cave research in Belize to ancient Maya studies.

Mrozowski, Stephen (Fiske Center for Archaeological Research, University of Massachusetts, Boston)**[258]***Heritage, Pragmatism, and Indigenous Collaboration*

Over the past 20 years, I have worked with the Hassanamisco Nipmuc of Massachusetts with the express goal of seeing how archaeology can aid the Nipmuc with their own heritage initiatives. In all these efforts, the centrality of pragmatic philosophy has been paramount. Given that North American pragmatic philosophy has strong roots in Indigenous practice, this paper outlines some of the critical intersections between pragmatism and Indigenous archaeology. An openness to indigenous knowledge, direct collaboration with the Hassanamisco, and a commitment to an open research process has resulted in an emphasis on linking Indigenous pasts to Indigenous futures. Our work with the Hassanamisco has also led to a rethinking of heritage goals that challenge traditional archaeological practice that have a profound impact on how Indigenous histories are pursued through collaboration.

Mueller, Johannes [38] see Biehl, Peter

Mueller, Natalie (Washington University, St. Louis) and Elizabeth Horton (Rattlesnake Master LLC)**[82]***Life in the Ruins: Historical Ecology in Settler Colonial and Industrial Landscapes*

Throughout the western hemisphere, historical ecologists working with Indigenous experts have made profound discoveries about the ways in which seemingly pristine ecosystems were shaped by Indigenous knowledge and practice over the course of thousands of years. Key methodologies include surveys of biodiversity and ecosystem structure around archaeological sites and/or ethnoecology, which applies a Western scientific lens to Indigenous knowledge. These approaches are complicated in the US Southeast by the scale and severity of colonial destruction: nearly all of the forests have been clear cut, prairies have been eliminated, and the vast majority of rivers have been modified, transforming floodplains and wetlands. Southeastern landscapes are dominated by simplified industrial ecosystems of commodity crops. Native species continue to be driven to extinction by introduced predators and pathogens and settler colonial land use. The vast majority of the Indigenous people of the Southeast were forcibly removed from their homelands, interrupting their care of the land and making it harder for communities to practice and reproduce ecological knowledge. Despite these immense challenges, it is possible to practice historical ecology in the Southeast, and doing so can provide insights into how to understand and rehabilitate industrial and colonized landscapes around the world.

Mueller, Natalie [151] see Grillo, Katherine

Mueller, Rachel, Christine VanPool (University of Missouri) and Todd VanPool (University of Missouri)**[266]***The Context and Meaning of Medio Period Casas Grandes Stone Effigies*

This project presents the analysis of ground stone effigies from Paquimé, Chihuahua, Mexico. Paquimé was the center of the Medio period (AD 1200–1450) occupation of the Casas Grandes region. These effigies are small figurines ground to resemble humans and animals. Our analysis, based on Di Peso et al.'s (1974) Casas Grandes report, indicate that mountain lion and bear pendants were most common animal forms, although many other animals were also present. The context and form of these effigies are consistent with ethnographically documented use of similar effigies among the historic and modern southwestern Native American cultures in which males primarily used these effigies for healing and hunting rituals. Human ground stone effigies could take the form of large 0.5 m tall effigies of the entire body or smaller effigies of human

heads. Phallic shaped objects are likely effigies of male genitalia as well. The larger human effigies are likely statuary items that are tied to specific ritual locations whereas the smaller heads and phallic effigies have a broader distribution across the site.

Clay, Culture, and Chains: Unearthing Underrepresented History through Pottery Production on St. Croix, USVI

While scholars have long studied the pottery production of African peoples in the Caribbean during the colonial era, there has been minimal archaeological research on the ceramics used by enslaved African and African-descended peoples on St. Croix, USVI. This paper represents the culmination of thesis research to conclusively establish defining characteristics of Afro-Crucian ceramics during the Danish colonial era. With the ceramic assemblage excavated by the Estate Little Princess Archaeological Project Field School (2018–2023), I utilize a combination of LA-ICP-MS testing and macroscopic examinations to determine key components such as paste recipes, potential clay sources, and vessel types. This research is bolstered by a collaboration with St. Croix's Caribbean Earth Skills program to conduct an experimental project comparing contemporary locally produced pottery with identified Afro-Crucian ceramic vessel types. Contextualized by participatory ethnographic research and archival records, this historical archaeological approach builds the capacity to recognize and memorialize the experiences and everyday contributions of Afro-Crucians whose persistence against the confines of slavery irrevocably shaped the development of St. Croix.

Toward the Development of a Temporal GIS for the Study of the Peopling of the Americas

The Peopling of the Americas remains a provocative topic in both North and South American Archaeology. Speculation about who the indigenous inhabitants of the Americas were, where they came from, and how they got here, began the moment European explorers first encountered them. Current archaeological data and theory indicate humans had reached the landmass of North America south of the Cordillera and Laurentide ice sheets at least by 16.5 ka and to the far south of South America by 14.5ka. Understanding the dates different routes were viable in relationship with known sites, climatic parameters, and genetic data is important in determining the pathway(s) traversed by the First Migrants into the Americas. This paper discusses the development of a geographic information system (GIS) and database to incorporate climate, archaeology, genetic, paleontology and other types of data as they occurred through space and time in the area commonly referred to as Beringia from about 35 ka through 16.5 ka. This GIS system will serve as a data warehouse specifically focusing on the PotA for archaeological study with a temporal dimension.

Dismemberment as Postmortem Disablement: The Disparate Mortuary Sites of the Collected

Acknowledgment of the educational value of pathological conditions in human cadavers prompted scholars of anatomy and anthropology to partition bodily tissues of the dissected among their colleagues. This scientific network of shared body parts, for the purpose of specialized study, segregated the divisible body into multiple sites—separate drawers in a laboratory, heart in a mason jar, kyphotic vertebral column hanging in the corner of an office, display cases in museums. Although bio/archaeologists typically study human remains associated with burial sites, mortuary treatments include those practices in which bodies have been manipulated by scientists. Bio/archaeological research of university laboratories and basements permits interrogation of the socially defined value of particular bodies and the ways in which this facilitated dissection and collection. It is argued that individuals who present with corporeal differences, perceived as pathological

or as a defect, were particularly vulnerable to dismemberment and more likely to experience postmortem dis-ablement, defined here by societal prevention of decedent's full participation in culturally desirable mortuary treatments. Efforts to reconstitute and repatriate skeletonized persons is complicated by the multisite formation that characterizes anatomical collections. A thorough analysis of archival documents, where available, have the potential to trace these dismemberments.

The Ties That Bind (and Break): Persistence and Upheaval in the Post-Chavín Landscapes of the Carabamba Plateau and Moche/Virú Chaupiyungas

Following the dusk of Chavín, the traditional narrative for the Virú and Moche Valleys—as well as many parts of the Northern Andes—has been one of conflict and upheaval. Though the late Early Horizon (~500–200 BCE) and Early Intermediate period (~200 BCE–600 CE) landscapes in these areas surely saw an explosion of fortified and defensive settlements that suggest rampant conflict, overemphasizing such patterns is done at the risk of overshadowing the many examples of persistence and continuity in these same landscapes. Indeed, the post-Chavín highland landscapes of the Carabamba Plateau and Moche/Virú *chaupiyungas* are rich with evidence for wide interregional networks of exchange, the florescence of large highland demographic and political centers, and the expansion of permanent highland colonies into the *chaupiyungas*. This paper explores these themes using a landscape perspective that synthesizes the authors' previous research in the *chaupiyungas* with a recent highland drone survey conducted during the first season of the Carabamba Archaeological Research Project (CARP). Using these data, we reconstruct and articulate some of the ties that bound these post-Chavín highland and chaupiyunga landscapes together while also calling to attention how such ties perhaps began to unravel with the coastal landscapes below.

Food for Thought: Exploring the Cultural and Ecological Significance of Greater Antillean Fisheries

The Greater Antilles is an archipelago of islands in the Northern Caribbean (e.g., Cuba, Jamaica, Hispaniola, Puerto Rico, and the US Virgin Islands). These islands are host to a melting pot of unique cultural identities and ecological biodiversity. It is well known that the long-term harvest of marine fishes greatly shaped human cultures and marine ecosystems in the region. Scholars have previously reported on the cultural and ecological importance of fishes to indigenous peoples of the Greater Antilles during the Caribbean

Ceramic Age (~500 BC–AD 1500). Scholarly discussions on the topic of marine fish harvest in the Greater Antilles range greatly from—conversations on the environmental implications of exploiting fish to examining the symbolic and ceremonial importance of fishes within Taíno traditions. I broadly synthesize archaeological findings, ethnohistoric accounts, and ethnographic data to analyze current knowledge pertaining to how the harvest of marine fishes influenced diet, fishing technology, and strategy, ritual/ceremonial practices, as well as marine ecology. Additionally, I comment on trends related to contemporary fishing in the region. I then discern potential future directions in research relevant to multiple facets of the topic described previously.

The 2023 Excavations at the Cosma Archaeological Complex, Ancash, Peru: A Journey Down the Rabbit Hole into the Andean Late Preceramic

Excavations at the Cosma Archaeological Complex, located in north-central Peru, have revealed a potential missing link, both temporally and geographically, in understanding the origins of corporate labor and the construction of public monuments associated with the Late Preceramic period. A suite of radiometric dates at two temple mounds with Kotosh-Mito style chambers ranging from 2900 to 2475 BCE were recovered from excavations at Cosma between 2014 and 2016. During the summer of 2023 excavations at the Kareycoto mound, the largest mound in the Cosma basin, exposed a previously unknown underground gallery system, reminiscent of those constructed at the site of Chavín de Huántar located in the Callejon de Conchucos. Previous gallery systems at the sites of Chavín and La Galgada date back to the Initial (1800–900 BCE) and Early Horizon periods (900–200 BCE), while the Kareycoto gallery was found in association with Late Preceramic floors and architecture at the site. This suggests that these architectural features may in fact date earlier than previously thought. This paper will present on the 2023 discovery and its implications for our current understanding of gallery systems in association with the Kotosh-Mito tradition.

Variability in Human-Animal Interactions at the Emergence of Animal Domestication in Southwest Asia

In his 2002 paper “Breaking the Mold,” Richard Redding wrote that “by focusing on the emergence of tactics of animal use that characterize the Neolithic, we may be missing aspects of the process that are not only interesting but critical to building and testing explanations.” Twenty years later, our understanding of the beginnings of animal domestication has changed substantially from the unilineal perspective that Redding criticized to a multiregional view emphasizing multiple origins, local context, gradual change, and stops, starts, and dead ends. This scenario emerged based on a growing archaeological record demonstrating significant variation in human-animal relationships surrounding the Pleistocene-Holocene boundary in Southwest Asia. This presentation uses Redding’s quote as a jumping off point to reflect on the nature and meaning of this variability. In doing so it touches on the value of assembling the multiple lines of evidence that Redding believed were so important and provides a synopsis of current research on the early emergence and evolution of animal management and domestication.

Munson, Jessica (Lycoming College)**[74]***Discussant***Munson, Jessica (Lycoming College), Matthew Looper (California State University, Chico) and Jonathan Scholnick (Bucknell University)****[323]***Ritual, Politics, and the Structure of Community Networks in Classic Maya Society*

Ritual and performance play important integrative functions in the creation, maintenance, and negotiation of social ties that bind communities together. The shared experience of these public displays establishes strong bonds between individuals, defining their membership in certain social groups while reinforcing cultural norms and values. Rituals, however, are not timeless traditions nor do they simply restore social equilibrium. Rather, such periodic gatherings engage diverse participants in interactive and ongoing political processes that unite and divide across multiple social categories. As emergent and fluid social institutions, communities can be defined by the sense of shared identity fostered by these spatially embedded ritual interactions. This paper examines the degree to which shared ritual traditions structure the formation of interregional community networks in Classic Maya society using inscribed records of these events from dated and provenienced monuments catalogued in the Maya Hieroglyphic Database. Community detection methods identify clusters of sites based on ritual similarity while multivariate analyses examine the diversity of rituals practiced by these groups to explore the underlying differences between them. Results of this study shed new light on the nature of governance and different political strategies employed by dynastic rulers during the Classic period (ca. 250–950 CE).

Muraski, Jill and Carl Blair (Michigan Technological University)**[286]***Conglomerate Mining in the Keweenaw*

In the inaugural season of the Keweenaw Copper Research Collective (KCRC), excavations at the Delaware Copper Mine in the Keweenaw peninsula conclusively demonstrated precontact Indigenous mining in conglomerate rock formations. Archaeologists revealed the conglomerate formation along the Hogan copper vein, recovering banded and expedient hammerstones along the way before landing in various mining pits.

These consisted of sloping pits, or dives, in the formation as well as a circular pit with a depth reaching greater than 1.5 m. Charcoal samples, often found in association with both varieties of hammerstones, were taken from the excavation areas. The results have yet to be returned, though expect to yield dates congruent with precontact mining.

How Unusual Is the Trajectory of Precolumbian Social Change in San Ramón, Costa Rica, among the Trajectories of Chiefdom Development? A Comparison Exercise

Recent literature on comparative archaeology has pointed out the need for systematic comparisons of trajectories of social change that use primary quantitative data and standardized variables. This type of comparison has the potential to discover and explore the diversity and complexity in the processes of social evolution, beyond the sole use of holistic typological categories. The emergence of chiefdoms is a topic, among others, that can be explored more in-depth by using the strategy just described. A first look at the precolumbian trajectory of social change in San Ramón, Costa Rica, shows that this region had both what appear to be typical features in other trajectories of chiefdom developments, as well as highly atypical elements. This first impression needs to be evaluated by a systematic comparison of the San Ramón trajectory with what has been usually taken by the archaeologists as typical trajectories of chiefdom emergence.

Religious and Political Resilience in the Ancient Moche World: Monumentality, Micro-chronology, and Environment in Úcupe, Lambayeque, Peru (200–900 CE); The Úcupe Cultural Landscape Archaeological Project: First Results of the 2022 Field Season

This poster will present the results of the first excavation campaign of our project (UCLAP) at the Úcupe Archaeological Complex, Zaña Valley, northern Peru. Composed of a dozen of huaca-mounds, Úcupe is an Early Moche (200-400 CE) site that extends over a plateau of 10 ha, located on the southern bank of the Zaña Valley. The site became particularly well known for the finding of spectacular Moche elite burials (e.g., the Lord of Úcupe); however, very little is still known about the development and historical trajectory of its monumental landscape. The goal of our project is to examine co-relationships between the progressive development of the site's monumental constructions and situations of environmental stress and climatic vulnerability that hit the site during Moche times. The 2022 field season of the project was focused on documenting the archaeological complex with diverse remote sensing techniques and excavating the foundations of the most prominent buildings: Huaca El Pueblo and Huaca E2-E3. Preliminary results of our mapping and excavation work and spatial and artifactual analyses of collections recovered are presented and discussed in this poster.

Murphy, Samantha**[228]***Examining Great Oasis Cemeteries in Iowa through a Population Level Analysis*

Great Oasis is a Late Terminal Woodland culture, dating between AD 900 and 1100, that has produced the earliest evidence for Mississippian contact in Iowa. Great Oasis peoples built unfortified farming villages throughout western and central Iowa, southwest Minnesota, and eastern Nebraska, and South Dakota. Several excavated village sites typically have an associated cemetery that includes both primary and secondary burials with no apparent discrimination based on age, biological sex, or status. This data allows for a community health-based analysis and examination of possible family lineages with the potential for generational health conditions. Researchers have established the overall health of individuals through an examination of the remains for frequencies of pathologies such as, porotic hyperostosis, periostitis, dental caries, and tooth loss. Nondestructive comparative examination of three Great Oasis cemeteries in Iowa have led to a better understanding of health overall during this period. Excavated in the 1960s, the ancestors from these cemeteries have been documented in the NPS NAGPRA database and published Notices of Inventory Completion and are currently reposed by the Iowa Office of the State Archaeologist Bioarchaeology Program awaiting repatriation to the 26 tribes that have ancestral ties to the state.

Murphy, Shambri (Chronicle Heritage)**[183]***The Presence of Fraxinus in Hohokam Pithouses*

This paper will investigate the presence of ash wood (*Fraxinus* sp.) in the context of burned pit houses of the Hohokam culture by comparing the botanical remains in burned pit houses to remains from unburned pit houses from previous data recovery projects in Arizona. To further understand the purpose of *Fraxinus* in burned pithouses, previous ethnobotanical studies of indigenous tribes such as the Hopi and O'odham and their use of *Fraxinus* will be consulted. In order to understand the effects of *Fraxinus* in a burned context, experimental methods will be utilized and recorded to compare the smoke output from a fire utilizing *Fraxinus* as a fuel source in contrast to other fuel sources commonly found in pit houses in the region. All methodology and results will be recorded to further understand how the presence of *Fraxinus* may contribute to a ceremonial atmosphere due to observable differences such as intensity or color of the smoke output or smell. Results of research from data recovery, ethnographies, and experimental methodology will be used to assess the presence of *Fraxinus* in burned pit houses and how it may contribute to the overall atmosphere of ceremonial burnings.

Murray, John (Arizona State University, Institute of Human Origins), B. Patrick Fahey (Arizona State University) and Cindy Hsin-yee Huang (Arizona State University)**[306]***Further Considerations of Tip Cross-Sectional Area for Determining Projectile Systems*

The origins and evolution of projectile technology have been a major research focus in paleoanthropology because projectiles are thought to have had crucial impacts on human adaptation and dispersal in the Pleistocene. Projectile technologies are often used as a proxy for changes in human cognition, cooperation, hunting strategies, and interpersonal or intergroup conflict. Mechanically assisted projectile systems, such as the bow and arrow, are thought to have provided a significant adaptive advantage over hand-thrown spears on some prey types due to the increase in power, accuracy, and range. Therefore, it is imperative that paleoanthropologists determine when and where these projectile systems arose and in what contexts they were utilized. Hughes (1998) developed a method for determining projectile systems that is based on tip cross-sectional (TCS) measurements. Our study expands on Hughes's approach, using Bayesian statistics to determine which projectile systems can be reliably distinguished using distributions of TCS metrics from a sample of ethnographic and archaeological tools of known function. Further, we consider other factors that may impact our ability to infer projectile technology using TCS such as raw material quality. This research has implications for the reliability of TCS methods as one line of evidence for identifying projectile systems.

Murray, Wendi (Wesleyan University) and Julie Unruh (Julie Unruh LLC)**[305]***Bags, Biomarkers, and Biographies: Keeping up with Archaeological Science in the Collections Repository*

Walk through any archaeological collection and you walk through a historical archive of collections storage practices. Best practices for collections storage evolve as materials science evolves, and storage decisions are realigned to maximize research potential. However, determining appropriate parameters for archaeological collections storage is complicated not only by varied research interests, but increasing concern about sample damage or contamination across diverse archaeometric methods. Given that storage history can play a major role in sample viability, collections managers have a crucial role to play in this evolving field. Concerned about the disconnect between archaeometric research needs and collections storage decision-making, we interviewed 13 researchers about nine different archaeometric methods—interview questions focused on issues of sample integrity/viability, potential causes of contamination, and how storage decision-making can impact research results. We share researcher insights about appropriate sample storage, highlight the need for more consistent dialogue between archaeological researchers and collections stewards, and suggest avenues for further research.

Myerscough, Autumn**[286]***Bone “Awls” of the Southwest*

Through conducting a microwear analysis, I argue that the use wear of the bone tools examined will determine their functional use. The collections of bone tools for this study are from various Mimbres (AD 200–1130) and Chacoan (AD 850–1250) sites (located in the North American Southwest). Many bone artifacts with narrow, pointed distal ends are defined as awls traditionally. Awls are generally defined as tools used to pierce holes in leather or other malleable substances. I argue that a detailed microwear analysis may suggest alternative uses of these types of bone tools beyond the narrow category of “awl.” Through this research I encourage my audience to ask if it is proficient to define awls by their morphology (tools with a narrow, pointed distal end) despite these tools possibly having varying functions. Through a comparison of bone tools from both types of sites in the study area, I intend to demonstrate that these bone tools commonly thought of as awls, may serve a variety of functions rather than the narrowly proscribed categories they are traditionally sorted into.

Mykhailova, Nataliia (Institute of Archaeology NASU)**[25]***Deer Offerings in the Stone Age of Eurasia*

The Deer Cult was a primary element of the myth-ritual complex of ancient hunter-gatherers. Deer worship included rituals related to natural and economic cycles, including the human life cycle. In the Upper Paleolithic, accumulation of deer antlers in caves in Western Europe and the Urals as well as images of deer

or deer heads in the monumental and portable art of the Franco-Cantabrian area are evidence of rituals devoted to the reproduction of deer. During the Mesolithic-Neolithic period of Northern Eurasia, the image of deer and elk became dominant in the myth-ritual complex. This rock art reflects the rituals of cervid reproduction and additional archaeological material point to the existence of sacrificial rites of deer and moose which over time developed into multilayered sanctuaries. Sacrificial offerings of deer, especially buried body parts or complete skeletons, found in Neolithic-Chalcolithic archaeological sites in Central Europe indicate that elements of the Deer Cult continued well beyond the transition to agriculture. The use of deer remains in agricultural magic is still well known among the peoples of North and Central America.

[282]

Preservation, Degradation, and Contamination: The Chemical Identification of Cochineal in Archaeological Environments

Although cochineal has played an important role in Mesoamerican societies, a lack of suitable methods has hampered its investigation by archaeologists. Luckily, recent developments in organic residue analysis suggest the possibility that cochineal production may be identified in the archaeological record through identification of carminic acid, its primary source of color. Prior to its application to archaeological materials, however, experimental archaeology must be conducted to build comparative datasets and establish the efficacy of methodological protocols. Experimental production of cochineal products was done to test the hypothesis that carminic acid residues form and preserve in inorganic matrices buried in archaeological environments. The ceramic and ground stone tools were analyzed chemically (HPLC with MS, DAD-MS, and/or MS-MS) before and after burial underground for one year. Although carminic acid concentrations did decrease modestly, most tools maintained measurable quantities of the water-soluble biomarker. In several samples, a distinctive spectral pattern indicative of carminic acid's degradation, though crucially not beyond recognition, was identified. Furthermore, this analysis validated the use of tools' inactive surfaces as controls for environmental and laboratory contamination. This poster concludes by reporting preliminary results from similar chemical analysis conducted on hypothesized cochineal production tools from Late Postclassic–early colonial Tlaxcala.

Connecting Archaic Age Communities in the Insular Caribbean

The study of ancient Caribbean communities through archaeogenomic methods has seen an increased interest in recent years. In our study in 2020, we demonstrated that the Archaic Age communities in the Greater Antilles exhibit a different genetic signal from the Ceramic Age communities in the Greater and Lesser Antilles. Still, we could not add more detail beyond those previously obtained from archaeological research. The low genetic variation—a consequence of repeated bottlenecks in the settlement processes of the Americas and the Insular Caribbean—imposes strong limits on the identification of genetic diversity, leaving open many questions about the interactions between and within precolonial communities during and at the end of the Archaic Age in the islands. This presentation provides a critical review of the potential and limitations of ancient DNA research in the understanding of genetic diversity in the Insular Caribbean and deploys newly developed methods identifying genetic relationships based on segments identical by descent (IBD). This method provides a new resolution in investigating connections and interactions between communities, exemplified here on the analysis of the genomes obtained from Canimar Abajo and archaeologically similar communities in the insular Caribbean.

A Differential Recovery Checklist for Zooarchaeology in the US Southwest

Differential recovery refers to the ways that faunal assemblages are sampled from the archaeological record. Its effects can be pernicious when interpreting data from multiple assemblages. As such, the topic is a mainstay in contemporary zooarchaeological research; however, in the US Southwest differential recovery has received less attention. One reason could be the excellent archaeological preservation of faunal remains in the region. Researchers may be more inclined to assume representativeness without consideration of differences in recovery among faunas. Here, we explore the interaction between recovery and other taphonomic variables from multiple large faunal assemblages recovered from the central Mesa Verde Region of southwestern Colorado and the Northern Rio Grande of north-central New Mexico. We analyze faunas from five sites: Tsama'uinge (LA 908), Ponsipa'akeri (LA 297), Shields Pueblo (5MT3807), Goodman Point Pueblo (5MT604), and the Haynie site (5MT1905). These sites represent varying degrees of sampling intensity and disturbance, spanning a continuum from low- to high-quality recovery. Our goal is to propose a suite of basic analyses to assist Southwest archaeologists in making decisions about the inclusion of individual faunal assemblages in large datasets. A standard checklist can improve data quality and strengthen interpretation in this region of extreme cultural significance.

High-Resolution Paleoenvironmental Shell Proxy Data: Implications for South Florida and Beyond

We present exploratory analyses of subannual environmental proxy data from a variety of freshwater, estuarine, and marine mollusk species from South Florida and the broader US Southeast. Using modern baseline specimens as well as specimens from archaeological contexts analyzed via microscopy and associated methodologies, we discuss best practices for shell sample selection and preparation as well as analytical methods. These data sources have the potential to allow for high-resolution reconstructions of environmental parameters in antiquity, including identification of shifts in the lengths of mollusk annual growing seasons. Such reconstructions can aid in improving the temporal understanding of cultural harvesting practices as well as the resiliency and sustainability of mollusk resources during periods of rapid environmental change.

Reciprocal Archaeology in the Time of Climate Change

Archaeologists have long recognized that partnerships with practitioners from allied disciplines enrich our contributions and create many-layered interpretations of the sites and communities we study. Working in the context of climate change, collaborations between archaeologists and scientific colleagues have expanded to include descendant communities, policymakers, and citizen scientists. Bringing archaeology to different audiences reinforces the critical place it holds in our understanding of human responses to environmental change, while challenging archaeologists to better communicate the relevance of the discipline. Collaborative practice demands a different kind of relationship, one that values a reciprocity holding archaeologists accountable while creating new opportunities for archaeological research. Collaborative practice transforms our research questions, methods, and knowledge production processes. This poster explores examples of reciprocal archaeology in the Middle Atlantic (North America), with an emphasis on the integration of interdisciplinary knowledge, traditional knowledge, and public history to generate a more unified response to the impacts of climate change on cultural heritage.

Palace Pottery Production on Cerro Baúl: The Particularity of Paste Recipes

Decorated ceramic vessels carried meaningful symbols and were an important element of the Wari Empire's political economy. Wari, a powerful early Andean state, expanded sometime near the middle of the first millennium and pioneered institutions that were refined and deployed by the later Inca Empire. Wari officials used pottery to display, serve, and consume alcoholic beverages. Vessels of different sizes and forms were smashed and incorporated into offerings of several kinds. Smaller pots of varying quality were included in the graves of people with different ranks, and matched sets may have been used for ceremonial toasting or other symbolic actions during ritual performances. Evidence for the production of decorated vessels has been found alongside or embedded in the residences of intermediate elites at Conchopata, a site near the empire's capital, and Cerro Baúl, the polity's furthest southern provincial center. In this paper, results from LA-ICP-MS analysis of raw materials and unfired sherds found in the palace at Cerro Baúl are compared to those from other vessels at the site and in the region to identify what types of pottery were made in the palace and assess their value and distribution.

3D Imaging the Granger House Ceramic Collection, Castleton, VT

Since 2019, the Castleton Hidden History Project has conducted excavations around Granger House, a nineteenth-century home on the campus of Vermont State University-Castleton that will become a local history museum. Ongoing interdisciplinary work centers on investigating the National Register-listed structure, the daily lives of its inhabitants, and the dynamic cultural landscape that surrounds the home. Four years of archaeological excavations have produced a wealth of artifacts. In this poster we focus on ceramics and the use of 3D technology to assist research and outreach efforts. Spanning much of the nineteenth century, ceramics recovered at Granger House include mundane cooking vessels, everyday dinnerware, and items that would have had pride-of-place in family collections. 3D scanning of these ceramics has allowed for the creation of a digital artifact repository, with extremely detailed models facilitating research into ceramic technology, styles, and social trends. Digital models are also being used to create interactive displays that will help the general public to interact with and learn about Granger House ceramics when the museum opens.

The Women of Fort St. Joseph, a French Colonial Settlement on the North American Frontier

Forts and fur trading posts conjure images of intrepid soldiers and jovial voyageurs engaged in masculine activities that implicated material objects like firearms, ammunition, smoking pipes, alcohol containers, and trade goods. Male colonial ambitions also structured many of the accounts that persist into the present. Yet, archaeological and documentary records from Fort St. Joseph, an eighteenth-century French mission, garrison, and trading post complex in southwest Michigan, provide ample evidence of women who played an important role in daily life. While much of the evidence is domestic and personal in nature, it nevertheless underscores the significance of women in the success of this colonial enterprise.

Living in Turbulent Times: Life on the Plaza in Nineteenth-Century Mesilla, New Mexico

The village of Mesilla in southern New Mexico endured a tumultuous nineteenth century. Between 1845 and 1855, Mesilla shifted back and forth between Mexican to US territorial control. During the US Civil War, the Union-controlled town was conquered by Confederates and briefly became the capital of the Confederate state of Arizona until it was reconquered by Union forces and placed under martial law. Conflicts between opposing political ideologies continued in subsequent years, resulting in a notorious shoot-out on the plaza in 1871. Less than a decade later, Mesilla was bypassed by the new Santa Fe Railway and fell into decline.

Nineteenth-century Mesilla serves as both a locus of significant historical events and as a microcosm of the struggles of the American territorial period in the Southwest. This paper draws on archaeological and archival data to see if and how this turbulent history shaped the material lives of Mesilleros living on the west side of the village plaza.

Use of Introduced and Native Plants by Early Humans in the Japanese Archipelago

This paper presents recent archaeobotanical findings on the use of plants by early humans in the Japanese archipelago. The first humans arrived in the Japanese archipelago about 38,000 years ago. Although there are not many archaeobotanical records from this period, pine seeds, hazelnuts, and acorns have been found, suggesting that these plants, which were native to the Japanese archipelago, were used as food. As the climate warmed and stabilized around 10,000 years ago, the number of settlements increased, and the evidence of plant use also increased. Gourds, hemp, and lacquer trees found from this period have no wild species in the Japanese archipelago today. It is possible that these plants were brought from the continent as important tools used for containers, fibers, and paints. Wild annual plants such as barnyard millet, soybean, and azuki bean originally grew wild in the Japanese archipelago and are thought to be early weeds that adapted to the open areas (disturbed environment) created by deforestation for settlement, and their usefulness as food was discovered by the Jomon people. Their seed size increased during the middle to late Jomon period (4,500–3,500 years ago), suggesting that domestication may have occurred in the process of using these plants.

The “Three Sides” of the Emblematic Early Azilian Blades with Flat Retouch along the Atlantic Façade

Recent research allowed us to draw a better picture of the period around 14,000 cal BP, the theater of a shift between Magdalenian and Azilian technical concepts. The rhythm of this changing is still difficult to describe precisely because of a radiocarbon plateau and the scarcity of Early Azilian (EA) sites excavated in good contexts with modern methods. These last years, the discovery of Le Rocher de l'Impératrice rockshelter in Brittany and the restudy of Murat Rockshelter in southwest France bring key information about this period characterized by a major cultural shift. Integrated techno-functional analysis of the lithics from these sites particularly focused on blades bearing flat retouch on their cutting edges. This typological form is particularly emblematic of these sites and others reported to EA. These blades and their characteristic form are the result of a long biography alternating phases of use and maintenance according to specific modalities. Our study allowed us to understand the functioning of these tools and track the diffusion of this concept along the Atlantic façade of Europe and to start thinking about the implications of these results for our understanding of the dynamics of idea diffusion and system transformation during this pivotal period.

The Snake Queens of Waka: Harnessing Sorcery and Divinatory Power in Service to Kaan

Our paper demonstrates the key role played by royal Kaan women in fortifying and consolidating Kaan's hegemony in the seventh–eighth centuries CE. We draw on archaeological, visual, and textual evidence from Waka', including a preliminary analysis of recently discovered Stela 51, and elsewhere across the realm. We address how the political actions of royal women served to consolidate the Kaan realm, helping to create the so-called “Golden Age” of their Late Classic supremacy. These women anchored themselves materially and

symbolically within the built landscapes they ruled and established enduring bonds through blood and political maneuvering. Part of these political consolidation efforts, we have learned, drew on the healing, restoration, and reincorporation of ruptured Early Classic monuments whose inscriptions had linked Waka's Early Classic nobility with key entrada figures, including Sihyaj K'ahk' and Spear-Thrower Owl. We argue that Lady K'abel endeavored to associate her legacy with the Early Classic Waka'-Teotihuacan connection, which itself was arguably founded on Waka's role as a place of prophesy. The implications of our findings contribute to a more nuanced understanding of Late Classic political history and have enduring significance for Indigenous women in the Americas today.

Habitar en el Irechequa Tzintzuntzani: Resultados preliminares del análisis lidar

Como parte del proyecto "Prospección Arqueológica de Tzintzuntzan, Antigua Ciudad de Michoacán", se analizó el paisaje norte de la cuenca del lago de Pátzcuaro para identificar la extensión de las modificaciones hechas en las laderas de los cerros, mediante la construcción de terrazas. A través de diversas técnicas de realce (como sombreados digitales multidireccionales, *sky-view factor* y clasificación de pendientes) aplicadas en un MDE derivado de lidar, se hizo un importante registro individual de terrazas y plataformas prehispánicas en un paisaje mixto, es decir, con áreas con vegetación de bosque de pino encino, áreas agrícolas y deforestadas, así como zonas urbanas modernas. En consecuencia, por primera vez, contamos con un registro individual de terrazas, su ubicación y disposición en gran parte del paisaje. De esta forma, presentamos los datos preliminares de un estudio que busca extender las investigaciones fuera del núcleo más denso de la ciudad, aportando un gran corpus de datos para comprender la manera en que los antiguos tarascos habitaron y construyeron un espacio complejo, a través de la organización familiar y que permitió el crecimiento de una de las ciudades más importantes para el Posclásico Tardío en Mesoamérica.

Characterization of Mendoza and Cortezo Pigments: Communities of Practice and Ceramic Production in Precolumbian Panama (AD 1300–1500)

We present the results of an exploratory pigment characterization of the Mendoza and Cortezo Red-Buffer ceramics. These ceramic styles produced from CE 1300 until the first part of the Spanish colonization tend to appear in association (Mendoza-Cortezo complex). Mendoza, distinguished for the ceramic plates decorated with polychrome geometrical designs arranged in concentric panels, marks the end of the polychrome tradition in Central Panama. Cortezo Red-Buffer is utilitarian pottery with red paint restricted to the lips, rims, or brushstrokes. Previous historical and archaeological research suggests organic and inorganic ingredients potters used to produce pigments. For this research, the surface of 20 samples was analyzed with laser ablation-inductively coupled plasma-mass spectrometry (LA-ICP-MS) to identify the composition of the black, white, and red pigments. These results are compared with the compositional recipes obtained with NAA to learn more about the production of precolumbian ceramics. This paper contributes to understanding communities of practice production of utilitarian and prestige items circulated in the Gran Coclé right before the Spanish colonization.

Needham, Andy and Stephanie Piper (University of York)**[147]***Breaking Down Boundaries through Collaborative Learning Communities: Integrating Outdoor Teaching into a Year One Introductory Archaeology Course*

Studying a non-school subject such as archaeology at university can be challenging. This knowledge gap can compound barriers for new students, including living away from home, arranging a new job, and making friends. Creating a collaborative learning community is therefore important for encouraging student engagement with unfamiliar teaching methods and a new subject matter. We present our reflections and observations from teaching a first-year undergraduate course: Artifacts and Materials. This course aims to introduce students to artifacts from diverse periods and places and how archaeologists analyze and interpret them, using lectures, seminars, and outdoor practical workshops. To address the combined pedagogic challenges of creating inclusive and collaborative learning communities, and enable deep learning of unfamiliar objects, materials, working techniques, and cultural settings, an integrated program of outdoor experimental archaeology was used to augment traditional classroom-based teaching methods. Student feedback suggests this combination can support the creation of a positive learning community. Shared practical tasks can encourage diverse contributions and support peer-group formation by discussing objects together. The experience of working with materials firsthand can encourage deeper learning. Finally, students noted that working in this outdoor space can promote well-being by reducing stress and anxiety and promote sociality.

Needham, Andy [257] see Little, Aimée

Neeley, Michael (Montana State University) and Craig Lee (Montana State University)**[265]***The Curation Continuum: An Example from the Henry Smith Site in Northeastern Montana*

Forager mobility is often linked to the organization of technology through the continuum of curated and expedient technologies. Curated technologies are expected to be associated with higher levels of mobility reflecting transport costs and longer use histories, in response to reduced access to raw materials. In contrast, expedient technologies are more closely associated with reduced mobility, lower artifact transport costs, shorter artifact use histories, and greater access to raw materials. With the curated-expedient dichotomy in mind, we examine the lithic materials from the Henry Smith site (24PH794), a late precontact bison kill in northeastern Montana. Our poster focuses on the use of cortex ratios to assess technological organization, the role of core and chopper classification in determining these ratios, and the core reduction strategy of local quartzite cobbles that results in large quantities of cortical flakes. Preliminary results indicate low cortex ratios which suggest an organizational practice of off-site lithic transport. Additionally, we explore how these values can be influenced by the variable classification of cores and choppers.

New Evidence on the Early Occupation of the Lakes Basin of Pacific Nicaragua

Evidence for early sedentary villagers is perplexingly difficult to identify in Pacific Nicaragua. Wolfgang Haberland thought he found Early Formative remains, which he named the Dinarte phase, on Ometepe Island, but our own efforts to resample those putative early deposits did not meet with much success. More productive have been our efforts to take a broader, whole-landscape approach. Sediment cores from the edge of Ometepe Island and from the Lake Managua (Xolotlan) shore just east of Managua document farming around both lakes by shortly after 1000 cal BC at the latest. On the slopes above Lake Managua, a paleosol below a thick volcanic sand deposit at La Arenera contains maize and cotton pollen with an inferred date of around 900 cal BC. This paper reviews this and other recent evidence for early village farmers in the lakes basin.

Tracking the Origins of Animal Management in a Neotropical Foraging-to-Farming Population Using Carbon Stable Isotope Analysis of Lysine

The middle-late Holocene in southern Belize saw shifts in subsistence strategies, including the introduction of managed plants and animals. Botanical and stable isotope data have been used to track the introduction of agricultural products into human diets, with maize first consumed before 7000 cal BP. However, the timing of the introduction of managed animals is less understood because early faunal assemblages are rare. Carbon isotope ($\delta^{13}\text{C}$) analysis of amino acids (CSIA-AA) is a powerful tool that allows researchers to track the biochemical origins of these compounds in consumer tissues. CSIA-AA analysis of directly dated human skeletons from two rockshelters spanning the transition to agriculture shows a trend of increasing $\delta^{13}\text{C}$ -lysine values indicating a C_4 -lysine origin in individuals by the Classic Maya period. Additionally, individuals that date to the middle Holocene demonstrate higher-than-expected incorporation of C_4 -derived lysine. Based on the low abundance of lysine in maize (C_4 -plant) and daily lysine requirements in humans, these results are only possible through trophic concentration of C_4 -derived lysine, possibly obtained by consuming maize-eating animals. We propose that human $\delta^{13}\text{C}$ -lysine values can be used to track the incorporation of managed, but not necessarily domesticated, animals into neotropical diets during the transition to agriculture.

The World's Largest Archaeological Jigsaw Puzzle: Excavations at Juukan Gorge 2022–2023

Since 2022 a team of archaeologists in collaboration with the PKK People has been re-excavating the Juukan

2 site. Under the rubble of the blast, we have found an in situ cultural deposit with largely intact material culture. This paper describes the process and methodology we have used to find this delicate sedimentary context beneath the blast rubble. We have used a variety of models ranging from ERT to large-scale geological applications to locate the floor of Juukan 2. Ultimately, however, the relocation and excavation has involved good old-fashioned archaeological method as over 200 m³ of backfill and rubble has been delicately removed to reveal a cave floor. Subsequent to its discovery we have embarked on one of the largest archaeological projects ever attempted in Australia, as we attempt to recover the cultural material of Juukan 2.

Sourcing Pensacola Communities of Practice: NAA of Mississippian Pottery on the Northern Gulf of Mexico Coast

The Pensacola variant of the northern Gulf of Mexico Coast was well connected to interior Mississippian groups, yet Pensacola lifeways do not fit broader patterns of subsistence, settlement, and political organization commonly thought of as hallmarks of Mississippian societies. Throughout the Pensacola culture area, people created hybrid cultures by adopting some Mississippian traits while retaining much of their existing regional lifestyles. Pensacola sites and assemblages are therefore quite diverse. We seek to better understand the social relationships that underlie patterns in the distribution of material culture at these sites. How connected were Pensacola communities with one another, with the monumental site of Bottle Creek, and with other Mississippian groups? We have employed neutron activation analysis (NAA) of Pensacola pottery across the northern Gulf Coast to provide direct evidence for the movement of people and ceramic vessels across the lower Southeast from ca. AD 1150–1700. The ability to identify geographic sources of clays and specific paste recipes allows us to situate potting communities of practice in particular places and to begin untangling the relationships among the people who made and used Pensacola pottery.

Unstable Frontiers: Isotopic Model of Agricultural Dispersal in the Subtropical Andes

The south of Mendoza province, Argentina, has been characterized as the southernmost limit of prehispanic agricultural dispersion in South America. This limit, originally defined by the presence of macrobotanical remains, was rediscussed in light of the stable isotope data of $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ obtained on collagen and apatite from human remains. These results showed a high diversity in human diets, with strong variability between the different individuals analyzed both at a spatial and temporal scales, especially for the last 2000 years BP. This paper presents the results of the spatial analysis, through the use of geographic information systems, applying interpolation methods (Inverse Distance Weighting). For this, a total of 629 human samples from the Subtropical Andes (central-west Argentina and neighboring areas) were used. We show the temporal evolution of the isotopic patterns in the region by subdividing the sample into three temporal units; pre-2000 years BP, 2000–1000 years BP and post-1000 years BP. The results show significant differences in the consumption of C_4 plants between the different analyzed periods. Besides, there is a growing dependence on the consumption of C_4 resources in some sectors of the analyzed area, interrupted by temporal span of decrease in their consumption.

Cultural Transformations in Conchucos after 500 BC

The decline of the Chavín Interaction Sphere in the mid-first millennium BC was followed by major religious, cultural, and economic changes over a wide region of highland and coastal Peru. In this paper, we discuss these phenomena from the perspective of our ongoing research in the Chavín heartland of Conchucos. Drawing on a large sample of radiocarbon dates we can now track these shifts from a more fine-grained historical perspective. Specifically, we outline evidence for the emergence and changing nature of local expressions of the Recuay archaeological culture. Material culture, architectural, and ancient DNA evidence suggest that at least some of the transformations during this time can be attributed to past population movements.

Indigenous Archaeology, Memory, and Ethnoarchaeology: A Multivocal Research in Collaboration with the Guarani for Land Repatriation in Brazil

This presentation explores my ethnoarchaeological research on a long-term interdisciplinary project in collaboration with Guarani communities toward Indigenous land repatriation in Brazil and offers a case study of a collaboration designed within the framework of Indigenous archaeological approaches. The project's planning and fieldwork were carried out with the participation of the Guarani, and during the research, their memory, oral traditions, perspectives, and interpretations were incorporated into the reports produced in support of a legal claim to their territory occupied throughout the past 1,000 years. Guarani resilience is presented here through a discussion of their sociopolitical struggle for land and indigenous rights. During fieldwork, the Guarani identified examples of plants (including for medicine), animals, deities, and other

cosmological beings, demonstrating their strong relationships with these sacred landscapes, which are essential to the continuity and maintenance of their Ñandé Rekó (the way of being Guarani). Decolonization is a fundamental aspect of Indigenous archaeology, and I argue that archaeologists can play a socially responsible role at the community level by engaging with descendant communities, by reshaping archaeological theory and practice as scholarly activism, and by recognizing that archaeology speaks not only about the past but also for those people who now embody it.

Relational Complexity in Mesoamerican Sacrificial Ritual Images

In Mesoamerican religious practice, ritual killings (allosacrifice) and so-called practices of self-sacrifice (autosacrifice) often coexist simultaneously. Therefore, the ethnographic, iconographic, and historical analysis should therefore focus on what may be called the condensation of ritual relations. Discussing materials like contemporary Wixárika ceremonies, late Postclassic Aztec veintena rituals, and scenes of codices, as well as other objects featuring ceremonial iconography, I want to show how Mesoamerican images of sacrifice express the contradictory character of rituals, focusing on moments of maximal tension.

Urbanism without Cities in Ancient Amazonia

The Middle Horizon was a time of political centralization in the Andes. During the same period one sees in the Amazon clear evidence of population growth, settlement nucleation, and landscape transformation, as it is attested by the increase in site size, the production of anthropic soils, construction of earthworks, and the establishment of road networks. Such pattern varied across the basin: whereas in the llanos de Mojos one sees the construction of truly monumental architecture, in the Central Amazon and elsewhere, settlement occupation span was maybe shorter. These cases show that there was a considerable range of forms of urbanism in the Amazon, none of them associated to the development of the state but based on a structural alternation between episodes of political centralization and decentralization as an outcome of the operation of kin-based domestic level economic activities based on the management of abundance.

Conceptualizing Consent: The Influence of Legal Language on Postmortem Agency

Across institutions nationally, willed-body (or cadaver donation) programs use language that, although often vague, typically provides some level of detail regarding what exactly donors are consenting to. This poster assesses use and recovery of the collected body in anthropological contexts, framed using the language of modern body donation. In reviewing a sample of willed-body programs, the authors found that 83 of 91 (91%) include language reflecting consent for education and 75 (82%) include language reflecting consent for research. When donating to these programs, education and research use are what the public generally understands they are providing consent for; however, it is still added explicitly to the language of these documents. This poster emphasizes differences in consent requirements between willed-body programs and archaeological collections of human remains. For example, many archaeological collections are used in teaching contexts—similar to modern willed bodies—but these largely require no manner of consent. The differential treatment of contemporary donated bodies and archaeological teaching and research collections will be the primary focus of this presentation, highlighting patterns and disparities in legal language from sources such as statutes and consent agreements.

What's Cooking at Devils Kitchen? Context, Content, and Chronology of an Early Site on the Modern Oregon Coast
Preliminary geoarchaeological investigations at the Devils Kitchen site (35CS9) produced a stratified archaeological record comprised of stone tools, debitage, and fire-cracked rock associated with alluvial deposition occurring between ~11,600 and 1900 ¹⁴C BP (i.e., ~13,470 and 1800 cal BP). The robust Holocene-age portion of this record demonstrates that the site was occupied throughout multiple periods of significant postglacial environmental change. Though most notably, the discovery of lithic artifacts between the position of wood charcoal samples radiocarbon-dated to between 11,000 and 5900 ¹⁴C BP (i.e., 12,700 and 6700 cal BP) seemed to suggest that a late Pleistocene-age occupation of the site was plausible—making it only the second known example in the region. The limited nature of the initial test excavations and augering meant that further work was necessary to increase chronological resolution of the site's lower stratigraphy. This paper reports the results of a multiyear effort to excavate a block of 22 new 1 × 1 m units at the site and presents a robust assay of new radiocarbon dates acquired to complement existing litho- and pedostratigraphic models of the site, providing clarification for the depositional context of the lowermost cultural materials recovered at the Devils Kitchen site.

The Demography of Fire

Over the past seven years, Alta Heritage Foundation (AHF) has responded to nearly a dozen catastrophic fires on the west coast. AHF is a 501(c) nonprofit that works with canine human remains recovery teams to identify cremains, the cremated remains of individuals who were cremated prior to the fire and stored in private residences, and retrieve them for families who lost homes in these fires. During this time, the AHF team has noted patterns in the homes and economic levels of the clients using our services. This paper discusses those differences and outlines the specific role that archaeologists play in assisting the victims of catastrophic fires.

Compositional Analysis in Historical Archaeology

Compositional analyses are commonplace in prehistoric archaeology. For example, lithic and pottery analysts regularly use geochemical methods to acquire mineralogical and chemical data that allow them to source

artifacts. The geographic patterning of sourced artifacts provides archaeologists with a rich dataset from which they infer seasonal procurement ranges, acquisition strategies, territorial boundaries, cultural resource preferences, and intergroup interaction, providing fundamental insights into landscape use and sociocultural organization. We contend that compositional analysis holds similar promise for the study of artifacts from historic sites. Here, we employ portable X-ray fluorescence spectrometry (pXRF) to acquire compositional data from pottery, glass bottles, and bricks recovered from Stoddartsville, a nineteenth-century milling village in northeast Pennsylvania. Our analysis of these data provides insight into the burgeoning regional economy, the development of local industries, and consumer agency.

The Missihuasca Hypothesis

While it has been established that the Natives of the Mississippian Ideological Interaction Sphere employed a number of magical plants toward entheogenic ends (Barrier 2020; Rafferty 2021; Simon and Parker 2018), e.g., *Nicotiana* spp., *Datura* spp., *Ipomoea* spp., etc., the general consensus has been that the use of N,N-Dimethyltryptamine, in the forms of jurema, ayahuasca, yopo, viho, etc., is limited to certain Indigenous peoples of South America. Based on ethnographic reports, however, there is evidence that the Cherokee in particular may have had access to N,N-DMT via *Gleditsia triacanthos*, or honey-locust—a deciduous tree in the family Fabaceae that contains the compound in its roots and holds a prominent place in Cherokee mythology. Moreover, the presence of β -carbolines in other plants utilized by Native Americans of the Southeast, e.g., *N. rustica*, *Passiflora incarnata*, and possibly *Ilex vomitoria*, suggests that *G. triacanthos* could have been combined with a number of MAO modulating plants, resulting in a concoction chemically similar to the South American tea, ayahuasca.

Animal Architecture: Historicizing Nonhuman Material Culture

As new research continues to reveal the cognitive richness and social complexity of animal lives and as recently developed technologies expand the materials that can serve as traces of the past (as well as the information that can be gleaned from them), the range of activities and actors that can be studied archaeologically and historically extends beyond the human. In this paper, I suggest that archaeologists can adapt methods that have been used to study human prehistory and apply them to illuminate nonhuman animal pasts. Drawing direct comparisons between the material traces of animal lives and the specific kinds of physical remains, archaeological methods, and anthropological theories that have been used to investigate human histories in the absence of texts and living memories, I show how animal architecture—hives, nests, mounds, dams—can be examined over time and space and probed using analogous methods to those employed to excavate and document human buildings and infrastructure.

Reclaiming and Activating Chinese American Heritage in Wyoming

The Rock Springs Chinatown in Wyoming was the site of the 1885 Chinese Massacre, where a White mob

murdered 28 Chinese coal miners. Survivors took refuge at the Evanston Chinatown, approximately 100 miles west. While archaeological research led by Dudley Gardner has been ongoing at both Chinatowns for over three decades, Gardner and his team have also worked on heritage-related projects such as memorials, collaborating on the reconstruction of the Evanston Chinese temple, and putting together a National Historic Landmark nomination for both the Rock Springs and Evanston Chinatowns. Recently, archaeologists have begun identifying descendants to begin a new phase of collaborative research. Preliminary discussions with descendants indicate that they are interested in using the archaeological sites as staging grounds for reunions, commemorative events, art, and activism in order to (1) highlight the 1885 Chinese massacre, which has been silenced in local and national histories; (2) facilitate the commemoration of transnational family histories that often post-date the massacre; and (3) provide an opportunity for descendants to speak about their own experiences with racism. Archaeological sites such as the Wyoming Chinatowns are important venues for descendants to reclaim their histories and for the wider public to participate in social change.

The Race Track: A Chacoan Legacy in the Northern Rio Grande

A portion of a retired race track was excavated in 2023 on Picuris tribal lands within the right-of-way of a planned infrastructure project. Just one of Picuris's many race tracks, the feature draws our attention to the ongoing heritage of Chacoan "roads" in the northern Rio Grande region, while also underscoring the local spiritual significance of the race track's destination—Jicarita Peak—located 14 miles to the southeast. This paper covers the background of the race track in the history and landscape of Picuris Pueblo, the results of our recent test excavations, and the significance of the race track as an ancestral connection to the Chacoan world.

Ancient Puebloan Agricultural Landscape Features, Northern San Juan Area

The recent lidar-aided discovery of more than 60 mi² (155 km²) of Ancestral Puebloan agricultural features, roads, and ritual features in the Northern San Juan area brings into question many of our preconceived notions about prehistoric lifeways. Agricultural features, the focus of this discussion, are consistent in location, morphology, engineering design, and apparent function across a 110-mile-long (177 km) expanse of Utah, Colorado, and New Mexico. These features, now almost imperceptible from the ground, include more than 1,060 miles (1,700 km) of constructed individual berms (ridges) thought to have originally measured about 1 m high, 2 m wide, and 100–200 m in length, and to represent more than four million human-days of labor. The ridges have a consistent orientation, believed to facilitate snow harvesting. Ridges do not follow contours but tend to be roughly perpendicular to regional land-surface slopes of 0°–3°, and parallel to local surface slopes of 0°–3°. This design maximizes runoff harvesting and minimizes erosion in sandy soils, and ridges are seldom present in steeper terrains. Scarcity of erosional features indicate successful design and runoff manipulation. The extent of apparent "fields," coupled with Chacoan great houses and roads may have implications for food production in areas further south.

Interspecies Relationships in Nordic Bronze Age Iconography

Despite roads and railways around the world being based on the widths of their bodies, nonhuman animals are now systematically excluded from much of modern Western life. In some of the most human-populated areas, animals are forbidden from indoor spaces and from many private outdoor spaces. However, these carefully curated and restrictive relationships we participate in today almost certainly did not exist in the past. Examples of Bronze Age rock art and other artifacts suggest a plethora of different potential interpretations of how interspecies relationships were formed and performed, represented, and upheld in prehistory. The wide range of “naturalistic” and imagined animal motifs on Nordic Bronze Age rock art panels, and their precise placement in rock and in the landscape, challenge classically anthropocentric and capitalistic narratives of interspecies relationships. They also serve to contest standard naturalist categorizations as well as modern Western ontologies. This project will demonstrate the value of posthumanist, experiential, and integrative landscape frameworks through case studies of rock art panels and artifacts with animal iconography from the Nordic Bronze Age. In doing so, it will contest rigid, naturalistic, and classically human-focused perspectives, moving toward a more holistic, posthumanist approach of understanding interspecies interactions in the past.

Application of Metric Sex Estimation Standards at Tell Abraq: A Study of the Humerus

Estimating sex in commingled assemblages may have an increased reliance on metric methods. These metric methods are often based on known collections that differ in geographical location and historical time period from the commingled collections to which they may be applied. In this presentation, we detail the testing of three different metric standards for the estimation of sex based on the humerus from the Tell Abraq tomb (ca. 2200–2100 BCE, United Arab Emirates). The purpose of this study was to see which metric standard most closely represented the sex ratios already previously established using morphological assessments of the pelvis. Measurements used for all four standards were taken multiple times. Of these, the epicondylar breadth, condylar breadth, and vertical diameter of the head had the highest representation. The number of estimated males and females were then compared by method. Overall, the Spradley and Jantz US standard most closely corresponded to the roughly 60% male, 40% female ratio established by the morphological assessment of the pelvis (despite being very disparate in time and space from Tell Abraq). This study shows the impact of population specificity on metric standards developed for the estimation of sex based on isolated elements.

Morro de Eten and the Social Interactions of the Middle and Late Formative Period in Northern Peru

Morro de Eten is located on the coast of the Lambayeque valley, and due to the characteristics of its cultural material, it has long been involved in the Cupisnique–Chavín dichotomy. In this presentation, it is not

discussed whether Morro de Eten corresponds to a Cupisnique or Chavín settlement. Instead, from the identification of the shared cultural attributes of the pottery, the paper explores the modes, scales, and frequencies of interaction to establish a similarity index. On the basis of this index, it is stated that since there is no homogeneity in the distribution of the set of features identified in Morro de Eten, the data reflect the agency and intensity of complex mechanisms of social interaction that developed in local, regional, and interregional scales between 900 and 550 BC.

The Intensification of Mimbres Cave Ritual: Empirical Phenomenon or Disciplinary Artifact?

Over two dozen cave shrines are known from the Mimbres Mogollon region, more than have been reported from any other cultural region in the US Southwest and Northwest Mexico (SW/NW). Despite some variation, the archaeological record of these sites is remarkably consistent and readily allows for their identification as shrines due to the presence of an ethnographically recognizable complex of offertory materials that includes prayer sticks (*pahos*), painted wood objects (*tablitas*), and cane cigarettes. It remains difficult to determine, however, whether this phenomenon represents a stronger interest in cave ritual among the Mimbres or is simply the product of more thorough cave survey in that region, especially the work of Hattie and C. Burton Cosgrove in the 1920s and Walter Hough in 1905. Neighboring regions show related patterns but fewer cave shrines. This paper synthesizes a wide range of data in order to place Mimbres cave ritual in its spatial and temporal context. Available data, including the few available ¹⁴C dates, supports the conclusion that cave ritual did indeed reach unprecedented levels during the Mimbres Classic (ca. 1000–1130 CE). Available evidence suggests that this intensification was driven simultaneously by population expansion, religious reformation, and environmental factors.

“A Sense of Stewardship”: Assessing the Archives of Alexandria Archaeology

In 1961, the city of Alexandria, Virginia financed one of the first municipally funded archaeological projects in the country, laying the groundwork for today’s Alexandria Archaeology which curates three million artifacts from over 250 sites. Since the 1960s, the program has witnessed urban renewal, the birth of the CRM industry, vast technological advancements in computing and conservation, and multiple interpretive shifts that gradually refocused our research onto the lives of ordinary and marginalized people who have lived, worked, and passed through Alexandria. This paper examines the roots of Alexandria Archaeology, traces its biography over the last six decades, and attempts to grapple with the effects of these “site formation processes” on the current state of archaeological collections. We will assess some of the current challenges and opportunities the program faces that must be understood within the historical, economic, and technological contexts that have shaped the program and its associated archives.

Material Proxies and Stylistic Indicators: On the Adoption of Foreign Forms of Governance at Xochicalco, Morelos, Mexico

With the collapse of Teotihuacan, the central Mexican highlands were plunged into a period of social restructuring, known as the Epiclassic (AD 650–950). This period saw the emergence of independent city-states, rising in the wake of a highly centralized hegemonic form of governance. There are few empirically informed theoretical models or heuristic approaches to explain the advent of Epiclassic sociopolitical structure(s). Yet, based on the material evidence found at Xochicalco we are now forced to acknowledge that the bulk points to emulations of elite Maya material culture and forms of symbolic expression. Therefore, far from the superficial stylistic similarities, as long debated among art historians, we now need to consider the presence of eccentrics, censers, architecture and associated sculptures, representations of mythological entities and deities, and most important of all, depictions of idealized rulers, as deriving from contemporaneous canons of Maya art and material culture. This strong resonance of the ideological realm of the Maya speaks of the well-informed translation of foreign forms of governance to a central Mexican setting. We thereby propose that the rulers of Xochicalco modeled their forms of governance on those that existed at the time, in the monarchical city-states of the Maya, in the east.

Use-Wear Analysis on Shell Artifacts

Shells feature prominently in prehistoric archaeological assemblages in the southeastern United States. However, serrated freshwater mussel shells, of the type found at a Late Woodland site in North Carolina and other area sites, have not been studied and their use been unknown. These freshwater mussel shells were given a serrated edge, with evenly spaced teeth along all edges of the shell, excluding the hinge. Denticulated shells do not show up in historic accounts from later sites, nor is there any clear contextual information about their use. Use-wear analysis was used to attempt to identify what these serrated shells were used for. Due to minimal previous research on shell use-wear, use-wear analysis methodologies were

developed for this project and tested on a sample of serrated shells from the Late Woodland site. Data resulting from use-wear analysis was used to identify possible uses for the serrated shells, and one of these uses was provisionally explored through exploratory archaeology process. Initial experiments showed that the shells may have been used on plant material, which provides a window into indigenous plant uses that have otherwise been lost due to taphonomic processes on site.

Shaped, Molded, and Buried: Differential Access to Ceramics in Early Bronze Age I Bab adh-Dhra', Jordan

New ways of looking at old evidence can help develop a better understanding of the relationship between early urbanism and social differentiation in the ancient Near East. In the Southern Levant during the Early Bronze Age I (ca. 3700–3000 BCE), the site of Bab adh-Dhra' was a center for mortuary activities for EBA communities. Bab adh-Dhra' is an important case study for archaeologists interested in the earliest expressions of differentiation and social inequality during the rise of urbanism in the Early Bronze Age. The sustained use of shaft tombs and later development of charnel houses by villagers across generations illustrates major changes in how people dealt with their dead and defined social relations. In this current study thousands of ceramic vessels from over 100 EB I tombs were statistically analyzed using size, form, function, ware patterns, fabric, and manufacture to compare the differential access to ceramic funerary assemblages across tombs. This research contributes to the wider discussion of how and why differentiation existed, how individuals asserted their own agency in the face of long-standing mortuary tradition, and how differentiation and social inequality developed in the Southern Levant during the Early Bronze Age.

Weaving with the Seasons: A Case Study of Jomon Baskets and Resource Management in Neolithic Japan

Evidence that basket weavers in the Neolithic Japanese archipelago had weaving techniques and knowledge of their adjacent climate and environment has been found in archaeological artifacts dating from approximately 8,000 to 2,300 years ago (Early to Late Jomon period) across the Japanese archipelago. Fewer than 1,000 basketry pieces, including fragments, have been excavated from archaeological sites, and they show continuity and change in weaving techniques that continues through the modern period. Earlier archaeobotanical studies of Jomon baskets show that these weavers used various materials from the nearby environment and seemed to know the best season for gathering and processing materials. In an affluent hunter-gatherer foraging lifestyle, material choice and availability in quality and quantity with a reasonable amount of time for crafting are necessary. In this study, I use ethnographic accounts from the 1960s through 2020s from basket weavers in nearby areas and archaeological observations regarding excavated baskets from (1) the Higashimyo site, Saga, and (2) the Korekawa site, Iwate. By comparing ethnographic accounts that hold TEK (Traditional Ecological Knowledge), this study seeks to understand the reasons for choice of basket material based on the subsistence calendar. Through the lens of weaving, the study shows how weavers interact with their environment.

Centralized Urban Planning and Economic Segregation: A Case Study Based on Wealth Inequality at Tell Asmar and Khafajah in Mesopotamia

This paper explores a possible correlation between central planning and economic segregation in ancient urbanized cities. A preplanned and constructed urban residential area may have fostered an aggregate of

inhabitants who had similar traits, such as ethnicity, class, wealth, occupation, and religion. Different clusters of people may be discerned between districts, neighborhoods, or particular sections within a neighborhood at the intrasite level. It is postulated that a top-down process designs a living quarter as a local defensive measure to an external military threat, which results in bringing together residents with similar economic traits. A case study to examine this correlation is drawn from the third millennium BC cities of Tell Asmar and Khafajah in central Mesopotamia. Excavations exposed dozens of houses within residential neighborhoods, and one of the occupation areas at Khafajah shows a well-planned project that took place around 2400–2300 BC. Through the use of the Lorenz curve and Gini index, the houses built by the centralized project exhibit a higher degree of economic similarity than those of other house levels at these sites. This correlation should be further tested with larger data from other ancient cities across the globe.

Reuse, Rubble, and Relations to Place at Ancient Maya Cities

This paper traces histories of reused stone and space at ancient Maya cities. Space/Place theorists have documented the ways that physical spaces have layers of meaning tied to their history of use. In the Maya area, archaeologists have documented myriad ways in which Maya individuals have engaged with and related to reused materials/places prior to European colonialism. These studies have shown how interacting with materials from the past is an important part of ritual practices that crafted a sense of community and validated ancestral connections to place. At the same time, contemporary activities relating to the reuse of ancient Maya sites and materials are undervalued and, in some cases, stigmatized. Through a focus on reuse, this paper reflects on the broader ways individuals and communities can engage with and forge connections to archaeological spaces. I argue that by tracing histories of reuse and contextualizing their significance and meaning, archaeologists can better frame and engage with the meanings that are generated in contexts of reuse, which has implications for community engagement and notions of heritage.

Adzes in Focus: A 2D vs. 3D Geometric Morphometric Analysis of Dalton Artifacts

Geometric morphometrics (GM) is a method of digitizing objects in a way that controls for variables, such as size and scale so that the shape of objects can be compared to determine differences and similarities. This method has become increasingly abundant in archaeological investigations of lithic tool assemblages. In studies regarding prehistoric peoples in the Americas, GM has predominately been used for 2D analyses of lithic points. It is generally agreed upon that data from a 2D GM analysis can be extremely beneficial in identifying morphological trends in lithic assemblages that can have a variety of cultural implications. However, there have not been many studies looking at the benefits of including a third dimension in these analyses. This research project uses 2D and 3D GM data collected from large lithic tools, Dalton adzes, in order to investigate the differences in statistical outcomes when using these two methods. The results of this study will help quantify the loss of shape data that occurs when conducting 2D GM analyses on large 3D lithic artifacts.

From Hunting to Herding in the Lake Titicaca Basin: A Preliminary Investigation of Faunal Assemblages, 9.0–3.5 ka
As the sole large-bodied animal domesticate in South America, camelids constituted a central component in Andean socioeconomies and were pivotal for the expansion of early complex societies. The timing and nature of domestication, as well as the subsequent spread of husbandry practices, remains a fundamental question in Andean archaeology. This paper examines faunal remains from the Lake Titicaca Basin, which is a suspected domestication center. The faunal assemblages from three well-dated sites, including Wilamaya Patjxa (9.0–6.5 ka), Soro Mik'aya Patjxa (8.0–6.5 ka), and Jiskairumoko (5.0–3.5 ka), show that the highland hunting practices consistently targeted wild camelids and Andean deer and a virtual absence of small mammals, birds, and fish. We further observe that the prevalence of camelids relative to deer increased over the period of investigation, consistent with a hypothesis of intensified exploitation and incipient management of camelid herds by at least 6.5 ka in the Titicaca Basin.

Less Writing, More Eating: Using Experiential Learning to Promote Engagement at a Small Liberal Arts College

Warren Wilson College is a small school in Asheville, North Carolina that integrates work, study, and community service through the lens of experiential learning. In this talk, I will discuss some of the pedagogical choices in my Archaeology of Food and Feasting course that promoted student engagement apart from traditional written assignments. More specifically, using the over 1,000-acre campus, farm, and garden, I show how the course explored social dynamics of food in the past through plant identification, foraging, zooarchaeology, ceramic analysis, and above all feasting. These hands-on experiences culminated in a “final exam” that encouraged students to obtain ingredients either from the Bounty and Soul food bank or from foraging and create a meal together as a class. As food and feasting are aspects of shared human experience both through time and space, the subject is ideal for building and sustaining a communal classroom centered on empathy and concern for an equitable and sustainable future.

Maya Ritual Beverages: Unveiling the Ingredients for an Ancient Alcoholic Offering

Balché is a ritual beverage elaborated with honey and tree bark that, during many centuries, has been fundamental for Maya religious rituals in Yucatán, as documented in precolumbian codices, historical sources, and ethnographic research. Some information at the Madrid Codex indicates that honey and/or balché may have been kept in pottery jars. Although Spanish religious authorities prohibited and persecuted its elaboration and consumption during the colony, Maya ritual specialists continued with its preparation, and balché is used to this day for several ancestral and new ceremonies. The aim of this paper is to offer the results of archaeometric experiments performed with honeys of different Yucatecan origins as well as with balché prepared both by contemporary Maya ritual specialists and by us in the Laboratory of Chemical and Microscopic Analyses of the Autonomous University of Yucatán. Our goal is to approximate chemical and paleobotanic evidence from the honey and the balché by enriching modern pottery fragments for their subsequent residue analyses, which allow us to propose the possibility of its archaeological identification. In

this way, we want to contribute to the analyses of archaeological artifacts and contexts in the discussion about honey and ritual in ancient Mayan beverages.

Cycles of Time and Body Partibility at the Ancient Maya Site of Chan Chich, Belize

The archaeological record of the ancient Maya reveals many examples of the living returning to human interments to exhume skeletal elements, expose the elements to fire or smoke, or to paint them with red pigment. At the ancient Maya city of Chan Chich, located in northwest Belize, skeletal remains dating to the Preclassic period (413–235 BC) show evidence of manipulation and possibly burning; charcoal from the burning event dates to AD 600–800, or the Late Classic period. Bones of the feet and lower body are articulated, suggesting a primary interment with at least one reentry event many centuries later. The partibility of ancient Maya bodies is well established as one facet of ancestor veneration (Geller 2012). I follow Geller and Strathern (2005) in considering the body as indicative of the collective rather than the individual. One interpretation of ancient Maya ancestral contexts is that this individual was chosen to venerate for actions in life or their relation to the still living, but many centuries of time between events requires additional reflection. In this contribution, the timing of the initial burial and timing of subsequent reentry are contextualized within the history of the site to understand the act of veneration.

Adversaries and Ancestors: A Comparison of Two Skull Caches from Northwest Honduras

At La Sierra, in the Naco Valley, the crania of five individuals were discovered in a niche at the front of a Late Classic (AD 600–950) house. Each skull was sitting on its own plate surrounded by obsidian blades. Sixteen km to the southwest, at the site of El Coyote, an ossuary containing two interment episodes of at least 14 individuals dating to the Terminal Classic (AD 950–1100) period was discovered next to a staircase leading to the main plaza. The skulls were placed near the outer edges of the chamber and the disarticulated postcranial remains piled in the center. Comparing these examples contributes to our understanding of the Mesoamerican tradition of manipulating human skeletal remains in order to affect sociopolitical processes among the living. We argue that human skeletal material—skulls in particular—are part of a wider relational process. The perceived world and everything it contains is animated by the same essence. Maintaining a connection to this essence is a crucial facet of Mesoamerican ritual practice. In order to interpret the two deposits, we draw on their archaeological contexts, ethnographic and ethnohistoric evidence, and iconography to help us conceptualize the materialization of ritual practices involving the human body.

Learning Together: A Specialized Residence for Acolytes at Group C, Xunantunich

Scholars have sought to identify ancient Maya spaces where specialized knowledge was transferred and acquired. Several historic accounts, including that of Bishop de Landa's in Yucatán, mention specialized residences for youths while they were being schooled. Analogous to boarding schools, housing exclusively for acolytes creates a focused environment for learning and for creating sodalities. Archaeologists have identified complexes that likely included living spaces for youths in training at several sites including Tikal, Copan, and Xunantunich. In this paper, we present findings from Xunantunich's Group C that support this interpretation. Our investigations have targeted two range structures that face each other across a courtyard. These vaulted

structures, C-2 and C-3, had rooms with high benches, each with an incised patolli board. The doorways were broad and faced outward across the courtyard. They lack the interior doorways and division of space typical of residential buildings. Additionally, they are associated with a relatively large sweat bath likely built to hold a larger group, as well as a modest patio group that we believe housed servants and attendants. Finally, the buildings are associated with large open spaces that are formally demarcated, which we suggest were used for drills, perhaps including rituals, processions, and combat training.

The Secret Lives of Paleolithic Teens: Puberty Assessment of Adolescents in the European Upper Paleolithic

In recent years, archaeologists have made real progress in understanding the lived lives of Paleolithic children, but adolescents from this period remain understudied. In this study, we use maturational markers developed on the skeletons of medieval English children to determine puberty status of 10 Upper Paleolithic adolescents from sites in Russia, the Czech Republic, Monaco, Italy, and France. With these data we address the following 3 questions: (1) Did these individuals look like children or emerging adults when they died and did that affect the way they were treated in death? (2) Was adolescence recognized as a special time in the life course of an individual in the Upper Paleolithic? (3) At what age was a child considered to be an adult in the Upper Paleolithic? Did this vary by sex, geographic region, and/or time period? We combine our puberty data with paleopathological assessments, aDNA information on sex and genetic relatedness, ethnographic data, material culture (grave goods), and other behavioral evidence to develop for the first time a picture of the lives of European Upper Paleolithic teens.

Historical Archaeology as a Device for Heritage Protection in West Patagonia

The relatively recent colonization of West Patagonia is perceived as a main component of cultural heritage by the communities of the Aisén region (Chile). Understanding colonial life makes sense in the construction of the narrative of local and regional identities. Hence, historical archaeology can play a key role in education and protection of material heritage, especially in a context where there is a limited written record.

Furthermore, historical archaeology has the potential for unveiling underrepresented processes and/or individual stories. We developed a research project for studying the variability of the rural record of household and ranch occupation of the recent past of Aisén, one which is very rich and diverse. The record ranges from large estancias to ephemeral sites across a wide variety of environments, including the coast, forests, and the steppe. We present a multilayered strategy aimed at studying the record at site and basin scales, material culture analysis, 3D recording of architectural heritage, and outreach. Experience thus far shows a high engagement of communities, making historical archaeology an appropriate device for heritage protection in West Patagonia.

Manifestaciones del poder Inka en la Cordillera Oriental (Usicayos, Puno, Peru)

Se ha conceptualizado que la relación entre un imperio arcaico y una sociedad conquistada ondula entre dos polos: el hegemónico y el territorial. Ambos sistemas conllevan distintas estrategias, las cuales son aplicadas según los deseos del imperio, pero también atendiendo a las características locales, sean geográficas, políticas y sociales. Los inkas no son ajenos a estas dinámicas, y habrían empleado diversas estrategias con la finalidad de extender y consolidar su poder fuera del núcleo; transformando política y económicamente a las sociedades conquistadas. El presente trabajo busca rastrear las manifestaciones materiales de dichas estrategias. Para ello, toma el caso del valle de Usicayos, ubicado en la provincia de Carabaya. Este valle habría desempeñado un papel importante por su posición estratégica como corredor natural entre el Altiplano peruano y las Yungas Orientales. En base a los hallazgos, se plantea que los Inkas consolidaron su presencia en el valle a través de la reocupación y ampliación de un asentamiento local, así como por medio de la construcción de un sitio estatal nuevo. También se habría ampliado y estandarizado el sistema vial. Por otro lado, las consecuencias de la política inka se refleja en el abandono de la mayor parte de sitios previos.

Diet and Mobility in the Diverse Geographies of the Lower Central American Land Bridge

Richard Cooke dedicated his career to the study of past human groups on the lower Central American land bridge (southern Nicaragua to northern Colombia) and their diversification in the tropical landscapes of the region. He has argued that the diverse geography of the landscape favored both endemism and diversity in human societies, who at the end of the sixteenth century spoke diverse, yet related, Chibchan and Chocoan languages. Moreover, approximately seven centuries before the European contact the region witnessed the arrival of Mesoamerican migrant populations from the north. The long precolumbian history of this complex scenario is accompanied by variation in the interplay between human populations and their surrounding environments. Thus, tracing the diversity of subsistence practices and residential mobility through time and space is critical to understand how these groups colonized tropical habitats and thrived to become complex societies. To assess these issues, we present preliminary data on a multi-isotope program (carbon, nitrogen, strontium, and oxygen) for populations from archaeological sites in Panama and Costa Rica during the last 2,000 years of precolumbian history.

Archaeology, Indigenous Archiving Practices, and the African Past: Researching the History of Atlantic Slavery in Peki, Ghana

This paper discusses the creative use of indigenous and conventional archives and archaeological data in unearthing the history of Atlantic slavery in Peki. This frontier Ewe community in present-day Ghana led the pan-Ewe Krepi state out of Akwamu and Asante hegemony, thereby altering the power dynamics of the nineteenth-century post-abolition Atlantic economy in the Gold Coast. Researching this complex history from an interdisciplinary perspective that draws data from egalitarian archival sources underscores the fact that non-literate societies have very sophisticated ways of preserving their histories and memories or that there are more “documents” or “archives” than we think—cultural landscapes, ritual practices, and monuments. I argue that African historical archaeologists should pay attention to the dialectics between indigenous archiving practices, oral traditions, and textual archives of the recent African past. Bridging egalitarian and conventional archives in African historical archaeologies is valuable for producing counternarratives that confront biases toward the Western documentary record and how they have been reified through ideological models of social evolution. This approach, however, requires cultural sensitivity and a commitment to collaborative community-engaged research that entails learning with Indigenous communities rather than only learning about them—essential tenets long championed in Ghanaian/West African archaeology by Professor Ann Stahl.

High-Altitude Adaptation in the Middle Paleolithic of the Zagros Mountains, Iran: A View from Houmian

Intensification of fieldwork in the Zagros Mountains over the past two decades have provided crucial new insights into the region, revealing a much more complex patchwork of MP lithic industrial variability than hitherto appreciated. We present a series of new case studies on the high-altitude MP rockshelter of Houmian in the Iranian Zagros. Posited to be one of the oldest, highest-lying MP sites in southwest Asia, contextualizing a series of new findings offers both site-specific and regional implications for cultural change and variability. This paper will focus on a reanalysis of the lithic and pollen records, making the claim for multi-seasonal occupation at ca. 2,000 m asl. A lithic techno-functional study identifies separate—and non-Mousterian MP—technological strategies of production within different layers of the stratigraphy. A use-wear

study reveals evidence of specific resources targeted by MP hominins in the surrounding landscape. We highlight a successful approach for extracting high-quality lithic use-wear data from museum collections using state-of-the-art portable equipment. These findings serve to both confirm and refute previous behavioral and environmental interpretations surrounding MP land-use in the Zagros. The resulting implications contribute to a reappraisal of the MP of the Zagros as a dynamic region of hominin complexity.

Owned in Life, No Longer Owned in Death: Remembering the Ancestors at the Pine Street African Burial Ground
Established in 1750 on the outskirts of Kingston, NY, the Pine Street African Burial Ground was consumed in the process of urban expansion by the mid-1850s and now sits in the backyard of a residential neighborhood. Despite the importance of Kingston in the history of New York, relatively little is known about the African American experience in the city. In this presentation, we will briefly summarize what is currently known regarding the early history of the burial ground before highlighting recent efforts to preserve the site, including the purchase and stewardship of the land by Harambee, a Kingston-based, African American-run community group. Harambee has implemented a multiyear, multifaceted plan for the Burial Ground including development of an on-site community center and museum, design and creation of a public memorial, and a program of educational outreach pertaining to the history and centrality of African Americans in Kingston and the Hudson Valley more broadly. We will then discuss how bioarchaeological research connects and contributes to these overarching goals of Harambee, presenting results based on two seasons of excavation.

The Black Burned Bits of Prehistory: A Celebration of Dr. Karen R. Adams

This paper provides a brief overview of Karen Adams's career and contributions, with a special emphasis on her extensive research and her legacy as a mentor to decades of junior scholars and budding archaeobotanists. Dr. Adams's investigations into the long history of people-plant relationships in the US Southwest and beyond exemplify the power of a mix of fieldwork, particularly building robust comparative collections, experimental archaeology, rigorous and innovative analytical approaches, and dedication to preserving accessible data. Pursuing an independent scholarly path, Dr. Adams's professional contributions and work are marked by collaborative and creative approaches, often combining Indigenous histories and traditions with archaeobotany and other plant sciences. Through a presentation that highlights a rich research career spanning the Pleistocene to the present day in publications as varied as children's books to journal articles, and hundreds of reports, we explore important themes in Dr. Adams's career that has improved our understanding of the past and the ways that people and plants have shaped one another for millennia.

Complementing and Complicating: Integrating Isotopic and Phenotypic Evidence at the Early Medieval Cemetery of Five Mile Lane

Isotopic and phenotypic methods are frequently employed in studies of migration and population affinity in the past; however, they are rarely integrated due to differences in scales. This paper presents a case study for the complementary use of multi-isotope ($^{87}\text{Sr}/^{86}\text{Sr}$, $\delta^{18}\text{O}$, $\delta^{34}\text{S}$, $\delta^{13}\text{C}$, and $\delta^{15}\text{N}$) analysis and odontometric analysis to address questions of mobility and kinship. The site of Five Mile Lane (SE Wales) contained 378 inhumations cut into a probable Late Bronze Age burial mound, with burials spanning the period ca. AD 400–1200. Multi-isotope analysis on 60 individuals demonstrated regional and long-distance mobility throughout the population, situating this community within wider networks by identifying likely migrants from elsewhere in Britain and perhaps beyond. However, analysis of phenotypic affinity suggested that individuals of diverse origin were not necessarily biological outliers, and some may have descendants buried within the cemetery. By combining both types of data, it was possible to reveal more about the lived experiences of these individuals, contributing to questions of kin-based networks of mobility with new forms of evidence. The integration of isotopic and phenotypic data in this case study enabled greater specificity in the interpretation of the site than was possible using singular or independent methods.

Thirty-Eight Years Later: An Evaluation of the Dissemination of Public Knowledge Concerning the 1622 Nuestra Señora de Atocha Shipwreck Site in the Florida Keys.

Named the most valuable shipwreck to be recovered, the Nuestra Señora de Atocha was part of the Spanish Tierra Firme fleet bound for Spain in 1622 until a severe hurricane sank the vessel off the Florida Keys. In 1985, treasure hunter Mel Fisher and a crew of salvage divers uncovered the main hull of the Atocha along with a vast number of valuables. The struggles between underwater archaeology and the salvage industry lie in the differing priorities, preservation techniques, knowledge production, and overall approaches to shipwreck exploration and recovery. This study explores how much information recovered from the Atocha made it into the public domain via publishing, media coverage, etc., in comparison to dissemination standards set by professional underwater archaeologists in the academic and private sectors.

Archaeological Illustration and Imaging: Documentation of Pañamarca's Archaeological Project

For decades now, with the appearance of analogue photography, and more recently of digital technologies, a debate has arisen about the functionality, advantage/disadvantage between different archaeological recording techniques—considering that their main objective is to capture as accurately as possible the archaeological heritage that is being uncovered. The mural paintings of Pañamarca create the imperative need to reproduce archaeological and artistic illustrations on 2D planes—because of the complexity of the traces and colors—which is complemented by a package of technological tools that gives us the possibility of accessing 3D models. In this presentation we present an overview of traditional and digital archaeological illustration in the history of research at Pañamarca with special emphasis on the archaeological fieldwork of 2022 and 2023. Finally, we present and preliminarily contrast the results of 2D and 3D recording, each with different recording techniques and approaches, but finally complementing each other to fulfill data gaps that allow for a deeper understanding.

Historia de los trabajos y las colecciones cerámicas de Cuicuilco con presencia Chupícuaro

La presencia de ciertos elementos de la tradición Chupícuaro en varios sitios de la Cuenca de México, durante el Preclásico tardío y terminal, es apreciada principalmente en la cerámica y las figurillas. Entre éstos ejemplos, destaca Cuicuilco, ya que desde sus primeras excavaciones se observaron rasgos que lo asociaron con esta tradición. Por lo anterior, en esta exposición se hace un breve recorrido de los trabajos arqueológicos de este sitio donde se destacan vasijas cerámicas y figurillas de esta tradición y la posible relación y amplitud geográfica de la presencia Chupícuaro en la Cuenca de México.

Artisan Communities, Regional Interaction, and Identity in Eastern Honduras

This paper discusses the role that two distinctive artisan communities from eastern Honduras, El Chichicaste and Dos Quebradas, played as producers of pottery and obsidian blades within local and interregional exchange networks. Analysis of pottery, obsidian, and settlement patterns from both sites disputes the common perception of this region as “intermediate,” less developed, and marginal. Instead, eastern Honduras was a dynamic region, interacting, exchanging, and selectively internalizing knowledge and practices with groups in Mesoamerica and the Isthmo-Colombian-Chibchan area. Data suggests that eastern Honduras was distinctive, with significant time depth (occupation dated from the Late Preclassic to Early Postclassic times), cultural continuum, and internal developments. The evidence indicates interregional and perhaps long-distance exchange of prestige goods and symbolic material culture via land and riverine networks. These foreign encounters and products, accessible mostly to elite rulers and merchants trading at nearby and long-distance markets, resulted in practices attempting to roughly replicate and reinterpret the array of cultural artifacts and ideology for local consumption. The outcome of these interactions resulted on a hybrid identity that incorporated local and foreign cultural features acquired, construed, and exchanged with neighboring groups.

The Efficacy of 3D Photogrammetric Models in the Documentation and Reconstruction of Dismantled Historic Stone Walls in Southern New England

Stone walls serve as indicators of both contemporary and historic property boundaries as well as significant features such as farms, roadways, and internal property routes. The northeastern United States, particularly New England, boasts an estimated 193,121 km (120,000 mi) of stone walls. In cultural resource management (CRM), it is not uncommon for culturally significant stone walls to be documented, dismantled, and restored. While 3D photogrammetry has been increasingly used in CRM, archaeologists continue to rely heavily on the use of hand-drawn maps, illustrations, and 2D photography. During work conducted by POWER Engineers on a transmission corridor in southern New England, several historic stone walls were documented using both traditional archaeological means and 3D photogrammetry. The research presented compares the cost, quality, and time to completion between three different methods of archaeological data collection and presentation, including the extrapolation of figures from traditional field drawings on graph paper, 3D photogrammetric modeling, and drawings rendered from 2D photographs when recording historic stone walls.

Can We Predict Archaeological Site Location? Should We?

Archaeological predictive models, whether formal or informal, are commonly used on compliance-driven projects, but their efficacy is rarely tested. Too often, we assume that models are “good” or “successful” when more sites are discovered in “high-probability” than in “low-probability” zones. In Florida, state guidelines for cultural resource management professionals mandate the use of a predictive model and stipulate specific testing requirements for each probability zone. Dave Anderson pioneered the use of site file data to answer “Big Picture” questions and his work at Fort Polk set a high bar for developing multiscale predictive models from broad survey data. As an MA student, Dave taught me not to shy away from large, messy datasets, but always to ask pointed questions and be wary of biases and logical fallacies. In other words, Dave taught me “how to think.” In this paper, I draw inspiration from Dave to test the efficacy of the Florida predictive model using data from the Florida Master Site File and other state-wide datasets. In doing so, I question the efficacy and appropriateness of predictive modeling as a regulatory tool and provide an alternative framework for consideration.

Medical Cannibalism in Scandinavian Folklore: Practical Uses and Religious Rationalities

Although cannibalism is a contested theme in anthropology, there is one area and era that has received little attention: Scandinavian folklore in the nineteenth and early twentieth centuries. The widely documented

practices represent a particular type of cannibalism that has been called medical cannibalism. Dead bodies were the most powerful medicine for any kind of disease and illness, and the fresher the corpse, the better. Warm blood from beheadings and executions were precious and popular medicines, together with, among other medicines, what was called “corpse-water,” “human-water,” “human-fat,” or “priest-fat,” which was melted or boiled human flesh or brain. The medicines worked in secular settings, but the strength and powers came from the ancestors and spirits. All diseases were spiritual attacks of bad spirits and therefore the powers to combat these malevolent attacks were found among the dead. Still, it was a religious system of mortality without morality, because murderers were more powerful than ordinary people. A murderer had the powers of at least two persons in his body and hence this power could be used for the betterment of others. The rationality of this particular type of cannibalism and practical magic will be presented and discussed in this presentation.

Cooking in Clay: A Diachronic Study of Potting and Cooking Traditions in Bronze Age Toumba Thessaloniki, Northern Greece

Toumba Thessaloniki, situated on the coastal plain of the Thermaikos Gulf in northern Greece, was one of the largest settlements in Central Macedonia during the Bronze Age. The prolonged occupation of the site spanning from the Middle Bronze Age through the Classical period resulted in the formation of an artificial mound of approximately 1 ha. The findings obtained in decades of excavation provides fertile ground to gain insight into past communities. This paper presents a diachronic examination of the cooking ware from Middle to Late Bronze Age Toumba. Examining an extensive assemblage comprising thousands of sherds, we employ an integrated approach that combines the study of the *chaîne opératoire* and morpho-functional characteristics, including macro- and microscopic analysis (thin-section petrography) and elemental analysis (WD-XRF), to investigate fabric, manufacturing techniques, and associated cooking habits. The objective is to identify communities of practice and reconstruct the organization of the local cooking ware production. Additionally, the evolution of “batterie de cuisine” will be examined as a means to explore changes in cooking practices over time. Ultimately, the findings will be discussed within the context of the intense mobility and cultural interactions during the Bronze Age with the Balkans and Southern and Central Aegean.

[89]

Under One Roof: The Physical and Digital Reorganization of the Historic St. Mary's City Archaeological Collections

The archaeological collections at Historic St. Mary's City span some 50 years of continuous research resulting in approximately 6.5 million artifacts, thousands of pages of field records, paper catalogues, and related documentation. In 2016 the entire collection was moved from multiple storage locations into one single repository at the museum. Over the past few years, staff in the Research and Collections department have been working toward strategies to rehouse, reorganize, and redocument the collections' materials where needed, revealing the various storage and data taphonomies of our collections. Recently, we have been focusing on digitizing legacy collections related to current projects and increasing accessibility both within the museum and public availability. These projects build on previous work and are centralizing information into a single cloud-based database. Some aspects of these efforts include new digital data standards and policies, condition assessments, storage procedures, and updating data and metadata about artifacts in the collection. This paper will discuss these strategies, their development, and our future goals for increasing accessibility to the collection.

Ogden, Brigid (University of Tennessee, Knoxville), Elizabeth Tarulis (University of Tennessee, Knoxville) and Taylor Bowden-Gray (University of Tennessee, Knoxville)**[319]***Straying from the Flock: A Stable Isotope Analysis of a Sheep Membrane Condom from Colonial Maryland*

This paper presents a stable isotope analysis of a membrane condom from the colonial Oxon Hill Manor Site (18PR175) in Maryland to shed light on the geographic origins of the artifact. Previous analysis using zooarchaeology by mass spectrometry (ZooMS) identified the condom as having been made from a sheep. The addition of stable carbon and nitrogen analysis of the condom's tissue allows for a tentative interpretation of whether the artifact was manufactured locally in Maryland or produced and imported from abroad. Our results provide a starting point for future research into the trade and manufacture of prophylactic devices in the eighteenth-century Atlantic World and their role in shaping broader colonial attitudes toward sexual health and hygiene.

O'Grady, Patrick and Thomas Stafford (Stafford Research LLC)**[94]***Utilizing Tooth Enamel from Extinct Megafauna to Date the Earliest Occupations at Rimrock Draw Rockshelter, Harney County, Oregon USA*

Camelops sp. and *Bison* spp. tooth enamel fragments recovered from late Pleistocene alluvial deposits at Rimrock Draw Rockshelter (35HA3855) in the northern Great Basin region of Oregon were used for AMS ¹⁴C dating. Five specimens yielded 11 AMS ¹⁴C dates ranging from 11,190 ± 25 RCYBP (13,170–13,080 cal BP [95% CI]) to 15,150 ± 40 RCYBP (18,650–18,260 cal BP [95% CI]). The youngest enamel dates are coeval with Clovis occupations elsewhere in North America; the older specimens predate Clovis by 5,000 years or more. Our results indicate that the geochemistry of basalt terrains in the northern Great Basin enables accurate ¹⁴C dating of enamel bioapatite (carbonate hydroxyapatite) from extinct megafauna tooth enamel from valley alluvium otherwise devoid of bone, wood, and charcoal. The sample preparation process is likely effective in other noncarbonate (basalt) terrains and expands the range of geochronology options for archaeologists needing reliable dates on nonconventional fossil material. The presentation will focus on two themes: a survey of the site characteristics and context and the recent advances made in AMS ¹⁴C chemistry as embodied in this research.

Ogundiran, Akin (Northwestern University)**[56]***The Oyo Empire, ca. 1570–1840: The Art of Being a Compositional State*

Yoruba sovereign states matured about the eleventh century in ideology, symbols of authority, and organizational structure. Governed by a system of monarchy comprising the divine king/palace officials and nonroyal lords, theirs was a political arrangement that placed the king as first among equals with the nonroyal lords who represented the corporate branches (*ilé*) of the political collective—the state (*ilú*). Those corporate units collectively granted the king the authority to rule. Each of these political actors—the king and the nonroyal lords—possessed ritual power and other assets that made the state an interdependent and compositional entity. This arrangement has confounded many theorists of state formation, who have placed the Yoruba states in the categories of segmentary or poorly centralized states. Moving beyond evolutionary typology, this paper seeks to contribute to the debates on state formation processes by focusing on how the Oyo Empire was constituted in the late sixteenth century and maintained from the seventeenth through the early nineteenth centuries, as well as the materiality of citizenship and corporate identity in the empire. Yet, power was diffuse, nested, and networked; a multipolar system evolved with generative constituent units that were simultaneously competitive and collaborative, thereby creating a compositional state.

Ogundiran, Akin (Northwestern University)**[250]***Discussant***[250]***Chair***Ohman, Alexis (NAVFAC Atlantic), Katharine Nusbaum (NAVFAC Atlantic) and Bruce Larson (NAVFAC Atlantic)****[267]***The US Navy and Cultural Resources Overseas*

NAVFAC Atlantic (LANT) is a government agency within the Department of Defense (DoD) that acts as a quasi-headquarters providing support both within the United States and overseas. As a Navy engineering facility, accounting for environmental concerns in the planning process also requires cultural resources assessments. LANT archaeologists are the DoD's only subject matter experts that provide cultural resources support for installations in Europe, Africa, and the Middle East. This poster will present two case studies from key installations overseas. Naval Station Rota in Spain contains features and artifacts from the Paleolithic, Neolithic, Roman period through the twentieth century. In the Horn of Africa, Naval Expeditionary Base Camp Lemonnier and Air Force Base Chabelley have yielded data from the Early Stone Age through World War II. Recent work collaborating with Army Civil Affairs has further facilitated connections with present-day communities in the area. Presentation of this work in an academic setting will highlight the role of the Navy as stewards of the host nations' cultural heritage located on military installations.

Okech, Malkia (African Digital Heritage)**[47]***Skills For Culture: A Methodology for Community-Oriented Digital Archaeology Projects*

African Digital Heritage (ADH) is a Nairobi-based nonprofit organization working to encourage a more critical, holistic, and knowledge-based approach to digital solutions within African heritage. Through this, we hope to cement the place of African culture in an era of rapidly changing technologies and endless frontiers. Our focus areas are digitization, innovation, research, and capacity building. This poster will present our pedagogical framework for immersive digital projects that work with archaeological data and the communities that inhabit these cultural landscapes. Our emerging curriculum is based on "Skills for Culture." "Skills for Culture" is a series of educational programs specially curated over the past four years for cultural heritage practitioners working at community level. It is informed by workshops, research, and evaluation and provides a step-by-step guide for practitioners looking to improve their programs, with insights from fellow community-based cultural heritage experts. While ADH is based in Kenya, we firmly believe that our methodology holds broader applicability for archaeological projects endeavoring to incorporate innovative technologies in a conscientious manner. Our poster presentation seeks to foster a meaningful dialogue with fellow presenters, offering an opportunity for knowledge exchange and mutual enrichment.

O'Keeffe, Amy (Trinity College Dublin, University of Dublin)**[115]***No Country for Old Crones: Exploring the Presence of Grandmothers in the Ancient Greek Archaeological Record*

In scholarship, there has been a past tendency to ignore and obfuscate mortal mothers; this also extends to the mothers who live to see their grandchildren. While there has been a sentiment in the past that motherhood is invisible in the archaeological record, there has been very little consideration given to the presence and roles of grandmothers in ancient Greek society. In looking beyond the nuclear family paradigm, it is possible to appreciate the importance of extended family in the role of childcare and support for new

mothers. By exploring a variety of evidence types, it is clear to see the presence and position of grandmothers in the public sphere. In this paper, the artistic representations of grandmothers will be explored, and the troubling stereotype of the “evil mother-in-law” will be discussed and challenged.

Biodistance Studies of Riverine Shell-Mound Builders from Ribeira de Iguape Valley (São Paulo and Paraná, Brazil)

Biodistance studies (craniometrics and aDNA) have been very useful tools to unravel the biological diversity of human populations in the past. In this abstract, we present biodistance analyses based on cranial measurements in order to further understand the relationship between hunter-gatherer groups that inhabited the Ribeira de Iguape Valley (São Paulo and Paraná, Brazil) and other Brazilian groups. These populations from Ribeira do Iguape are associated with the building of riverine shell mounds, using terrestrial gastropod shells during the Holocene. Our results point to a great morphological diversity in the Ribeira de Iguape region from the Early to the Late Holocene. The early Holocene individual shows a very distinct cranial morphology when compared to the middle and late Holocene groups, while these later populations show affinities to individuals associated to the middle and late Holocene coastal shell-mound occupation. We discuss these results, including new data on the paleogenomics of individuals from the Ribeira do Iguape region and the coastal groups.

Tracing Collection Histories for Repatriation: The Fisher Mound Group

Before repatriation, NAGPRA practitioners need to track down all components of a collection to prevent their tribal partners from having to repatriate the same collections multiple times. This involves tracing often labyrinthine collection histories over decades of archaeological research and curation. Collection histories can get complicated when collections are split between multiple institutions due to repeated excavations, decades of distinct curatorial practices, and collaborative research with minimal paperwork for tracking movements of boxes. Split collections and sparse documentation lead to complicated legal and logistical challenges in the NAGPRA process. This poster highlights a case-study on tracing collection histories using Fisher Mound Group as an example. The Fisher Mound Group in Will County, Illinois was excavated by multiple entities, including George Langford from 1926 to 1929, the University of Chicago in 1940–1941, and George Horner of Northwestern Illinois University in the 1940s. Over the years, materials from these excavations were curated at the University of Chicago; Yale University; University of Illinois, Urbana-Champaign; the University of Wisconsin, Milwaukee; and Indiana University. Materials and documentation moved between these institutions, and several others, making Fisher Mound Group a good example of the effort NAGPRA practitioners make to trace collection histories in facilitating best-practice repatriation.

O'Leary, Matthew (Syracuse University)**[311]***Untangling the Collection: French-Associated Ceramic Assemblages at Fort St. Frédéric*

This paper details preliminary analysis of a selection of the R. W. Robbins collection excavated at the Crown Point State Historic Site, New York, in the 1960s. It leverages differential trends in ceramics from mid-eighteenth-century French and British military occupations to better interpret the practices of the French fort community at Fort St. Frédéric. The inherent porosity of early modern frontiers, coupled with dynamic cultural entanglements and the necessities of backwoods subsistence, resulted in French colonial settlements that often included considerable material from non-French sources. This history complicates attempts to culturally associate archaeological layers in contexts with both French and British/American occupations, particularly among collections excavated without contemporary scientific standards for archaeological field methods. This paper focuses on ceramic vessel form and decoration to understand the material legacies of differing taskscapes and socioeconomic tastes between rival European powers within the eighteenth-century world-system.

[259]*The Historical Ecology of South Florida Shark Diversity and Indigenous Harvest*

Sharks are among the world's most endangered vertebrate taxa, including recent estimates of approximately 71% loss in abundance over the past 50 years due to human impacts. Zooarchaeological baselines of shark diversity, distribution, and exploitation hold great promise for contributing essential historical context in the assessment of contemporary patterns in shark species loss and vulnerability to human-caused extinction. Yet, shark historical ecology receives relatively less archaeological attention compared to ray-finned fishes or marine mammals. The marine and estuarine environments of south Florida are home to an array of shark species and conservation efforts. Here, we focus on shark assemblage data from three ancestral (ca. 2000–300 BP) Indigenous sites spanning south Florida. We review and compare shark taxonomic diversity, cultural contexts of deposition and significance, and local ecologies engaged by Indigenous peoples in the past. Drawing on new ZooMS data, we also consider methodological challenges and advances in the identification of zooarchaeological shark specimens. Ultimately, this review provides a foundation for considering the contribution of zooarchaeological baselines to regional shark historical ecology as well as global perspectives of human-shark interactions through time.

[284]*Ritual and Domestic Life at Usacorral: Preliminary Investigations and Community-Based Research at a Long-Occupied Community Site in the Northern Callejón de Huaylas, Peru*

Usacorral is a 10 ha mixed-use and long-occupied ceremonial, habitation, and agropastoral complex situated at 3,625 m asl in the north-central highlands of Ancash, Peru. Preliminary fieldwork at Usacorral employed test excavations, mapping, spatial analysis, and community-based research methods to understand the site's occupational history and diversity of social practices. The site's most prominent features include a nucleated

domestic cluster with plaza spaces, animal corrals, tomb chambers called chullpa, and a large rectangular platform (35 × 40 m, ~3.5 m high) with a central circular structure surrounded by other walled spaces. Excavations exposed 8 m² of this platform, and the exposed architectural elements, marine resources, precious stones, sculptural fragments, and ceramic materials indicate ritual activities in the form of offering rare and imported goods in and around the platform's central circular chamber. Survey, surface collection, mapping, and spatial analysis of the architecture beyond this platform reveal a multiuse site where people lived, worshipped, and buried their dead from the Recuay through Akillpo cultural phases (1–1450 CE). This poster presents these data, presents hypotheses for further research, and develops a comprehensive community-based research plan for more extensive investigations at Usacorral.

A River Runs through It: Recent Analyses of the Multi-sited Lil'wat Village of Lokla in Mount Currie, British Columbia

This paper presents the results of the most recent field season of the Lil'wat Villages Project. In its near decade of work our project has continued to employ a multidisciplinary approach to the archaeology heritage within Lil'wat territory. Our investigations aim to deepen the understandings of their oral histories about their villages and other sites. Over the years, this collaboration has investigated eight villages, most of which are storied places, with events associated from the Time of Transformation to the times of their abandonment. In 2023, investigations were focused on the southern portion of Lokla, a moderately sized pithouse village that is bisected by the Birkenhead River north of Mount Currie, British Columbia. Intact cultural deposits and features were encountered within three house pits, with evidence for three discrete occupation events spanning over 2,500 years. We will discuss how the village is contemporaneously occupied across the Birkenhead River, a split form of community organization.

Victims of Mesoamerican Royal Funerals: Companions of the Dead or Sacrificial Victims?

Since the seminal studies by Alain Testard, there has been debate over the function of victims in royal funerals in different parts of the world. In the case of Mesoamerica, did the wives, servants, dwarves, slaves, and other immolated individuals serve as “companions of the dead,” as “belongings” of the deceased rulers? Or did they participate in the classic sacrificial system defined by Hubert and Mauss, in which the king as “sacrificer” dedicated them to some divine entity? Another possible interpretation is that the divinized sovereign was the recipient of the sacrificial act. In this paper I will examine sixteenth-century sources that describe royal funerals in central Mexico, the Mixteca, and the Maya area to try to answer these questions, particularly analyzing the function of *ixiptla* (deity representative or impersonator) of specific victims and exploring the possible divine status of the dead sovereign.

Classical Nahuatl or Language of the Aztecs: Historical Appropriation and the Enduring Legacies of (Neo)Colonialism

Nahuatl, often referred to as the “Aztec language,” is one of the languages most widely identified, both in the academy and in public awareness, with prehispanic cultures. In archaeological and historical research, it often receives the name “Classical Nahuatl” and is conceived of as the most original form of the language that was used immediately following the Spanish conquest and was supposedly almost identical to the language of the “Aztecs.” This term, coined through a European lens and inspired by Classical antiquity (with Latin as a model for the first descriptions and grammars of Indigenous languages), assumes the existence of a homogenous reference model, a paradigm that has strongly influenced history, anthropology, and archaeology. Assigned to

the studies of “antiquities” and petrified as an idealized, imaginary, and fictional historical form, Classical Nahuatl was appropriated by the academy and separated from contemporary speakers. Like Latin, Classical Nahuatl is in fact assumed to be a dead language—despite the fact that some 1.5 million people today struggle with the discrimination and challenges associated with keeping their language alive. This paradigm, internalized by Mexican state ideology, attests to an unbridgeable gap between the glorious precolumbian civilizations and the impoverished contemporary Indigenous people.

Unveiling Silenced Narratives: Ethical Codes and the Challenge of Knowledge Dissemination Facing Middle Eastern Archaeologists

This paper delves into the glaring disparities faced by Middle Eastern archaeologists in disseminating their invaluable knowledge about their own heritage, elucidating how prevailing Western-centric ethical codes fail to redress these issues effectively. A profound asymmetry exists, wherein Middle Eastern archaeologists encounter structural violence hindering their ability to contribute on par with their Western counterparts in the field. This predicament is a complex web of impediments stemming from rigid publishing institutions, language barriers, and exclusive networks that perpetuate the marginalization of scholars from the Global South. Highlighting the inadequacies of current ethical codes, this paper underscores the urgent need to reformulate these guidelines, ensuring they are not only culturally inclusive but also cognizant of the unique challenges faced by scholars from underrepresented regions. It suggests solutions such as fostering collaborative partnerships, advocating for linguistic diversity in scholarly discourse, and dismantling the systemic biases ingrained in academic networks. This presentation offers a critical examination of the structural violence faced by Middle Eastern archaeologists, emphasizing the imperative for a more equitable and inclusive approach within the global archaeological community.

[264]

Religious Belief and Cooperation: A View from Ancient Greece

Recent work in the interdisciplinary field of the Cognitive Science of Religion has proposed that the in-group cooperation needed for the development of the large, complex human societies that first appeared during the Holocene was fostered by belief in the existence of supernatural beings that monitor humans and punish misbehavior. Two competing hypotheses have been put forward in this context: the “Moralizing High Gods (MHG) Hypothesis” and the “Broad Supernatural Punishment (BSP) Hypothesis.” The MHG Hypothesis contends that belief in one or more moralizing omniscient gods underpinned the development of complex societies, while the BSP Hypothesis proposes that it was fear of supernatural monitoring and punishment by non-MHG supernatural phenomena that fostered the development of sociopolitical complexity, and that MHGs followed rather than preceded the appearance of complex societies. Here, we report preliminary results of a study that is using textual and archaeological evidence for Ancient Greek religious beliefs and practices to test these hypotheses. Emulating a previous study that tested the hypotheses with Viking data (Raffield et al. (2019)), the study seeks to answer two questions: (1) Did the Ancient Greeks perceive themselves subject to supernatural monitoring and punishment? and (2) were the Ancient Greeks’ gods MHGs?

Oosterwijk, Barbara (University of Exeter), Linda Hurcombe (University of Exeter) and José Iriarte (University of Exeter)**[112]***Talk to the Hand: Experimental Research on the Painted Hand Depictions of Cerro Azul, Colombia*

Experimental research holds great potential for answering questions about the materiality of rock art, revealing insights into the practice of creating images and what it can tell us about the people who produced them. At Cerro Azul in Amazonian Colombia, multidisciplinary documentation methods revealed that hand depictions were created using a variety of techniques. Hands were simply printed into the rock surface or stylized and decorated with zigzags, spirals, or lines. This presentation shows an experimental and comparative archaeological study of the materiality of Amazonian rock art using Cerro Azul as a case study. Paint recipes were re-created using a variety of both mineral and plant-based coloring agents, as well as exploring the use of different binders, mixers, and grinding techniques. To further understand the technological means for creating prehistoric rock art, the results were compared with pigment analysis (pXRF) of the Cerro Azul paintings. The outcomes of these methodologies reflect how experimental techniques can enhance our understanding of rock art sites beyond the insights provided by traditional methods.

Oré Menéndez, Gabriela (University of Nevada, Las Vegas)**[172]***Mapping Up and Down: Automatic Mapping of Highland and Coastal Sites Using Multispectral-Based Image Analysis Methods from Aerial Images*

Mapping archaeological sites has become more precise, faster, and cheaper than ever, especially once archaeologists began using unmanned aerial vehicles (UAVs or drones) to capture high-resolution aerial views of archaeological sites. Nevertheless, the next step, manually tracing structures and archaeological features from orthophotos, is still daunting and time-consuming, particularly when the obtrusiveness of the sites, like high reflectance, non-contrasting features, or vegetation cover, prevents us from getting an accurate picture. Using multispectral image classification techniques, like band manipulation and supervised pixel-based classification, the proposed methodology offers a fast and efficient solution to get an initial map of an archaeological site. This poster offers an easy-to-follow workflow to map structures using aerial images. We will compare how this method works in two different sites in Peru: (1) Cerritos, a stone-based prehispanic site located over a steep hill in Huarochirí, and (2) the port city of Islay, an abandoned settlement from the early republican period located on the coast of Arequipa. Additionally, to follow equity principles in research, we share the step-by-step workflow made available through long-term digital repositories and discuss the alternative use of open-source tools.

Orr, Andrew (Argonne National Laboratory), Peregrine Gerard-Little (Argonne National Laboratory) and Konnie Wescott (Argonne National Laboratory)**[270]***A Geographic Information System Approach to Mapping Disturbed Landscapes for Cultural Resources Management: United States Air Force Academy*

Situated on 7,484 ha (18,494 acres) at the foothills of the Rampart Range in Colorado, the main campus of the United States Air Force Academy (USAFA) has experienced human activity across the precolonial, historic, and military eras, as well as natural disturbance from water courses and soil slumping along steep slopes. Both natural and cultural activities have resulted in ground disturbances potentially affecting the integrity of cultural deposits. Using a geographic information system approach, this project delineates land disturbances at USAFA, resulting in a map that illustrates disturbed areas along with the severity of disturbances. Using historical imagery from before, during, and after the construction of USAFA, and high-resolution lidar data, land disturbance features were mapped for the entirety of the campus. A total of 953 disturbance features were mapped manually while 48,959 features were automatically assigned a disturbance value from existing built environment geospatial data. The resulting disturbance map and geospatial data provide a tool for informing USAFA's future planning activities and decision-making, including consideration of impacts on cultural resources. The mapping efforts indicate that undisturbed land accounts for approximately 46% of the installation with remaining land containing some severity of disturbance.

How It Started vs. How It's Going: The First Year of a Cultural Compliance Rule for New Mexico Trust Land
The New Mexico State Land Office implemented a new Cultural Properties Protection (CPP) Rule on December 1, 2022. This statute mandated changes to a decades-long culture of "you break it, you buy it" regarding damage to cultural properties caused by extractive industry in the state. Implementation resulted in the identification and protection of hundreds of cultural properties. The initial year of cultural compliance requirements also highlighted policy gaps in need of future development. This poster will provide multicultural perspectives on the successes and inadequacies of the CPP Rule, and how it can be a model for other state trust land agencies.

Resultados preliminares de la primera temporada de campo del Proyecto Arqueológico Nestepe/Rancho Cobata (PANCO): Reutilización de monumentos Olmecas durante la transición del Formativo al Clásico
En esta presentación se expondrán los resultados preliminares del Proyecto Arqueológico Nestepe/Cobata (PANCO), relacionados con la reutilización de monumentos olmecas en la región de Los Tuxtlas, durante la transición del periodo Formativo al Clásico. Investigaciones previas sugieren la existencia de fases ocupacionales, correspondientes a dichos periodos, en el contexto arqueológico de las cabezas colosales encontradas en el Grupo Nestepe y Grupo I de Tres Zapotes, así como en el sitio Rancho Cobata. Por ejemplo, Pool determinó que el Grupo I y Nestepe presentan un arreglo arquitectónico fechado para el Formativo Tardío. Por otro lado, fragmentos de cerámica diagnóstica del Clásico fueron hallados en las excavaciones de la cabeza de Cobata. En el 2022, el PANCO realizó excavaciones arqueológicas en Rancho Cobata y en el Grupo I de Tres Zapotes, para refinar la secuencia cronológica de las ocupaciones y los tipos

de actividades asociadas a las cabezas colosales halladas allí. Los datos recabados dan cuenta de cómo, tras el colapso del sistema político olmeca, las cabezas colosales de Tres Zapotes y Rancho Cobata mantuvieron un rol social activo entre los pobladores de la margen occidental de Los Tuxtlas, desde el Formativo Tardío hasta inicios del Clásico Temprano.

Apropiación, síntesis y representación en la etapa Blanco y Negro de Chavín

La forma final del sitio de Chavín de Huántar se estableció fundamentalmente en la llamada etapa Blanco y Negro definida por Kembel. Hay allí elementos de la arquitectura y del paisaje que son indicios de algún programa de reestructuración social en clave de una renovada jerarquización y la intención de su encubrimiento. En primer lugar tenemos el re-uso de ejes arquitectónicos de la etapa Montículos Separados, usados ahora de manera dependiente. A esto se suma la Plaza Circular como elemento de una extraña novedad, ya que reúne singularidad con cierto arcaísmo debido a su forma, posición y el diseño de su piso. Finalmente, está la presencia de portadas y corredores que indican puntos y líneas de desplazamientos que remarcan la disposición espacial. El resultado fue un ambiente más jerarquizado que expresó una síntesis de la totalidad social basada en la representación de elementos antiguos subordinándolos a un nuevo orden. Esto indica una estrategia donde la apropiación de cierta tradición y capacidades sociales llegó a un nivel especial, y no fue la comunidad en conjunto necesariamente quien la habría determinado. Este proceso pudo incluso ser inevitable.

Nuevos hallazgos de la Sala del Imaginario Moche en Pañamarca

Durante las excavaciones realizadas en los años 2022 y 2023 en la Sala Hipóstila, ahora llamada Sala del Imaginario Moche, ubicada en la parte oeste de Pañamarca, se identificaron seis pilares, cinco de ellos, por lo menos, conteniendo representaciones de personajes humanos, animales y mitológicos, los cuales fueron parcialmente vistos en el 2010. En la parte central de este espacio, existen cuatro pilares que se miran entre sí, presentando en sus caras frontales, personajes humanos y zoomorfos que miran o se dirigen hacia el centro, posiblemente para recibir a los actores humanos de altos grados que pudieron ingresar a este edificio. Los citados pilares, agrupados en pares, se encuentran unidos por elementos arquitectónicos como banquetas, un posible trono asociado a una estructura semicircular, también finamente decorados. Cada elemento arquitectónico se encuentra decorado, hasta en más de un momento, quedando clara la intención de la población Moche de Nepeña de demostrar, al menos en el interior de esta Sala, la importancia de la relación y conexión entre la fauna y el mundo social moche.

Ortman, Scott (CU-Boulder)**[63]***Discussant***[206]***Chair***Ortman, Scott (CU-Boulder) and Kaitlyn Davis (Northern Arizona University)****[206]***Pottery Assemblage Change from the Sixteenth to Nineteenth Centuries in the Pueblo of Pojoaque*

Most studies of colonial period Tewa pottery have focused on complete vessels collected in recent times. Between 2016 and 2019 a team of students and volunteers at the University of Colorado, Boulder, had the opportunity to study excavated potsherd collections from 1952 excavations by Florence Hawley Ellis at two sites within the Pueblo of Pojoaque. The Garcia site contains an assemblage dating from the Spanish contact period through the Pueblo Revolt, roughly 1500–1680; and the Old Pojoaque Dump contains an assemblage dating primarily to the colonial period, from 1706 to about 1900. In this paper I summarize some of the most interesting patterns we observed, including (1) evidence for the in-migration of Tano potters from the Galisteo Basin in the seventeenth century, (2) several changes related to the incorporation of wheat into the economy, and (3) evidence of efforts to mimic the appearance of cast-iron cookware. We also had difficulty establishing internal divisions of the colonial period. These findings provide a basis for comparison of assemblages from contemporary Hispano sites.

Ortner, Vaughn (University of Pennsylvania [Alumnus]) and Marie-Claude Boileau (Penn Museum Center for the Analysis of Archaeological Materials)**[166]***The WPA Ceramics Laboratories of the Penn Museum: A Collaborative Legacy*

For decades, scientific approaches have acted as a cornerstone to the processes used by archaeologists to answer questions about past societies. However, just under a century ago, the integration of archaeological science into the wider discipline was undergoing its early steps. One formative series of research projects during this period included those undertaken by the WPA ceramics laboratories (1935–1942), a joint effort between the Works Progress Administration and the University Museum of the University of Pennsylvania (now called the Penn Museum). These efforts employed federally funded workers and the burgeoning methods of ceramic technological analysis to reveal more information on the museum's various ceramic collections than previously possible. Extensive research into the history and legacy of these original museum laboratories reveal their role as a catalyst for the subsequent proliferation and continued development of ceramic analysis techniques, especially that of ceramic petrography, and archaeological science as a whole. Archival evidence proves that the scholarly networks formed by those involved in the WPA projects enabled the principles and methods of ceramic technological analysis to spread throughout the discipline, with the museum laboratories serving as an early nexus and exemplar of the great possibilities held by these new approaches.

Osborn, Jo (University of Exeter), Gaspar Morcote Rios (Universidad Nacional de Colombia), Francisco Javier Aceituno (Universidad de Antioquia) and José Iriarte (University of Exeter)**[36]***The Missing Mammals of Cerro Azul (Guaviare, Colombia): Extreme Fragmentation in Neotropical Zooarchaeological Assemblages*

Ongoing research by the LASTJOURNEY project has investigated multiple archaeological sites located near rock art panels in the Serranía La Lindosa, Colombia, to explore human-environmental interactions during the Late Pleistocene / Early Holocene transition. Due to severe taphonomic conditions in the Colombian Amazon, only one of these sites, Cerro Azul, has produced zooarchaeological materials. Preliminary analysis of this assemblage identified the presence of fish, reptiles, and small mammals (Morcote Rios et al 2021).

Curiously absent, however, are many of medium and large mammal species depicted in the painted rock art just meters away. Rather than reflect hunting practices or dietary preferences, it is suggested that absence of these animals is the results of neotropical taphonomic conditions. New analyses of unidentified bone fragments addresses whether the presence of larger mammalian taxa has been obscured by extreme fragmentation and considers the potential implications for future neotropical zooarchaeological research.

The Exchange and Consumption of Incensarios in Middle Postclassic Sauce, Veracruz, Mexico

Incensarios or incense burners are ritual items used in a variety of settings, some in households and some in more formal ritual contexts within Mesoamerica. I analyze residential inventories from the center of Sauce and its hinterland to describe the structure of exchange and consumption of incensarios during the Middle Postclassic period (AD 1200–1350) in south-central Veracruz, Mexico. Many of the incense burners in the Gulf lowlands region are large, elaborate specialty items that could have been restricted in exchange and/or only used by larger households. Information about their production and chronology is scanty, but as a household ritual item not commonly considered in economic analyses, any evaluation of incensarios within the context of local exchange and consumption contributes to a better understanding. Results indicate some restriction for incense burners recovered during the Sauce Archaeological Project (SAP). The largest concentrations of incensarios were found near Sauce, which suggests that political elites may have had more access or use of these items. In the hinterlands of Sauce, incense burners are found with household mounds that were larger, potentially more elite residences, consistent with the interpretation of incensarios recovered with politically elite and potentially wealthier households.

When Is a Living Shoreline Erosion Control Project Suitable to Protect a Coastal Mound Site? Establishing Preliminary Suitability Criteria Based on a Case Study, Adams Bay (16PL8) Mound 1, in Plaquemines Parish, Louisiana

Many archaeologists studying coastal archaeological sites are weighing the costs vs. benefits of implementing erosion control structures to protect sites threatened by sea-level rise and/or land loss. However, little literature is available about the types and applicability of erosion control structures, such as living shorelines, as protection measures for coastal sites as part of an overall conservation plan for the resource. This paper presents criteria for assessing erosion protection measures for coastal earthen mound sites threatened by land loss based on the Adams Bay Site (16PL8), a Plaquemines site located in Plaquemines Parish, Louisiana.

Identifying Depositional Processes: Statistical Cluster Analysis at Sacred Ridge

The site of Sacred Ridge has the earliest identified Extreme Processing assemblage in the Four Corners region, with over 14,000 fragments of human bone (representing at least 33 individuals) deposited in two pit structures around AD 810. During excavation, over 9,000 point locations were taken with a total station. During analysis, all fragments were examined with the goal of bone identification, estimation of demographic information (age at death, sex), and identification of taphonomic indicators. These fragments were then subjected to a refitting exercise, resulting in a refit rate of approximately 35%. This presentation will examine the depositional patterns of these refits utilizing a Monte Carlo approach to simulate random mixing. We identified four clusters that could be identified as potentially representing depositional actions (such as the deposition of a basket of bone fragments). We quantified within/between cluster refits using Simpson's Diversity index, and we found that refits tend to occur within clusters, particularly for the long bones, suggesting that the body was processed based on element, further supporting the systematic nature of the body processing at Sacred Ridge.

Nubian Ceramic Traditions on Elephantine Island, Egypt

The southern border of Egypt with Sudan (prehistoric Nubia) was always a culturally fluid area. As archaeological studies of the site of Elephantine Island have illustrated, there are features representing Egyptian and Nubian cultural affiliation. The pottery in particular can be of Nubian or Egyptian tradition suggesting that peoples of both groups might have lived together at the site. To clarify this, petrographic analysis was conducted on 35 sherds of Nubian pottery from Middle Kingdom layers at Elephantine Island. The focus was on fine-ware vessels and cooking pots. The former relates to long-standing fine-ware traditions in Nubia (C-Group and Pan-Grave types) and could reflect trade, while the latter may indicate Nubian populations living in Egypt. The results showed that most of the pottery was probably made in Egypt in the Aswan area. A few fine-ware vessels may have been made in Nubia. This confirms that people making pottery locally in the Nubian tradition were living in southern Egypt at this time.

A Cross-Cultural Comparison of Man's Best Friend: Insights from Casas Grandes and the North American Arctic
 Human-animal relations are inherently dynamic in nature, and in recent years archaeologists have started to explore alternative approaches to shed light on anomalous patterns that deviate from traditional models of understanding. Archaeologists traditionally assumed that they could account for cultural differences globally by employing Western divisions of nature vs. culture, thing vs. person, and humans vs. animals. Those interested in the study of ontology must recognize that ancient societies may function in radically different conceptual worlds, often informed by exposure to differing environmental conditions. By examining human-dog relations in both the Casas Grandes culture in Northern Mesoamerica and the Thule culture in the North American Arctic, this paper highlights the benefit of cross-cultural comparison in examining how environmental factors affect individual and collective ontological perspectives. We draw on archaeological evidence of excavations from multiple sites in both regions ranging from AD 800 to 1450/1500, as well as ethnographic analogy from historic period Inuit groups. Through a comparison of ontology, we aim to present alternate modes of inquiry that account for differences specifically related to the treatment of dog species and the unique environments they live in.

Lyobaa Project: Results of Subsoil Geophysical Study in the Ancient Zapotec Monuments of Mitla, Oaxaca
 This paper presents the methodology employed, as well as the results obtained from the geophysical research conducted in the archaeological site of Mitla, Oaxaca, during the 2022 season of the Lyobaa Project. In this project, noninvasive geophysical techniques, such as ground-penetrating radar (GPR), electrical resistivity tomography (ERT), and ambient noise tomography (ANT), were utilized for surface scanning of the Church Group and the Columns Group. With the support of these techniques, it was possible to identify previous construction phases of the site and determine the physical conditions of some of the structures and the soil beneath these structures. The research was conducted with the collaboration of a multidisciplinary team from the National Institute of History and Anthropology (INAH), the National Autonomous University of Mexico (UNAM), and with the financial assistance of ARX Project A.C.

Pacheco-Fores, Sofia (Hamline University)**[11]***Discussant***Pacifico, David (University of Wisconsin, Milwaukee)****[248]***The Casma State Heartland: A Community-Centered Regional Perspective*

This presentation explores the development, apogee, and denouement of the Casma State in the hinterland context of its capital city, El Purgatorio. El Purgatorio developed within a congested countryside populated by ethnically homogenous people who recognized their own north-central coastal identity. In the fourteenth century, the encroachment of the Chimú Empire provoked the consolidation of the Casma heartland into an urbanized landscape. At its core was El Purgatorio, a city that saw massive growth and density increase from AD 1290 to 1405, followed by a rapid exodus and subsequent Chimú-Casma rule in the valley. Recent evidence from Casma State sites around El Purgatorio supports the theory of this unusual urban growth. More generally, the current evidence for the development of El Purgatorio and its hinterland provides reactivated interest in alternative models of urbanism, including that of low- and medium-density urbanism. It raises questions about the knock-on effects of these urban forms with respect to models of state formation including that of the secondary state and the shadow state. Only by examining the smaller settlements and communities that compose and surround urban capitals are we able to get a nuanced and clear picture of social intensification in the ancient world.

Padilla, Eliseo (INAH, MNA) and Karent López Guzmán (Instituto Nacional de Antropología e Historia)**[240]***La colección Chupícuaro del Museo Nacional de Antropología: Conformación e investigaciones*

A finales de la década de 1910 llegaban al Museo Nacional de México los primeros objetos de la cultura Chupícuaro como parte de la colección Guillermo Heredia. Posteriormente en 1926 se integraban aquellos que procedían de las excavaciones de Ramón Mena y Porfirio Aguirre, y durante los años cincuenta el acervo de esta cultura aumentó con el resguardo del material arqueológico que procedía del Salvamento de la Presa Solís; estos episodios marcaron el inicio de la catalogación de uno de los acervos más grandes de esta cultura que tuvo su auge a finales del Preclásico en el valle de Acambaro al sur de Guanajuato. En esta ponencia se aborda la historia, la creación y evolución de esta colección a partir de la implementación de una base de datos realizada con la revisión de cédulas, archivos históricos y datos en las piezas que permiten su manejo e investigación, registro que ha permitido la reconstitución de casi 400 entierros con sus mobiliarios funerarios.

Padilla, Eliseo [240] see López Puértolas, Carlos

Padilla-Iglesias, Cecilia (Institute of Anthropology, University of Zurich) and Robert Bischoff (Arizona State University)**[323]***Using Agent-Based Models to Explore How Behavior Affects Archaeological Networks*

Archaeologists use a wide variety of material culture and methods to construct and analyze networks. Just how these networks relate to past behavior is an open question, as we lack information on the relationship between behavior and material culture in the past. We do not have adequate datasets of people interacting with people alongside corresponding records of the objects involved in the interaction at the scale and duration used in most archaeological networks. One potential solution to this problem is to use computer simulations. Agent-based models allow us to provide virtual agents with simple instructions and then observe the emergent results. Our simulations allow the agents to interact, learn, move around, and make and trade objects. The result is a network of people-to-people interaction and an archaeological record of discarded

artifacts that can be used to create material culture networks as typically done by archaeologists. Since each type of social interaction is tracked, this approach allows us to correlate specific behaviors with specific patterns in different types of material culture networks. Learning, trading, visiting, and communal hunting behaviors all provide varying levels of correlation with the material culture networks.

A Stratified Past: A Geoarchaeological Perspective of the Sayles Adobe Terrace Site

This paper is a condensed summary of my master's thesis "Stories in the Sand: Excavation and Analysis of The Sayles Adobe Terrace (41VV2239) In Eagle Nest Canyon, Langtry, Texas" (Pagano 2019). It presents an overview of the background, methodologies, analyses, and conclusions of work completed at the Sayles Adobe terrace site excavated in 2016–2017. Sayles Adobe (41VV2239) is a deeply stratified, multicomponent terrace site located in Eagle Nest Canyon (ENC; also known as Mile Canyon) near Langtry, Texas. The terrace sits less than 50 m downstream from previously excavated rockshelter sites, Kelley Cave (41VV164) and Skiles Shelter (41VV165), which are noted for their rock art panels and immense quantities of discarded burned rock. The deep, stratified deposits of Sayles Adobe and 10 radiocarbon dates spanning the Late Paleoindian to Late Prehistoric periods suggest Sayles was occupied at times not documented in the archaeology of the two nearby shelters. Low-velocity flood events in the canyon sealed and preserved Sayles Adobe deposits, often as low-density occupation surfaces.

La Playa in the Broader Early Agricultural Period

This presentation will situate La Playa site within a broader narrative of the development of the Early Agricultural period (EAP). We review evidence for the obvious parallels of technological development that occurred at La Playa and other EAP sites in both Northwest Mexico and the US Southwest. These changes are then placed in an updated reconstruction of the transmission of agricultural lifeways from Mesoamerica to the North American Southwest. We infer environmental changes during the Middle Holocene Climatic Optimum concentrated populations in the more humid uplands and margins of the North American Southwest, including a southern zone where maize cultivation was acquired. Subsequently, viable cultivation

localities were occupied by the spread of proto-southern-Uto-Aztecan who eventually introduced agriculture across the North American Southwest through a combination of migration and diffusion events.

Empowering Communities: Democratizing Knowledge Production in Science Communication through The Community Archaeologist

Science communicators are in an unprecedented time of digital innovation and global connectivity that has given rise to accessible and engaging projects, including podcasts, TikToks, apps, and interactive websites. These platforms have demonstrated how the power to create and disseminate narratives can shift from a select few to the collective voices of the many. Nevertheless, science communicators, particularly in archaeology, continue to explore successful methodologies to empower communities, especially those historically marginalized. In this paper, we explore our approach to democratizing knowledge production through our work with *The Community Archaeologist*, a digital science communication magazine dedicated to sharing narratives of history and heritage that reflect Oklahoma's diverse cultural landscape. Throughout its development, our editorial team has prioritized building enduring and diverse collaborations, ensuring representative authorship, fostering independent content creation, and promoting multimodal engagement. We have also worked to reduce barriers that might hinder community participation, such as financial constraints, time limitations, and a lack of writing experience. While our approach is an ongoing endeavor, it is making strides toward a more equitable and inclusive archaeology.

If Threads Could Talk: Listening to Andean Textiles at the Louisiana University Museum of Art

In the mid-1990s, the LSU Museum of Art received a collection of nearly 60 Andean objects as a donation from a private collector. More than half of the items donated are textiles and/or tools used in making textiles, all thought to have come from Peru. Beyond this geographic pointer, little information came with the collection, so the catalogue entries for these items are overwhelmingly sparse. My research, as part of a MA program in anthropology at LSU, began as an effort to better classify these nearly forgotten items and to fill out the catalogue. In this paper, however, I aim to move beyond stylistic and cultural historical classifications by adopting an object biography approach and considering textiles as agents, I explore their multiple lives as they passed through various hands over time. As I try to make the "threads talk," I dwell on their physical manifestations, visualities, and material conditions at various key moments in their past and current lives. More broadly, I use the textile collection as a springboard to investigate the historical intricacies of acts of collecting and the current challenges in studying museum collections.

Paling, Jason (Plymouth State University) and Justin Lowry (SUNY Plattsburgh)**[157]***Overland Travel Routes and Exchange Spheres of Pacific Nicaragua Using Obsidian and Ceramic Data from Chiquilistagua*

The emergence of social complexity often incorporates social, political, and economic inter- and intraregional interactions. In this paper we examine the emerging social spheres and exchange networks that developed during the Tempisque period (500 BC–AD 300) among small prehistoric agrarian hamlets near Lake Managua. Geochemical analysis of ceramic and obsidian artifacts, in conjunction with GIS predictive modeling, presents possible overland travel routes and exchange spheres, and we then discuss the role these networks had in lower Central America.

Palka, Joel (Arizona State University)**[86]***Return to Aztlan: Aztec Pachuca Green Obsidian in Maya Sites at Mensabak, Chiapas, Mexico*

Archaeology at Mensabak, Chiapas, Mexico, recovered large amounts of green obsidian from mines at Pachuca, Hidalgo, which were managed by Mexica-Aztecs in Late Postclassic times (ca. 1300–1520 CE). Excavations in coeval Maya habitation sites at Mensabak recovered obsidian sourced with XRF equipment at the Field Museum. The analysis indicated that the percentage of Pachuca obsidian ranged between 35% and 50% at various Mensabak sites. Mesoamerican sites with Aztec influence, such as the cacao-growing Soconusco province in Chiapas, typically have high percentages of Pachuca obsidian (35%–65%). Yet, most Late Postclassic sites in Chiapas have only 0%–10% Pachuca obsidian, indicating that Mensabak was important to Aztec people. Mensabak likely drew Aztec traders and pilgrims, as well as Maya merchants interacting with them because of its Aztlan-like island shrine. Importantly, Pachuca obsidian occurs in larger percentages at Mensabak sites with Maya elites, pointing to elite agency in exchange networks and their leadership in ritual and politics.

Palmer, David (Coastal Carolina University)**[303]***People, Trees, Rice: Consequential Intersections and Complicated Relationships in the Lowcountry*

Multiple dramatic changes in human-forest relationships are manifest in the landscape of the coastal region that spans southern North Carolina to northern Florida known as the Lowcountry. Ecologically diverse bottomland hardwood forests managed by Native Americans since at least the Woodland period were destroyed by settler-colonist newcomers who created a rice monoculture region nearly denuded of trees that was replaced after the Civil War by a mosaic of pine plantations, re-wilding relict rice fields, and residential and tourist construction. All of these landscapes are the result of cultural land-use practices. The managed landscapes that resulted from Native Americans applying generations of Indigenous Knowledge were illegible to European and European-American settler-colonists interested in the commodity value of trees for timber and naval stores, or who saw them as obstacles to lucrative plantation crops like indigo and rice. This latter group radically transformed the landscape through the forced labor of captive Africans and Native Americans. Archaeological evidence from Laurel Hill, Brook Green, and neighboring rice plantations; geospatial data from historic maps and imagery; documentary and oral historical sources; and environmental data examined for this study help us to disentangle the complicated relationships of people and forests in this region.

The Importance of Collaboration: Reflections from a World War II Forensic Archaeology Field School

The recovery of past service members from historic military sites is a specialized archaeological niche with substantial forensic influences. It receives distinct notice by governments around the world as they recognize the importance of closure for their nations and families of those Missing in Action. Although this type of archaeology is typically removed from the sociopolitical discussions in precontact North American archaeology, such as decolonization and Indigenous collaboration, the privilege of being part of an academic team from the United States working on foreign soils toward the recovery of American World War II losses offers practitioners a unique place to reflect on these concerns. Notably, we are free to maintain our conflict narratives within our culture but are variably enabled by the communities around the physical recovery sites. The convergence of these perceptions has the potential to generate potent connections even 80 years after the events. When these perspectives are integrated into field school models, students are positioned for powerful multicultural and applied experiences while mastering archaeological field methods. This presentation reflects on the global intersections and narrative constructions inherent in conflict-related archaeology. Two World War II cases from Germany are considered, representing differing levels of community engagement and interest.

The Evolution of the Two-Room Temple during the Middle Formative in an Interregional Perspective between the Mixteca Alta and the Valley of Oaxaca

The study of the Zapotec temple, its origins and evolution, has significant implications to understanding the social complexity in early societies. This paper follows the proposal of the one-room temple as the origin of the two-room temple, also called Zapotec temple, and exposes its evolution showing the characteristics of those temples identified in San Martín Tilcajete, San José Mogote, and Monte Albán for the early phases of San José, Guadalupe, Rosario, and Monte Albán I-II. In addition, this paper focuses on the one-room temple excavated at Tayata in the Mixteca Alta, pointing out that its function, as well as the rituals and beliefs involved, were similar or shared with those societies from the Valley of Oaxaca. As part of the conclusions, this paper mentions the lack of data about the evolution of the Mixtec temple, having few samples in the region for early times in the Mixteca Alta, such as the one-room temple in Tayata and the temple T of two-rooms in Monte Negro, opening this topic for future consideration and discussion.

Preserving the Maritime Cultural Heritage: Digital Recording Applications on the Nineteenth-Century Schooner Equator

The schooner *Equator* was originally built in 1888 in California by the renowned shipwright Matthew Turner and sailed in the South Pacific by Scottish writer Robert Louis Stevenson. After the southern journeys, the ship went through multiple redesigns for different purposes in the west American coast. These events made the ship a unique example and testament of modern maritime history. Because of its cultural and historical relevance, the Port of Everett kept the vessel since the second half of the twentieth century. However, the preservation of the hull is not feasible any longer and the local authorities have decided to disassemble it. Given these circumstances, a salvage archaeological project was executed to record and preserve all the information regarding the architectural features of the *Equator*. To accomplish this task, different methodologies were applied including aerial recording for photogrammetric processing with an unmanned aerial vehicle (UAV) and laser scanning through light detection and ranging (lidar). The poster seeks to present the results obtained from both processes and explore their possible applications in archaeology.

Rock Imagery, Cultural Landscapes, and Indigenous Ontologies in the North American Southwest

How we frame the study of rock imagery (i.e., petroglyphs and pictographs) conditions the types of questions we ask, the types of data we employ, and ultimately the types of conclusions we draw. In the North American Southwest, the study of rock imagery has long focused on the images, less so on the rocks, and only rarely on the landscapes in which it exists. This is due largely to a heuristic bias that prioritizes the interpretation or decipherment of the imagery that all too often results in ambiguous or self-proving inferences. New lines of inquiry are looking beyond the mere images to ask how the Southwest's Indigenous communities use rock imagery in social and spiritual dialogues with themselves, neighbors, ancestors, and deities. These approaches generally couple analytical and digital methods and techniques germane to landscape archaeology with ethnographic information on relevant Indigenous ontologies pertaining to land, spirit, being, power, history, and morality—a blending of formal and informed methods. We illustrate examples of this fledgling Southwest focus with case studies from southwestern Colorado and southern Arizona.

A Federal Framework to Integrate Native American Traditions in the Care of Ancestors and Cultural Property Held in Museum Collections

Federal agencies and repositories holding federal collections have been bound to curation standards often developed without consideration for nontangible values and needs and a legacy of collecting practices intended to preserve the past yet uninformed by the interests and concerns of descendant communities. In 1990, NAGPRA established that tribal communities had rights above those of the collection holder. In 2023, new NAGPRA regulations propose that standards of care defer to Native American community norms. Sharing and ceding authority is an important and meaningful shift in recognizing community expertise within archaeology and museum practice. This paper explores how federal laws and policies can promote—and hinder—incorporation of tribal preferences and methodologies in collections care, within the context of NAGPRA, and beyond. Although tribal viewpoints and preferences are elicited through consultation, recent federal policies on co-stewardship and Indigenous knowledge increasingly incorporate and rely on tribal expertise and practices. Yet honoring cultural customs can conflict with other federal requirements. NAGPRA has helped transform relationships and practices. Reframing duty of care is another pivotal opportunity to collaborate and reform collections management to incorporate culturally appropriate and respectful care for ancestors, cultural items, and other cultural material under our stewardship.

Community Archaeology and the Nuniaq Culture Camp: Undergraduate Perspectives on Practicing Community-Based Archaeology in Old Harbor, Alaska

In July 2023, the Old Harbor Archaeological History Project partnered with the Alutiiq Tribe of Old Harbor and the Old Harbor Alliance to co-facilitate Nuniaq Culture Camp on Sitkalidak Island, Alaska. Thirty-five Alaska Native children and teens from Old Harbor attended a five-day culture camp, in which they participated in archaeological excavation, Alutiiq/Sugpiaq harvesting practices, beadwork, and dance, among other activities. These activities, both new and familiar, were run by Elders, cultural experts, and our group of archaeologists. Here, we reflect on our experience participating in Nuniaq Camp as undergraduate archaeology students. Each day we worked with small groups of youth and community members to excavate a house and midden at the Ing'yuuq site (KOD 114), as well as sift, wet screen, and identify material belongings. We found our positionality as student leaders aided in developing a welcoming learning environment by embracing transparency, humility, and empathy. Teaching was reciprocal; we learned from the children, Elders, and cultural experts about the perspectives, traditions, and day-to-day lives of Sugpiaq people, rooting the archaeology into relevant contexts. As some of the youngest leaders, we formed genuine connections, friendships, and mentorships with the youth as we served as role models and support.

Under the All-Seeing Eye: The Archaeology of Native Californian Resistance at Mission Santa Clara

The façade of Mission Santa Clara de Asís features the All-Seeing Eye of God, a symbol that serves as a reminder of the omnipotence of the Christian God. This symbolism reinforces ample archival evidence that the Franciscan missions of Alta California—like Spanish missions elsewhere in the Americas—were strictly controlled social spaces that relied on real and perceived surveillance to enforce cultural conversion. Yet, recent archaeological research at Mission Santa Clara and other nearby missions in central California paints a more complex picture of how Native Californians navigated the structures of missionary colonialism. A key insight is drawn from the spatial distribution of certain features and materials from the Native neighborhood at Mission Santa Clara, including large quantities of projectile points and lithic debitage as well as features thought to represent traditional mourning ceremonies. Taken together, these archaeological patterns demonstrate that Indigenous people maintained spaces that were outside of the control of Franciscan missionaries and other colonial officials, underscoring the notion that Native Californians rejected large portions of the mission project.

The Past and Future of Archaeological Prospection

Archaeological prospection refers to the identification of subsurface cultural features by nonintrusive techniques. The prospection literature exhibits a simple evolution from pioneering application of techniques to their more common use. The method developed by Luis Barba and colleagues at the Laboratorio de Prospección Arqueológica, UNAM, represents a separate prospection lineage in that it employs a whole battery of techniques systematically and synoptically, it is multidisciplinary, holistic, applicable in a wide variety of natural and cultural settings, and it can address anthropologically important problems requiring observations at scales much larger than that of excavation. We illustrate this method with an example from collaborative research in Coixtlahuaca, an urbanized region in ancient Oaxaca. Prospection is typically ancillary to excavation, but as we illustrate, in many contexts this relationship should be reversed, especially when the research problems call for data that excavation cannot produce because it would be costly, destructive, too small scale, unethical, or illegal.

Geomatics for Landscape Archaeology: Dreams of Eternal Youth

Geographic information technologies already have a long history of use in archaeology. In fact, archaeology has perhaps been the field of humanities where these technologies have reached the most widespread development, in many cases becoming part of the “standard package” of work for any archaeologist. To what extent is this true, or are they still more a part of a specialized field of work? Is there still room for innovation or have we reached a more static and conformist full maturity? What has been their impact after all these years in the ways we approach landscapes? What scenarios can we conjecture for the coming years?

[285]

Tale of Tells: Regional Variability of Bronze Age Ceramic Assemblages in the Eastern Carpathian Basin

During the Middle Bronze Age (ca. 2000–1500 BC) the Eastern Carpathian Basin was populated with tell societies of various cultural traditions. Tell sites play a focal role in any narratives that address Bronze Age societies in this area. They are often seen as key to maintaining cultural traditions and are used in defining relative and absolute regional chronologies, exploring cross cultural relationships and evaluating social structures. This poster focuses on multiple tell sites along different waterways within the territory of the Ottomány-Gyulavarsánd culture. While it is often assumed that traditions were shared across different tells and non-tells in a given area and internal homogeneity at large is presumed by the use of the archaeological culture concept, the degree to which material culture demonstrates shared cultural traditions in the Lower Körös area remains to be seen. The poster compares the use of decorative techniques, stylistic elements, and stylistic grammar to evaluate the extent and scale of consistency in cultural traditions across the landscape. By utilizing both excavation and surface collection assemblages the analysis aims to assess variation in practices over a larger portion of the Lower Körös area.

Revisiting Bipolar Technology's African Distribution and Diversity

Bipolar reduction is a central strategy in Pleistocene archaeology, recognized as an archetypal “expedient” technology. It entails hammer and anvil flake production, suitable for stabilizing smaller cores during miniaturized flake production. Despite its widespread occurrence and decades of study, debates persist in the

bipolar literature. These debates center on how and why ancient toolmakers used bipolar reduction (e.g., the wedges vs. cores debate) and whether shifts in humans' use of bipolar technology delineate periods in Paleolithic archaeology. This paper assesses Horta et al.'s (2022) "Lithic Bipolar Methods as an Adaptive Strategy through Space and Time," a recent bipolar technology metastudy, focusing on their use of African archaeological evidence. We augment their survey with (1) search terms for African bipolar technology instances and (2) a reevaluation of bipolar implements as cores rather than wedges. The results show a strong correlation between periods of lithic miniaturization and bipolar technology, supporting the widespread assumption that bipolar implements represent cores and not wedges. Our study demonstrates the complexities of understanding ancient humans' use of expedient technologies across space and time.

The Archaeoacoustics of Tenam Puente, Chiapas, Mexico: Auditory Monitoring of an Ancient Monumental Zone
Current research on ancient Maya cities is radically revising our knowledge of their economies. Scholars are beginning to identify the archaeological remains of marketplaces, currencies, and other elements of extensive commercial exchange. However, the surveillance of ancient economic spaces and institutions is rarely investigated in archaeological research, including the ways that built environments were used to organize economic institutions such as ancient marketplaces, and to facilitate oversight and interventions by political authorities. Were these marketplaces controlled by the invisible hand of the market, or by the all-too-visible hand of political rulers? This study examines elite surveillance of an ancient marketplace at the Maya city of Tenam Puente, one of the most important political capitals on the western Maya frontier during the Late Classic (600–900 CE) and Early Postclassic (900–1250 CE) periods. This presentation investigates the acoustic characteristics of the monumental zone that facilitated the monitoring and policing of various urban locations by the city's rulers and administrators.

Sourcing Gary Points at the Poverty Point Site and Chert from the Trans-Pecos and High Plains Regions
The chert source analysis of Gary projectile points at the Poverty Point site reveals the movements of communities and/or toolstone resources. The study investigates westward connections at the site as indicated by the potential influx of Edwards Plateau chert. Varieties of Edwards Plateau chert from the Trans-Pecos and High Plains regions of Texas are macroscopically similar to varieties of St. Louis and Ste. Genevieve "northern gray" chert from the Highland Rim. The possibility that Edwards Plateau chert is being utilized at the Poverty Point site is investigated through the reflectance spectroscopy analysis of 312 Gary projectile points recovered at the site. Results may demonstrate the presence of western influences not previously investigated.

Park Huntington, Yumi (Framingham State University) and John Warner**[30]***Sacred Landscape, Mesocosm, and Cosmology: The Late Formative Period at Jequetepeque-Jatanca*

How does architectural construction relate to the surrounding landscape and a broader cosmological framework? This paper discusses the relationship among architecture, geography, and cosmology at the site of Jequetepeque-Jatanca in the Jequetepeque Valley on the northern coast of Peru. This site was occupied mainly during the Late Formative period (approximately 500 BCE–100 CE) by local coastal populations, resulting in the construction of six monumental architectural compounds located on a relatively undifferentiated flat plain. Only one partially elevated structure exists at the site, a unique acropolis that radiocarbon tests and excavations indicate was the very first building constructed there. This acropolis could be understood as a mesocosm for its relationship to the surrounding sacred mountains and even celestial bodies, functioning as a specialized meeting place between the divine and human realms. We argue that the acropolis exhibits a specific cosmological relationship with the nearby mountain Cerro Cañoncillo, creating an almanac based on alignments of solstices and equinoxes that connected the site's inhabitants to a larger cosmic framework. This paper will discuss the rationale behind Jatanca's geophysical location and spatial considerations for its ritual practices, including an analysis of its surrounding environment.

Parker, Caitriona (University of Massachusetts, Boston)**[319]***Food as Freedom: Examining Afro-Indigenous Foodways at the Late Eighteenth- to Early Nineteenth-Century Seneca Boston-Florence Higginbotham House, Nantucket, Massachusetts*

In the face of White settler-colonialism and objection to the forces of anti-Black racism in the eighteenth century, Nantucket's New Guinea community formed as a racially diverse group of Africans, African Americans, Native Americans, and Pacific Islanders. Central to this community was formerly enslaved Seneca Boston and his Afro-Indigenous family. Archaeology conducted at the Seneca Boston-Florence Higginbotham House (built 1774) is helping to reveal how the Boston family strategically negotiated racial and ethnic identities to persist. This paper combines zooarchaeological data with documentary archaeology to present a comprehensive foodways analysis of the first generation of Bostons. By understanding the social implications of food for the Boston family, this analysis reveals the ideologies and economies that influenced how the Boston family procured, prepared, and consumed their food. While food is not an inherent indicator of racial or ethnic identity, this paper views food as an expression of cultural values. By examining food in a mixed-race household, this paper allows a greater understanding of food's role in identity negotiation in free, Afro-Indigenous contexts in New England and offers insight into racial autonomy and cultural persistence in Diasporic communities.

Parker, Evan (National Park Service)**[261]***Chair***Parker, Evan (National Park Service)****[261]***Investigating Middle Preclassic Domestic Occupations of the Puuc Region, Yucatán, Mexico*

Research conducted by the Bolonchen Regional Archaeological Project over the last several decades has firmly established the presence of Middle Preclassic occupations across the Puuc region. Survey and excavation at sites such as Xocnaceh, Yaxhom, and Kiuc have identified and confirmed the antiquity of a variety of forms of Middle Preclassic public architecture. Domestic compounds have also been identified through survey. This paper examines Middle Preclassic household archaeology across the northern Maya Lowlands and reviews the relationships between domestic architecture and public spaces. At the Middle Preclassic Puuc village of Paso del Macho, domestic architecture was constructed in the site center upon initial occupation around 900 BC but was eventually covered by public architecture around 500 BC. Domestic architecture then began to spread outward from the settlement core and increasingly began to diversify with regard to formal construction characteristics and layout. Recovered ceramics suggest little

differentiation in pottery economics between public spaces and domestic compounds, indicating that social differentiation may have other material proxies.

Proteomic Sex Estimation of a Gendered Sacrificial Context in Pampa la Cruz, North Coast of Peru

Protocols of ritual violence result from an interplay of political structures with multiple social factors, including roles of gender and age. These patterns often manifest as a biological sex-bias in sacrificial bioarchaeological contexts. In the Chimú Pampala Cruz site (AD 1050–1520), 86 individuals were interred surrounding three high-status nonadult individuals with ages ranging from 6 to 15 years old. One of the high-status individuals had highly preserved male gendered clothing. A full analysis of the context requires accurate sex assignment of the individuals, both high-status and associated sacrificed nonadults, that could test the alignment of sex and gender as well as any sex bias among associated nonadult sacrificial victims. Anatomical markers are ambiguous for this age and not informative. Proteomic sex estimation was therefore attempted to resolve the biological sex of the high-status individuals and quantify sex-bias among the associated sacrificial victims. Proteomic sex estimation of the male gendered individual was male biological sex, confirming cisgender, due to unambiguous detection of the biomarker peptides from the Y-chromosome form of amelogenin. Extension of proteomic sex estimation to other individuals will highlight other relevant factors such as sex bias among associate sacrificial nonadult victims.

Tracing Theoretical Approaches to Constructing and Contesting Whiteness in Southeastern Archaeology

Whiteness has been an especially salient phenomenon in shaping the histories, identities, and landscapes of the US Southeast, even as social and political rhetoric have long worked to render Whiteness invisible and implicit. However, explicit archaeological examinations of Whiteness have been comparatively limited within the theoretical terrain of critical race studies, especially as our discipline grapples with the legacy of colonialism and White supremacy on those we study in the past and ourselves. In this paper, I highlight the dialectical relationship between archaeology and White social constructs, which informs the way that land managers, heritage tourism, and popular media subsequently maintain “useable pasts.” I trace the influence of dominant theoretical frameworks that Southeast archaeologists have favored on the ways that we have engaged Whiteness as a racial construct and a process. Though Southeast archaeology has long been presumed to lack meaningful contributions to broader archaeological theory, I argue that both archaeological sites and practitioners in the Southeast are especially well positioned to direct the trajectory of meaningful developments in critical Whiteness studies.

Modeling the Persistence of Helminth Infections in Small-Scale Societies

Parasitic infections present in human populations are often correlated with increased sedentism,

interaction with domesticated animals, and urbanism. However, parasitic population trends are rarely used to infer ancient human behavior. In this study we examine the relationship between soil-transmitted helminth (STH) infection rates and small sedentary communities. We propose a deterministic dynamical model based on modern studies of human-parasite *Ascaris lumbricoides* populations to estimate the minimum human population (breakpoint) necessary to sustain a STH infection. Dynamical models describe the motion of a point (e.g., STH or human populations) through time and deterministic models exhibit no randomness. We hypothesize that human movement between communities of varying size can maintain an endemic STH population within small communities below the breakpoint. Preliminary results indicate that a breakpoint does exist for human-parasite relationships. Also, the model indicates that STH populations can take decades to become extinct when human populations are just below the breakpoint, supporting our hypothesis that small perturbations due to human movement can sustain an STH population. In future studies, we will test our model with current and archaeological small communities evincing helminth infections and develop an agent-based model. These models can be used to understand human mobility and social network exchange.

A Box Labeled "Mystery. Misc. Headaches": Inherited Problems in Collections Management

The term "curation crisis" describes the challenges facing collections care on a large scale: issues of limited space, staff, and funding and of meeting federal curation standards. Yet, beyond these big picture problems, some of the greatest challenges of managing archaeological collections are the smaller collections problems one inherits from previous collections managers, past archaeologists, short-term volunteers and interns, and colleagues. These problems can take the form of partially finished projects, a box of found-in-collections items simply labeled "mysteries," artifacts pulled for analysis, loans, or exhibits that were never returned to their boxes, or a loss of institutional memory, among myriad other to-do list items that were never completed. This paper presents a selection of inherited collections problems, explores their causes, and offers strategies for dealing with these problems and reducing the scale, if not the quantity, of problems our successors in collections management will inevitably inherit.

Urbanization in Ancient Tonga: The Tongatapu Low-Density Urban System

The concept of low-density urbanization has been an important development in recognizing the diversity of past human settlements. However, the key challenge to studying low density urbanization with archaeological data, particularly in tropical zones, has been the difficulty in acquiring past built environment data. The introduction of lidar mapping has proven revolutionary in our understanding of low-density urbanization by capturing the data necessary to understand the core functions of settlements, highlighting the importance of social interactions in generating social and economic growth. In this paper we present an integrated approach that combines lidar survey and archaeological fieldwork with recent developments in settlement scaling and growth theory to understand the built environment of Tongatapu; the location of an archaic state whose influence spread across the southwest Pacific Ocean between the thirteenth and nineteenth centuries AD. Results indicate a long trajectory of settlement growth on Tongatapu with earth mounds constructed in the first millennium AD, and that the processes of urbanization began well before the development of an archaic

state. The further use of quantitative approaches will provide new insights into the diversity and sustainability of Pacific societies and our understanding of the low-density urban phenomenon.

Factors Influencing Obsidian Procurement and Use in the Snake River Plain, Idaho, and Its Environs

Many tool-quality obsidian sources can be found across the Snake River Plain (SRP) in southern Idaho and adjacent geologic areas. This material was widely used in prehistory, with some artifacts discovered as far away as the Ohio River Valley. In order to better understand the selection and use of regional obsidian sources, we undertook experiments to evaluate the material properties and to compare the performance differences based on standardized instrumental testing. Specifically, we use surface profilometry and impact hardness testing to estimate the structural and mechanical properties of SRP and other regional obsidians and compare this performance data to the known distribution of provenanced artifacts. We additionally “fill in” this provenance dataset with our own geochemical analysis of lithic artifacts and sub-source variation, using pXRF and LA-ICP-MS of obsidian sources in northern Nevada, western Wyoming, and eastern Oregon. We predict that material that possesses greater textural homogeneity, impact resistance, and reduced surface roughness will be preferentially selected for use. These represent more predictable materials, and their frequency of use should increase through time, as obsidian sources are discovered and exploited. Our results have implications for regional lithic procurement, as well as noteworthy long-distance transport of some eastern SRP/Yellowstone-Teton obsidian sources.

Best Practice Recommendations for the Treatment of “Discovered” Human Remains Lacking Provenance

In recent years there have been a number of high-profile cases where human remains were “discovered” resulting in media attention due to the unethical conditions in which the remains were encountered. Unfortunately, the discovery of human remains lacking provenance in academic laboratories or museum archives is common, particularly after staff turnover or structural reorganization within an institution. While the details and excuses for these incidents vary, in all cases the origins of these poorly treated remains are misconduct on behalf of the individual(s) who accepted and mistreated the remains, and potentially on the institution through a failure of accountability and quality assurance practices. Regardless of the circumstances of the discovered human remains, this presentation seeks to provide guidance for what to do when human remains lacking provenance are encountered. The importance of reporting (both internally and externally), documentation, and analysis to ensure proper final disposition is paramount. It is also vital for individuals to recognize their limitations as experts and to contact the appropriate legal authority to avoid continued unacceptable treatment and liability for mishandling the remains. These recommendations are based on the

ethical principles of non-maleficence, respect for persons, scientific integrity, stewardship, transparency, and truth-telling.

Teaching Curation: Using Collections to Foster Disciplinary Reflection and Research Opportunities among Undergraduates

Despite decades-long acknowledgment of a curation crisis, undergraduate education in archaeology continues to emphasize excavation as central to the discipline and to our understanding of the past. Moreover, lab classes that emphasize analytical skills are more common than those that teach curation procedures. Whether consciously of it or not, this conveys to our students that collections management is not their concern, does not matter to archaeologists, and is irrelevant to the investigation of archaeological collections. Yet collections management can be much more than routine management of artifacts for storage and display; it can be a generative process that leads to object-focused interpretations and new research questions. Following Voss (2012), the University of Toronto, Ontario Heritage Trust, and Archaeological Services Incorporated developed a community-engaged, experiential learning undergraduate course focused on collections management. It emphasizes student skill development, the research potential of underreported existing and legacy collections, the sociopolitical context of excavation, and sustainability.

The Arkansas Connection and David G. Anderson

From the mouth of the St. Francois River in eastern Arkansas, up along the Ohio River, and northeast to the Varney-culture inhabitants of greater Cahokia, ancestral Quapaw people defined the archaeology of both the central Mississippi River valley and David G. Anderson. Understanding a vast swath of precolonial history across more than 10 centuries necessarily entails big data of a sort sufficient to demonstrate similarities and historical linkages in celestial knowledge, mound construction, and ceramic design and technology. In honor of DGA, we focus our pattern recognition on mollusk shells and pottery temper, lunar alignments, and mound and pottery forms.

Woodland and Mississippian on the Boundaryland: A Case Study from the Yadkin-Pee Dee Drainage

This paper addresses foundational questions regarding the chronology of the large Late Woodland period

village of Forbush Creek in the Yadkin-Pee Dee drainage of North Carolina. Ceramic and radiocarbon evidence suggests that while multiple occupations are present, the excavated area primarily dates to AD 1200–1400. Interactions with other communities farther south in the drainage are explored through analysis of complicated stamped ceramics. Previous theories interpreting the history of the drainage (Berger and Hutchinson 2019; Jones 2017) are critically examined in light of new data from Forbush Creek and analysis of ceramics, lithics, radiocarbon dates, burials, settlement patterns, ecology, and community politics from across the drainage, and the reasons for the slow pace of Mississippianization in the Piedmont are explored.

The Paradox of Livestock: Transformative Agents and Tools of Resilience

The introduction of Eurasian domesticated animals during the European colonial invasion of the Americas led to rapid, large-scale transformations of North American landscapes, irrevocably altering the relationships between Native people and Native landscapes. Paradoxically, these same alien animals were employed by Native actors as part of strategies for resistance and resilience. This contradiction exists both in the North American Southeast, where livestock were often slow to catch on, and in the Southwest, where cattle ranching dominated the Spanish colonial mission system. In both contexts, despite radical differences in history, ecology, and culture, the day-to-day decisions of seventeenth- and eighteenth-century actors set in motion large-scale and, at times, ferociously rapid feedbacks that were neither intentional nor predicted, but nevertheless transformed human ecosystems and the daily lives of the colonized and colonizer.

Trapichillo: Una mirada hacia las interacciones interregionales tempranas en el valle de Catamayo durante el I ro y 2do milenio BCE

En las últimas décadas las investigaciones arqueológicas en el área andina han dirigido, con gran interés, su

mirada hacia los hallazgos efectuados en el extremo norte de Perú y el sur del Ecuador. El carácter temprano de las ocupaciones y su participación en redes de intercambio interregional han desempolvado nuevamente antiguas inquietudes sobre el carácter de las redes de interacción tempranas que conectaron los fenómenos culturales entre distintas regiones geográficas y culturales. En la presente ponencia reviso la información arqueológica sobre las ocupaciones tempranas del valle de Catamayo, ubicado en los Andes bajos de la provincia de Loja al sur de Ecuador; y expando la discusión sobre los desarrollos locales, las influencias regionales, y las esferas de interacción tempranas a partir de la información preliminar de las excavaciones que se llevan a cabo en el sitio Trapichillo.

The Evolution of Plant Resource Diversity in Precolonial Puerto Rico with Direct Implications for the Rest of the Greater Antilles

Except for Jamaica, the earliest human occupations in the Greater Antilles date to ca. 6000 cal yr BP. Contrary to older ideas, the view taking shape now is that survival strategies incorporated a range of plant domesticates along with wild resources obtained through foraging, collecting, hunting, and fishing. This should not be surprising, since the earliest colonizers of the Greater Antilles originated in Central America, where agriculture is well documented by ca. 5000–7000 BP (Piperno and Pearsall 1998). In this paper, we trace the evolution of plant resource diversity through time from the earliest occupations of Puerto Rico. The earliest settlers on the island created anthropogenic landscapes, which later colonists further modified with new introductions of plants originating in lowland South America. Radiocarbon and paleoenvironmental records are integrated with biodiversity trends in modeling dispersal and colonization processes in the precolonial Caribbean. Applying measures of biodiversity, richness, and evenness to microbotanical datasets available for Puerto Rico reveal declines in diversity for both the initial and later colonizing populations of the island. These findings are consistent with expectations from agroecology, whereby productive domesticates are identified and over time exploited in greater proportions to other taxa, both wild and domesticated.

Silk in the Brambles? Evidence for Xiongnu Dress from Circular Graves

Though the well-preserved textile finds from Noin Ula are some of the best known archaeological objects from this period in Mongolia, textiles and leather objects from Xiongnu circular graves are comparatively understudied. In part this is due to differences in preservation; circular graves are shallower than terrace tombs and organic artifacts found in these contexts, though not uncommon, are fragmentary and mineralized. In this paper, we present data on textile and leather traces from more than two dozen circular graves from three different regions of the Xiongnu world. Microstratigraphic analysis of mineralized organic matter sheds light on the relationships between different materials used to construct garments and burial trappings, while preserved structural elements like seams, hems, and linings speak to the technical skill of Xiongnu craftspeople. Importantly, the predominance of woven wool textiles belies the notion that the Xiongnu relied heavily on imported Chinese silk and suggests that some weaving may have been local. Combining technical analysis with multiple forms of microscopy to compare the complete textile *chaîne opératoire* across graves, sites, and regions, this paper shows that even fragmentary and trace organic remains can help address economic, technological, and political questions.

Isotopic Evidence of Long-Term Aquatic Resource Use at Tanada Creek, Alaska

Salmon are considered a critical subsistence resource in the Copper River basin, Alaska both currently and traditionally. Salmon migrations typically occur during a relatively short period in the summer, and provide a reliable, abundant influx of food. The duration of their presence in the basin and history of use are not well understood. In the past, runs of anadromous fish were likely impacted by the presence of glacial dams that blocked the outlet of the Copper River and caused Glacial Lake Atna to occupy the basin until about 10,500 years ago. Nataef Na' is an archaeological site near a known salmon stream, Tanada Creek, in the upper Copper River basin. Hearths at the site were radiocarbon dated to before and approximately 6,000 years after the draining of Lake Atna. Sediments from these cooking features were subjected to the stable isotope analyses of carbon and nitrogen to examine past fish use and changes in diet during an environmentally transformative period.

El legado del Laboratorio de Prospección Arqueológica de la UNAM en el estudio de residuos químicos en el Mediterráneo

Las técnicas de análisis de residuos químicos desarrolladas en el Laboratorio de Prospección Arqueológica de la UNAM se han aplicado también en contextos europeos y principalmente del Mediterráneo Occidental, favoreciendo un acercamiento interdisciplinario al estudio del uso del espacio y de los contenidos de los recipientes cerámicos de diferentes periodos. En particular, gracias a la combinación de los *spot tests* desarrollados en México con la cromatografía de gases acoplada a espectrometría de masas, en conjunto con resultados de trabajos etnoarqueológicos y de arqueología experimental, se han podido investigar las diferentes fases del ciclo de vida de los alimentos, desde su producción, transporte (principalmente en ánforas y dolia), pasando por la preparación hasta su consumo. Aquí se presentarán algunos ejemplos de las investigaciones realizadas en el marco de diferentes proyectos e instituciones (UNISI, UNICAL, ERAAUB, IA-UB, INSA-UB, MdM CEX2021-001234-M, RACAMed II - PID2020-113409GB-I00) y de las continuas colaboraciones con el Laboratorio de Prospección Arqueológica.

Land Use and Settlement-Pattern Change in Mauka Kawaihae, Hawai'i Island, 1790–1930

Pre-1778 land use in Hawai'i Island's leeward Kohala uplands has been extensively documented by archaeologists, particularly those studying the ancient *mauka* (upland) Leeward Kohala Field System. However, "historic" (post-1778) land use—particularly in the uplands—is not as well understood. In this poster, I provide a review of the documentary and oral records associated with the late eighteenth- to early twentieth-century settlements and agricultural land use patterns in mauka South Kohala, focusing in particular

on the *ahupua'a* (traditional land tenure units) of Kawaihae 1 and 2. These *ahupua'a* include a detached section of mixed dryland and intermittently irrigated agricultural fields known as the South Kohala Field System as well as the remains of two historic villages—Ho'ēpa to the north and Mākelā to the south. Finally, I review some of the prior historical and archaeological work and add to the record using archaeological data collected during Google Earth mapping and archaeological fieldwork between 2017 and 2022. Overall, these data provide additional context for the timing and nature of agricultural expansion in the pre-1778 field system located *makai* (downslope) of these settlements.

The Search for Remains and Material Evidence on World War II Bomber Crash Sites: Combining Geophysics and Traditional Archaeological Approaches

During World War II, the United States and other countries lost many airmen in plane crashes. Crash sites vary considerably in size and complexity, with buried and near-surface components that must be located, assessed, and perhaps excavated. Geophysical survey is one way to improve the cost/time effectiveness of crash site investigations and recoveries. In this poster we explore how Ohio Valley Archaeology Inc., in partnership with the Defense POW/MIA Accounting Agency, used geophysical survey and excavation together to characterize portions of a B-24 crash site in France, along with transit mapping and RTK GNSS to georeference spatial data in a wooded setting. In addition to detecting the main impact crater, we argue that the geophysical data also may show the location of a wing and a secondary fall out zone created by the impact or post-impact explosion. Initial excavations, guided in part by the geophysical survey results, focused on the edge of the impact crater.

Preparing the Surface (PRESUR): The Forgotten Step of "Seasoning" Food-Processing Ground Stone Tools and Its Implications for Use-Wear Analysis

In Southwest Asia ground stone tools used in food processing, like mortars and querns, started proliferating at the end of the Paleolithic. Recently these tools have received increased attention with researchers attempting to establish what food these tools were used to process through microscopic use-wear and residue analysis. However, there is an aspect of tool use that most use-wear studies neglect to recognize: "seasoning" the tool. Seasoning is the act of preparing the tool before initial use by processing then discarding material, thus "sealing" the active surface and preventing harmful grit and rock particles from entering the foodstuff. Not considering this crucial step in tool surface preparation potentially means that use-wear analyses, both qualitative and quantitative, fall short when assessing subsequent use. My study is an experimental program based on ethnographic data and input from current culinary traditions and tests ways of seasoning tools that would have been available to people in Southwest Asia 15,000 years ago. It will track the wear traces resulting from experimental seasoning on tool replicas, creating a baseline for future

research, while refining current approaches in ground stone use-wear analysis and improve our understanding of past foodways.

Using Unmanned Aerial Vehicle (UAV) Photography to Develop Preservation and Management Plans at S'edav Va'aki, Arizona

As part of the Arizona State University field school at S'edav Va'aki, the research team reached out to ASU faculty from the Unmanned Aerial Systems department to develop a plan for capturing true color and infrared imagery and photogrammetric data from the project area. The goals for these images were focused on developing high-resolution baseline data to complement on-the-ground recording efforts and to estimate (1) the locations and extent of active erosional processes, (2) the volume of vegetation and clearance needs in and around archaeological features, and (3) the locations and subsurface extent of features such as ancient canal segments and middens expected to be within the project area based on previous excavations in and around the site. In this poster we outline the potential of using UAS imagery for the development and continued monitoring of land management plans in an urban setting. We highlight some of the complications of this project including the proximity of the site to an international airport and previous land disturbance.

Challenges in Dating Maroon Contexts in the Great Dismal Swamp

Speckled with mesic islands and peat hummocks, the soggy lowlands and standing water of the Great Dismal Swamp in Virginia and North Carolina were home to thousands of African and African American Maroons (ca. 1608–1863) and a significant feature of the landscape of Indigenous Americans for many centuries prior. In part due to the extensive reuse and repurposing of material culture by the Maroon communities seeking refuge deep within the swamp, temporally diagnostic artifacts are rare. Soil conditions and possible waste disposal practices mean preserved organic materials are even more rare. These combine to create challenges archaeologists dating the occupations of individual Maroon sites and establishing a higher-resolution temporal picture of Maroon activity across sites in the morass. Sayers (2014) and his Great Dismal Landscape Study successfully obtained OSL dates from a feature at one North Carolina site and more recent attempts to obtain scientific dates from two sites in Virginia have met with mixed results. This paper discusses the difficulties and what the new results can illuminate about the resistance history of the present-day Great Dismal Swamp National Wildlife Refuge.

Ancient Mitochondrial DNA and Genetic Variation in Northwest Mexican Populations

The development of genetic sequencing technology has allowed for the recovery of ancient DNA from bone samples belonging to individuals who lived thousands of years ago, opening a window to the past and to better understand the dynamics of ancient civilizations. This study describes the genetic variation found on the mitochondrial genome of 112 individuals from northwest Mexico who lived between 2,000 and 500 years ago. Haplotypes were assigned, genetic diversity was estimated and a principal coordinates analysis was applied to group samples according to their genetic distance. Haplogroup frequencies differ from those found in previous studies from Mesoamerican samples, with a higher prevalence of haplogroups B and C (28% each), A (25%), and D (18%). Four clusters were recovered from the pCoA with a high level of genetic variation, which indicates a great amount of gene flow between populations and that genetic differentiation is better explained by cultural aspects through time, rather than geographical distance.

Excavation at AZ T:12:220(ASM) / Las Cremaciones

Recent discussions surrounding cultural resource management in the Phoenix Basin have highlighted the importance of synthesis across firms, projects, and cultural resources. This poster examines archaeological investigations at AZ T:12:220(ASM), colloquially known as Las Cremaciones, with the purpose of compiling data available from past excavations to provide a holistic idea of what is known about the site. AZ T:12:220(ASM) / Las Cremaciones is a large prehispanic Hohokam village located in Laveen, Arizona, to the south of Phoenix, near the confluence of the Salt and Gila Rivers. In the fall of 2022, Terracon was involved in excavations that intersected the southwestern portion of AZ T:12:220(ASM) / Las Cremaciones and excavated a 30% sample of all non-mortuary features, inclusive of pit structures, thermal features, pits, and an oversized surface. This poster will present the results of Terracon's excavations and contextualize these data within other investigations conducted at the site to contribute to a broader understanding of what is known about AZ T:12:220(ASM) / Las Cremaciones.

Sourcing Maya Lowland Chert Resources: A Multimethod Perspective

Within the Maya region, chert artifacts remain one of the most common material types recovered from archaeological excavations and are a core line of evidence when reconstructing ancient economy. However, methods for sourcing of chert through Mesoamerica have largely been underutilized. Archaeologists are often left wondering how these artifacts moved within regional and local exchange networks, and the influence particular source areas had over settlement patterns and economic development. Recent methodological developments within the field of chert provenance analysis have provided the opportunity to revisit these research issues. This paper will discuss the preliminary results of microscopic and geochemical analysis from recent geological sampling of northern Belize chert outcrops.

Aportes de la prospección geofísica para entender los asentamientos en medios lacustres de la cuenca de Zacapu, Michoacán, México

Hace más de tres décadas, Luis Barba y su equipo del laboratorio de prospección arqueológica del IIA, UNAM iniciaron una colaboración fructífera con investigadores del CEMCA en la cuenca de Zacapu (Michoacán) que continúa hasta nuestros días con instituciones francesas como el CNRS y la Universidad Paris I/Panthéon-Sorbonne. En este peculiar contexto lacustre, la aplicación de las distintas técnicas de prospección geofísica (magnética, eléctrica y georradar) ha revolucionado el conocimiento de estos asentamientos a pesar de las fuertes alteraciones provocadas por la agricultura moderna. Los datos obtenidos han permitido documentar un importante desarrollo arquitectónico en la zona durante el primer milenio dC y ofrecen nuevas perspectivas para entender la función y organización de los sitios. En esta ponencia se presenta un balance de los trabajos realizados incluyendo los más recientes y se plantean algunas propuestas para rescatar la amplia variedad de vestigios que, año tras año, desaparecen bajo el paso de los tractores en estos campos agrícolas.

The Longue Durée: Food Insecurity and Climate Change in Precontact Tennessee

Dispersal and organizational changes of Indigenous communities ca. AD 1450–1550, over much of the North American midcontinent, has been attributed to a number of causes: drought, warfare, changing alliances, and access to resources. Potential connections between droughts and the end of the Mississippian period in the Middle Cumberland River Valley (MCR) of Tennessee are rooted in the phenomenon known as the “Vacant Quarter.” For decades scholars have suggested that these shifts, and the ultimate dissolution of Mississippian society in the MCR, may have occurred partially in response to severe droughts during the fourteenth and

fifteenth centuries. However, to date there have been few efforts to directly connect paleoclimate data with archaeological evidence from the region. To understand why people left these once-fertile environments, we focus on the social consequences—namely, food insecurity—and work backward to the root causes. In this paper we combine data from zooarchaeology with tree-ring calibrated drought indices, paleoethnobotanical data, paleodemographic profiles, and settlement patterns, to highlight the *longue durée* of persistent food insecurity for Mississippian period communities of the region.

[103]

An Evaluation of Virgin Branch Social and Political Complexity through Painted Ceramic Design and Style

Social complexity in prehispanic societies within the North American Southwest has been studied through a variety of research avenues. Among the Virgin Branch people within the Moapa Valley of southern Nevada, archaeologists have pursued this topic through the study of architecture, burials and associated grave goods, and exchange networks. Among Virgin Branch archaeologists working in the Moapa Valley has been the competing notion of whether Virgin Branch society was egalitarian (Lyneis 1992) or ranked (Rafferty 1990). This study revisits this long dormant debate through the lens of a research medium not previously used to explore the nature of Virgin Branch social complexity—namely, painted design and style complexity on pottery. Inspired by a cross-cultural study conducted by Peter Peregrine (2007), this paper presents an exploratory assessment of Virgin Branch social complexity, through an adaptation of Peregrine's (2007) methods, using painted ceramics recovered from Adam 2 and the Main Ridge community. This study uses a comparative statistical approach to evaluate social complexity at Adam 2 and the Main Ridge community against Peregrine's (2007) findings as a means of assessing the utility of this analytical approach to the study of social complexity in the Virgin Branch region.

The Shipwreck of the French Fleet in Las Aves de Sotavento, Venezuela: A Seventeenth-Century Maritime Disaster

This presentation underlines the importance of Venezuela's underwater cultural heritage through continued research into the shipwreck of French King Louis XIV's fleet, which struck reefs in the Las Aves de Sotavento, in Las Aves Archipelago, Venezuela, the night of May 11, 1678. The fleet consisted of 30 vessels. At least 12 ships sank during this single event, taking the lives of likely hundreds of men. Preliminary studies suggest that we are in the presence of one of the largest and most important shipwrecks of the Atlantic World and the Caribbean. They also indicate the urgent need to research and safeguard this submerged archaeological site as a unique part of the world's cultural heritage.

Perez Rodriguez, Veronica (University at Albany, SUNY)**[160]***Life after Urbanism: Investigating Classic Period Cities and Settlements in the Mixteca Alta, Oaxaca*

Those of us working in the Mixteca Alta region of Oaxaca have heard the saying that the “Classic period” in the region took place earlier, in the Late Preclassic. While the Classic period (AD 300–800) was a time of urban florescence in the Valley of Oaxaca, Basin of Mexico, Puebla, and the Mixteca Baja regions, investigations into finding large Classic period urban settlements in the Mixteca Alta region, have so far proven to be elusive. There have been mapping and a few excavation projects into what are thought to be Classic period sites at Yucuñudahui, Cerro Jazmín, Cerro de la Virgen, Cerro Encantado, Topiltepec, and Cuquila, but only two sites, Yucuñudahui and Cerro Jazmín have been excavated and dated using radiocarbon methods. And so far, only Yucuñudahui has yielded radiocarbon dates placing its occupation in the Classic period. This paper discusses new radiocarbon dates and occupation history data from Cerro Jazmín and compares it to the chronological information available for other Classic and Postclassic period sites throughout the region. The objective is to offer a broader regional perspective on how Mixtec communities and urban settlements fared after the initial period of urban florescence in the Late Formative period.

Perkins, David and Ian Beggen (University of Michigan)**[266]***Assessing Interobserver Variation in Lithic Analyses of Resharpener*

Interobserver variation is a known phenomenon within macroscopic and microscopic lithic analyses. Thus far, many researchers have conducted extensive studies of variation between experts and novices in lithic analyses, and these studies have shown the importance of careful supervision and repetition of measurements. Here, we present findings from a study of interobserver variation of lithic analysis of a real archaeological collection of projectile points from the North American Southeast. This study adds to the body of knowledge concerning general lithic analysis and provides novel insights relating to analyses of resharpener in hafted bifacial technologies, including those involving gross linear measurements, indices of retouch, and more advanced methods such as geometric morphometrics. Observations and outcomes of this study further indicate the necessity for redundancy of measurements between observers. Further, this study highlights how lithic analyses of resharpener patterns of hafted bifaces can lead to drastic misinterpretations of the archaeological record.

Perla Barrera, Divina (UADY-PARYNA), Julien Sion (ArchAm-CEMCA-PARYNA), Fiana Hernández (UNAH-PARYNA) and Jennifer Arguijo (UNAH-PARYNA)**[118]***Materialización de las nuevas interacciones en la zona fronteriza entre Mesoamérica y el Área Istmo-colombiana durante el Postclásico Temprano: Un acercamiento desde Los Naranjos, noroeste de Honduras*

En los territorios considerados como los márgenes fronterizos entre Mesoamérica y el Área Istmo-colombiana, la transición entre el Clásico y Postclásico (siglos IX-XII dC) corresponde a un periodo de reorganización de sus sociedades. Particularmente en el noroeste de Honduras se caracterizaron notables evoluciones en los centros ocupados después del 800 dC, en su patrón de asentamiento, el repertorio arquitectónico y cerámico, o los ritos funerarios. En muchas ocasiones las novedades identificadas en la cultura material parecen concretar el desarrollo de nuevas redes de interacción con habitantes dentro y fuera de la zona fronteriza, mediante la integración de artefactos foráneos en su parafernalia o la adopción de nuevas prácticas. Aunque no se comprenden con precisión tanto las modalidades de circulación de bienes

como su significado sociopolítico, esta integración local de prácticas sociales y objetos compartidos con otros grupos que habitaban en un área geográfica muy amplia podría materializar verdaderas comunidades de prácticas. Sin embargo, estos procesos se desarrollaron diferentemente según los territorios, con base en dinámicas locales propias. Para aportar nuevos datos, se presentarán los resultados obtenidos en Los Naranjos y sus comparaciones a escala regional. Asimismo, se propondrán nuevos ejes de investigación que incluirán aspectos tecnológicos e iconográficos.

The Spatial Distribution of Pleistocene Archaeological Sites and Paleoenvironmental Records across North America
Research into the timing and process of human migration to North America at the end of the Pleistocene relies heavily on accurate paleoenvironmental reconstruction to understand habitable locations at the time. However, Pleistocene-aged archaeological sites in North America are rare, and specific paleoenvironmental information for these sites is often inferred from equally rare, nonlocal pollen records. Moreover, many of the trusted pollen records lack adequate temporal resolution. This poster examines the spatial relationship between Pleistocene archaeological and pollen sites across North America and evaluates the quality of pollen records in terms of their temporal continuity and resolution. Additionally, we address the challenges associated with obtaining Pleistocene-aged pollen records in different regions. Through this analysis, we identify geographic areas where future pollen research should be prioritized and explore the potential advantages of using non-pollen-based paleoenvironmental proxies.

Domestic Life at Río Viejo, Oaxaca

Recent fieldwork has investigated the Late Classic and Postclassic occupation at the floodplain site of Río Viejo in Oaxaca, Mexico. The residential features uncovered detailed domestic life in the settlement after political decentralization. Though causal factors for the Late Classic political decline at Río Viejo are yet to be confirmed, archaeological evidence suggests that this was a period of considerable change. Termination ceremonies were identified in Late Classic strata, which marked a shift from communal practices in the Late Classic to private domestic ceremonies in the Early Postclassic. Political decline in the Late Classic was also coupled with settlement decline throughout the region. Ongoing excavations at Mound 2, a large residential platform at Río Viejo, detailed domestic life associated with a large potential water management feature. This paper will discuss archaeological evidence of domestic life during the Postclassic transition and will present preliminary data on a possible recessional agricultural feature. New data will reveal the relationship between water management practices and changes in domestic space after the political decline at Río Viejo.

Perry, Jennifer (CSU Channel Islands)**[304]***Jeanne Arnold's Legacy on California's Channel Islands*

In honor of Jeanne Arnold, I discuss major theoretical and methodological themes in her research on the northern California's Channel Islands including (1) her focus on Late Holocene households as relevant units of past decision-making and current analysis, (2) lithic tool production and exchange, specifically chert resources and microlith industries on Santa Cruz Island, and (3) environmental context in relationship to major drivers of complexity within Chumash societies. In contrast to the emphasis placed on context in archaeological interpretation, what is not considered and articulated as often are the contemporary contexts of scientific inquiry in which different types and scales of context are situated. Citing publications from the early 1990s to early 2000s, both her own and responses to them, I also consider the gendered and processual context of California archaeology in which she operated and advanced anthropological understandings of island economies and hunter-gatherer societies. Finally, I reflect on how this broader context influenced responses to Arnold's work and how her contributions continue to inform archaeological research on the Channel Islands today, with recent scholarship having expanded on her hypotheses and datasets in important ways.

Recent fieldwork in the intertidal zone of southwestern Puerto Rico has revealed a landscape of over 40 heretofore undocumented shell mounds (some as large as 4,200 m² and as tall as 10 m above the surrounding tidal plain) formed by millennia of targeted human foraging activity focused on genus *Arca*. Initial radiocarbon dates indicate that these mounds were formed between roughly 1200 cal BC and cal AD 450 (with further dates forthcoming), associating them with some of the earliest inhabitants of Puerto Rico, and making them contemporary with other, more distributed, middens in the surrounding region. Relatively undisturbed ancient landscapes of such size and density have no known parallels in Puerto Rico, but these features do share taxonomic similarities to other sites in Puerto Rico, the Virgin Islands, and the Lesser Antilles. Here, we present the results of combined archaeological excavation and paleoenvironmental reconstruction of nearshore habitats in the environs of the anthropogenic landscape, to evaluate and disentangle a series of equifinal behavioral explanations for their formation, persistence, and ultimate abandonment. Ultimately, we anticipate that this work will provide valuable insights into the interface between human foraging activities and paleoenvironmental change in an early period of Caribbean archipelagic occupation.

Peters, Ann (University of Pennsylvania Museum)**[29]***Chair*

Peters, Ann (University of Pennsylvania Museum)**[29]***Cordage and Binding Practices: From Artifacts to Bodies to Bundles in the Paracas Necropolis Mortuary Tradition*

The Paracas Necropolis mortuary tradition is famous for its embroidered garments and imagery, though the textile bundles built around each individual also have a complex sequence of other artifacts within huge cotton wrapping cloths, stitched and bound in place; other offerings are adjacent. Cordage is used to position the bodies of the deceased, and to unite diverse artifact components. Production practices for cords and other bindings include raw materials sourcing and processing to create structures employed for specific purposes. What may be the significance of raw materials, such as reeds, animal tissue, bast fiber, cotton, or human hair? Binding materials with different properties are employed in groups of artifacts that share forms of utility, such as types of weapons and feather ornaments. Was the organization of artifact production linked to their subsequent uses in hunting, combat or ritual, and social leadership within those realms? The mortuary data most directly reflect funerary practices and subsequent events to honor the dead. As cordage was both created and utilized as part of the ritual process, we can consider its relationship to sequences of postmortem events, social diversity in the cemetery population and the contributors to each tomb assemblage. ***Images include human remains.

Peterson, Emily [50] see Echavarri, Mikhail

Peterson, Jane (Marquette University)**[129]***Expanding the Niche: Gender and Bioarchaeology among Prehistoric Farming Groups*

In the early 1990s when I began my explorations of changing divisions of labor associated with agricultural transitions in the Levant, archaeology was grappling with the tip of the biocultural iceberg that was “gender” (sensu Fausto-Sterling 2000). During the intervening three decades, discussions of gender in archaeology have broadened. Studies have spread across many time periods and regions, and research is less often confined to edited volumes and special issues focused specifically on gender. In a real sense, gender studies have become a bigger part of mainstream archaeological literatures. This paper specifically examines the progress that archaeologists and bioarchaeologists have made leveraging datasets across disciplinary boundaries to enhance our understanding of gender in the past. While this crossover between material culture and biological data has been slow, its momentum seems to be building. Increased interest in gender is discussed using case studies from early agricultural contexts. The results are heartening because they describe a range of gender-inflected activity and kinship pattern variation that has often been masked by unilineal, developmental models that are coming under increasing theoretical scrutiny.

Peterson, Ryan (Indiana University, Bloomington)**[224]***Chair***Peterson, Ryan (Indiana University, Bloomington)****[224]***Hot Spot Analysis: Copper Production in the Northern Lake Superior Basin*

North America’s Native Copper Industry is one of the oldest metalworking traditions in the world, with metal use in this region dating to over 9,500 years ago. While several studies have focused on copper mining and use, few have focused on copper production. As a result, little attention has been given to the waste materials generated during the production process. The study of waste materials is vital to understanding what metallurgical production systems look like and how they are structured. This paper will examine the

geospatial organization of copper production throughout the Archaic period in the northern Lake Superior Basin. The organization of copper production will be examined through morphological analysis of copper waste materials from copper production sites across this region. This information will then be examined geospatially using the Optimized Hot Spot Analysis tool on ArcGIS to identify where stages of production took place as people and copper moved across the landscape. The structure of this production system will then be interpreted through a relational approach to production that seeks to understand the relationships that form between people, material culture, and the environment through assembling in the production process.

Physics and Ballistics of the "Rabbit Stick," or Straight-Flying Boomerang

Straight-flying boomerangs—in North America commonly referred to as rabbit sticks—were used worldwide for both hunting and combat. When properly designed and implemented, the boomerang functions as an airfoil and gyroscope, slicing through atmosphere, generating lift, and traveling impressive distances. However, due to their combined rotational and forward velocity, boomerangs experience differential lift along the wing, resulting in the tendency to tilt, which combined with gyroscopic effects, can cause them to “precess,” in some cases returning to the user. Straight-flying forms, originally much more common than returning types, must be properly designed to overcome this tendency, but effective straight-flying designs can take various forms. Substantial kinetic energy combined with the focus of impact forces to small areas of the wing also makes boomerangs formidable weapons, but until now their ballistic potential remains largely unexplored. This paper describes the different characteristics that allow boomerangs to fly straight and presents results of throwing experiments with replica Southwest forms, where ballistic variables were recorded.

Thoughts on the Most Recent Katun of Archaeological Heritage Management in Belize

Archaeological heritage management (AHM) involves identifying, protecting, managing, and preserving material remains of past human activity. In Belize, the Institute of Archaeology-NICH oversees AHM, including archaeological permitting, artifact management (including human remains), site designation and access, community/public engagement and education, and more. It also requires diverse interactions with rights holders, stakeholders, and interest groups related to Ancestral and present-day Maya heritage and the many other diverse communities and cultures of this small nation. At a fundamental level, the AHM system developed in Belize works. Indeed, it is the system within which all the other research presented in this session was produced. However, no system is perfect. In this paper, we explore details of the AHM system in Belize and how it stands out from other systems we have encountered. We will assess the successes and challenges that have emerged in Belizean AHM over the past two decades, including the lessons learned during the COVID-19 pandemic. Our dataset primarily comprises qualitative information, such as oral and documentary histories from Belizean and foreign scholars and managers, official guidelines, policies, and legislation, institutional data where available, and our combined experiences with AHM in Belize, Mexico, Guatemala, Honduras, Nicaragua, and beyond.

Technologies of Surveillance, Technologies of Care? Colonial Census, Biopolitics, and Networks of Surveillance in Southern Guatemala

Technologies of surveillance are a common element of diverse forms of extractive early modern colonial projects as a method of effectively extracting value from humans/nonhumans. The forms surveillance takes vary widely, frequently blurring into technologies of “care” for laboring bodies to ensure their continued productivity. Theories of bio/necropolitics highlight these intersections between surveillance and care in the exploitation of (re)producing bodies, or what Berlant’s “slow death” frames as the management of the “physical wearing out of a population.” *Padrones* (census documents) emerge as one of the more effective technologies of such dispersed surveillance and care in colonial Guatemala, as they tracked the number and location of tribute paying individuals in the region’s native communities, including last known sightings and probable whereabouts of those missing/escaped from where they “belonged.” These documents also reveal a form of paternalistic “care” recording bodily health, injuries, births/deaths, and wayward spouses as part of managing the wear of colonial extraction on native bodies and communities. Through archival, GIS, and social network analysis, this paper materializes these ephemeral early modern colonial technologies of surveillance and looks to bridge the premodern/modern divide in studies of surveillance by highlighting the persisting coloniality of surveillance/care in Guatemala’s contemporary/recent past.

Pfannkuche, Sara and George Vassilatos (Illinois State Archaeological Survey)**[137]***Curating Donations: Ethical Curation of Pesky Collections*

Archaeological objects are frequently donated by private citizens to professional organizations. These include the legacy collections of professional or avocational archaeologists, many of which date to the period when the profession of archaeology was being formalized, and objects found in the attic of a grandparent's house. These collections range from well-documented to completely unprovenanced. Archaeological repositories can provide a permanent home for these materials, but curators must strive to develop robust protocols for cataloguing and caring for donated collections if they are to be better off than they were in private hands. This presentation will look at how the Illinois State Archaeological Survey (ISAS) cares for donations to ensure the accessibility of these collections for consultation, research, and outreach. This presentation will cover how donations are housed across a variety of Midwest archaeological repositories for comparison before discussing the ethical care of donations in ISAS's repository specifically. Topics raised will include establishing donation protocols that fit your institution's resources, how to handle legacy donations, and increasing the value of donations through data sharing.

Phillips, Amy (Draper Natural History Museum, St. Cloud State University), Avery Shawler (University of California, Berkeley) and Chloe Winkler (Draper Natural History Museum, Buffalo Bill Center)**[200]***What Faunal Remains from Wolf Scat in the Greater Yellowstone Ecosystem Can Tell Us about Canid Presence in the Past*

The authors analyzed scat collected from gray wolf (*Canis lupus*) packs in the Greater Yellowstone Ecosystem from 2019 to 2021. Faunal remains in the scat were identified to element, using comparative collections from the Draper Museum of Natural History, and assessed for surface modification and abrasion. This information was supplemented by species identification provided by guard hairs identified using a compound microscope. The results provide information on the taphonomic signature of wolves which is of use in assessing zooarchaeological assemblages. The feeding behavior of wild wolves, as inferred from faunal remains, can be used to identify canids at human occupation sites where no canid bones are present. Differences found between faunal assemblages from wild wolves and domestic dogs could provide insight into the formation of sites and when canids were present at the site. This in turn can provide insights into the process of domestication. For example, wild wolves are unlikely to have been present at human occupation sites when they were in use. Canids in the process of domestication likely inhabited sites concurrently with humans, but their taphonomic signature would reflect a more diverse diet than domestic dogs, which depend largely on humans for their food.

Phillips, Bruce, Erik Steinbach (Logan Simpson), Travis Cureton (Logan Simpson) and Craig Fertelmes (Logan Simpson)**[281]***Evolving Hohokam Irrigation Strategies at La Plaza: A Multidisciplinary Approach*

Hohokam irrigation canals were first excavated in the lower Salt River Valley in the early Pioneer period (AD 1–700), possibly as early as AD 200 at Las Acequias in east Tempe. In the area, substantial expansion occurred in the Sedentary period (AD 900–1150) and continued into the Classic period (AD 1150–1450).

During this time, Canal Tempe was a large main canal serving the site of La Plaza, now beneath central Tempe. The canal primarily irrigated land on an ancient terrace overlooking the Holocene floodplain. In recent excavations on the Arizona State University campus, the main canal was expected but not found. Rather, two relatively large main/distribution canals were discovered on the adjacent floodplain. Multiple analyses were conducted and data synthesized, showing that the larger canal (Feature 9) appeared to carry large volumes of water mostly during the springtime; low-velocity flows were rare. In contrast, the final channel of the smaller canal (Feature 12) may have carried water year-round. This suggests a major change in water intake and distribution strategy late in the Hohokam occupation.

A Multi-method Analysis of Ceramic Production at Precolumbian Peñitas, Nayarit

Located along the Rio San Pedro in west central Nayarit, Mexico, the site of Peñitas was an important precolumbian center with at least two major occupational eras, achieving its greatest prominence during the Early/Middle Postclassic period as a major center within the Aztatlán Tradition. While few sites along the coastal plain have received detailed analyses of their ceramic assemblages, Peñitas is one exception. In the 1950s and 1960s, UCLA archaeologist Jacques Bordaz examined not only kilns, but also used the seriation of ceramic types to trace diachronic patterns of ceramic production and use at Peñitas. Using Bordaz's work as a starting point, this study uses a multi-method approach to better understand ceramic production at Peñitas. Namely, neutron activation analysis as well as ceramic petrography are used to address differences in production techniques as well as variation in the raw materials used. This study has wider implications as previous research has suggested widespread trading of Aztatlán ceramics within the coastal plain. This study demonstrates that this may not be the case. Furthermore, differences in production within the Peñitas assemblage identified through petrographic study may also indicate distinct potter traditions within the site over time.

Reconsidering the Impacts of Late Mississippian Chiefdoms on Early Spanish Entradas: A View from Western North Carolina

The Late Mississippian world was populated with several chiefly polities competing for regional dominance in a constantly shifting sociopolitical landscape. In the mid-sixteenth century, two Spanish entradas, led by Hernando de Soto and Juan Pardo, would become entangled in this competitive landscape, attempting to bring late medieval European sociopolitical worldviews into an Indigenous American system. The Soto and

Pardo expeditions have often been characterized by scholars as a particularly disruptive series of events which altered the trajectory of Indigenous history. This paper instead explores how Indigenous leaders accepted the appearance of Europeans in the Mississippian world and recenters Native perspectives concerning the events of the sixteenth century. Using the Late Mississippian landscape of western North Carolina as an example, this paper reconsiders the impacts of these encounters, not as an early destructive colonial event, but rather a series of interactions that would enable Native leaders to reorganize and assert their political power and prestige through their interaction with Soto and Pardo. This paper uses archaeological evidence, including radiocarbon dating, to challenge early Spanish texts and to destabilize the European historical narrative of the sixteenth-century Southeast, demonstrating the power of Indigenous political systems within early contact studies.

Neolithic to Bronze Age Human Impact on Island Landscapes and Faunal Communities: Exploring the Wild/Domestic Dichotomy

This paper synthesizes zooarchaeological and stable isotope evidence from the eastern and western Mediterranean to consider the influence of humans on island landscapes and ecosystems from the earliest Neolithic through the Bronze Age. How did the importation of new faunal species, whether domestic or wild, affect the extant endemic island communities? While the Neolithic is often regarded as a critical time of species introductions, it is likely that reintroductions also took place later in time in order to sustain or bolster island populations. To what extent were wild, non-endemic taxa managed by communities, and did these strategies overlap with those for domestic livestock management? Additionally, what role did marine resources play in the diet of island communities, and how did this change through time with concomitant changes in terrestrial faunal assemblages? Did mainland farmers adapt to island ecology by supplementing domestic food production with wild and marine resources, and if so, are there identifiable patterns in transitions? The combination of faunal analysis and multi-isotope studies has the potential to provide new insight into the nature of human-animal interactions on Mediterranean islands during the first half of the Holocene.

Untold Stories from L'Anse aux Meadows: Highlights from the Wooden Collections

L'Anse aux Meadows, a UNESCO World Heritage Site and the first European settlement in North America, is located in the northernmost part of modern-day Newfoundland, Canada. During the eleventh century, Norse Greenlanders established a frontier site for short periods of time, a “gateway to resources” further to the south. During the archaeological investigations at L'Anse aux Meadows by Parks Canada in the 1970s, large quantities of worked wood were discovered. While only a handful of artifacts were identified, most of the collection consists of leftovers from woodworking activities, as well as unworked twigs and branches. In the last decade in particular, small finds, construction timbers, and boat parts excavated in other Norse settlements across the North Atlantic have started to get the attention they deserve. However, the numerous woodchips and twigs are still too frequently left aside. At L'Anse aux Meadows, this material is common and has the best potential for digging into past woodworking strategies. In this presentation, I highlight the previous research done on the wooden collections from L'Anse aux Meadows and trace a path for future work.

Dart Points and Chusquea Shafts in the Argentine South Puna

This presentation focuses on the use of the atlatl and dart system since the earliest known occupations in the Salt Puna of NW Argentina ca. 9800–7000 BP, specifically in the region of Antofagasta de la Sierra (Catamarca). Within this study area, we examine various metrics of lithic projectile points together with very well-preserved shaft fragments found in cave and rockshelter contexts located above 3,500 masl. These shafts were made from *Chusquea lorentziana* canes and *Salix humboldtiana* rods, both allochthonous resources from the eastern lowland ecoregions. These fragments include proximal and distal ends of foreshafts and proximal ends of dart mainshafts that bear a dimple—a telltale sign of dart use. A possible atlatl hook made of onyx (Cueva Salamanca I site) and split feathers of aquatic birds, used to make dart deflectors (Peñas de la Cruz I site), lend further support to the early use of this weapon system. Comparisons will be made with other archaeological finds in the Puna region at large and with neighboring regions. We will also investigate the use of darts during the Altithermal (7500–6000 BP) to understand the relationship between climate, environment, animal behavior, mobility, and the subsistence of these early hunter-gatherer groups.

Collaborative Curation of Kuikuro Collections: The AIKAX Portal

This paper describes the development and implementation of the AIKAX Portal, a digital database that consolidates the data of more than three decades of ethnographic and archaeological research and collections among the Kuikuro indigenous people of the Upper Xingu. The Xingu Indigenous Territory (TIX) encompasses 20,000 km² in the southern portion of Amazonia in the Brazilian state of Mato Grosso. As part of the Kuikuro Ethnoarchaeological Project of the Upper Xingu, we have been conducting participatory mapping of cultural heritage and interdisciplinary archaeological research in this region in collaboration with the Kuikuro people. It is the longest-running collaborative research project with Indigenous peoples in Brazil and is considered a reference in this field. The AIKAX Portal arose from the need to integrate, make accessible, and return to Indigenous peoples research data scattered across various institutions and frequently inaccessible to Indigenous peoples, who are the primary owners of these collections. This is a direct requirement of the Kuikuro. The database and its derivatives—catalogues and story maps—serve as a shared resource for the online socialization of Kuikuro's culture if they so choose.

Ceramics of the Middle Usumacinta Region: Relationships over Time

Since the beginning of the Middle Usumacinta Archaeological Project, researchers have observed that ceramics from several archaeological sites in the region share similarities with those from the site of Ceibal, located in Petén, Guatemala. After conducting several years of research at sites in the Middle Usumacinta region, including Aguada Fénix, the peripheries of Aguada Fénix, El Tiradero, La Carmelita, La Orilla de Laguna Naranjito, Buenavista, Pajonal, El Codo, and Rancho Zaragoza, we have identified several ceramic types dating from the Middle Preclassic: 1000–350 BC to the Terminal Classic: AD 810–950. Among all the archaeological sites investigated so far, the importance of Aguada Fénix stands out. At this site, we have recovered ceramics that have been dated to 1000 BC at Ceibal, but in Aguada Fénix it seems to be even earlier. Each of the investigated sites also features ceramics characteristic of the Middle Usumacinta region, showing important relationships among them through time. We have also identified Olmec ceramics at some sites. These results provide important data on the cultural process of the region and represent a very significant analysis with more than 95,326 ceramic fragments.

An Exploration of Late-Terminal Archaic Domestic Architecture and Settlement Patterns in Southern Connecticut

Archaeological investigations have resulted in evidence that suggests a shift in settlement patterns occurred in Connecticut during the Late and Terminal Archaic periods from interior wetlands to large river drainages. While sites dating to the Late Archaic period are common throughout the New England region, the archaeological record concerning settlement patterns, occupational duration, and domestic architecture remains lacking. Archaeological data collected between 2021 and 2022 from the Tenmile River Native American Site, in Cheshire, Connecticut, provided compelling evidence for a large, round domestic dwelling structure likely dating to the Atlantic Phase of the Terminal Archaic period. This paper aims to explore Late and Terminal Archaic architecture, and how understanding the types and sizes of domestic dwellings as they relate to seasonal and longer-term occupations, may provide insight into shifts in technology and lifeways during these time periods.

Place, Noah**[69]***Disease Ecology of Human Treponematoses in the Southwest US/Northwest Mexico*

Human treponemal diseases (yaws, endemic syphilis, and venereal syphilis) have a long and storied past in the North American Desert West, with the earliest case dating back roughly 1,500 years. The identification of lesions associated with treponemal disease at two Cienega phase (400 BCE–50 CE) sites in southern Arizona and northern Sonora, however, move the presence of these diseases back at least 500 years. This period represents a unique stage in the development of southwestern societies, as settlement sizes began to grow and maize cultivation intensified. While the number of identifiable cases appears low, the presence of infectious disease in these growing settlements provides important information to understanding the disease ecology of these pathogens in the Desert West. The lack of identifiable infectious diseases before the Cienega phase indicates that settlements were beginning to reach population densities large enough to facilitate the spread of disease by skin-to-skin contact. ***This poster will contain illustrations of human remains.

Planto, Rebekah (College of William and Mary)**[325]***Chair***Planto, Rebekah (College of William and Mary)****[325]***Matters of Scale: Depositional Processes and the Archaeology of Daily Life at Bacon's Castle*

Home to Virginia's oldest standing house, the Bacon's Castle site is the most visible remnant of a (post)colonial landscape, continuously occupied as such since at least the 1640s. The extant portion alone, where archaeology has concentrated, has been inhabited over multiple generations by a complex community of bound laborers, tenants, sharecroppers, as well as the plantation's owners. Previous archaeological projects have identified features, established chronologies, and yielded a vast legacy collection. Yet, high levels of stratigraphic disturbance, and the ephemerality of the material record before ca. 1680–1700, combined with the narrow scope of most CRM projects, have conspired to leave much of the vast legacy collection unanalyzed and uncontextualized. Through an intrasite comparative analysis of several artifact assemblages recovered over the past 40+ years, I explore evidence of both gradual, cumulative processes of quotidian activities, and abrupt depositional episodes relating to specific events. Findings facilitate reimagining the colonial landscape not only as an expression of its owners' ideology and power, but as a populated space and a multivocal product of the negotiated pluralism and rising structural inequality that reshaped the Chesapeake over the last half of the seventeenth century.

Plata Aguilera, Olganydia (Columbia University) and Erin Pugh (Barnard College)**[84]***Settler Colonialism in the Picuris Watershed*

This paper tracks the relationship between Picuris Pueblo and San Antonio del Embudo, a settlement in the Picuris homeland downstream of the Rio Pueblo. Embudo (now known as Dixon) is the product of two colonial regimes, beginning with the Spanish appropriation of the lower Picuris watershed to create the Embudo Land Grant in 1725, followed by settlement's annexation by United States, following the 1848 signing of the Treaty of Guadalupe Hidalgo. Archival evidence dating to the declaration of the land grant, the defensive architecture of the central plaza, distributions of ceramic types from midden fill, and local ethnohistories all point to a stronger relationship between Embudo and the Tewa pueblos, despite the closer proximity of Picuris. This paper also considers the impact of US colonialism on both Embudo and Picuris, particularly following the construction of the railroad, the introduction of wage labor, and the growing presence of Anglo settlers in the watershed. While offering an archaeology of conquest, expropriation, and occupation in the Picuris homeland under Spanish and US settler colonialism, this paper also highlight the depth of cultural exchange that has occurred.

Archaeologies of Legacy: Southern Memory and the Archaeological Archive at 87 Church Street, Charleston
87 Church Street, now known as the Heyward-Washington House, is one of the most extensively excavated sites in downtown Charleston, South Carolina, representing a cross-section of urban life spanning the earliest decades of the eighteenth century to its reimagining as a historic house museum in 1929 on the leading edge of the historic preservation movement in the city. Most of the excavated material now forms the basis of an expansive legacy collection, produced by Dr. Elaine Herold in the 1970s whose long career appears in flashes throughout the Midwest and eastern United States during the latter half of the twentieth century. The collections she generated represents the complex entanglement of curatorial practice, social memory, and interpretation in the production of the archaeological archive. Particularly profound are the impacts of Lost Cause perceptions of the Southern past on understandings of this site that are prevalent in Charleston during the initial period in which these collections were produced. Following the lead of historians, this paper considers the formation processes of the 87 Church Street archive, and how the taphonomy of memory impacts our interpretation and understanding of this collection.

Effects of Rainfall Patterns on the Distribution and Prevalence of Earthen Terraces

Earthen agricultural terraces are prevalent worldwide and have continued to be built and used for millennia. Yet relative to their stone-faced counterparts, earthen terraces are often characterized as less intensive and productive, requiring less time, labor, and material resources to construct and maintain and likewise producing lower yields. While the validity of these claims necessarily varies and depends on the specific

characteristics of any context, the general question of why farmers may invest in earthen rather than stone terraces remains pertinent, as much for the present as for the past. Aside from time, labor, and material costs, environmental considerations are essential to consider, particularly with respect to water availability. Looking at annual rainfall patterns, this paper draws on Donkin's 1979 catalogue of agricultural terracing in the Americas to investigate how rainfall quantity and seasonality relate to the distribution and prevalence of earthen terraces. While rainfall quantity is essential for agriculture in general, I predict that the seasonality of rainfall leads to structural considerations that help determine whether earthen or stone-faced terraces are more suitable for certain environments. This work is conducted in Google Earth Engine and shows the potential of cloud-based geospatial platforms for conducting large-scale comparative environmental studies.

Firefly Synchronicity in Platform Mound Building by Indigenous Peoples of the Florida Peninsula, USA

Although archaeologists commonly situate the value of our field in its capacity to identify broad-scale patterning in human societies over the long term, critiques of the essentialism and linearity of social evolution led many to abandon this goal in favor of shorter-term, local histories. Drawing from calls for a “process archaeology” that recognizes continuous change or becoming, and its application to complex societies, we use firefly synchronicity as a framework for understanding patterning in the timing of the construction of platform mounds by Indigenous peoples of Tampa Bay, on the western coast of the Florida peninsula, USA. Archaeologists now recognize that Indigenous peoples of eastern North America began constructing platform mounds earlier than commonly been accepted, yet early platform mounds are often interpreted as having little regularity in form, timing, or location. Bayesian modeling of radiocarbon dates and isotopic studies of oyster (*C. virginica*) shells from three sites in Tampa Bay reveals rhythmic coordination in the construction of platform mounds across the first millennium CE.

[96]

Evidence for Land Tenure and the Creation of Commons among the Virgin Branch Ancestral Puebloans

The Cultural Resource Management Program of the Gila River Indian Community recently surveyed over 4,000 acres of Kaibab Paiute tribal lands in northern Arizona, recording over 85 archaeological sites. The survey examined broad basins and small hills, in areas of relatively low slope, but bordered by the Vermillion Cliffs. Most of the newly recorded archaeological sites are associated with the Virgin Branch Ancestral Puebloan culture and the Pueblo II period (900–1150 CE). This effort recorded a pattern of artifact deposition that suggests that habitations were culturally excluded from a portion of the landscape. I hypothesize that this exclusion was related to cultural ideas about the control of Commons, and that habitations represented a claim on surrounding land and/or resources. This hypothesis is supported by evidence for dispersed, seasonal, single-room habitations in other parts of the project area. These habitations are spaced along low ridges, suggesting that each denoted a “territory” or area of “control.” I propose a model where a habitation structure represents a land claim, and where habitations are therefore barred in and around certain resources, such as lithic material sources and springs.

Landscapes of (Re)Conquest: Archaeologies of Cultural Transformation in Medieval Iberia and Occitania

This paper presents the highlights of the “Landscapes of (Re)Conquest” project (2018–2023), which has investigated the impact of conquest, migration, and cultural transformation in the frontier societies of medieval Iberia and Pyrenean Occitania. Focusing on specific regional case studies, it considers how the creation of frontier societies resulting from variable episodes of conquest and regime change resulted in both continuities and discontinuities in the cultural landscape. This is visible in long-term trends associated with centers of authority, urbanism, rural settlements, religious infrastructure, and the exploitation of natural resources. It also considers examples of resilience following conquest, regime change, and migration, particularly foodways connected with ethno-religious identities, ceramic production and use, architecture, and construction.

The Ethnohistoric Narratives Confronted to the Archaeological Reality: A Case Study from the Mississippian Sites of Cahokia, Moundville, and Spiro

During the French colonization, Louisiana and the Mississippi Valley in general were the background of a quantity of testimonies about Native American societies that were met at the time by the French explorers. A few of these Frenchmen had lived among Native American societies for a various amount of time, the most noticeable example being probably Antoine-Simon Le Page du Pratz, who lived among the Natchez society. While he was close to the Sun elite, he wrote *Histoire de la Louisiane française* [History of French Louisiana], and he was particularly interested in describing the funerary ceremonies he witnessed. In particular, his description of the funerals of the Natchez elite gives us an interpretive perspective of archaeological vestiges, especially concerning the Mississippian cultures. Through the study of three examples from Cahokia, Moundville, and Spiro sites, we will try an analysis of the archaeological materials related to the ethnohistoric documents. In which instances do the colonial and ethnographic documents assist us to apprehend archaeological remains? What are the limitations of such an interpretation? This methodology has given relevant results in interpreting Mesoamerican and Andean vestiges in the past decades.

3D Documentation of a Basketmaker Petroglyph Panel in Southeastern Utah

Our research involves creating and analyzing a 3D model of an inaccessible petroglyph panel in southeastern Utah. The rock art panel occupies the cliff face of an alcove approximately 10–30 m above the modern ground surface. Such heights make documentation difficult; this lofty position likely caused the initial archaeologists who recorded the alcove in 1961 to miss the panel. The development of photogrammetry and drone technology provided an effective way to overcome the challenge of inaccessibility. A drone systematically captured over 1,300 partially overlapping high-resolution images of the cliff face, including a few measured control points. These images were then “stitched” together using digital software (RealityCapture) to generate a 3D model of the cliff face and petroglyphs. This model allows observers to view the panel comprehensively without visiting the field and to export 2D images of the cliff face as needed. Much of the imagery appears to derive from the Basketmaker II period (~400 BC–AD 400); earlier elements are also present. Generating a permanent record of an inaccessible petroglyph panel using a noninvasive and efficient method meets the objective of both heritage management and archaeological research. This approach has wider applicability in other archaeological contexts.

In the Many Realms of John Pohl: An Introduction to a Double Symposium

This double symposium brings together a select group of archaeologists, ethnohistorians, museum professionals, and social justice advocates who have either collaborated with John M. D. Pohl directly or took inspiration from his remarkable half-century career. A trailblazer in the study of Mixtec, Nahuatl, and Zapotec civilizations of southern Mexico, Dr. Pohl is equally noted for bringing the ancient Indigenous past of the Americas to life through his numerous publications, collaborative field research, codical studies, blockbuster exhibitions, film and media production, dazzling artwork, and not least his inspired teaching at various universities across the United States. The panels are organized around two fundamental areas that reflect John Pohl's interdisciplinary endeavors, the first in scholarship and the second in media and advocacy. The speakers are both current and former students together with emerging and senior scholars who are currently engaged in innovative research ranging from investigations into the Classic, Postclassic, and colonial cultural transformations across Mexico, Guatemala, and the United States; the use of cutting-edge technologies in the field and lab; digital media in museums and architectural reconstructions; and Indigenous representation in the public interpretation of their cultural histories.

Rare and Isolated Artifact Occurrences from the Caves of the El Malpais Lava Fields of New Mexico

After more than a century of sustained looting, the lava tube caves of El Malpais have lost volumes from what was once an unparalleled record of cave use by Ancestral Pueblo people. Occasionally, artifacts stolen from the caves appear on public auction blocks, offering a brief glimpse of what used to be. In general, archaeologists seeking an understanding of the nature of ancient subterranean practices are left with the few materials overlooked by pothunters. Rare and isolated artifact occurrences in caves today may reflect greater frequencies in the past, and through interpretation of such items, we may open a window on past chthonic activities, both ceremonial and pragmatic. These items often have ethnographically described functions or analogs from surface contexts, which serve as invaluable aids to decipherment. Certain cave features are also unique. For example, only a single instance of parietal art is known from a cave dark zone at El Malpais. Nonetheless, this panel holds precious clues to Ancestral Pueblo beliefs concerning caves. In an exciting development, recent Park Service consultation with neighboring Pueblos has led to the disclosure of previously confidential information pertaining to artifacts cached in caves.

The Potentials of Airborne Geomagnetic Survey Systems for Cultural Resources Management: Preliminary Results of Experimental Geophysical Investigations in Eastern Hungary and Central Arizona, USA

Simultaneous innovations in unmanned aerial vehicles (UAVs) and geophysical technologies present the possibility of a potentially groundbreaking approach to archaeological geophysics: airborne geophysical survey. As part of an ongoing effort on behalf of the Environmental Management Office of the Arizona Army National Guard to integrate conventional and remote sensing survey methods for cultural resources management, we conducted an exploratory project to assess the applicability of aerial geophysics for archaeological site detection and mapping. Using the Sensys MagDrone R4 survey system, we conducted large-scale surveys of two complex archaeological sites, a fortified Late Bronze Age settlement in eastern Hungary and an early Sedentary period Hohokam village site in the northern portion of the Florence Military Reservation in Pinal County, Arizona. In this paper we present our preliminary findings from multiple geophysical survey campaigns. We evaluated the airborne geophysical survey results in light of preceding pedestrian geophysical and conventional surveys. We also present a novel data processing approach using computational methods for the detection and classification of archaeologically relevant magnetic anomalies.

Monumental Memories: Addressing the Association between Fort Ancient Villages and Woodland Earthen Monuments
Since early archaeological investigations in the Ohio River Valley, scholars have speculated on the relationship between late precontact Fort Ancient villages and earlier Woodland mounds and earthworks. However, few have empirically addressed the association between these sites and their placement on a persistent landscape. We seek to determine the association between Fort Ancient villages and earlier earthen monuments both broadly and by Fort Ancient temporal component and subregion. In doing so, we employ archaeological site modeling through geographic information systems (GIS) considering parameters including soil type, distance to rivers, and slope to test settlement patterns against environmental conditions in comparison to earthen monument locations. In addition, we utilize aggregated site data to quantitatively evaluate and provide a nuanced exploration of community settlement during the Fort Ancient period. These methods coupled with an analysis of Fort Ancient village site layouts incorporating Woodland mounds illuminate the association between Fort Ancient communities and Woodland earthen monuments. Our findings contribute to the recognition of persistent landscapes and social memory in the Ohio River Valley and advance our collective knowledge regarding site formation processes in the region.

Seventeenth-Century Fort Ancient Mortuary Practices and Ritual Space

The 2023 investigation of the seventeenth-century Fort Ancient village of Augusta, Kentucky, focused on a section of the community's cemetery and ritual space. It was conducted in advance of planned improvements to the historic town of Augusta's sewage treatment system. Although six extended adult burials were documented within an 80 m² excavation block, the significance of this research lies in the documentation of

features reflecting ritual activities that would have taken place near each grave. These features included large, individual rock-chinked poles, intensely fired hearths, evidence for ritual feasting, the intentional breakage of ceramic vessels, possible grave structures, and clay lined grave shafts. These characteristics are similar to those documented at the contemporary Fort Ancient villages of Hardin and Larkin, and at the later lower Shawnee Town, an eighteenth-century village located upstream from Augusta. Significantly, these features are described in ethnohistoric and historic documents as elements of Shawnee mortuary practices. These investigations suggest that there are strong links between precontact Fort Ancient groups of the middle Ohio valley and historic Shawnee people.

Monitoring Cultural Change through Ceramics: A Data Comparison from Typology, Sourcing of Pastes, and Symmetry Analysis of Ceramics from the Prehispanic Tarascan Region

As a common material and highly plastic technology, in Mesoamerica ceramics are used to define spatial and chronological units of past social, political, and economic structures. In the present study, we compare (1) the use of the type-variety classification as a *chaîne opératoire*, (2) the use of INA and thin-section petrography in sourcing ceramic pastes, and (3) symmetry analysis of the design structure of ceramics. The samples come from central and northern Michoacán from the Late Preclassic to the Late Postclassic periods (200 BCE–CE 1522), primarily from sites in the Lake Pátzcuaro and Zacapu Basins. The goal will be to determine how each method monitors the timing and rate of sociocultural stability and change and to propose what kinds of social processes each method is able to document.

Social Inequality and Cohesion through Rural-Urban Feasts at the Lowland Maya site of La Corona

Lowland Maya feasts were critical for communal cohesion but also marked social distinctions among participants through differential display of status symbols and contributions. For these reasons they provide important insight on patterns of socioeconomic inequality and integration. In this paper I present material analyses data from Late Classic period (AD 250–900) feasting deposits to discern patterns of socioeconomic inequality across the settlement density continuum. I specifically discuss data from settlement clusters that likely represented neighborhoods in rural, peri-urban, and urban settlement density zones in the La Corona region in northwest Petén, Guatemala. While commensal events were critical in community formation and identity building, they also played a pivotal role in marking internal distinctions in neighborhoods.

The “X”-Ray Files: Preliminary Results on the Identification of Shark Species Using X-Ray Technology and Its Implications for a Better Understanding of the Economic and Symbolic Role Played by Sharks in Prehispanic Andean Societies

Shark fisheries were an important economic activity carried out by small-scale maritime communities in the prehispanic Andean coast since at least the second millennium BC. New evidence found in Huanchaco, north coast of Peru, suggests that during the fifth and seventh centuries of our era, sharks became an essential

source of proteins in the daily diet and a powerful symbol in their ceremonial practices. Complete sharks have been found in votive offerings buried in the temples, and selected shark teeth have been recovered in the burials of powerful fisher-chiefs. Although shark teeth allow accurate identification of shark species, they are not always present in archaeological contexts. Calcified vertebrae are found in abundance throughout fishing sites on the north coast of Peru; however, they are more challenging to identify due to their similarities across shark species. In this paper, we present experimental analysis using X-rays on the shark centra from Huanchaco as a potential tool to determine sharks down to family and species. In addition, we discuss the significance and role of sharks within marine ecosystems exploited by coastal populations as well as their cultural significance within prehispanic Andean maritime communities.

Contemplating Disjoint Change in the Tuxtlas Formative-Classic Transition

Like a schizophrenic Mesoamerican Janus, the first centuries CE in the Tuxtlas region look backward or forward with neck-snapping deviation depending on where, when, and at what an observer looks. A millennium-old tradition of differentially fired wares persists in some parts as fine-paste orange wares dominate serving assemblages in others. Hieroglyphic writing and monumental sculpture are embraced or rejected differentially between and within lowland and highland settings. Subregionally distinctive autochthonous and allochthonous architectural layouts are elaborated, modified, and replaced as individuals and collectives jockey to employ tradition, novelty, and extra-regional networks to their advantage. In this paper I reflect on a model of change I proposed in the early 2000s focused on ceramic use and production in the central Tuxtlas from a perspective expanded regionally, empirically, and theoretically by subsequent survey, excavation, analysis, and historical research at Tres Zapotes and in its environs.

The Changing Job Market in Academic Archaeology: Analysis of a Decade of Data from the Archaeology Academic Jobs Wiki

Tenure-track employment is a highly sought-after career path for many graduate students. Recent surveys have helped to document the supply of applicants in terms of the numbers of graduates per year and per institution. However, the demand for applicants for tenure-track jobs has not been studied in detail. We examine the text of advertisements for tenure-track jobs to get insights into the archaeology academic job market. Using data from the community-edited Archaeology Academic Jobs Wiki, we explore changes in the academic job market over time. We examine the numbers of positions advertised per year and the ratio of tenure-track to untenured positions. We analyze job titles and descriptions to identify trends in topics and methods. We investigate the complexity of the advertisements and instructions to applicants to see how the details of the application have changed over time.

"They Are Ours": Bringing Together Past and Present Church through Burial Excavations at the First Baptist Church Site
At the request of the descendant community, Colonial Williamsburg archaeologists in 2022 excavated three burials from among 62 discovered on the site of the First Baptist Church. Despite poor preservation and a

dearth of identifying information, archaeological evidence recovered from these burials speaks clearly to aspects of the lived experience of the interred. Coffin construction, burial clothing, and dietary pollen are among lines of evidence that have contributed valuable details to an emerging picture of this early nineteenth-century congregation. Combined with osteological and DNA analysis, the archaeological evidence has helped to humanize anonymous burials, and to build connections between a living church community and its founding members. ***Images of human remains will be included in this presentation.

Evidence of Exchange in Precolumbian Ceramics from Isla Colon, Bocas del Toro, Panama

Isla Colon, the largest island in the Bocas del Toro archipelago on Panama's northwest coast, has a unique density of archaeological features in the region. Sitio Drago, the largest site yet found on the island, includes ceremonial and settlement mounds and a diverse and sizable assemblage of subsistence remains and cultural materials. Evidence of cultural interactions in the form of lithic tools and possible "prestige goods" were uncovered dating to between AD 750 and 1450. Overall, Sitio Drago has the most diverse ceramic assemblages in the area and was likely tied to overland and maritime exchange networks. Stylistic analysis noted the presence of pottery types from at least five distinct culture areas, ranging from Central Panama to Nicaragua. Ongoing research focuses on data collection and archaeometric analysis to investigate questions of scale, chronology, and cultural practices within these networks. To assess what material was moving across Central America in the past, petrographic and geochemical analyses have been undertaken to determine the provenance of different types of pottery. As several distinct groups of ceramics are evident stylistically as well as compositionally, the sources and amounts of these different kinds of pottery may indicate the underlying relationships between disparate communities.

Reconstructing Violence: A Multiscalar Approach to Cranial Trauma

When analyzing traumatic injury in highly commingled and fragmentary collections, interpreting violence can be particularly challenging as reconstructing the full extent of fractures in an individual is not possible, and not all traumatic injuries are indicative of violence. In these cases, cranial trauma can be the most suggestive of interpersonal violence in the past; however, highly fragmented skeletal remains can be difficult to incorporate into statistical analyses. This paper proposes a multiscalar analysis using a zonal approach to examine complete crania, complete cranial elements, and specific zones per cranial element to understand trends in the location of trauma to the skull while maximizing sample sizes for statistical analyses. While contributing methodologically to the study of commingled/fragmentary skeletons, multiscalar analyses are also appropriate as they recognize the multiple intersecting identities, both individual and communal, that make up intentionally commingled skeletons. At the Early Bronze Age site of Bab adh-Dhra', this approach was used to better understand patterns of interpersonal violence from the A22 charnel house during the occupation of a densely populated, walled town. Results show that each line of evidence can contribute novel findings for interpreting violence, making their incorporation important for robust understandings of the past.

Movimientos rituales en el sitio de Yucu Ñuu Dahui durante el Clásico en la Mixteca Alta, Oaxaca

La conferencia pasada presenté algunas ideas sobre el estudio del movimiento en los sitios arqueológicos a partir del propio movimiento. Continuando con esta temática, en esta ocasión me enfocaré en la movilidad ritual al interior del sitio de Yucu Ñuu Dahui. Este asentamiento es emblemático de la Mixteca Alta debido a que se considera una gran ciudad del Clásico o la fase Flores (300-900 dC). Gracias a los recorridos arqueológicos y a la fotogrametría realizada con dron (con la que se obtuvieron modelos de elevación, curvas de nivel, ortofoto y modelos 3D del terreno), se observó que el sitio fue, al mismo tiempo, un gran santuario. Debido a su extensión, monumentalidad y a que integra diferentes santuarios, tanto construidos como naturales, lo considero un paisaje sagrado. Los análisis que realicé me permitieron conocer aspectos de la movilidad en el sitio y proponer varios movimientos rituales o peregrinaciones al interior de éste. Asimismo, observar la interconexión y aproximaciones a los diversos santuarios.

Lithic Technological and Use-Wear Analysis for Two Paleoindian Sites at the Kanorado Locality, Kansas

This paper presents results of an analysis of lithic artifacts from the Kanorado Locality in the High Plains of Western Kansas. The Kanorado Locality is a stratified Clovis-age and Folsom/Midland occupation along Middle Beaver Creek. The Clovis adaptation in the Great Plains is well-documented, but not as thoroughly understood as subsequent occupations. This paper considers lithic materials from two sites at the locality, 14SN101 and 14SN105. Clovis-age and Folsom/Midland materials and those dating to later cultural periods are contained in distinct buried soils. Therefore, these sites facilitate comparison between Clovis and later Paleoindian components. This project examined each artifact field catalogued as a lithic ($n = 409$) from these two sites and recorded its technological attributes. Any debitage larger than 6 cm² or 5 g, in addition to all tools, were examined for use-wear using low-power microscopy. A dedicated experimental comparative collection was produced for this project and designed to closely reflect the raw materials represented in these two assemblages. Results situate Clovis-age adaptations in local temporal context, by way of comparison with Folsom/Midland and later activities in the same locality. The results of this analysis are also considered in terms of prior Clovis use-wear studies in differing environmental contexts.

Considering Pb Mixing in Lead Isotope Analysis (LIA) of Tin Artifacts

LIA of tin metal must consider the U-Th-Pb characteristics of cassiterite ore. The initial Pb content of cassiterite is <1 ppm and Th is <0.005 ppm. However, it contains as much as 50 ppm U. Therefore, 206 Pb and 207 Pb accumulate over time, potentially allowing the definition of an isochron. However, given the age of most Eurasian tin ores (300–30 Ma) and the relatively low U concentration, little radiogenic Pb is produced. Unusually, U-enriched 300 Ma cassiterite (50 ppm) would generate only 2.5 ppm of Pb, which mixes with the ~0.5 ppm of initial Pb. Thus, every tin LIA is a mixed value. Only one of the 140 LBA European tin ingots contains less than the 3 ppm U limit expected in Variscan ore. Therefore, most tin objects contain an additional Pb source: inclusion of galena or zircon in the ore concentrate; contamination by residual Pb metal in the smelting/casting ceramics; and recycling of tin metal into a new composite object. Accordingly, conducting a detailed mixing analysis is essential to correctly interpret the results of LIA of tin ingots and other artifacts. Here, we present the results of such an analysis on the European ingot assemblage.

Evidence of Seaweed Use by Coastal Communities of the Atacama Desert Coast, South America

Seaweeds have been part of the daily life of coastal populations worldwide. Despite the wide range of species and human uses, seaweeds have been under-researched in the human sciences and historical ecology compared to other marine resources. The archaeological record of seaweed is scarce because of preservation biases and the lack of specific studies. On the Pacific coast of South America, algae macroremains have been recorded in archaeological sites along the Peruvian and Chilean coasts from 14,000 years cal BP onward, although the evidence is scattered and lacks systematization. This work provides a synthesis of the archaeological record of the Atacama Desert to evaluate the long-term uses of these resources for coastal populations. The outstanding preservation conditions of organic remains in this coastal desert provide direct evidence of two genera of kelp-type seaweed (*Lessonia* and *Macrocystis*) in several archaeological contexts. These data suggest the uses of kelp as raw material for cordage, personal objects, mortuary offerings, mummification of human bodies, fuel, and possibly as mortars for architectural purposes. We discuss this evidence with ethnographic data of seaweed uses in the Atacama Desert, to visualize the historical importance of these resources for the coastal populations of South America's Pacific coast.

The Cummings Site: An Early Woodland Occupation in the Etowah River Valley of North Georgia

Cummings (9BR710) is a multicomponent site with occupations dating from the Late Archaic through the Middle Mississippian periods. It is located about 3 km northwest of the Etowah Indian Mounds in Bartow County, Georgia. The site is situated about 500 m from the Etowah River. Over the past five years

archaeological investigations have focused on the Early Wilbanks Phase (AD 1250–1375) occupation and the site's relationship to Etowah in the thirteenth century. Current research however has identified an Early Woodland component based on the recovery of significant quantities of Dunlap Fabric Impressed pottery. The presence of steatite fragments and Savannah River points may indicate a transitional Late Archaic–Early Woodland manifestation. The occurrence of Cartersville Series ceramic types, including Cartersville Check Stamped and Cartersville Simple Stamped (but no Cartersville Linear Check Stamped) suggests this occupation continued into the Middle Woodland period. Based on the ceramic and lithic artifacts and the presence of pit features, possibly associated with domestic habitation, Cummings likely represents a small settlement, perhaps representing a nuclear family or two, engaged in the harvesting, processing, and storage of forest resources. A comparison of results with other nearby sites and elsewhere in north Georgia will also be provided.

Expanding Archaeological Outreach through Middle-Grade Literature

Though greatly expanded both in quantity and diversity of subject matter in recent years, literature for the middle-grade audience largely fails to include storylines featuring archaeology, particularly evident in graphic novel formats. As archaeology is not a prominent piece of traditional public education, young people may not be exposed to the field until much later in life. This project addresses this lack of archaeological literature for younger audiences by introducing and expanding their knowledge of archaeology in an age-appropriate and inviting way, outside the classroom. Though improving, a significant portion of literature on archaeological sites is intended for an academic audience or older members of the public. To fill this niche, I have written and illustrated a middle-grade graphic novel centering around the historic site of Fort St. Joseph in Niles, Michigan. Set at an archaeology summer camp, this novel brings archaeology to the present while exploring the past.

Gathering and Growing from Past to Present: Building Future Foodways and Indigenous Landscapes in Turtle Island

How can archaeological data contribute to Indigenous food sovereignty efforts and biocultural restoration of Indigenous landscapes? We present two projects from northern Turtle Island from vastly different ecologies (Saskatchewan and Ontario), where paleoethnobotanical research has been effective for connecting archaeologists, Indigenous scholars, and community members seeking decolonized foodways and revitalized Indigenous landscapes. In the Bridge to Land Water Sky Living Lab in Saskatchewan, paleoethnobotanical, archived ethnographic, and community knowledge are braided together to create a cohesive narrative of First Nations human-plant relationships across time. In the “Collaborative Archaeologies, Decolonized Foodways” project in Ontario, food residues from archived Indigenous ceramics are queried from different ways of knowing to understand past foodways and to help inform current and future food sovereignty efforts. These two projects work toward connecting the past to present and to help strengthen connections to land and nonhuman communities. In this presentation, we show the potential of such approaches, the challenges of such research, and the importance of pursuing collaborative projects focused on foodways and sustainability in Turtle Island.

Galapagos Marine Plastic Pollution: A Perspective from Contemporary Archaeology

Marine plastic pollution is an issue threatening most places around the world, including the remote and

unique Galapagos archipelago, a UNESCO World Heritage Site. Building on how archaeology of the contemporary world can help address urgent and global environmental issues, this paper offers suggestions for an archaeology of plastic pollution in Galapagos. Two approaches to study plastic pollution in Galapagos are presented: (1) the study of plastic bottles as material culture found on shores of one uninhabited island of the archipelago and (2) the use of object itineraries as an archaeological framework to organize a story-writing workshop with local students. With PET bottles being one of the most recurrent findings on beach clean-ups around the globe, this paper adopts an archaeological approach to their analysis in order to re-create their itineraries. Through an analysis of labels, stamps and production/expiry date, this paper evaluates bottles' origin, pathway, and use, while suggesting solutions. As the issue of plastic pollution is deeply entangled with human behavior, this paper also aims at understanding perceptions of the issue, its sources, impacts and solutions. Results of a story-writing workshop to explore perceptions of marine plastic litter itineraries by students from Santa Cruz will be presented.

Unlocking the Secrets of Maya Writing: Justin Kerr and the Decipherment of Maya Script

The documentation effort within the realm of Maya writing research spans nearly a century and a half, commencing with the systematic recording of Maya inscriptions during the latter part of the nineteenth century. Throughout the initial half of the twentieth century, archaeologists associated with the Carnegie Institution distinguished themselves through their exceptional dedication. Their endeavors encompassed the comprehensive documentation and subsequent publication of a substantial corpus that would prove to be of paramount significance in the subsequent decoding of the Maya script. Among the most preeminent documentation undertakings in the latter half of the twentieth century is the pioneering documentation by Justin Kerr, who employed innovative photographic rollout techniques to capture inscribed ceramic vessels. In the late 1990s, Kerr was a trailblazer in recognizing the vast potential of the World Wide Web, making his documentation freely accessible to the public on the Internet. The advancements achieved in the decipherment of the Maya script to date owe much to Justin Kerr. I intend to underscore the particular significance of Justin Kerr's vase documentation in the decipherment process, and I also aim to engage in a discussion regarding the open-access paradigm, which Justin Kerr was the first to introduce to Maya research.

Forager Adaptations to Andean Cloud Forest, Peru

Cloud forests are montane tropical rainforests typically characterized by persistent fog, diverse microclimates, and rich biodiversity. Although some regions have long histories of development of technological and sociopolitical complexity in cloud forests (e.g., the Mayan highlands), in the central Andes cloud forests have often been considered inhospitable landscapes, only meaningfully colonized by humans following the development of technologies, such as agricultural terracing, which allowed for greater extraction of resources. However, excavation of three sites in the Chachapoyas region of Peru reveal a history of human colonization dating to at least the middle Holocene (ca. 5500 cal BP), and possibly as early as 10,600 cal BP. These groups of foragers drew resources from a variety of microenvironments across the cloud forest ecosystem; site occupation histories and technology suggest continuous use of certain landscapes through the Formative period (ca. 3200–3400 cal BP). The technologies present at these sites differ from forager tools recovered from coastal and highland contexts, highlighting adaptations to the cloud forest that include maximizing available raw materials and use of locally available plant foods.

Raised Field Nutrient Cycling: Implications for Hydrologic Controls and Landesque Capital

Beginning around AD 600, the Barbacoan speaking peoples of the northern Ecuadorian highlands began building alternating ridge and canal raised field systems. One of the leading hypothesized functions of these raised fields is their role in nutrient cycling. In this scenario, decayed organic matter is mucked from the canals and redeposited atop the agricultural ridges supplementing crops with growth limiting macronutrients. This paper explores this hypothesis in the context of highland Ecuadorian raised fields and examines some of the potential implications for long-term use, hydrologic management, and landesque capital. To examine this hypothesis, we draw on the results of soil analyses conducted on raised fields at the site of Zuleta and examine historic aerial images that show complicated raised field hydrologic networks indicative of intentional design features. We also discuss the benefits that this use of raised fields might have had on soil fertility and how raised fields may continue to provide these benefits even hundreds of years after their abandonment.

Variation in Household Kitchen Activities at Housepit 54, British Columbia: Reflections on Jeanne Arnold's Legacy

Jeanne Arnold left us with a legacy of archaeological research into households, social change, and technological variation in the various contexts across the North American west coast. Her work was always characterized by attention to multiple sources of archaeological insights spanning lithic analysis to subsistence studies. Here, we reflect in Arnold's legacy in light of our multidisciplinary studies of the deeply stratified Housepit 54 at the Bridge River site in British Columbia. Our research currently focuses on variability in kitchen activities with the goal of understanding relationships between subsistence production and social relations throughout the history of the house and associated village. In this paper, we present outcomes of studies on hearths and ovens that include micromorphology, paleoethnobotany, geochemistry, zooarchaeology, and lithic technology. Results suggest that cooking features varied between routine kitchen activities across most floors while occupants of select floors developed larger ovens likely used for social events. These results offer implications for how we understand social change during the history of the house.

Indigenizing Heritage: A Perspective from Cochiti Pueblo, New Mexico

Cultural heritage is commonly associated with the preservation of the physical traces of past human existence which are held to be our collective inheritance and to inspire our common future. It is often contrasted with natural heritage defined as natural places distinguished by their natural beauty or outstanding biodiversity, ecosystem, and geological values. From an Indigenous point of view this perspective, however valuable, fails to acknowledge the deep interconnectedness of people and other-than-human beings such as mountains and rivers, plants and animals, clouds and rain. We develop our argument by looking at how Cochiti Pueblo has responded to two external challenges—the building of Cochiti Dam and the Las Conchas fire. These cases are particularly informative because they bring cultural values into sharp focus and suggest some steps toward the reintegration of heritage as a response to the challenges of the Anthropocene.

“Sowing” Children in Arid Lands Irrigated with Artificial Hydraulic Canals in the Moche Valley, North Coast of Peru
The discovery of hundreds of sacrificed children in the North Coast of Peru, has opened new opportunities to study ritual violence in ancient societies. Current studies have identified that mass sacrificial events were performed at moments of sociopolitical and economic instability due to climatic anomalies such as ENSO events. More recently, it has been suggested that child sacrifice was performed as part of a sanctioned violence program executed to exert sociopolitical control by the Chimú elites. In 2022, excavations in a new sector at Pampa la Cruz, Huanchaco, uncovered a set of 48 sacrificed children buried in direct association with artificial irrigation canals and agricultural fields built by the Chimú state. In this paper, it is suggested that child sacrifice could have played a symbolic role to “energize” the fields and crops by pouring young blood on the newly artificially irrigated lands. In addition, the discovery of *Spondylus* shells and miniatures of silver artifacts in association with the sacrificed children, indicate more sophisticated sacrificial ceremonies in order to increase crop production. Parallels with Inca cosmology is employed to establish the ideological principles of such sacrifices and the role played by children in Chimú economy.

Sounds of Change: Mapping Auditory Experiences through Time in the Greater Chaco Landscape

Recent work has demonstrated that audibility between habitation sites, monumental construction, and other landscape elements was an actively managed aspect of the Ancestral Puebloan built environment both within Chaco Canyon and the Greater Chaco Landscape (GCL). GCL communities were inhabited for hundreds of

years, during which the layout and relationships between features of the built environment transformed. These changes resulted in different sound environments and thus different auditory experiences over time. Focusing on the Morris 40 community, located on Ute Mountain Ute Land in northwest New Mexico, the authors modeled estimated soundsheds using the Archaeoacoustics Toolbox for GIS to explore how sounds produced within the landscape may have been heard and experienced as the community was established, grew, and declined between 750 and 1300 CE.

Forget Projections, Be the Change: Crushing Archaeology Career Myths to Inspire New Trajectories for CRM

One of the most popular narratives at this time in archaeology, promoted by Altschul and Klein 2022, is that there will be a dearth of archaeologists now and into the near future, particularly archaeologists with master's degrees or higher. This presentation will bust the myths regarding the role and necessity of advanced degrees in CRM and present some critical areas that CRM archaeologists, academics, and students can look at now to drive innovative transformations to the CRM business at all levels of the career. This includes a discussion of legal requirements vs. business practices, assumptions we are making regarding the role of education for CRM today, and some practical steps that can be taken to transform our expectations and practices for CRM career trajectories.

Community from the Ground Up: Launching the 1857 Slave Dwelling Project at Thomas Jefferson's Poplar Forest

Ongoing work at Thomas Jefferson's Poplar Forest strives to explore the history and legacy of those who shaped the landscape of this National Historic Landmark, beginning in the 1760s and continuing through emancipation. This includes collaborative efforts with members of the local African American community to explore historic sites, families, and individuals associated with the enslaved men, women, and children who lived and labored on this Virginia Piedmont plantation over time. Recent archaeological research has focused on a standing brick quarter that was built in 1857. This new project provides a unique opportunity to both preserve and restore a place that can powerfully speak to the stories of slavery and emancipation associated with the history of the plantation as well as the lives of Black tenants who lived in this building into the early twentieth century.

Prout, Michael (CSULA Anthropology)**[221]***The Liminal Space between Two Plazas: Insights into Ancient Maya Ritualistic Cave Activities at Las Pacayas*

The Cueva de los Quetzales was initially reported in 1991 by the Petexbatun Regional Cave Survey and more intensively investigated in 1993 in conjunction with the Altas Arqueológico de Guatemala's excavation of the surface site of Las Pacayas. The site is located 12 km south of Dos Pilas and 7.5 km east of Aguateca. The cave is noteworthy in running through the highly modified hill on which Las Pacayas was built and has an opening in the ceiling that was positioned on the boundary where the two principal plazas meet. Offerings dropped through the opening formed a conical mound 3–5 m deep in the chamber below. J. Eric Thompson calls attention to such large ritual cave deposits in his 1959 article "The Role of Caves in Maya Culture." Excavations within the mound left no doubt about its ritual nature in producing over 300 fragments of ceramic drums, portions of 43 ocarinas and flutes, and a human skeletal assemblage among the artifactual material dating from the Late Preclassic to the Late Classic. This paper provides the first analysis that relates the osteological component to this very specialized ritual context.

Prufer, Keith (University of New Mexico), Dolores Piperno (Smithsonian Institution), Nadia Neff (University of New Mexico), Mark Robinson (Exeter University) and Douglas Kennett (University of California, Santa Barbara)**[217]***Early and Middle Holocene Food Choices, Farming, and Diet Quality in the Neotropical Maya Area*

Despite a century of research into the lives and diets of the northern neotropics' earliest populations, our understanding of food production and consumption and its impact on diet quality remains relatively impoverished. We present a first view of data generated from archaeological sites in the Maya Mountains of southern Belize where a decade of research is fundamentally changing how we view early human relationships with food in tropical environments. These data come from dietary isotopes derived from ancient humans and fauna combined with data from microbotanical starch grains extracted from ancient dental calculus and grinding stones as well as modern domesticated and wild edible plants. These data were generated with an emphasis on quality control for dietary proxies. We see evidence for consumption of root crops by 10,000 cal BP and seed, yam, and squash crops by 7500 cal BP, including maize. These developments suggest a protracted period of subsistence farming lasting at least 5,000 years before investments in surplus agricultural production drove major demographic shifts starting after 4000 cal BP.

Pryor, John (CSU, Fresno) and Waylon Coats (Vice Chair Southern Sierra Miwok)**[99]***Toward a Miwok Archaeology of Yosemite California*

While there is a long history of archaeological work in Yosemite National Park, this work is grounded in Western European traditions of archaeology that does not take into consideration perspectives of the people who produced much of the record this archaeology sets out to understand. These people had their own sense of time, space, and values that affected how they inhabited Yosemite, which in turn affected the materials they left behind. Because humans construct the worlds we live in through culture, the authors of this poster suggest that it is impossible to understand the archaeology of Yosemite using Western European

constructs of time, space, and values. We feel that it is way overdue for a completely different approach to the archaeology of Yosemite, an archaeology grounded in a Miwuk worldview. While this poster takes a Miwuk perspective, it does not want to imply that Yosemite belonged to the Miwuk. It was shared space, seen as sacred to a number of Native American peoples. This poster is a logical extension of earlier work by authors that laid out the broad-brush strokes of Miwuk Archaeology. This poster attempts to apply this archaeology to the specific location of Yosemite.

Challenges of Community-Based Heritage Work: Rights Holders, Stakeholders, and the Palimpsest Nature of the Archaeological Record

Preservation projects differentially affect rights holder and stakeholder communities. Heritage management professionals can try to accommodate such disparate communities through active collaboration, consultation, and accountability practices. Yet, compliance practices in the heritage profession, as well as the political-economic dynamics and legal architecture behind them, variously structure, constrain, and empower avenues for engagement with affected communities. This can result in a failure both to consider and pursue consultation and collaboration with certain ethical clients. This poster explores the complicated history of ownership, occupation, and heritage imaginaries in the development of site management practices for part of the S'edav Va'aki (formerly known as Pueblo Grande) Museum and Archaeological Park in Phoenix, Arizona. To overcome such challenges, heritage professionals must grapple with the totality of material remains and land-use histories and commit to active community engagement as an essential part of any project, rather than passive means of providing opportunities for consultation.

Preparing for the Great War: How Lidar and GPR Helped Locate Military Training Resources

To date, no comprehensive study examining World War I training had been available for the Department of Defense (DoD). In 2017, the Alabama National Guard partnered with the Mississippi National Guard and Panamerican Consultants on a DoD Legacy Resources Management Program project (CR 18-834) to synthesize existing research on the various types of World War I technology, tactics, and training, and the physical remnants of that history. The research team developed a survey tool to form a baseline inventory from all branches of DoD for both architectural and archaeological resources. Five case study locations were selected for further intensive research and the application of research questions; identifying the types of properties associated with training; and as a means to evaluate properties with reference to local, state, regional or national significance using the National Register of Historic Places Criteria. This paper will discuss the use of geophysical techniques to identify World War I resources for ground truthing.

Entering Chahk's Realm: Ancient Cave Use and Ritually Deposited Speleothems in Postclassic Architecture at Punta Laguna, Yucatán, Mexico

As rainwater seeps into caves over millions of years, it creates calcium carbonate formations known as speleothems. Ancient Maya peoples associated speleothems with the Earth Monster's fangs, the Serpent

Deity, and caves from which Chahk, the rain god, brings rain. As such, speleothems are animate embodiments of fertility and ritually pure water called *zuhuy ha*. In 2022, the Punta Laguna Archaeological project found 12 speleothems associated with a miniature masonry shrine at the site of Punta Laguna in Yucatán, Mexico. This paper presents the findings of the subsequent 2023 cave survey and mapping project. Additionally, the authors note three benefits of combining surface settlement and adjacent cave data to provide a more holistic understanding of ancient Maya peoples. Caves provide insight into the preliminary steps necessary for some surface rituals to occur. The transportation of speleothems between caves and built environments questions the traditional Western binaries that distinguish between natural and constructed landscapes. Lastly, a comparison of surface and subsurface activities suggests that the life force, or *ku* in Yucatec Mayan, of caves was dynamic and could both animate new spaces and create artificial caves within surface settlements.

Artificial Pools at Middle Preclassic Period Nixtun-Ch'ich', Petén, Guatemala

Recent work at Nixtun-Ch'ich', Petén, Guatemala has revealed several artificial ponds. Many of the pools occurred naturally but were enhanced through the construction of floors and walls and the manipulation of groundwater flow. Some of the pools contained large ritual deposits, including ceramic sherds, animal bones, greenstone objects, and roller stamps. However, others did not appear to have held such deposits. Two of the pools and at least 21 buildings, including three E-Groups and a triadic group, formed the site's east-to-west axis urbis. This row of constructions dominates the landscape of Nixtun-Ch'ich'. One of the two axial pools also borders an essential north-to-south avenue, which divides the city into quadrants along with the axis urbis. Thus, this pool, along with an adjacent temple, form the conceptual center of the city. Thus, the pools were critical to the sacred landscape of Nixtun-Ch'ich'.

Gruta do Gentio II: Data on the New Excavations and Isotopic Signals from the Site

The Gruta do Gentio II is an iconic site in the archaeology of Central Brazil because of its early occupation and rich excavation history. Situated in the interfluvial region of the Central Plateau, renewed investigation (after 35 years) offers new perspectives for the site. Data produced during the 1970s and 1980s revealed a wide variety of remains dating from the Early to the Terminal Holocene, found in association with human burials and rock art never seen in this area. In this presentation, new isotopic data from multiple systems using preserved tooth enamel and bone are presented with new AMS dates. The context of the human remains is reviewed and remains are situated against an isotopic baseline. Dates on preserved macrobotanical remains suggest that the site may be one of the oldest occupations to date in the lowlands of South America. The dates of the most recent burials are slightly before the arrival of the Europeans and show secondary burials. This suggests possible

correlations between ethnographic groups, enabling various correlations between archaeology, linguistics and ethnography, especially with groups of the Macro-Jê speaking people (e.g., Bororo).

In Process: The Development of an Automatic Deep-Learning Phytolith Analysis Workflow

In this paper we present our lab's latest results using deep-learning (DL) to identify and analyze phytoliths, robust inorganic silica "casts" of plant-cells. This use of DL technology will revolutionize phytolith analysis transforming the possibilities of this paleoethnobotanical method. Previous studies carried out in relation to the automated detection and classification of objects such as mounds or potsherds in images have demonstrated the potential of DL in the field of archaeology. Studies with pollen or cells have also shown DL's potential in bioarchaeology. Regarding phytoliths, previous works have shown the potential of automated classifications, but these studies focused on single-cell phytoliths. Our lab recently demonstrated that it is possible, using a pretrained DL model, to identify and classify multi-cell phytoliths, specifically three key grass husk multi-cell genera: wheat, barley, and oat. Focused on the wave pattern, the negative space between the phytoliths, our DL algorithms produced an identification accuracy of 93.68%. Building on this success, we have continued to develop our algorithms for Near Eastern plant taxa with positive results. This research ultimately aims to facilitate paleoenvironmental analyses at a landscape scale, making the prehistoric environment and human impacts in those environments visible at a scale otherwise not possible.

Bioarchaeological and Genetic Analysis of the Tzintzuntzan Ossuary

This poster will present the first results from the bioarchaeological analysis of more than half a ton of human skeletal remains recovered from the ossuary of the ancient city of Tzintzuntzan on the shores of Lake Patzcuaro in the state of Michoacán, Mexico. In addition to conventional morphological analysis, more than 100 individuals from this ossuary have been sampled for ancient DNA analyses. The results of these analyses provide new insights about the population structure of Tarascan-era west Mexico. Ancient DNA analysis has also provided richer insight into the individuals that were placed in the ossuary, as most of the bones were extremely fragmentary and therefore could not have age, sex, stature, or other biological markers assessed.

Archaeobotanical Remains from the Roman Harbor Vada Volaterrana

We present preliminary botanical data and interpretations from the ancient Roman harbor of Vada Volaterrana, located in the modern province of Livorno, Italy. The harbor was supported by a network of structures immediately surrounding the port at Vada's San Gaetano site. A 2015 GPR survey identified a series of rectangular buildings of unknown purpose in the southern sector of this site whose subsequent excavation produced several botanical and faunal remains. In 2019, a collaborative project between the University of Pisa and Troy University began investigating the cultural activity at San Gaetano's buildings I, L, and M. Archaeobotanical samples were collected during the 2017 to 2023 field seasons. Paired with architectural, artifactual, and zooarchaeological data, our botanical results help uncover shifts in both subsistence patterns and cultural enterprises at this building complex.

Digging Deeper into Tsenacommacah: A Temporal and Spatial Analysis of the Precontact Archaeological Record at Virginia's Flowerdew Hundred Plantation

Decades of archaeological work at Flowerdew Hundred, a tobacco plantation located in the Chesapeake region of Virginia, have focused primarily on its seventeenth-century occupation by English elites, indentured servants, and enslaved Africans. This research perspective has obfuscated the presence and impact of the Weanock (a Late Woodland people situated in the political territory of Tsenacommacah) and other precontact Native groups whose activities on the landscape are equally well-documented in the material record. Archaeological investigations exposed numerous precontact features and over 20,000 artifacts attesting to a substantial Native presence on the site over the millennia preceding European colonization. This poster characterizes Flowerdew's 10,000 years of indigenous habitation by enlisting artifact and contextual data from three sites catalogued comprehensively into the Digital Archaeological Archive of Comparative Slavery (www.daacs.org). We explore the spatial and temporal variation in over 16,200 lithic and 8,700 ceramic artifacts excavated from subsurface features and stratigraphic deposits distributed across the area of study. In doing so, we present a framework for understanding precontact activity areas and settlement patterns at Flowerdew Hundred and offer an essential baseline for further research into the complex social dynamics that continued to play out between Native peoples and the site's occupants after 1619.

Guidelines for Creating a Typology for Mass-Produced Nineteenth- and Twentieth-Century Burial Container Hardware
The analysis and historical study of burial container hardware and other mortuary artifacts is crucial in establishing a useful discourse between the multiple lines of evidence recorded and recovered in historical cemetery investigations. Exact identification of types and styles of burial container hardware is vital in defining the chronology of burial, which is necessary in situations where grave markers have been lost or moved from their original locations. In addition, variations in hardware styles and forms, as well as materials of manufacture, indirectly reflect aspects of socioeconomic class, status, and/or community involvement in the funeral process. A full understanding of the burial container hardware exposes aspects of the deepening

control of the professional funeral industry in the production and distribution of funeral merchandise during the late nineteenth and early twentieth centuries.

An Archaeologist and a Historian Walk into a Classroom . . .

During the fall 2022 semester, we co-taught a Special Topics in Anthropology course entitled the Culture and History of Food and Drink. From our respective academic backgrounds as a historian and an archaeologist, we provided students with both an anthropological and a historical perspective to examine how specific foods and beverages contributed to historical change over time, and how they affected, and continue to affect, human culture. Additionally, we considered how foods and drinks help to shape, convey, and retain cultural identity. Using food items such as grains, coffee, chocolate, and even Spam, students learned how these foods shaped and changed human history and culture. Purposely designed for a small class size, we strived for a classroom environment where students were actively engaged with the course materials in a variety of ways, including hands-on activities, guest lecturers, discussions of their own experiences with food, and of course, the sharing of food. As we prepare to teach the course again, we share our successes and lessons learned, in particular how we assessed students.

Compositional Analysis of Glass Beads from Missouri Historic Sites Using Laser Ablation–Inductively Coupled Plasma–Mass Spectrometry

Chemical analysis of glass beads using laser ablation–inductively coupled plasma–mass spectrometry (LA-ICP-MS) is a commonly applied technique in archaeometric analysis. The compositional study of glass and glass objects provides insight into the raw materials used, and their manufacturing processes and workshop origins. Among many early historic period North American contexts, they also provide insight into the chronology of cross-cultural relationships between Indigenous peoples and European settlers as glass beads were a commonly traded item. This poster will present preliminary results from the compositional analysis of an assemblage of monochrome and polychrome glass beads and bead fragments from Missouri historic sites, using LA-ICP-MS.

Resources, Technological Traditions, and Social Networks: A Study of Late Neolithic Cooking Vessels in the Lake Taihu Region

During the Songze cultural period, there were two distinct technological pathways for the production of pottery cooking vessels, including *Ding* (tripod) and *Yan* (steamer), used in the vicinity of Lake Taihu. In areas like southern Jiangsu, Shanghai, and Jiaying, plant debris was commonly mixed with clay to create fiber-tempered vessels. In contrast, areas like Anji and Yuhang primarily used mineral tempers. This division in culture and technology can be attributed to geographical separation. During the mid-Holocene period, a significant marine transgression occurred, possibly connecting Lake Taihu to the Qiantang River near Linping and forming a bay. While the bay gradually filled with sediment by the Songze cultural period, it is plausible that residual water bodies remained. These rivers and lakes acted as barriers, separating the hilly region of Tianmu Mountain from the main Songze cultural area in the southeast and northeast of Lake Taihu. Consequently, the exchange of materials and interactions of social groups was impeded, leading to the gradual emergence of distinct social networks in each region. As a result, communities adapted to their specific environments and developed unique technological traditions of tempers. This will serve as crucial clues for interpreting the formation process of the Liangzhu culture.

Community-Defined Heritage and Uncertain Futures

This presentation considers heritage as defined by members of stakeholder communities that have experienced a history of displacement as well as the pressures of disaster capitalism/neoliberal development. It explores the value of community-defined concepts of heritage to the process of preserving heritage as defined by scientific and academic communities. How does a community conceptualize the past and cultural heritage when confronted with significant environmental change? What strategies are being practiced on individual and community levels to protect places and activities that support the transmission of cultural knowledge? As specialists consider the future of threatened heritage sites and identify strategies for preservation, how might these localized, community-driven actions affect their decision-making? How is our work as scientists and researchers supporting the heritage interests of threatened communities? While archaeologists and other researchers are concerned with issues of preservation in the face of development and climate change, local communities may feel a greater urgency to protect their day-to-day lives. This qualitative work was informed by interviews with members of communities of relevance.

Serving the State under Surveillance: Material Correlates of the Watched on an Inka Royal Estate (Cusco, Peru)

Excavations at the fifteenth- to sixteenth-century Inka royal estate installation of Cheqoq (Maras, Cusco) reveal domestic spaces likely inhabited by both the watched (the retainers to the nobility) and the watchers (the intermediate elites overseeing laborers). Typical interpretations of the presence/absence of luxury goods cannot be relied on in the complex settings in which surveillance disciplined state subjects into imperial purposes and imperial values. With knowledge of the laboring conditions of the residents of Cheqoq (through archival sources and more), one can contextualize the presence of certain kinds of goods as more than mere wealth. I describe the possible material correlates of an overseer or administrator household at this royal estate. I also detail the evidence for being watched found in retainer laborer households, including misfired imperial ceramic vessels from Cheqoq's pottery workshop. I ask whether the "toting effect," in which high-status goods make their way into households not otherwise experiencing the liberties of a high-status life, might be leading to misinterpretation. The material record of being watched while living under coercive labor conditions offers a view of daily experiences in exploitative settings.

Popularización: Aspectos favorables y negativos para la meliponicultura del siglo XXI

La meliponicultura en México, así como en gran parte del mundo, ha experimentado un creciente interés y

popularidad. Un mayor número de personas y grupos se están involucrando en la actividad lo que ha llevado a su expansión tanto de las regiones donde se practica, como en el número de especies que se están utilizando. Han surgido nuevos factores que deber ser tomados en cuenta para evitar impactos negativos sobre la biodiversidad y sustentabilidad de la actividad. En esta presentación, expongo algunos de los beneficios que la creciente popularidad de las abejas sin guijón y sus productos han traído para la conservación de la actividad y al mismo tiempo se discuten los posibles riesgos que su expansión acelerada puede traer para su mantenimiento. Es importante tomar conciencia y desarrollar una planificación conjunta entre sociedad, productores y tomadores de decisiones, sustentada en evidencias científicas, para evitar que en aras de la conservación se destruya y pierdan recursos invaluableles.

Temporalities of Middle Bronze Age Cemeteries in Transylvania

The Middle Bronze Age in Transylvania was a time of rapid population growth and centralization, the emergence of shared regional identities mediated through mortuary practices, and the institutionalization of large-scale trade and exchange networks that moved metal and salt from this resource-rich area across the Carpathian Mountains and Basin. Communities established cemeteries where they buried urns filled with cremated remains. This poster presents the results of new radiocarbon dating and Bayesian modeling of mortuary activity at the two largest known cemeteries: Sebeş-Între Răstoace and Oarda de Jos/Limba-Şeşul Orzii. These new data demonstrate that mortuary activity at these sites occurred over a short period of time, which has consequences for our understanding contemporaneous variation in burial treatments, open access to burial rites, and processes of site abandonment during this important era of social, political, and economic transformation.

Archaeologies of Flow in the Southern Jequetepeque: The Organization of Infrastructure, Irrigation, and Roads

Canoñillo probablemente derivó su importancia inicial de su posición a lo largo de los principales corredores de tránsito que conectaban la costa y la sierra. Su ubicación en el margen del desierto no se presta fácilmente al asentamiento. El río Jequetepeque se encuentra a 8-10 km. Los pequeños lagos cercanos no pudieron sustentar una gran población agrícola y no podemos estar seguros de su antigüedad. Las dunas de arena masivas se arrastran a través de la pampa y las quebradas frecuentemente descargan inundaciones repentinas. Para establecer una ruta viable, los habitantes de Canoñillo tuvieron que adaptar su entorno. Una elección de ubicación "natural" requirió un enorme esfuerzo humano y una estrategia inteligente para crear y mantener. Tales estrategias cambiaron con el tiempo, en relación con los cambios ambientales, económicos y sociopolíticos. Dada los "seres de la tierra" en el mundo andino, la infraestructura de Canoñillo materializa así nociones de gobernanza. En este artículo discutimos investigaciones preliminares sobre los caminos, canales y sistemas de campo, junto con muros diseñados para canalizar el agua que fluye y

la arena que sopla. Nuestros datos indican dos períodos principales de expansión agrícola, en el Formativo tardío y en el Intermedio Tardío temprano.

Fire Lookout Viewsheds in the Malheur National Forest

Fire lookout towers are early twentieth-century structures built by the US Forest Service for the purpose of early wildfire detection. As the Forest Service moves away from staffing fire lookout towers, some call for the decommissioning and tearing down these structures, including within the Malheur National Forest. However, these historic towers still serve a purpose. Viewshed analysis demonstrates that the combined viewshed of several lookout towers covers more than what a single person alone can see. Therefore, lookouts are an invaluable resource as wildfire danger increases throughout eastern Oregon. Although fire lookout towers are historic structures, they continue to serve a crucial role in early fire detection within the Malheur and thus should be protected and maintained.

Islands of Ideology: Exploring Group Formation in Hawai'i and Sāmoa

Social consent was essential to promote cooperation and group identity. Because of disciplinary attention to top-down processes of power accumulation and political classification, how social notions of social consent in middle-range societies were modified and diversified is poorly understood. The societies of Polynesia provide an opportunity to better understand the circumstances under which different power strategies were employed to build larger-scale communities within divergent ideological frameworks. Highly variable systems of leadership developed in the region at the intersection of two notions, one associated with the sacred and exclusive nature of leaders and the other associated with populism and consensus building. This paper will examine the archaeological signatures of these processes using Hawai'i and Sāmoa. These societies contrast markedly, occupying different subregions of Polynesia and possessing fundamentally different political structures by the eighteenth century. At the same time, leaders in Hawai'i and Sāmoa employed similar notions of mana to legitimize their actions and position. The archaeological record of both areas allows exploration of inequality, concessions, and public works to better understand how such variability in political structure operated and how the ideological framework of these places was modified to meet the needs of both leaders and communities.

Plants Are Friends and Food: Reinterpreting Fort Ancient Plant Use through Indigenous Ontologies and Traditional Ecological Knowledge

Paleoethnobotanical analyses over the past several decades have shed light on the subsistence practices, agricultural strategies, and environmental interactions of members of the Fort Ancient culture, an Indigenous

society that thrived in the Ohio Valley from the eleventh to the eighteenth centuries. Largely absent from these conversations, however, are discussions of non-comestible uses of plants or considerations of traditional ecological knowledge (TEK). By combining different sources of knowledge, a more holistic view of plant usage by Fort Ancient peoples may be established—one that allows us to better understand relationships between people and plants in the past and present. In this paper, we synthesize the existing literature on Fort Ancient paleoethnobotany and reinterpret patterns that historically have been more grounded in human behavioral ecology approaches of dietary choices and resource management by drawing on perspectives from Native ethnobotanists. We conclude with our goals for a future community-based research program that marshals paleoethnobotanical analysis in the Fort Ancient region in relation to contemporary food sovereignty efforts and ecological reconstructions that have the potential to inform modern conservation protocols.

Teaching with Collections: The Power of Object-Based Pedagogies

Collection-based pedagogies present an exciting platform for active, inquiry-based learning and advancing the goals of equitable teaching. They engage interactive, critical, reflective, creative, affective, and other approaches that anchor learning and build community in the tangible, physical presence of objects. This presentation is about teaching with, not strictly about, artifacts and material culture. There is a range of curricular possibilities for object-based teaching: collections can serve an illustrative role where connections between course material and objects are content-related. Collections can also play an effective role in developing or strengthening essential and transferable skills, like critical thinking and evidentiary reasoning, and help cultivate dispositions or habits of mind, such as patience, deep attention, empathy, grappling with ambiguity, and accepting multiple perspectives. Collections here are expansively conceived, including artifacts, ethnographic or historic objects, and fine art. A nineteenth-century landscape painting can activate a conversation about settler expansion and Indigenous erasure, for example, while a comparison of contemporary and precontact Mexican ceramics can reveal stories of survivance and adaptation.

Open Ocean Fisheries of Indigenous California: Origins and Technological Inferences

Pelagic fishing entails substantial risks and investments in fishing equipment, including sturdy boats, paddles, hooks, lines, nets, and spears. In the context of Indigenous California, this fishing practice has been linked to population growth and the evolution of fishing technologies over the past 1,500 years. However, in local environments such as Santa Catalina Island, communities engaged in open ocean fishing and successfully captured large-bodied fish, like tuna, several millennia earlier in history. Through an interdisciplinary approach encompassing zooarchaeology, geographic information systems (GIS), historical documents, ethnographic accounts, and contemporary fishery data, this study examines global tuna fishing methods. The aim is to gain deeper insights into the technologies and strategies utilized by Indigenous islanders. By employing osteometry, I estimate body sizes to better comprehend fishing capabilities before the advent of sewn-plank canoes and single-piece shell fishhooks. The results demonstrate that the earliest evidence for large-bodied, pelagic fishing began on the southern Channel Islands ca. 5,000 years ago and gives new insight on Indigenous watercrafts and fishing practices.

[156]*Origins and Tenacity of Myth: Part I—Archaeology*

“Origins and Tenacity of Myth” is a comprehensive study of Pecos River–style (PRS) pictographs in the Lower Pecos Canyonlands of Texas funded by the National Endowment for the Humanities. It is a collaborative project between Texas State University and Shumla Archaeological Center. This presentation addresses the archaeological component of the project and two of the study’s research questions: (1) Are PRS murals single compositions or a random collection of images? (2) Did the artists follow strict painting conventions in their creation? To answer these questions, we used digital microscopy to systematically analyze intersecting paint layers in three complex PRS rock art panels. We graphically diagrammed the microscopy results using Harris Matrix Composer software to establish the murals’ stratigraphy and then used Adobe Photoshop to replicate the paint sequence through digital, layered illustrations of each rock art panel. The results demonstrate that the paint application order of the murals was rule-governed and that they were rendered during a single painting event. Further, recent radiocarbon ages for PRS demonstrate that artists strictly adhered to this paint application sequence in mural production for at least 3,500 years between 5500 and 2000 cal BP.

Ragsdale, Corey (Southern Illinois University, Edwardsville)**[11]***Discussant***[80]***Chair***Ragsdale, Corey (Southern Illinois University, Edwardsville)****[80]***Population Replacement and Radiation and the Decline of the Great Moravian State*

Great Moravia is credited by historians as the first Slavic state, existing briefly in the ninth and early tenth

centuries. Internal disputes, Magyar incursions, conflicts with the Frankish Empire, and climate change events contributed to the decline and demise of the Great Moravian state. Although these events are supported by archaeological and historical records, the fate of the people and potential changes to population structures throughout Moravia is not well understood. This study examines potential population replacement events corresponding with the demise of the Great Moravian state from neighboring areas, as well as potential destinations of displaced people from the center of Mikulčice. Dental morphological data from ninth- to thirteenth-century sites throughout Moravia, Bohemia, Poland, Hungary, and Germany are compared using biological distance analysis. Results support a major shift in the biological population structures of settlements in Moravia after the tenth century, likely as a result of colonization from modern-day Hungary and Germany. Additionally, the results support a multidirectional radiation of migrants from Mikulčice to Hungary and Bohemia. This study sheds light on the nature of migration events to and from an area within Central Europe that experiences a major cultural shift coinciding with the decline of a state.

Exploring the Orange Period in Southern Florida's Inland Tree Islands

Orange period (6000–3000 BP) communities in Florida have been defined by the manufacture of fiber-tempered ceramics within eastern Florida and have a well-defined chronology. Orange period communities engaged physically with the landscape through shell and sand terraforming and community mobility. Contrastingly, the Archaic period in south Florida is not adequately defined in chronology nor material culture with the general consensus that fiber-tempered Orange pottery has not been well recorded near Lake Okeechobee. Most of the investigative work around tree islands in southern Florida, identifies Archaic sites as discrete and temporary camp locations, potentially obscuring interregional mobility and habitation of these communities. Recent wetland restoration conducted by the USDA-NRCS identified several freshwater hammock sites with fiber-tempered Orange ware ceramics within southeastern Highlands County. We have been able to identify and preserve a unique arrangement of Orange period sites within a large seasonally wet landscape not previously investigated archaeologically. Historic maps and aerial imagery, high-definition lidar-derived DEM maps, and twentieth-century landscape-use records are used to explore and preserve a large and understudied archaeological landscape. This can help archaeologists to expand regional chronologies of under researched south-central Archaic Floridians.

The Legacy of the Destruction of Juukan Gorge in Australia

On the 24th of May 2020, mining company Rio Tinto destroyed significant rockshelters at Juukan Gorge, in the western Hamersley Range of Western Australia's Pilbara Region, as part of its iron ore operations. This event had devastating consequences for the Puutu Kunti Kurrama People, who have now lost one of their most important cultural sites. The destruction also had an impact on the heritage and mining industry in Western Australia. The fallout from the blast sent shockwaves around the world. The event attracted global media attention, and condemnation from across the political spectrum. Many asked the question "how could this happen?" The answer was apparent to those of us who operate within the framework of Western Australia's outdated and industry-favoring heritage legislation. Everything from government policy to industry practice and (sometimes) the representation of Indigenous representative bodies was predicated on the assumption that an approval to impact a site will pass without issue, regardless of significance—as state priorities for mining benefits

tended to trump heritage protection. Following the destruction of Juukan Gorge, we talk about the fallout, both from the perspective of PKK Traditional Owners, and from a heritage management perspective.

Engaged Bioarchaeology: Centering Descendant Voices in the Excavations of a Historic Mission Church in Belen, New Mexico

An engaged bioarchaeological project includes the Indigenous or descendant community from the beginning of the project, centers their questions, and brings forward their knowledge of the past to create more nuanced conversations about their ancestors. Shifting the focus from solely the goals of the anthropologist to a shared vision of recovering the past is a first step in decolonizing bioarchaeological practices. Our work, conducted at the request of descendant community members, aims to recover the lost history of the founding community of Belen, NM. Excavations revealed the location of the original mission church and resulted in the exhumation of some ancestors buried within and around the church. Our research intertwines descendants' questions with bioarchaeological analyses to offer a deeper understanding of history and lived experiences in a frontier town, the intersections of sociopolitical processes of colonial conquest, and the erasure and resiliency of a community that continues to thrive into the twenty-first century. By engaging with these multiple lines of inquiry, we encounter a broader framework of restorative justice for those marginalized, assimilated, and vanished, while working toward recovery and reinstatement through the testimony of histories from both the ancestors and descendants that have been silenced through colonial practices.

Getting Creative with Photogrammetry: Adventures in Dos Mangas, Ecuador

Photogrammetry, the science of converting 2D images into immersive 3D models, traditionally adheres to a strict set of guidelines and specialized tools. However, this poster explores the spirited realm of photogrammetry with rule bending and limits to achieve success in Dos Mangas, Ecuador. In this resource-constrained setting, innovators defied convention, proving that unconventional approaches can yield great results. Dos Mangas, known for its limited space and technology, became an unlikely playground for

Photogrammetry. Armed with creativity rather than high-end equipment, demonstrated that the essence of photogrammetry lies not only in sophisticated tools but also in adaptability and creative thinking.

Metamorphoses of Human and Nonhuman Agents within the Shaft Tomb Burials in Ancient West Mexico

This paper will contextualize the diverse range of materials found in several shaft tombs throughout West Mexico. I argue that there are examples of ontological ecologies connected to animals and the seasons by understanding the connections between the landscape and the materials found in the tombs. I explore how the metamorphoses of several animals such as frogs and flies, and the contributions they play in the landscape relate to the mortuary practices of the tombs. I believe that human and nonhuman agents, such as animals and plants, are entangled in a relationship of consumption and transference and that the people of this region were intentional with establishing a space where an infinite cycle of giving and taking was established. By contextualizing materials associated with mortuary practices, iconography, ethnographies, and Mesoamerican codices, we can understand why the specific materials in the shaft tombs were built in the first place, which can also get us closer to understanding their broader networks.

Changing Attitudes at Chavín de Huántar (Peru): Archaeology, Heritage, and Landslides

This ethnographic study examines the relationship between the local people of Chavín de Huántar, Peru, and their sense of identity as Chavínos in relation to the national museum, the monument, and the 2022 collapse of the mountain peak Shallapa. Through face-to-face interviews with local townspeople, local workers on two different archaeological digs, foreign archaeologists, and business owners, the study delves into the various opinions of the Chavín National Museum, the memories of the role the Chavín Archaeological Site played in the past, the amount of pride the monument brings now to Chavínos, and the impact of the fall of Shallapa. Using an anthropological lens, this study demonstrates the evolution of the perspective of archaeological sites in a growing town and its impact on the local population.

An Integrated Approach to Urban and Artifact Analysis of Residential Buildings in Late Postclassic Guiengola, Tehuantepec, Oaxaca

This paper explores ethnogenesis and cultural hybridity by analyzing survey and lidar data in 72 buildings from the Guiengola archaeological site in Oaxaca, Mexico. Specifically, it examines the Zapotec people's domestic construction and pottery assemblages in four areas of this fortified site during the Late Postclassic period (AD 1250–1521). By analyzing the various configurations of domestic buildings on the site, it was possible to understand how the city's settlement evolved over a period of 100 years. Additionally, this study uncovers

the motivations behind the Zapotecs' decisions to keep using, adopting, or creating new pottery styles and how their domestic practices were affected in their new coastal surroundings. The findings reveal the integration between the incoming Zapotec settlers and existing local traditions. This research challenges traditional notions of cultural boundaries and highlights the complexities of cultural exchange. It emphasizes the importance of interdisciplinary approaches in understanding cultural adaptation and assimilation. Ultimately, this research provides evidence of cultural hybridity in the archaeological record and paves the way for further investigations into the mechanisms behind it.

Xanamus and Petroglyphs: A Study of the Construction Techniques of the Tzintzuntzan Yácata Lining System

In the prehispanic city of Tzintzuntzan there are architectural elements that form the main ceremonial center of the last capital of the Tarascan Empire. The best known are the *yácatas*, monumental pyramids of a mixed plan built on the Great Platform, characteristics of the Purhépecha culture. Used by the Tarascan builders as a cladding system, the so-called *xanamus* are unique architectural elements due to their singularities and their arrangement on the exterior walls of the *yácatas*. The present work intends to address the *xanamu* as a characteristic cladding system of Tzintzuntzan architecture. Therefore, the objective is, firstly, to situate the *xanamu* in its constructive function within the Tzintzuntzan *yácatas*. Secondly, their intrinsic characteristics, their implementation on the walls of the *yácatas*, the process by which they were carved, and the possible tools used by the Purhépecha builders will be presented. Finally, a specific analysis of the *xanamus* petroglyphs will allow us to understand the motifs used and the techniques used to carve these engraved images.

Starch Spherulites: What We Know and What Is Next for This Promising New Method of Paleoethnobotanical Analysis

Starch spherulites are a promising new paleoethnobotanical discovery. Well-studied in food sciences, starch spherulites form when amylose from plant starch recrystallizes in spherulitic morphology. This requires processing by humans (mainly through heat, although pH impacts this dynamic) in an aqueous environment. The identification of starch spherulites in the archaeological record opens an exciting new line of research into baking, boiling, and other forms of food processing deep into prehistory. With several papers now published, including their initial description, where they were experimentally formed using traditional Maya maize processing techniques of nixtamalization (Johnson and Marston 2020), and their first archaeological identification, at the 23,000-year-old site of Ohalo II, Israel (Ramsey and Nadel 2021), followed by their discovery at a Maya site (Santini et al. 2022) and their recent recovery from early Pottery Neolithic ceramics in the Southern Levant (Ramsey n.d.), it is clear that starch spherulites will be found in many contexts and regions around the world. Accordingly, there is a need to outline best practices and begin a broader discussion with other interested paleoethnobotanists to establish a solid methodological foundation. To that end, this paper summarizes our current understandings of spherulite formation and preservation and outlines future research directions.

Movers or Moved? An Iso-histological Approach to the Postmortem Movement of Prehispanic Maya Human Remains
Death was not the end for many members of prehispanic Maya communities (250 BC–1560 AD). Indeed, the inclusion of human remains in structures that continued to function indicates that the dead (or their significance to the living) maintained social if not biological vitality. Although there is also ample evidence that Maya people re-entered burial contexts in the past, displacing human remains in the process, researchers assume that isotopically nonlocal people from such contexts were movers during life. The possibility that they were moved after death remains understudied yet has significant implications for understanding past migration processes. The innovative iso-histological approach therefore integrates isotopic and histological analysis to distinguish between Maya movers during life and those moved after death. This will refine current isotopic interpretations of Maya migration processes in the past, as the sociocultural motivations underpinning each of these behaviors differed. This approach will also shed light on body treatments among the prehispanic Maya that would have facilitated the movement of human remains (e.g., excarnation, bundling). Importantly, this research is not limited to Maya archaeology but offers a framework for applying the iso-histological approach for assessing the posthumous movement of human remains in other archaeological and forensic contexts.

Intervening Impersistence on the St. Johns River, Florida

The shell mounds of the St. Johns River basin in northeast Florida are among some of the longest-lived places in North America. The repeated occupation over 9,000 years in duration attests to the attention paid to these places through depositions and encounters. Depositional histories reveal how places grounded histories by enabling compendia of biographies, things, times, and otherworldly powers to be encountered in place. Yet, close attention to the contexts of inhabitation reveals tensions and anxieties when places were left alone and then returned to. These tensions speak to broader anxieties regarding the inherent impersistence of places, and the need to intervene on their behalf to ensure they are returned to the broader landscape.

Contributions of the Proyecto Santa Maria (PSM) to the Prehistory of Central Pacific Panama and Beyond

The PSM was a multidisciplinary project in Central Pacific Panama with the major fieldwork carried out during the years 1981 through 1986. The goals of the proposed research were to identify the relationships between settlement types and subsistence strategies in the range of environmental zones found in the Rio Santa Maria watershed from the first entry of humans into the region until the appearance of permanent large agricultural villages. In order to record a representative sample of sites, random transects (500 m wide) were selected for survey in each of the five environmental regions in the watershed stretching from the coast to the continental divide. Additional purposive surveys were made along coastal shorelines, around lakes and in rockshelters. During the course of the project 430 of the 510 sites documented were found in the transects. The results have challenged traditional views about the peopling of the region and shed light on the early development of agriculture and complex societies in the Americas. This paper focuses on the impacts that PSM research has made on the prehistory of Central Pacific Panama, the Isthmo-Colombian region and the American tropics in general.

There's an App for That: Cost-Effectiveness of Lidar/Photogrammetry Smart Phone Applications for Virtual Osteology

The use of three-dimensional (3D) models for skeletal analysis has become common practice for osteological research. However, current methods for obtaining the 3D models are either too costly, such as computer tomography (CT), or require time-consuming postprocessing such as scanners or cameras. Recent advances in technology have resulted in the development of affordable 3D image-capturing methods using smartphone applications. Structure-from-motion (SfM) photogrammetry and lidar software applications such as Scaniverse and Polycam, coupled with the increased quality of high-resolution cameras in smartphones can provide an alternative to conventional methods of capturing osteological data. The study involves cranial 3D models from the Maxwell Museum of Anthropology documented forensic collection created with an iPhone using the two applications. Existing CT scans and 3D models from a surface scanner will also be included in the study. A suite of landmark data and craniometric measurements will be collected from each 3D model and compared against physical measurements using statistical analysis to determine the degree of accuracy of each model. The results will offer a low-cost alternative method of documenting skeletal collections in places where a scanner or CT imaging is not an option such as in situ archaeological contexts or remote osteological repositories.

Using Geospatial Methods to Identify Intact Buried Mounds at the Mitchell Site, Illinois

The Mitchell site is a major Mississippian (1050–1400 CE) mound center located roughly 10 km north of Cahokia Mounds, Illinois, the largest mound center in North America. At a minimum, Mitchell consisted of 11 earthen mounds; however, only one mound is visible today. In 1960, salvage investigations, including limited mound excavations and widespread trenching across other areas of the Mitchell site, were conducted in advance of new interstate (I-270) construction. As this work occurred prior to the National Historic Preservation Act, several of the mounds were bulldozed and utilized for highway construction fill, and three were left partially intact but were buried under highway cone fill. In advance of current Illinois Department of Transportation (IDOT) proposed lane widening of I-270, the Illinois State Archaeological Survey (ISAS) had the opportunity to review notes and materials from the 1960s salvage excavations and conduct new geospatial investigations to determine the extent of remaining intact mound deposits. Employing minimally invasive terrestrial sediment coring, lidar analysis, and historic image review, we determined intact mound deposits are likely preserved underneath modern fill at several documented mound locations. This recent work allows for more informed preservation and avoidance planning to protect the mounds from further destruction.

A Multisite Assessment of Mobility in Coastal and Interior Nicaragua through $^{87}\text{Sr}/^{86}\text{Sr}$ Analysis

Migration and mobility have long been topics of interest in Nicaraguan prehistory, but research addressing these inquiries in the Greater Nicoya has relied primarily on linguistic analyses and the comparison of artifact typologies. Archaeological science is increasingly benefiting from the use of strontium isotope analysis as a proxy for mobility and migration. Here, we present the most thorough strontium isotope analysis of human remains and environmental baseline samples in Nicaragua to date. We analyzed strontium isotope ratios of 50 human teeth, primarily first molars, from 11 archaeological sites in four regions along Nicaragua's Pacific coast and interior. We identified isotopic outliers and compared them to a strontium isoscape we constructed through the analysis of 40 vegetation samples along the coast. While the majority of individuals we analyzed appear to match their local signature, we identified several potential immigrants and discuss their origins in this presentation. Our study offers a new approach to consider mobility in this historically understudied region. ***This presentation contains images of human remains.

Obsidian Networks of the Southern Yukon-Alaska Borderlands

The archaeological record of Eastern Beringia (Alaska and Yukon) plays an important role in understanding global human dispersals and settlement and is a proving ground for testing ideas about high-latitude hunter-gatherer land use, technology, and socioeconomic interaction. Obsidian provenance studies provide an excellent means to address these issues. More than 60 geochemically distinct obsidian groups have been recognized throughout Eastern Beringia. Three of the most important sources—Wiki Peak, Mount Edziza, and Hoodoo Mountain—are confined within or are adjacent to the Yukon-Alaska borderlands and provide insights into people's movements and interactions across major drainage systems and ecoregions through time. We describe these obsidian sources and patterns in their use based primarily on the stratified and well-dated record from the Little John site, which was first occupied ca. 14 Kya. We share insights from both Little John and the regional small site record to suggest (1) a rapid pace of landscape learning and identification of obsidian sources upon initial human colonization, (2) the strong influence raw material package size exerts on obsidian distribution, and (3) effects of volcanic eruptions on raw material procurement and transport.

Using Experimental Archaeology to Engage the Public in Arkansas

One aspect of the Arkansas Archeological Survey's mission is "to share what we learn with the people of Arkansas." But how do we share and explain larger concepts such as innovation and technique changes in hunting or gardening when all we have archaeologically is a broken spearpoint or a resharpening flake from a hoe blade? Experimental archaeology and replication of tools has been essential to answering this question in Arkansas. People will stop at a table showing replica tools almost immediately upon seeing it and most people are excited when offered the opportunity to actually try out the tool. After a couple of attempts at throwing a spear with an atlatl or using a pump drill, engagement and questions abound. When these activities are

done in small groups, constructivist, collaborative, and reflective pedagogical approaches are utilized. Participants have experiences that lend themselves to better understanding how the technologies work and bring these up to help other participants understand things as well. Students and members of the public come away from engagement with experimental archaeology and replica tools with an appreciation of the skill and innovation it took to design those technologies and with more respect for Native American ingenuity.

Diachronic Analysis of Sequential Enamel Stable Isotope Analysis in Human Populations

The agricultural-demographic transition highlights a positive correlation between increasing consumption of agricultural products and population. However, this correlation varies regionally. In Eurasia, agriculture and population growth coincide with increasing sedentism hypothesized to drive population change. In the Amazon, agriculture and sedentism likely preceded population growth. Modeling suggests population shifts are dependent on increasing fertility, carrying capacity, and decreasing mortality. We explore the relationship between age-at-weaning as a proxy for inter-birth interval and relative population change in the neotropics during the transition to agriculture. If inter-birth interval decreases through time, this may indicate increased fitness and fertility. We present preliminary results of sequential-enamel sampling of phosphate by laser-ablation to create community-level diachronic sets of oxygen ($\delta^{18}\text{O}$) and carbon ($\delta^{13}\text{C}$) values as a proxy for early childhood diet using multi-tooth dental samples of adult individuals from two rockshelter sites in modern-day Belize. A relative change in $\delta^{13}\text{C}$ sample values correlated to early life stages indicates the introduction of solid foods. A relative change in $\delta^{18}\text{O}$ sample values indicates weaning cessation. An age-at-weaning estimate based on isotopic changes relative to dental mineralization age is calculated for each individual. Changes in the timing of weaning may indicate a mechanism for population change.

The Use of Legacy Collections as Education Opportunities for Undergraduate Student Internships

The Center for Archaeological Research (CAR) at the University of Texas, San Antonio (UTSA) offers semester long internships to undergraduate students from UTSA's Anthropology Department. The internship program offers students an opportunity to gain hands-on experience in laboratory methods, independent research, curation standards, and collection management. Students work on CAR's legacy collections—i.e.,

older projects in need of rehabilitation—under the supervision of archaeological professionals. This work is mutually beneficial, resulting in rehabilitated collections for CAR and experience with real-world applications, career development, and skill acquisition for the students. Based on individual interest, each student completes a final project involving a rehabilitated collection. This poster provides summaries and displays data gathered by CAR student interns from projects completed on the Baker Cave collection.

Beyond the Fields: Lenape Domesticated Landscapes in the Minisink National Historic Landmark

Discussions of Indigenous agricultural systems in the northeastern United States have focused almost exclusively on the cultivation of maize, beans, and squash. General models focus on the cultivation of these plants in ridged fields or fields of small hillocks. While the fields and crops grown within them are important, I argue they are only one part of a larger domesticated landscape. Using data from the Minisink National Historic Landmark, I focus on how the Lenape created a domesticated landscape into which agricultural fields were integrated and became central too. I argue Lenape agricultural systems probably have their root in agroforestry practices focused on enhancing mast nut production that originated during the Late Archaic. Drawing on paleoethnobotanical and landscape data, I argue that Lenape agricultural systems were not focused solely on domesticated plants as traditionally defined but also included the encouragement, maintenance, and cultivation of disturbance adapted species growing on the edge of their fields. In particular, I focus on the cultivation of ruderal plants and fleshy fruits. I argue that to better understand the complexity and utility of Indigenous agricultural systems in the Northeast, the full extent of how Indigenous people domesticated their landscapes must be realized.

[98]

Repatriation and a Biological Profile of Indigenous Remains of West Texas

The subject of this study is an Indigenous precolonial individual from southwest Texas. The individual was obtained from a private collector and is dated to the Archaic. With tribal approval and support an emphasis has been made to establish an ancestral profile with the end goal of repatriation. To facilitate this, the Indigenous individuals in the region have requested a biological profile to gain insight into the individual's life. Analyses of mitochondrial DNA haplogroups and stable isotopes $\delta^{15}\text{N}$ and $\delta^{13}\text{C}$ are included in this process. $\delta^{15}\text{N}$ and $\delta^{13}\text{C}$ isotopes result from the population's diet and crops that were relied on. Mitochondrial DNA haplogroups give insight into population relationships and potentially establish ancestral ties with modern populations today. With permission, consent, and transparency the haplogroup is compared with modern Indigenous individuals of west Texas. Repatriation is the main goal of analyses while confronting the handling and trafficking in today's world of Indigenous ancestors obtained from private collectors and other establishments.

The Role of Lactating Mothers in High-Elevation Seasonal Occupational Durations in the Rocky Mountains

The study of high-elevation archaeology in the Rocky Mountains continues to enhance our understanding of the seasonal rounds of precontact hunter-gatherers in the region. Yet the specific seasonality and quantity of time Indigenous people spent at high elevations each year is unclear. Ethnographically, we know that hunter-gatherers in general, and Native Americans in particular, spent summer months in extended family groups. Because of the demographics of hunter-gatherers, and the tendency of hunter-gatherer women to breastfeed each child for 3–4 years, most family groups would have contained a lactating mother. Interdisciplinary

medical and anthropological research indicates that lactation is physically expensive, demanding additional calories, vitamins, and nutrients, while high-elevation environments increase demands on the body through hypoxia, cold temperatures, and difficult topography. This paper hypothesizes that, if there is a physiological limit to how much time a family group could spend hunting and gathering at high elevations, the needs of the lactating mother would provide that limit. Additionally, I hypothesize that her needs would direct the kinds of resource procurement the group would prioritize.

Provenance and 3D Geometric Morphometry of a Large Obsidian Biface Cache from Central Oregon: Preliminary Perspectives

Caches of stone tools offer unique opportunities to study lithic technology crafting at extremely short temporal scales. We created digital 3D models of 378 obsidian bifaces from a cache located in central Oregon (35DS751) and submitted them for X-ray fluorescence and geometric lithic morphometric research (GLiMR) analyses. The raw materials from this cache were from local eruptive sources. In this poster, we explore ways in which 3D scanning and geometric morphometry can be used to extend traditional lithic tool studies of technological design and lithic production sequences.

[70]

Exploring the Question of Heterarchy versus Hierarchy at Urcuquí, Ecuador

Heterarchical and hierarchical power distributions in a society affect the distribution of labor within that society. In a heterarchical society, the labor is generally reciprocal community labor used to maintain a cooperative relationship despite distance between lived settlements (Scaffidi 2020), whereas hierarchical societies will have labor distributed in higher amounts to those with the least amount of power and vice versa (Crumley 1979). Urcuquí is a population located northeast of Ibarra, in the northern highlands of Ecuador, occupied from AD 500 to 1500 and was commonly thought to be a part of the chiefdom of Otavalo (Salomon 1986). Labor was an important part of the sustainability of Urcuquí, and previous research has noted collective labor in the region in earlier time periods (Sharp 2020). Skeletal analysis of human remains for osteoarthritis, enthesal changes, linear enamel hypoplasia, and paleopathological lesions associated with infectious disease allow insight into past patterns of labor and demonstrate how labor was organized at Urcuquí. In this poster, we will present the patterns of activity and labor based on skeletal analyses of 33 burials from Urcuquí to investigate power distributions for this society. Photos of human remains.

Who's "Public"? Whose "Outreach"?

Within CRM, completing public outreach as part of a mitigation program is common practice. Public outreach is an important mechanism to engage the public, but generally centers on archaeologists educating the mainstream public through books, fliers, signs, and videos. For the CDOT 550/I60 Interchange Project, the consulting parties agreed that appropriate mitigation should include a combination of archaeological data recovery, tribal engagement, and the production of a film. Ultimately, mitigation moved beyond obtaining and sharing archaeological information, into a program that sought to support the affected tribal communities through partnerships between tribal elders, tribal youth, cultural specialists, and professional archaeologists.

The project funded tribal interns during their training by tribal elders, cultural specialists, and archaeologists equally. The intent of the program was to value multiple perspectives, democratize the narratives, and provide equal funding opportunities for traditional and archaeological knowledge transmission. This multidirectional system was enriching to tribal youth and professional archaeologists and was further bolstered by the publicly available film that recognized tribal perspectives alongside archaeological ones, providing a more holistic understanding of these places.

Putting Archaeology Southwest's Indigenous Collaboration Model into Practice: A New Mexico Example

Archaeology Southwest is undertaking an Indigenous Cultural Landscape Report for Petroglyph National Monument, just west of Albuquerque, New Mexico. The work at Petroglyphs involves a number of goals, including tracking and documenting the physical, natural, and cultural history of the 7,200 acres comprising the monument. A large component of the research is assessing the monument, either as whole or in parts, as a Traditional Cultural Property/Place—a TCP. As part of this assessment process, working with monument staff, we have engaged many tribal groups. Petroglyph National Monument has 29 Pueblos and Tribes who have self-identified as affiliated and interested groups. A large component of our work over the last two years has been outreach and engagement with many of the Tribes. To date, significant interaction is ongoing with 21 of the 29 affiliated Tribes, through virtual and in-person meetings, field visits and inspections, and visits to tribal headquarters. This presentation will briefly describe Archaeology Southwest's Indigenous Collaboration Model and its implementation via creation of an Indigenous Cultural Landscape Report (ICLR) for Petroglyph National Monument.

Collecting Colonialism: Disembodied Culture at the Temple Anthropology Laboratory and Museum

Like many small- to medium-sized anthropology departments in North America, Temple University houses a collections repository with a complex and poorly documented past. Beginning in the 1950s, more than 200 collections accumulated with limited direction, including ethnographic collections, archaeological collections, and several collections that defy geographic or thematic categorization. The laboratory and repository built in 1973 is now obsolete and we are at a pivotal point in finding a new identity within the university as an exhibition and teaching space. This includes understanding how our collections should and should not be used in the future. As a case study, I will discuss the development of an exhibit, *Collecting Colonialism: Disembodied Culture at the Temple Museum*. Students critically examined two collections that include a variety of unrelated archaeological, ethnographic, and unclassified objects. By allowing students to explore and present the ethical concerns associated with these collections, they gained experienced navigating the real conundrums and difficulties faced by museums of all sizes and descriptions. Although I am still uncertain of the long-term value in maintaining these collections, the challenges I struggle with as a museum practitioner were valuable teaching tools to prepare students for the often-messy world of museum collections.

Reedy, Chandra (University of Delaware)**[255]***Discussant***Reedy, Chelsea (Texas State University; HDR Inc.)****[268]***Food and Fortitude: A Story of Life within Presidio San Sabá as Told through Zooarchaeological Analysis*

Presidio San Sabá was the largest military outpost in the Texas region during the mid-eighteenth century. This research project is a continuation of Arlene Fradkin and Tamra Walters's previous faunal analysis conducted on a portion of the site's assemblage. This inquiry will focus on comparing the areas within the interior plaza to provide insight into dietary practices and to see if socioeconomic status use of certain areas can be inferred. It is documented that different communities (military, religious, ethnic) were residing in specific parts of the fort. Comparing these areas will provide insight into dietary practices and even dietary differences between varying communities. This faunal analysis of the presidio's assemblages will attempt to determine the people's use of wild versus domestic resources, aquatic versus terrestrial resources, element selection, butchery practices, size class, and hunting practices.

Reents-Budet, Dorie (National Museum of Natural History, Smithsonian Institution), Ronald Bishop (National Museum of Natural History, Smithsonian) and Bernard Hermes (Proyecto Arqueológico Nakum, Isla de Flores)**[251]***Innovation, Not Imitation: The Classic Period Ceramics of Belize*

Entertaining the initial assessment of Belize as a secondary outpost of ancient Maya culture, Belize's subordinate role should be reflected in its ceramic record based on conventional archaeological assumption. However, research since the 1980s proves this to be untrue. Our paper presents an overview of compositional trends in Belizean ceramic paste composition obtained by neutron activation analysis, with a consideration of stylistic and typological categories. Combined with our colleagues' excavation data and pottery analyses, the ceramic record reveals Belizean sites to have been vital Classic period players on the ancient Maya stage, producing unique pottery and participating in ceramic artifact circulation and political interaction throughout the ancient Maya world.

Rees, Mark (Louisiana Public Archaeology Lab, University of Louisiana, Lafayette) and D. Ryan Gray (University of New Orleans)**[1]***Archaeology in the Unfolding Aftermath: Creative Mitigation of Anthropogenic Disasters in New Orleans and the Mississippi River Delta*

Louisiana has been called a state of disaster. The flooding of New Orleans in the wake of Hurricane Katrina in 2005 drew national attention to the effects of social inequalities, unpreparedness, and key vulnerabilities. Five years later, a catastrophic explosion on the Deepwater Horizon drilling rig produced the largest marine oil spill in history. Hurricane Ida in 2021 devastated parishes in the Mississippi River petrochemical corridor sometimes referred to as "Cancer Alley." Environmental, economic, and infrastructural impact response and recovery in the aftermath of those disasters involved cultural resource management (CRM) archaeology, including site monitoring and alternative mitigation. These events transpired in the context of coastal erosion, subsidence, sea-level rise, and intensifying storm surges. Archaeological perspectives on landscapes and deep history reveal such engineered disasters are inextricably linked to anthropogenic environmental changes and social inequality. An archaeology of disaster and equity focused on environmental justice and the heritage of vulnerable communities requires creative mitigation rarely pursued in CRM.

Sustainable Urbanism in the Maya Lowlands: Thirteen Years of Research in the Bajo el Laberinto Region, Southern Campeche

Since 2011, a multidisciplinary team of researchers has been investigating the development of dense urbanism along the southern edge of the Bajo el Laberinto. Anchored by Yaxnohcah in the east and Pared de los Reyes in the west, the area was settled at ca. 900 BCE and occupied until ca. 1500 CE, constituting one of the longest cultural histories in the Maya Lowlands. In addition, it supported very dense populations throughout the Classic period, with new communities and neighborhoods appearing, possibly linked to an expanding market economy. The long-term occupation of the region was supported with sustainable environmental practices over millennia, punctuated by modifications in land-use strategies at critical junctures. In this paper, we highlight the major findings of our 13 years of research in the Bajo el Laberinto area focused on Yaxnohcah and present our interpretations regarding the intersection of population dynamics, political economies, and land-use strategies during significant cultural crossroads. These findings lay the foundation for our ongoing research in the area, which has become a regional endeavor that also encompasses the northern rim of the Bajo el Laberinto centered on the prominent city of Calakmul.

Co-creating Knowledge about Iowa Sites and Increasing Awareness of Iowa's Descendant Tribes through Community-Engaged Archaeology

In June 2023, the University of Iowa Office of the State Archaeologist (OSA) completed a yearlong project for the University of Iowa (UI) Community Engaged Scholars Program in collaboration with the Elgin Historical Society & Museum (EHS) and Meskwaki Nation. The partners aimed to share knowledge about archaeological and historical sites along the Turkey River in northeast Iowa, which is archaeologically very dense but sorely under-documented. The project was prompted by an inquiry to OSA from the EHS who recognized that many area residents had large family artifact collections, but the people with contextual knowledge were aging and sadly passing away. In an effort to encourage community members to share their guarded knowledge and document these sites, the partners organized four community events, including two events called an "Archaeo-blitz" where local residents worked with professional archaeologists to identify their artifacts, record site locations, and learn collections care tips. These events included Meskwaki and Ho-Chunk Nation historians, artists, and dancers, whose participation encouraged public involvement and reinforced for both local residents and Native people the continuing Tribal interests in the area. This paper communicates project outcomes and reflections from the collaborative team.

Perspectives on the Organization and Use of Lithic Technology: A Modern Ethnographic Case Study in East Turkana, Kenya

Expedient technology has taken on several meanings within the study of stone tools. However, the range of behaviors associated with the term expedient and its manifestation in the archaeological record is dependent on the socioecological and functional contexts in which technology is used. Acquiring a deeper understanding of such contexts is challenging, given the infrequent opportunities to observe stone tool production and utilization within extant systems. In 2018, we began working with Daasanach pastoralists in Northern Kenya to document stone tool use from an ethnographic perspective. The Daasanach maintain a core-and-flake technology for use in a variety of functions within the context of herding livestock in remote settings. Over the last three years, we have undertaken extensive interviews with modern tool users and have observed the processes of stone tool production, utilization, and discard. While the Daasanach use of lithic technology could be considered expedient, it is integrated into a complex foraging strategy and cultural framework whose archaeological manifestation is conditioned by the broader availability of stone in the places where they live. The complex interaction of culture, ecology, and material patterning described by this study questions the relationship between the archaeological record and the complexity of the technological system.

Reintroducing Spiro Mounds

Spiro Mounds, located in eastern Oklahoma, is known almost solely for the spectacular collection of well-preserved ritual objects unearthed when looters tunneled into the Craig Mound in the 1930s. The dramatic story of the looting and subsequent dynamiting of the Craig Mound has led many archaeologists to believe the site has no remaining intact archaeological deposits. This paper, intended for those unfamiliar with the site or recent work there, will provide an overview of Spiro as a much larger ritual center among many related mound sites using what we have learned from geophysical survey and recent excavations at the site.

Political Dynamics through the Discourse of the Baah Sajal of Yaxchilan

During the eighth century, the stone monuments of Yaxchilán and its area of influence recurrently recorded individuals with the title *sajal*, a position associated with leaders of corporate groups with functions related to the government of peripheral sites, administration, war, and circulation of goods. Among all the *sajals* of Pa'chan, only K'an Tok' Wayaab held the appellative *baah sajal*, "principal *sajal*," a position that allowed him to appear on the monuments of the most important buildings in the city, such as Structure 33, to demonstrate their rank vis-à-vis other influential groups. In this way, the present paper aims to analyze how K'an Tok' Wayaab exposed his hierarchy through the monumental discourse on the Hieroglyphic Stairway 2 and, above all, the consolidation of Structure 1 as a possible seat of its corporate group within Yaxchilán. This analysis will also allow an understanding of the *sajals'* role in the political dynamics of Yaxchilán toward the last years of this capital.

Reich, David [311] see Comer, Elizabeth

Reid, Amy (Center for Archaeological Studies, Texas State University)**[332]***The Documentation, Conservation, and Exhibition of the Skiles Collection*

The Skiles Collection, named for landowner Jack Skiles, consists of Indigenous, Euro-American, and Asian-American cultural material from the Lower Pecos Canyonlands Archaeological region. Beginning in the late 1930s, the Skiles Family amassed an exceptional collection of cultural material representative of the Indigenous peoples who once lived in the canyon where significant archaeological sites such as Bonfire Shelter, Kelly Cave, Skiles Shelter, and Eagle Cave have been recorded, and of the historic laborers associated with the second transcontinental railroad. The Indigenous component of the Skiles Collection includes a wide array of artifacts made of faunal bone and lithic, as well as uniquely preserved perishable artifacts. Over multiple generations, the Skiles were consistently good stewards of the archaeological sites located on their property, and in 2016 the private collection was relocated to the Center for Archaeological Studies at Texas State University (CAS) for an evaluation, limited conservation, and temporary curation. This paper provides an overview of the collection's contents and condition, and an account of CAS's work evaluating, rehousing, documenting, and conserving the Skiles Collection. The collection's research and educational value will be discussed, as well as the *Ancient Life in the Lower Pecos Canyonlands* exhibition that resulted from it.

Reid, Amy [281] see Smith, Heather

Reid, David (University of Illinois, Chicago) and William Ridge (University of Illinois, Chicago)**[86]***The State of Andean Obsidian Artifact Provenance: A Social Network Analysis (SNA)*

Obsidian was both a common domestic good and a highly sought-after exotic material imbued with ideological significance in the past. In the south-central Andes of Peru and Bolivia, obsidian procurement and distribution greatly expanded during the Middle Horizon (CE 600–1000), contemporaneous with the expansionary states of Wari and Tiwanaku. This paper reviews the contribution of the Field Museum's Elemental Analysis Facility (EAF) in the study of Andean obsidian provenance over the last two decades. Using pXRF and LA-ICP-MS, the EAF has generated hundreds of new data points on the movement of obsidian across disparate geographic zones and social boundaries. Here, social network analysis (SNA) is used as an exploratory tool to investigate broad-scale patterning of obsidian procurement and distribution. Results are explored in relation to the social role of obsidian within the political and ritual economies of expansionary states and bottom-up exchange networks that linked disparate regions at this time. Trends within the obsidian "big data" are further analyzed considering geographic proximity to obsidian sources and GIS-modeled mobility routes.

Reilly, Matthew (City College of New York)**[258]***An Archaeology of Return? African Diaspora Heritage in the Wake of the Slave Trade*

Analytical vectors of the African Diaspora have traditionally run east-to-west, charting the journeys of captive Africans from Sub-Saharan homelands to spaces and systems of racial violence in the Americas. Historical archaeology continues to shed light on the realities of such experiences across the spectrum of oblivion and resistance, though displacements and diasporas that navigate different currents across the Atlantic remain underexplored. In this paper, I draw from sites of ongoing research in Liberia and Barbados to suggest not new mappings of the African Diaspora, but new imaginings, journeys, and emancipatory projects to suggest

what an archaeology of return might look like. Beyond the vectors of movement for people and things, I argue that an archaeology of return must be a project of heritage and racial justice.

Strategizing Food Security under Colonial Rule at Purun Llaqta del Maino, Chachapoyas, Peru

How does colonialism impact local food strategies? This paper considers this question at Purun Llaqta del Maino (PLM), Chachapoyas, Peru; a site with continuous occupation from the Late Intermediate period (LIP; AD 1000–1450), the Late Horizon (1450–1535), and the early Spanish colonial period (1535–1700). Like many Andean regions, Chachapoyas was colonized in the sixteenth and seventeenth centuries by the Inka and Spanish in quick succession. Such colonial expansions can affect food systems by introducing new foods, extracting food and labor through taxes, and introducing or reifying inequalities that alter food access. I present archaeobotanical results from household and public contexts from the LIP through Spanish colonial occupation to investigate variation in food availability and access over time. I consider availability a measure of food acquisition on a community-wide scale, which I measure by tracing ubiquity of plants through time. Access, on the other hand, relates to households' ability to acquire available foods and I employ intrahousehold comparison to trace access. Combining data on availability and access, I consider how imperial impositions affected PLM foodways as well as the strategies that inhabitants employed to negotiate these changes with their biological and cultural needs for adequate foods.

Remote Sensing Survey at Spring Lake, San Marcos, TX

Spring Lake forms the headwaters of the San Marcos River. The area surrounding the lake has hosted prehistoric peoples since the Paleoindian era and remains a place of cultural reverence for contemporary Indigenous communities. In the early twentieth century, an amusement park, hotel, and golf course were built around the lake which brought thousands of patrons to the area for decades until its eventual sale to Texas State University (TXST). Today TXST oversees its preservation and conservation, as well as education and research initiatives related to this important resource. To understand evidence of the history of the anthropogenic landscape preserved in buried contexts at one of several archaeological sites associated with the lake, 41HY160, we used a 400-megahertz ground-penetrating radar (GPR) to detect surface and subsurface anomalies and GPR-SLICE to analyze resulting geospatial data. We present our reconstruction of the historic golf course and discuss the impact of the course's features and infrastructure on archaeological deposits. Conclusions will summarize the utility of this data and approach to archaeological research at Spring Lake.

[120]

Recent Archaeological Investigations of Wiki Peak and the Beaver Creek Drainage

The headwaters of Beaver Creek are located in the Nutzotin Mountains in northeastern Wrangell-St. Elias National Park and Preserve. Beaver Creek originates at Beaver Lake near the community of Chisana and

flows east to the to the Alaska-Yukon border before heading north to join the White River. An important feature of the Beaver Creek headwaters is the Wiki Peak obsidian source. Wiki Peak obsidian has been found at some of the oldest archaeological sites in Eastern Beringia and continued to be transported over long distances until the late Holocene. This implies a long history of human activity in the Beaver Creek area. Another unique attribute of the headwaters area is the presence of an extensive tephra layer known as White River Ash. Two eruptions, stemming from Mt. Churchill approximately 1147 and 1830 cal BP, are thought to have caused large-scale ecological changes and may have caused the displacement of people living in the area. Past archaeological research in the headwaters area has been geographically limited in scope. Recent investigations by the National Park Service were focused on providing a more comprehensive view of past human interactions with the headwaters of Beaver Creek and the greater Wiki Peak landscape.

Returning Home: Zooarchaeological and Bioarchaeological Insights on Nasca Domestic Foodways and Local Mortuary Traditions at Cocahuischo, Peru

Excavations between 2010 and 2012 at the Nasca site of Cocahuischo (300–700 CE) recorded domestic and mortuary activities of a large local community composed of 130 house structures, patio preparation spaces, and dozens of cist tombs. Employing zooarchaeological and bioarchaeological techniques to the human, vertebrate and invertebrate remains from Cocahuischo, we explore interhouse variability in acquisition, processing, and sharing of animal remains as well as the demographic and health profiles of human tomb burials. Our analyses reveal that the raising and consumption of guinea pigs was a central part of foodways, which was supplemented by camelid meat and coastal invertebrates. Higher proportions of camelid remains and greater intensities of burning on fauna recovered from a possible workshop highlights divergent provisioning strategies for laborers. Human burials from stone cist tombs at Cocahuischo include individuals from a range of demographic profiles, with non-metric traits indicating several instances of direct kinship ties. The results from our analyses attest that local communities at the end of the Early Intermediate period (~600 CE) were managing their networks in response to changing sociopolitical dynamics, mainly the emergence and increasing influence of the Wari in the Nasca region.

On the Shoulders of Giants: A History of Archaeological Research in the Mogollon

Since its inception by Emil Haury during the height of the cultural-historical period of American archaeology, the idea of a Mogollon cultural tradition has exhibited considerable dynamism through time. The concept has since developed as a means to delineate a mountain highlands–based cultural tradition from that of the identified Hohokam and Ancestral Pueblo culture areas of the early twentieth century into an effective vehicle to highlight regional adaptations, trade and exchange networks, and various frontier transitions in the precontact Indigenous Southwest. In this paper, we provide a brief historical synthesis of archaeological research in the Mogollon area while arguing for an inherent dynamism in research there compared to adjacent cultural regions in the US Southwest. We then explore how external geopolitical and historical factors have shaped perception and possibilities in Mogollon archaeology to the present day.

Using Isotopic Geochemistry to Relate Ceramics to Raw Materials

The provenance of ceramics assessed through chemistry is most commonly approached through a comparison of ceramics with other ceramics of known origin. More rarely are chemical analyses employed to relate objects to their geological context. This problem derives from the inherent limitations of elemental analysis and is commonly found in studies that employ a single- rather than multiproxy approach. Among available proxies, isotopic geochemistry offers the advantage of preserving the signatures of different raw materials used to produce ceramics. Here, we present studies involving the isotopic analysis of ceramics and raw materials from multiple contexts in Mesoamerica and the Mediterranean region. These studies demonstrate the strength of the approach for associating ceramics to their raw material, how new insights are gained by identifying the geological context, and the importance of integrating the isotopic approach with methods of elemental chemistry and mineralogy.

The Creation, Racialization, and Perpetuation of Aztec and Maya Human Sacrifice Mythology (with a Case Study from Yucatán)

In the sixteenth century, European settler-colonists in the Americas developed tropes of barbarity that they applied to Indigenous American populations. Primary among these tropes were allegations of “human sacrifice” performed for millennia in the precontact past and the colonial present. In this paper, an art historian and a historian, both scholars of colonial Mesoamerica, argue for the agentic construction of these rhetorical devices. Using the sixteenth-century Catholic mural cycles of Saint Michael the Archangel at Mani as a case study, they examine changes in iconography and pigment selection in the first decades of the Franciscan evangelical campaign. These seemingly mere aesthetic choices will trace and reveal the unintended

consequences of the racialized biases with which Europeans created the concept of “human sacrifice”; as a result, paradoxically, a Marian-centric form of Catholicism developed in Yucatán. This case study is but one example of how colonial processes and neocolonial misunderstandings—not actual precontact practices—led to the construction of Mesoamerica’s “human sacrifice” culture.

La ocupación de los grupos canoeros y europeos criollos en tiempos coloniales y republicanos en torno a la barrera biogeográfica de península de Taitao/golfo de Penas (~46°-48°S), Patagonia occidental, Chile

Las prospecciones arqueológicas realizadas en las áreas costeras insulares y continentales en torno a la extensa barrera biogeográfica conformada por península de Taitao y golfo de Penas (~46°-48°S) en el borde Pacífico nos revelan una importante evidencia de registros materiales de tiempos coloniales y republicanos. Estas son producto de actividades originadas tanto por grupos canoeros (cazadores-recolectores-pescadores marinos) como por europeos/criollos, en momentos en que se desarticulan y transforman los modos de vida de los primeros luego del contacto europeo. Esta área comienza a ser visitada y ocupada bajo nuevos términos geopolíticos, económicos extractivistas y estratégicos, reconfigurando aquel espacio. Es así como, a través del registro material, discutimos variables como intensidad de ocupaciones, diversidad de sitios, subsistencia, dieta y cronologías de ocupación en relación al uso del borde costero durante tiempos históricos, permitiendo entender así las características de la ocupación humana en este espacio archipelágico. En una escala más amplia, discutimos la evidencia arqueológica para entender cómo opero esta barrera biogeográfica en el archipiélago patagónico y su rol en la circulación, movilidad marítima y contacto de las poblaciones canoeras y, posteriormente de los grupos europeos/criollos. Agradecimientos: Esta investigación ha sido financiada por los Proyectos ANID-FONDECYT 1210045 and ANID-Regional R20F0002.

Can Archaeofaunal Data Track Site-Specific Occupational Intensity? Case Studies from the Late Pleistocene in the Southern Cape of South Africa

The ubiquity of archaeofaunal remains and discarded bone at Paleolithic sites make these useful datasets for investigating a range of site formation processes, including anthropogenic site-use activity. Occupational intensity is a common theme in current research and is often linked to demographic changes in the past. Given its association with early evidence of human behavioral complexity, the Late Pleistocene in the southern Cape of South Africa may be important in interrogating links between socio-demographic changes and site-specific occupational intensity. In this paper, zooarchaeological and taphonomic data are evaluated as proxies for occupational intensity in the southern Cape. Geoarchaeological and micromorphological data from three Middle Stone Age sites—Klipdrift Shelter, Blombos Cave and Pinnacle Point—are used to ascertain whether specific layers have increased or decreased periods of occupational intensity at each site. Various zooarchaeological and taphonomic data are then compared to this reference data to assess the value of faunal proxies in tracking temporal changes in occupations. The results show that anthropogenic bone surface modifications appear to be effective in tracking occupational patterns, with trampling a particularly useful indicator. The implications and limitations of these proxies are discussed, particularly with regard to settlement patterns in the southern Cape.

Building a Deeper Understanding of the Archaeology of Food through Photographs and Critical Reflection

The archaeology of food is rarely revelatory of an individual's diet or of individual meals. Instead, it is usually indicative of a community's procurement and processing patterns, consumption patterns, cooking methods, and disposal practices. But how can we teach students to understand this distinction and to look for and investigate these larger patterns in their own lives and in the archaeological record? In this session, I'll suggest that photo documentation of and guided reflection on a meal they eat can encourage our students to start thinking more deeply about the archaeology of food and all it can (and cannot) reveal. By reflecting on what they ate and why they ate it, where the various ingredients came from, the labor put into the meal, what is left behind for future archaeologists, and where those various components end up, students can think critically about both their individual role in our food system and their connection to larger cultural systems. This single exercise beautifully reveals the complexity of our students' lives and enables them to better seek out evidence for complexity in the lives and societies of past peoples, ever impacted by identity, environment, infrastructure, and economics.

Stepping toward a Paradigm Shift: The White Sands Footprints

Prehistoric footprints indicate presence, behavior, and the interactions between different animal species. The discovery of footprints at White Sands National Park in New Mexico has shown how tracks can transform our understanding of American prehistory and crucially the history of its first indigenous inhabitants. In September 2021 we announced footprints on a former lakebed (playa) dated by seed layers to the Last Glacial Maximum some 21,000–23,000 years ago, which have been confirmed via other dating methods. This presentation discusses the implications of the evidence of the footprints at White Sand, reveal what they can say about the peopling of the Americas more generally, and show how American archaeology is on the cusp of a paradigm shift in which footprints traces will transform our knowledge of the first Americans over the coming decade.

Dietary Inferences based on Starch Residues from O'Malley Shelter, Southern Great Basin

This poster presents a history of prehistoric plant use based on starches recovered from plant processing tools at O'Malley Shelter, Lincoln County, Nevada. O'Malley Shelter (26LN418) is an important archaeological site in the Clover Mountains near the Great Basin's southern margin, with an 8,000-year-long record of occupation. Extraction and analysis of starch residues from an extensive sample of milling stone, ceramic, and basketry artifacts provides a record of the use of starch-bearing plants through the past several millennia, including pinyon pine, acorns, geophytes, native grasses, maize, and other important plant foods. The dietary plant food history from O'Malley Shelter is considered in relation to other prehistoric dietary trends in the Great Basin region.

Painting Pictures: There Is Madness in Archaeological Methods

One of the critiques *The Dawn of Everything* was subject to was that it failed to provide a clear method or had

no method at all and that it was unscientific. There is some truth to these critiques since *The Dawn of Everything* does have its problems. However, underlying these critiques is a more pervasive problem, that of over-trusting the role of scientific methods and techniques, quantitative approaches, and technological means to understand the past. Despite the rhetoric, many of these so-called scientific approaches are anything but scientific in the strict sense of the word. They are just fast science, and as Byung-Chul Han has recognized, a purely hectic rush produces nothing new. It only reproduces and accelerates what is already available. More than providing strict scientific evidence or following stringent methodological rules, *The Dawn of Everything* does do something very well, something that most “science” in archaeology fails to do, and that is provide a picture of life in the past. People will never understand what it was like to live in the past through overly complex graphs or distribution maps, but they can through loose connections, multiple examples, and descriptions of past practices and lifeways.

Historic and Recent Investigations of the Geology and Paleontology of Vicksburg National Military Park

Vicksburg National Military Park (VICK) was established in 1899 to commemorate the 47-day siege of Vicksburg, which ended in a Confederate surrender on July 4, 1863. VICK’s significant history extends even further than the Civil War as the park contains evidence of life from the fossil record. While the oldest exposed geologic formations in VICK belong to the eponymously named Oligocene-age Vicksburg Group, gravels sourced from older Paleozoic rocks upstream in the Mississippi River system can also be found below the topmost Quaternary sediments (mostly comprised of Pleistocene loess that characterizes the park’s bluffs). Multiple intersections exist between the geology and paleontology at VICK and the archaeological record. Jasper effigy beads from the Middle Archaic period represent the earliest known human interactions with the local geology. Later, effigy pipes from regional Mississippian sites have been linked to a Vicksburg Group formation exposed in the park due to fossils identified in the material. Famous historical scientists including Charles Lesueur, Charles Lyell, and John Wesley Powell also studied the geology and paleontology of Vicksburg. In 2022, a field inventory of VICK’s fossils was conducted, and the findings, as well as historical narrative interwoven with these resources, were summarized in a comprehensive report.

Richard, Francois (University of Chicago)**[250]***Ann Stahl's Archival Imagination*

In *Making History in Banda*, Ann Stahl stages an encounter with Rolph Trouillot's *Silencing the Past* to develop an inspiring discussion of sources, interdisciplinary thinking, the supplemental use of archives, and the fraught dynamics of historical production in the crafting of visions of Africa's past. Providing a robust support for her work in Banda, Stahl's attentiveness to matters of historical epistemology is one of the book's major contributions, and, I would argue, one of her most powerful scholarly legacies, which has guided the work of so many of us on the materiality of Africa's recent (and less recent) pasts. This paper revisits Stahl's thoughtful epistemology of history, by placing it in conversation with the archival/historical turn that informed its development and more recent trends in "archive theory."

Richards, Emma (Beloit College), Willa Richards (University of Wisconsin, Milwaukee) and Simone Bruhy (University of Wisconsin, Milwaukee)**[330]***From Barbies to Bones: Celebrating Dr. Patricia B. Richards's Legacy*

As the daughters of archaeologists, we've lived on, worked at, and visited scores of archaeological sites across the Midwest. Cumulatively, we've been witness to nearly every decade of Patricia B. Richards's career. Our mother's revolutionary ability to seamlessly merge her roles of mother and archaeologist gave her daughters an extraordinary gift: not only did she let us into her professional world, she made us feel deeply at home there. We slept on cots in her office, her students and colleagues became our friends, we did homework in her lab or in the front row of her classes, we did data entry, we did fieldwork, we cleaned and sorted, we edited. In doing so she deeply influenced our personal and professional identities. In honor of our mother's retirement, we share our favorite memories of our time spent with her in the field and the lab. This paper not only celebrates her impact on the field of archaeology but serves as a reminder of the strength found in being a woman, a mother, and a mentor.

Richards, Julian (University of York Archaeology Data Service)**[63]***Discussant***Richards, Katie (New Mexico State University)****[284]***Painted Pottery on the Fremont Frontier*

Frontiers are dynamic regions of integration and exclusion where identity and culture are negotiated. The relationships between the heartlands of the North American Southwest and many of its resulting frontiers have been explored; however, it is still not clear how interaction between Fremont peoples and those in the greater Southwest influenced identity and culture on this northern frontier. This poster uses painted pottery production, distribution, and use to explore Fremont within their broader regional context. The results of this analysis suggest Fremont painted designs are closely related to the design horizons produced in the Four Corners region during the AD 900s and early 1000s. These designs were adapted to create a distinctive Fremont design style that remained relatively static for nearly 300 years and is found in similar archaeological contexts across the region. When these results are situated within the social, demographic, and historical context of the greater Southwest, they suggest that during the Late Fremont period, the region became a dynamic frontier of the northern Southwest where people maintained a shared social identity and used painted pottery to signal both a heritage in and separation from their southern neighbors.

The preliminary season of the Sebittu Project on the Erbil Plain of Iraqi Kurdistan was conducted over four weeks this summer. The project includes seven Neo-Assyrian sites on the plain with the goal of documenting the agrarian economy during the Neo-Assyrian period (ca. 900–600 BC) in northern Iraq, the heartland of the Assyrian empire. The initial identification of the sites was part of the larger Erbil Plain Archaeological Survey (EPAS) headed by Jason Ur when documenting over 900 sites via pedestrian survey over several field seasons. This survey data led to the choice of seven clustered sites not only due to their proximity to one another but also the high percentages of clear Neo-Assyrian ceramic material. These seven sites include ancient villages, hamlets, and farmsteads located in the Erbil Directorate of the modern Kurdish Autonomous Region (KRI). The 2023 preliminary season included both pedestrian and geophysical survey, at two sites, as well as a test excavation trench. This work was done to explore the feasibility of working at small, flat sites within agricultural zones in the region. The results from this season, as well as implications for further fieldwork and research will be discussed here.

Richards-Rissetto, Heather (University of Nebraska, Lincoln)**[74]***Discussant***Richards-Rissetto, Heather (University of Nebraska, Lincoln), Ethan Jensen (University of Nebraska, Lincoln), Allison Bain (Université Laval) and Sophia Perdikaris (University of Nebraska, Lincoln)****[148]***Fostering Preservation and Public Engagement of a Colonial-Era Site on Barbuda with Photogrammetry*

The threats to cultural heritage on the Caribbean island of Barbuda are multifaceted, stemming from natural disasters, rising sea levels, political and economic policies, and infrastructure development. While such threats are not new, their increasing and combined detrimental impacts are leading to the exponential damage and

destruction of cultural heritage. Highland House, a colonial complex spanning the eighteenth to early nineteenth centuries, situated on Barbuda's highest point, is exposed to harsh environmental conditions and dramatic climate events. While climate change, resulting in more dramatic and frequent climate events such as hurricanes, is increasing deterioration rates of the structures at Highland House, changing social, political, and economic practices also threaten the site. This paper explores the potential of employing aerial (drone) and ground-based photogrammetry to collect 3D geospatial data for documentation, preservation, and dissemination efforts of Highland House. The Barbuda Council, a local authority, collaborates on the project to foster cultural heritage preservation through tourism efforts. 3D models were generated from combined aerial and ground-based photogrammetry of the site's extant structures for multipurpose use including historical reconstructions and web-based models accessible on and offsite to promote broader public awareness of the site and encourage the public to visit Highland House.

El Juego de Pelota en la Huasteca y las redes internacionales del Golfo

No es una revelación nueva que exista evidencia arqueológica para el Juego de Pelota en la Huasteca, una región que forma el límite septentrional de Mesoamérica y de la costa del Golfo. Se han documentado canchas de pelota en sitios arqueológicos y figurillas de barro que llevan indumentaria protectora de jugadores, como rodilleras o yugos. De las figurillas sabemos que tanto hombres como mujeres fueron jugadores, un aspecto cultural destacante porque fue un papel típicamente asociado con hombres en Mesoamérica. Desafortunadamente se sabe poco más sobre el significado y el ritual del Juego de la Pelota en la Huasteca por falta de excavaciones sistemáticas en la región. Además, no se han encontrado representaciones narrativas sobre rituales asociados con el Juego de Pelota como en El Tajín, Las Higueras, Chichen Itza y otros sitios. Esta ponencia se enfoca en ejemplos de Juegos de Pelota en el sur de la Huasteca para argumentar que sitios con canchas formaron parte de la red de intercambio ideológico del periodo clásico y mantenían relaciones a lo largo del Golfo con ciudades como El Tajín o Santa Luisa.

Tails from the Animal Storerooms: Case Studies on the Uses and Limitations of Natural History Collections Using Multiproxy Approaches

Natural history collections (including zooarchaeological collections) provide essential information for archaeologists. They are primarily used in identifying bones and other hard tissues, and they provide references for biomolecular and isotopic studies. Biomolecular data from these collections are increasingly the subject of historical ecological research or used to build reference libraries of molecular data. However, natural history collections are never free of issues and often have problematic taphonomic histories, especially in expansive and/or multigenerational repositories. In this paper, we present a conversation between a zooarchaeologist and molecular biologist about two case studies highlighting ways to tackle the uses and limitations of natural history collections through multiproxy approaches. First, we consider zooarchaeology by mass spectrometry (ZooMS) analyses of modern and archaeological rabbit specimens. This project became unexpectedly complex due to decades-old misidentifications of comparative rabbit specimens used to generate baseline ZooMS data; ultimately, we found creative ways to update the taxonomic identifications of these (mostly) rabbits. Second, we consider identifying research value in "oddball" specimens collected over decades from zoos and animal breeders; these specimens, including zebras and lovebirds, can contribute to comparative studies and used as sources of genetic and molecular data not typically found in North American zooarchaeological collections.

Gallery of the Condor: The Earlier End of Chavín's Underground Structures

In 2019 a new gallery was detected by the Programa de Investigación Arqueológico y Conservación en Chavín de Huántar in Chavín's Building D, which was explored in 2022 and excavated in 2023. Named for a sculptural stone vessel depicting a condor left during gallery closure, the compact gallery differs notably from others in its planning and construction, and unusually was intentionally closed well before the end of the Chavín era. The gallery originated as a small surface structure that became a gallery as Building D grew horizontally and vertically, engulfing a space not initially intended for subterranean use. Access to the structure was maintained by the later addition of an entrance corridor and long ventilation duct, costly measures to retain the use of a very small, if already ancient chamber. Excavations reveal gallery use across an extended time, with earliest layers lacking ceramics, correlating with unusual features of early construction including banquettes and corbelled ceilings. Overall, the contents and features of the gallery suggest an early stage of gallery conceptualization, construction, and usage ancestral to both the standardization of the numerous later phase Chavín galleries and the apparent need to access past ritual spaces.

Late Holocene Nearshore Marine Productivity, Climate Change, and Changing Sociopolitical Dynamics on California's Northern Channel Islands

Understanding the social, political, and economic dynamics of coastal hunter-gatherer-fishers was a hallmark of Jeanne Arnold's multi-decade archaeological research. Arnold integrated marine climate records and archaeological data to develop hypotheses about the evolution of political hierarchy, exchange systems, and

territoriality on California's northern Channel Islands (NCI). This research was highly influential and spurred a series of lively debates that continue today. While marine climate records for the Santa Barbara Basin (SBB) are among the best in the world, with 25–50-year sequences for the Holocene, these records are averages for the SBB as a whole. This leaves key questions about local marine conditions near specific sites and villages, especially since marine climate and productivity (e.g., temperature and upwelling) are known to vary considerably across the NCI. Here we build on decades of NCI research by presenting compound specific and bulk stable isotope data from archaeological California mussel shells from across the Late Holocene NCI, including some of the sites excavated by Arnold. We also describe the curation of Santa Cruz Island archaeological collections at the Smithsonian Institution. These data illustrate the value of legacy collections for evaluating long-standing archaeological research questions and understanding climate change.

With a Little Help from My Friends: New Radiocarbon Dates from the Great Hungarian Plain

The expanded availability and use of radiocarbon dating by archaeologists has significantly reshaped the understanding of long-standing prehistoric narratives. These advances have also challenged the cultural-historic notion of archaeological cultures that have dominated research for over a century. In this paper, we examine recently collected radiocarbon dates from multiple projects working in the Körös River Basin in eastern Hungary. These dates span the Neolithic and Copper Age (ca. 6000–2600 BC) and complicate the previously neat and orderly picture of prehistoric sociocultural trajectories. In particular, we look at four aspects that have been challenged based on the radiocarbon dates. (1) The process of tell abandonment and the dispersal of large settlements at the end of the Neolithic. (2) The chronological and sociocultural relationship between Late Neolithic and Early Copper Age cultures units. (3) The absolute chronology of the Tiszapolgár and Bodrogkeresztúr cultures in the Early Copper Age. (4) The apparent gap in radiocarbon dates shortly after 4000 BC as it relates to demographic processes. We conclude by placing the Körös Region into the broader context of the Great Hungarian Plain and southeastern Europe to explore regional variation in cultural trajectories throughout the fifth and fourth millennia.

A River Runs through It: Tales of River Management Practices on the Great Hungarian Plain

People are intricately connected to the land around them, and throughout time, people have manipulated their surroundings to better fit their immediate social, cultural, economic, or subsistence needs with little to no thought about long-term environmental consequences. The Great Hungarian Plain is no exception, and during different periods in the past, people have significantly altered the landscape with varying outcomes. Through three case studies, one historic (eighteenth–nineteenth centuries) and two Late Neolithic (5000–4500 BC), this paper will compare how people on the Great Hungarian Plain interacted with and transformed the braided river channels that traversed the landscape. These transformations reflect peoples' knowledge and understanding of sustainable water management and the impacts of human-induced landscape changes.

This paper presents a synthesis of recent research that illuminates the reality of forager childhoods at several sites dated to the terminal Pleistocene and early Holocene in the region of Liguria (NW Italy). Indeed, recently published data from the sites of Arma di Nasino, Arma Veirana, Caverna delle Arene Candide, and Grotta della Bàsura not only underscore the role and place of children in prehistoric societies at the time, they also reveal how children may have contributed to creating the archaeological record, with concomitant implications for its interpretation. Furthermore, life history and funerary data from several individuals from these sites also permit a discussion of how the last hunter-gatherers of the region partly organized their lifeways around the reality of caring for and moving children across this rugged landscape. This shows that far from being afterthoughts in these groups' organization, children were central considerations in as well as active agents in it.

Archaeological sites in the high dry deserts of eastern Utah have yielded remarkably preserved collections of perishable technological components of past lifeways. This includes many examples of projectile weaponry. These objects can add direct evidence to studies focused on the adoption of the bow and the persistence of the atlatl in specific regions, an argument frequently based on changes in projectile point technology. Unfortunately, many of these sites with incredible organic preservation were heavily impacted by looting and other poorly documented collection practices in the twentieth century. These wayward practices have led to a loss of context and cultural affiliation for these rare objects. This presentation focuses on adding temporal context to perishable projectile weaponry housed at the Utah State University Eastern Prehistoric Museum through direct radiocarbon dating. Because many of these objects have very limited spatial association due to their removal from archaeological sites by private collectors, temporal context is one of the only ways to better associate these objects with the people and archaeological cultures who created and used them in their daily lives.

Cremation during the Early period (1000 BC–AD 600) in the Archaeological Site Matecaña (Pereira)

Four funerary urns from the archaeological site Matecaña (Pereira, Risaralda, Colombia) were analyzed to understand the cremation mortuary practice during the Early period (1000 BC–AD 600). This archaeological record does not count with direct descendants and is under the stewardship of the Universidad de Caldas, which follows adequate processes to allow a good conservation and protection of the human remains that are treated with respect and dignity. The cremains went through an anatomical classification that led to establishing the Minimal Number of Individuals with the Landmark System, as well as a reconstruction of their biological profile and an interpretation of the macroscopic changes made by heat exposure, such as colorimetry, the degree of cremation, presence of heat-induced changes, and the temperature that the incineration reached. The results showed that the funerary cycle had three processes divided into 11 stages. During the first moment, the biological death of the individual leads to rituals and a temporary deposition. After this, the second process is where the cremation is carried out, following the skeletonization of the corpse. The combustion of at least 28 individuals of different ages (fetal, infants, and adults) was intense (400°C→ 600°C) and finalized with their burial in funerary urns from a typology of the Early period.

Dating the Petroglyph Cave of the Purrón Dam Complex of the Tehuacan Valley, Mexico

Rectilinear planes cut into one of the gypsum outcrops near the base of the north face of Cerro Mequitongo, the hillock that rises above the south end of the massive Purrón Dam, created a subterranean space. The labor invested in excavating this man-made cave (Tc-511), its walls plastered with a thin veneer of stucco and decorated with petroglyphs belonging to different time periods, suggest it had a religious/ceremonial purpose. Petroglyphs allude to hunting, the ballgame and animals active during the rainy season. A charcoal sample obtained from a stucco spall yielded an age of 400–200 BCE, coeval with the age of a hearth on the alluvium that accumulated behind the Stage 1 construction of the Purrón Dam. It is hypothesized that this man-made cave served to organize the people in building and maintaining the dam during its initial construction and working on other soil conservation and water management projects located within the Lencho Diego Canyon. The dates, petroglyphs, and the ceramic types recovered allow for a secure dating of the cave and Stage 2 of the dam to the Middle and Late Santa María Phases. Both features continued to be used in the subsequent Early and Middle Venta Salada Phases.

Rennes-le-Château, History and Myth in Competition

In a small French village, discussions of medieval heretics and history have become combined by modern tourists. Popular literature has only added to the issue. Since the publication of pieces like *Holy Blood, Holy Grail* and *The Da Vinci Code*, the line between fact and fiction has grown thin. In 1965, excavations in Rennes-le-Château, the village which produced the original legend from which these fictions draw their fact, were banned. This stemmed from the multitude of treasure hunters who believed there were great stores of gold or the Holy Grail to be discovered. Some of the most extreme acts of destruction involved breaking a church altar and disrupting graves. In the 1990s, a tourism initiative was launched to promote the Aude region as “Cathar Country.” Now modern-day visitors come for the legends and romanticized versions of the Cathars and the Holy Grail, mixing myths and the history of a brutal genocide with esoteric assumptions, making it nearly impossible to tell fact from fiction. I seek to discuss the difficulty in presenting history to an audience to compete with myth, and the challenge in deciphering a history riddled with fiction and conspiracy when traditional archaeology is banned.

Green Acres: The Valle de Yaxhom and Puuc Prehistory

It has long been recognized that the two principal physiographic subdivisions of the Puuc are the wedge-shaped Valle de Sta. Elena, just south of the Puuc escarpment, and to its south, the Bolonchen Hill District. One goal of the PARB project was to explore the eastern manifestations of these two regions for possible differences in civic and residential organization. This contribution examines the development of social complexity in the eastern tip of the Valle de Sta. Elena, a shallow basin known as the Valle de Yaxhom, today renowned for its fertile soils. Ground and lidar survey by the PARB project indicate that it, too, was the major concentration of population in our regional sample, beginning with the construction of impressive Middle Formative monumental acropolises and peaking during the Terminal Classic period. This overview examines patterns of civic architecture within our sample, as well as the relationship of settlement to landforms and soils. We examine the question of whether the Valle was in fact a single community, and whether it exerted influence over neighboring communities to the south, as reflected in their civic architecture. Finally, we consider the broader economic and political position of the Valle within the region.

The Buttermilk Creek Ranch Sites 41BL1431 and 41WMI498: Examining Land Use at Two Prehistoric Lithic Resource Areas in Bell and Williamson Counties, Texas

The Buttermilk Creek Ranch (BCR) is located within the upper Buttermilk Creek Valley in Bell and Williamson Counties, Texas. Across this landscape, valley incision dissects chert-bearing limestones of the Lower Cretaceous Edwards Group exposing extensive outcrops of tool quality stone. In direct proximity to BCR, are the well-known multicomponent sites Gault (41BL323) and Debra L. Friedkin (41BL1239). Recent archaeological survey at BCR identified two large lithic procurement sites, 41BL1431 and 41WMI498. The density of chipped stone artifacts and workshop features recorded at these sites is considerable and indicates intensive raw material acquisition occurred. As part of the survey, chert sampling across BCR has allowed for the development of a lithostratigraphic model of the Upper Buttermilk Creek Valley. This presentation provides a summary of the survey results, site delineation, Global Navigation Satellite System (GNSS) methodology, and spatial patterns in chert variability. An initial interpretation of the data is presented detailing high density debitage areas and discrete loci that reveal preferences in raw material selection relative to elevation. Particular attention is given to identifying debris loci with Paleoindian technological signatures to better understand lithic raw material procurement at BCR in relation to Paleoindian camps and workshops at nearby Gault and Friedkin.

Institutional Analysis of the Social Property System and Its Application for the Management of Cultural Resources in Mexico

In Mexico, archaeological sites are located on private, communal, ejido, federal, or vacant land. The exercise of land ownership rights determines the type of technical and legal protection, which is usually assumed by the Mexican State. Generally, to mitigate risks, official archaeologists must carefully collaborate with public, private, or common-pool resources and develop strategies to promote site management. This paper presents an institutional analysis of the different approaches in which social land property boards—those formed by

members of an agrarian nucleus or people with communal property or interests in a community—can contribute to the conservation of archaeological resources and their operational potential for the Mexican case. Based on recent fieldwork experiences at a collectively owned site in southeastern Mexico, I discuss the unique challenges of involving a community in the exercise of its land ownership rights in parallel to archaeological conservation, and the potential of such participation to encourage local community archaeological stewardship.

Multimodal Digital Documentation of Actun Tunichil Muknal, Belize

Actun Tunichil Muknal (ATM), located in western Belize, is among the most touristed archaeological caves in the Maya area and is well known for its striking physical characteristics and intact cultural deposits. Though well surveyed and studied, the cave and its many fragile and at-risk offerings had not been digitally documented. A collaborative program of scanning was conducted in summer 2023 using complementary imaging modalities across scales and resolutions. These included SLAM-based mobile lidar—which was ideally suited to the complex, partially flooded passageways and high, narrow chambers of the cave—as well as structured-light scanning (of individual objects or features) and photogrammetry. Particular attention was given to the human skeletal remains and ceramic vessels that lie within close proximity to visitor routes within the cave. The result of this integrative approach will be a fused multi-resolution digital twin of ATM that will not only serve as an accurate geometric record of the cave and its contents but will enable researchers to better visualize spatial contextual relationships and facilitate taphonomic analyses. An accessible, online, interactive version of the digital twin will be available to guides and the interested public as well.

Savor Your Subsistence: Foodways at Kotið, a Small Viking Age Dwelling in Northern Iceland

We present food production data from the 2022–2023 excavations at Kotið, a small, non-elite Viking Age (ninth century AD) domestic dwelling located in Skagafjörður, north Iceland. Macrobotanical and zooarchaeological remains provide key data to better understand early subsistence strategies, including hunting, fishing, animal husbandry, wild plant gathering, and cereal cultivation. Little is known about the role small domestic sites such as Kotið played in the political economy and ecology of the early Icelandic settlement period, but the evidence for cereal cultivation, livestock consumption and fishing begin to tell a dynamic story of early Icelandic foodways.

All That Glitters (for Now): Multi-method Approaches to Informing the Archaeological Response to Sea-Level Rise on the Golden Isles of Georgia

The immense and unprecedented challenge posed by sea-level rise will require archaeologists to combine

efforts and expertise in multiple disciplines and realms of practice. Whether from the perspective of salvage, mitigation, preservation, or triage, cultural heritage professionals are engaging with myriad data to develop contextually situated responses to the encroaching tides. Here, we describe recent archaeological investigations on the Georgia Coast that seek to inform contemporary responses to sea-level rise. Engaging with settlement records and paleoenvironmental data, we present analyses that will inform discussions on how archaeologists can, and should, consider localized, historically situated environmental impacts, coastal geomorphology, and the history of archaeological investigations as components in our collective response to climate change.

Crafting Collaborations: Reflections on Collaborative Archaeology with the Community of Huancas (Amazonas, Peru)
In 2012, the Peruvian Ministry of Culture designated pottery from the town of Huancas (Amazonas, Peru) as Cultural Patrimony, celebrating the longevity of this crafting tradition that potters have maintained since the Late Horizon period (ca. 1470–1535). Due to the rise of tourism in Amazonas, interest in local archaeological sites has grown. In 2022, together with community members, local researchers, and students, I conducted archaeological fieldwork at seven sites in Huancas. This project was designed as a collaborative one, centering the interest of the Huancas community to learn more about these sites and better manage tourism. In this paper, I reflect on conducting collaborative work as an early career scholar and the challenges faced, particularly when a nation's history with Indigeneity complicates the notion of descendant communities (Herrera 2011). Collaborative archaeology requires time and trust, which is difficult for graduate students working with limited time and resources. However, there is no singular collaborative approach and projects can adjust based on self-reflection and sociopolitical context (Cipolla et al. 2019; Colwell-Chanthaphonh and Ferguson 2008; Wylie 2019). Through this case study of collaborative work in Latin America, I consider how early career scholars developing creative solutions have much to offer this discourse.

Exploring Production and Exchange of Post-Tiwanaku Cabuza-Style Ceramics (Southern Peru, Twelfth Century CE) through Visual and LA-ICP-MS Analysis

The dispersal of Tiwanaku-affiliated populations before and after the collapse of the eponymous state took on distinct cultural expressions throughout the western south-central Andean valleys. The proliferation of diverse Tiwanaku-derived ceramic substyles in the region signaled the emergence of local craft traditions and identities. Among these substyles, the Cabuza style represents long-term adherence to Tiwanaku vessel forms and design elements coupled with decline and innovation in production resources and technologies. Yet we know little about the practices and resources that define the Cabuza style, how it compares with contemporaneous Tiwanaku-derived styles, and the implications for the identity of its makers. Here, we present results of compositional and stylistic analyses of Cabuza-style ceramic fragments recovered from Los Batanes, a twelfth-century settlement in the Sama valley (Tacna, Peru). Consisting of serving and utilitarian

vessels, the Sama-Cabuza assemblage captures a broad range of production practices and choices. By comparing LA-ICP-MS data of an initial sample of Sama-Cabuza with compositional data from clay sources and contemporaneous post-Tiwanaku ceramic assemblages elsewhere in the region, we investigate the ways that compositional and qualitative attributes of Sama-Cabuza ceramics reflect diversified local practices and/or exchange of products and knowledge among post-Tiwanaku communities.

Life and Death after Chavín: A Comparative Mortuary and Bioarchaeological Analysis of Salinar from the Perspective of José Olaya-La Iglesia (Huanchaco, Moche Valley)

On the north coast of Peru, the collapse of the Chavín Sphere of Influence ca. 500/400 cal BC had a marked impact that brought about sociopolitical changes within the Moche Valley. For many years, archaeologists have investigated structural changes (e.g., settlement patterns and architectural shifts), violence, and altered subsistence patterns in the subsequent Salinar (ca. 400–50 cal BC). Here, I present data on a large mortuary ($n = 112$) and bioarchaeological ($n = 84$) analysis of a Salinar cemetery excavated at the José Olaya-La Iglesia site, Huanchaco (400–200 BC). Importantly, characterizing mortuary patterns and bioarchaeological of this coastal fishing community highlights notable intra- and intervalley similarities and differences with contemporary communities. I argue there are significant contributions to understanding life at the turn of the millennium in this region through the study of mortuary practices and bioarchaeological analyses that both support and challenge preexisting ideas of “Salinar.” *** Human remains will be shown in this presentation.

Disasters in Temporal Context: Linking the Past and the Present: The RVCC Puerto Rico Hub

The IPCC sixth Assessment Report (2023) highlights that human-induced climate change triggers widespread and rapid changes that disproportionately affect communities in socially produced conditions of vulnerability to disasters. Academic convergence is needed as we search for solutions. Archaeology stresses that past instances of climate change can provide long-term perspectives of the conditions in which people have addressed livelihood challenges. Looking at the past provides transformative insights for developing tools to prepare for current and expected climate change impacts. However, mainstream disaster researchers often fail to capture the complexity of processes unfolding at local, meso-, and global scales; overlooking the limits of disaster risk governance or the complex ways in which societies—from governments to communities—respond to known, new, and unfolding risks. This presentation shares how the Puerto Rico RVCC Hub integrates different forms of knowledge, including those given and transmitted from the past, to advance a comprehensive understanding of disaster outcomes. Deep knowledge exchange that delves into how communities organize around risk improves the understanding of past instances where climate hazards could have triggered catastrophes. A more nuanced approach to examining the past improves how archaeology contributes to the construction of scenarios for an uncertain future.

Sea-Level Rise, Climate Change, and the Geoarchaeology of Barbuda: A Systematic Survey of Seaview / Indian Town Trail
Sea-level rise, coastal erosion, and other climate-related hazards pose threats to coastlines around the world.

Understanding these nuanced processes sheds light on the risks that local communities and heritage managers face, as well as on the longer-term impacts of human activity over the coasts. This presentation shares the progress of our geoarchaeological research on Seaview and Indian Town Trail in Barbuda. Initial analysis identified the ecological and physical processes that changed coastal morphology as sea level rose from the Early Holocene to the present. These processes explain the erosion rate and coastal retreat of the extant coastal dune ridge that exposes the coastal lowlands to sea-level rise inundation under future climate scenarios. During the 2023 expedition, the NSF IRES International Research Effort conducted a systematic survey of Seaview and Indian Town Trail successfully assessing the severity of inland erosion and soil degradation, modern and historic uses of the land, the distribution of archaeological refuse, and the relationship between those two important sites of the indigenous past of Barbuda. This type of study design is particularly urgent for tropical oceanic islands, where accelerated climate change and disaster capitalism are pressing social vulnerability and threatening the continuity of islander identities.

La Cueva de las Manitas: Conservación y arqueología experimental

Cueva de las Manitas is located in the municipality of Cuicatlán, in the state of Oaxaca, Mexico, a place that is part of the Tehuacán-Cuicatlán Biosphere Reserve (RBTC). It is a rockshelter painted with anthropomorphic elements such as human bodies and hands (the reason for its name), zoomorphic, and symbolic elements. Complementing the paintings are other artistic manifestations, including sculptures and natural figures, which were intentionally completed to make them look like fantastic faces. The stratigraphic sequence that has begun to be revealed denotes a long occupation of the cave, extending from hunter-gatherers' occupation to modern times. Many important studies are taking place giving us amazing news on the cultural significance of this cultural heritage. In this paper we will present evidence of the tools used for the creation of the paintings. In addition, the results of experimental archaeology will be presented to understand the creative process, the organic materials utilized, and generate a hypothesis for the meaning of this rock art. Evolving knowledge about the cave gathered through its excavation and conservation in the coming years, will expand public awareness of this region and its importance in the development of agriculture, which gave rise to civilization in Mesoamerica.

Precolumbian Metallurgy at the Late Moche–Transitional site of Huaca Colorada, Jequetepeque Valley, North Coast of Peru

Since 2009, the Late Moche–Transitional site of Huaca Colorada (ca. 700–900 CE), located in the Jequetepeque Valley on the North Coast of Peru, has been a focus for excavations by the Proyecto Arqueológico Jatunca-Huaca Colorada-Tecapa. These excavations have produced definitive evidence for the production and consumption of metal objects at Huaca Colorada. To date, more than 2,000 metal objects and hundreds of crucible, slag, and gangue fragments have been excavated from this site. Such an assemblage of materials spanning the entire metallurgical production sequence is rare at Moche and early Middle Horizon period (ca. 600–1000 CE) sites and thus presented a unique opportunity to investigate precolumbian metallurgy on the North Coast during this time. This paper presents a summary of the extensive typological and archaeometric analyses conducted on this assemblage to date. This dataset has been used to reconstruct the *chaîne opératoire(s)* of metallurgy at Huaca Colorada, and when combined with Bayesian chronological modeling of over 70 radiocarbon dates from the site, how these practices varied diachronically. The results

also elucidate the interrelationships between metallurgy and other craft production activities at Huaca Colorada, as well as the important role of metallurgy within the site's ritual economy.

A Zoontological Approach for Examining the Role of Animals in Ancestral Maya Ritual and Society

Animals played a fundamental role in mythology and religion among the ancestral Maya. Iconography often depicts animals, including humans dressed as animals, taking part in feasts and ceremonial performances. Archaeologically, the remains of these important animals are recovered from ritual contexts such as burials, altars, caches, and other special deposits in elite contexts, suggesting the symbolic value of animals enhanced status relationships. This project combines theoretical approaches from social zooarchaeology with stable isotope analyses of animal remains to provide a "zoontological" view of ritual variability in the upper Belize River Valley region of the Maya lowlands from the Middle Preclassic through Early Postclassic periods (900 BC–AD 1250). Zooarchaeological data suggest variability in faunal assemblages among polities, perhaps indicating unique ritual economic systems at each site. Multi-isotope analyses (C/N/O/Sr/Pb) of animal skeletal remains facilitate the reconstruction of individual animal biographies, including their diet and geographical origins. Samples of more than 15 species of mammals, reptiles, and birds from ritual contexts identify instances of purposeful animal management and possible exchange. By generating animal biographies, results suggest the potential for isotope analysis in directly addressing the strategic ways people involved animals in interactions between the living and cosmological worlds.

Colonialidad y negociación de imaginarios: Una mirada a las relaciones williche-español desde el lago Ranco, Sur de Chile, siglos XVI-XVII

El pueblo williche o "mapuches del sur", reconocidos como tal al menos desde fines del siglo XVIII (Parlamento de Negrete 1793), habitaron el denominado Futa Willi Mapu. Al comparar con las áreas septentrionales del País Mapuche, este territorio tuvo una organización diversa, y según las fuentes, poco unificada; pero un aspecto relevante es que habría permanecido en gran parte "libre" del control directo del aparato colonial durante alrededor de dos siglos (1598/1604 a 1793/1796). No obstante, los escasos registros escritos y testimoniales, y sus interpretaciones historiográficas, dan cuenta del carácter particular de la relación entre estas parcialidades con los españoles, basado en los intereses propios de los colonizadores y aquellos de los dirigentes indígenas. El registro arqueológico indígena de esta época nos puede entregar luces respecto de aspectos socio-económicos y políticos de estas poblaciones, los cuales pueden complementar las fuentes históricas. En este trabajo discutimos aspectos organizacionales de las poblaciones del Futawillimapu (actual Región de los Ríos, Sur de Chile) y su relación con el aparato colonial, a partir del registro arqueológico de un contexto indígena ubicado a los pies de la Cordillera de los Andes, en la cuenca del lago Ranco.

Roberts, Ted (UES)**[293]***Chair***Roberts, Ted (UES)****[293]***Alcohol Use and Archaeological Practice*

The role of alcohol in the practice and culture of American archaeology has rarely been critically investigated. Although most practicing archaeologists agree a link between alcohol use and archaeology exists, the nature of that dynamic is often left unexamined. There is little doubt that the consumption of alcohol serves some function or plays some part in the profession, but few systematic studies have been published exploring the attitudes, opinions, and feelings on the use of alcohol in archaeology. This paper seeks to explore current views regarding the consumption of alcohol in the culture of archaeology and how alcohol affects the agency and identity of archaeologists. This pilot study builds on a critical review of available literature with results of recent data derived from web-based surveys undertaken by practicing archaeologists and archaeology students ($n = 208$) in conference settings. These data are then used to provide possible context and implications to the complex correlation between alcohol use and archaeology/archaeologists in a profession rapidly undergoing seismic shifts in the way issues of inclusion, substance use, and appropriate conduct are viewed and prioritized in today's workplaces, campuses, and communities.

[251]*Centering the Edge: The Preclassic Ceramics of Belize*

For many years the notion of a core (or center) versus periphery (or edge) dominated models of prehistoric Maya development. However, in 1979 David Freidel argued against the idea that there was a center or edge, asserting that the lowland Maya belonged to an interaction sphere. Many early models largely reflected modern political and linguistic boundaries, and ignored Belizean sites, which continue to be researched extensively in large measure because of the receptiveness of the Belize Institute of Archaeology to the excavation and analysis of prehistory in this geographically "edge" country. In this paper we will explore the Center versus Edge model with respect to Preclassic ceramics. From the earliest occupations, ceramics in Belize, an area described as part of the theoretical "edge" are, in fact, similar to those found at sites in Mexico and Guatemala. The general pattern is one of mutual engagement, reinforcement, and innovation in prehistory, leading to the conclusion that there is no center or edge in the data and should not exist in its interpretation.

Community Archaeology in Belize

This paper examines community archaeology in Belize: its recent history and contemporary practice. Community archaeology, following the work of Sonya Atalay, is archaeology done “with, by, and for” Indigenous and local communities. It produces an archaeology that is vibrant and meaningful for local and research communities alike. We present examples of community engaged archaeological research from across Belize and from the work of each of the coauthors. Our case studies illustrate the importance of collaboration between researchers, local, and Indigenous communities and the role of education and public engagement across generations. We demonstrate how community archaeology in Belize is on the forefront of advancing both knowledge-making and the practice of archaeology in Belize and is an example for archaeologists working elsewhere in the Maya area and across the globe. Community archaeology produces a better archaeology for communities and researchers enhancing all aspects of the archaeological process and its outcomes.

Amazonian Wetland Domestication: A Spatial Analysis of Precolumbian Zigzag Features in Lowland Bolivia

Recent archaeological studies show that precolumbian communities began modifying southwestern Amazonia approximately 3,500 years ago. Previous research within lowland Bolivia has primarily focused on the fields and forest islands that populations built to elevate themselves and their crops from seasonal flooding. However, a series of zigzag earthworks found in the 1990s to the east indicate that ancient communities may have harnessed floodwaters to catch fish. This study collects and analyzes spatial data from other recently identified zigzag features in the West Central Llanos de Mojos (WCM), demonstrating that these earthworks form potential wetlands with the capacity to affect water flow and accumulation for over 600 m² of land. Results indicate that potential wetlands are distinguished by two unique patterns of zigzag features, which differ in size and relationships to major bodies of water and nearby anthropogenic features. Large-scale environmental transformations of this kind would increase the duration and scale of wetlands, including riparian habitats and resources that ancient communities could have exploited. This suggests that anthropogenic landscapes within WCM are more complex than previously thought and that inhabitants may have intentionally manipulated water to bring wetlands under their control.

Integrating Low- and High-Precision Chronologies in North American Archaeology

Many archaeologists have questioned the value of using aggregated radiocarbon ages as a proxy measure of past human population growth. Most of these criticisms revolve around the lack of precision in these aggregated approaches. Higher-precision Bayesian approaches have often been presented as a better alternative. However, Bayesian approaches have their own limitations, especially when it comes to theory building and research design. This presentation proposes a new multiscale theory of human population growth that relies on the integration of low- and high-precision chronologies. We present two different case

studies illustrating how high-precision Bayesian chronologies confirm low-precision summed probability distribution approaches. We propose that Bayesian approaches will be most valuable for theory building and hypothesis testing when they are integrated with aggregated, coarse-grained chronologies. We pay tribute to Bob Kelly's vital role in making this future possible.

Water, Creation, and Celestial Phenomena at La Casa de las Golondrinas, Guatemala

La Casa de las Golondrinas is a Mesoamerican sacred rock art and pilgrimage site located in the southern end of the Antigua Valley in the central highlands of Guatemala near water sources and routes of travel. Recently, mapping efforts have found that the natural site, 500 m long, was culturally structured with hundreds of images and many Precolumbian structures. This paper will focus on motifs and features recorded by the Proyecto Arqueológico del Área Kaqchikel (PAAK) that are concerned with water and by extension rain-making, and the interwoven life forces of creation, fertility, reproduction, and cycles of time. The images also include references to sky-related phenomena including the sun, the moon, Late Postclassic deities, and constellations. This paper will discuss these images with reference to the Mesoamerican ethnographic literature and the social and physical contexts of the images.

Domestic Space and Food Production in the Mesoamerican Neotropics during the Early Holocene

Discussions on the peopling of the tropics have tended to characterize tropical forests as barriers to early human foragers due to the difficulties in obtaining sufficient nutrition from hunting and foraging activities. New research on these pioneering settlers is transforming our understanding of ancient subsistence practices and migration, ecological adaptation, and cultural developments in the tropics. We present data from the Maya Mountains of southern Belize, where we document food processing from contexts over 9,000 years old. Our data document food management strategies from shortly after the Younger Dryas as evidenced by intensive use of grinding stones for plant processing. We document an early Holocene plastered domestic space as well as cobbled living surfaces. These data were generated with a focus on high precision chronologies and demonstrate the active engagement of early peoples with plant resources and investment in landscapes with profound implications for cultural and environmental trajectories.

Robinson, Rebecca (HKBU)**[26]***Make a List, Check It Twice: Bureaucratic Surveillance in the Early Chinese Empires*

The early Chinese Empires, the Qin and Han, governed their lands and peoples using an army of bureaucrats who were responsible for, among other things, creating a vast quantity of administrative documents. Of particular interest to the state was the population—the governments kept population registries, updated annually, which not only provided them with relevant information for taxation and labor obligations but also served to tie individuals to their place of registration, preventing them from moving about the empire or taking on new identities. Recently excavated documents have revealed the extent of the states' attempts to track the population and enforce compliance with laws. This paper shows that the creation and maintenance of these physical records was a fundamental part of state population surveillance. The documents, census records, and administrative lists, usually written on wooden boards and created with the assistance of the population, were visible examples of the state's monitoring of the population. Not only did the state have information about the people but the people knew that the state was watching, and that the extensive documentation would make it difficult for anyone to escape state surveillance.

Robitaille, Jerome (Monrepos, LEIZA), Lisa-Elen Meyering (Durham University, UK), Sabine Gaudzinski-Windheuser (Monrepos, Leiza, Germany), Olaf Jöris (Monrepos, Leiza, Germany) and Paul Pettitt (Durham University, UK)**[93]***Unraveling the Complexity of Magdalenian Engravings on Gönnersdorf Plaquettes: Investigating through Manual and Controlled Robotic Experiments*

Our AHRC/DFG-funded Household Art project explores the content and wider context of the 15,800-year-old Gönnersdorf/Andernach Upper Paleolithic engraved plaquettes (portable schist) curated at MONREPOS, Neuwied (Germany). We use state-of-the-art 3D scanning microscopic and use-wear technologies in MONREPOS'S TraCEr laboratory and visual psychological experimentation including virtual reality conducted at Durham University (UK) to identify individual engravers, their personal idiosyncrasies, and the extent to which their engraving was influenced by the natural shape of plaquettes (pareidolia). This adds to our understanding of the art's positioning and importance in a Magdalenian domestic environment. We discuss current results, including the hand-preference of artists, the sequence of engravings, and the reuse of plaquettes over time.

Robles, Erika (Harvard University)**[79]***Chair***Robles, Erika (Harvard University)****[79]***Jewels, Flowers, and Paper Bows: Ornaments on Instruments for Sacrifice and Self-Sacrifice in Nahua Prehispanic Art*

By analyzing the codices, ceramics, and prehispanic sculpture, it is possible to identify different instruments employed both for the extraction of blood itself and for the sacrifice of victims. In these sources, maguey spines, bone awls, flint knives, and even the quadrangular stones where the victims lay during the sacrifice were adorned with jade or turquoise beads, flowers, paper bows, and feathers, among other symbolic elements. These ornaments manifested concepts of fertility, preciousness, perfection, blood, sacrifice, and self-sacrifice. However, there is a distinction between the artifacts destined for sacrifice and those intended for self-sacrifice, since they form sets not only for their function but also for their ornaments. Likewise, the archaeological context has revealed the existence of bejeweled bone awls, suggesting that the artifacts used for ritual penance could have been lavishly adorned as shown in the artistic images, reinforcing both their purpose and their symbolism.

Robles García, Nelly (Instituto Nacional de Antropología e Historia)**[160]***Discussant***Robles García, Nelly (Instituto Nacional de Antropología e Historia), Saburo Sugiyama (Arizona State University), Yuma Takada (Okayama University, Japan), Damián Martínez (Instituto Nacional de Antropología e Historia) and Miguel Ángel Galván (Instituto Nacional de Antropología e Historia)****[239]***New Perspectives of Monte Albán-Atzompa Complex through New Lidar Mapping Survey*

Monte Albán, the central mountain area in the Oaxaca Valley was largely modified around 500 BC and functioned as a ceremonial precinct and state headquarters for more than 1,300 years. As one of the objectives under the umbrella program of “Out of Eurasia,” we here explore the worldview, the underlying conception of time-space that was often materialized in calendar systems, and the cognition of nature and human communities. We focus on the astronomical alignments of cities, specific buildings, and the general site orientations retrievable from our precise maps in the whole valley’s contexts, and examine them by ArcAstroVR, a new archaeoastronomy program, built on Stellarium. We are recording all architectural features, sculptures, murals, and elite tombs, with multiple strategies, including drone-mounted lidar, Slam-lidar, 3D scanners, and photogrammetric devices. We mapped more than 17 km² covering most of the Monte Albán-Aztompa complex, recoverable today in a modern urban expansion context, for the first time to three-dimensionally reconstruct one of the largest and oldest hilltop urban centers in Mesoamerica. As a final goal, we search how governments integrated their rulership into the human cognitive systems and materialized their honor systems in monuments, cityscapes, landscapes, and skylscapes.

Rockwell, Heather (Salve Regina University)**[20]***Dispatches from an Archaeological “Backwater”: Microwear as a Proxy Measure of Paleoindian Landscape Use in the Far Northeast*

Archaeologists have been examining and publishing on the fluted point period for over a century. However, the northeastern United States has received comparably less attention from the professional discipline, with one colleague describing prehistoric archaeology in New England as an archaeological backwater. This may be in large part due to the added complexity of working in the area. Unstratified, shallow buried sites, containing few to no organics are the norm in this region, leaving archaeologists with little more than lithic artifacts to interpret human behavior. I examined stone tool assemblages from a wide range of archaeological sites in the region dating to the fluted point period and based on their inferred uses combined with interpretations of occupation span I argue we can see evidence of seasonally specific behaviors. I further argue that the northeast offers unique opportunities to address questions of landscape use and colonization at the end of the Pleistocene. Far from being an archaeological backwater, this challenging region provides us with superior temporal control untainted by questions of Pre-Clovis. And holds important implications for the archaeological visibility of colonizing populations.

Improvisation and Creativity at an Emergent Andean Center

Ann Stahl continues to produce a rich, and provocative scholarship, one that has inspired scholars across regions and generations. She has long positioned herself within “intellectual crosscurrents,” drawing on literature from a wide range of disciplines. Most recently, this has resulted in a critical reflection on creativity and improvisation (Stahl 2019). In this paper, I engage Stahl’s writing on creativity in a region quite far from Banda, Ghana. I explore how her thinking on creativity might productively shift Andeanists away from lingering structuralist tendencies. I focus on Tiwanaku, a center of Andean creativity during initial urbanization in the fifth and sixth century AD. Specifically, I consider the creativity and improvisation associated with early (cal AD 420–590) polychrome Qeya ceramics and the various aesthetic communities of practice implicated in their complex itineraries. I deploy some of Stahl’s strategies to investigating generative processes and examine how some of the analytical spaces for investigating creativity might help us reframe the practices associated with these evocative materials.

Archaeology of Dugout Canoes in Global Perspective

Dugout canoes, typically made by felling trees then hollowing out logs by burning and chipping, are a widespread form of watercraft throughout the world, and one with great antiquity. There are archaeologically known dugouts from Europe, Africa, Asia, and the Americas, as well as from Australia and Oceania. Early examples of dugouts date to as much as 8,000 years ago, dugouts have persisted even as other kinds of watercraft have been devised and developed, and people still make dugouts for water travel in some parts of the world today. This paper introduces a symposium about the archaeology of dugout canoes, canals and portages associated with dugout canoe travel, replicative studies of building dugouts, and modeling patterns of canoe travel in the past by outlining a global perspective on the significance of this form of watercraft to peoples of the past. Many papers in the symposium concentrate on dugout canoes in particular areas of the Americas, and we therefore review here some ethnohistoric and archaeological background from these areas. We also consider the contributions that archaeology of dugouts and dugout canoe travel in the Americas can make to broader conversations about the archaeology of traditional and vernacular forms of watercraft worldwide.

Lapidary Objects from a Funerary Context: The Origin to the Last Abode

Within the daily activities of a population, there were the events of the death of community members. These practices led the population to look for certain objects that needed to be placed next to the deceased people in the burial process with different functions and meanings. But what is the life story of these items? Was the raw material local or foreign? Did the villagers make the ornaments by themselves, or did they get them already manufactured? Questions like these have been our starting point for the application of archaeometric techniques that have allowed us to know the origin of the resources and the forms of production that were used for the elaboration of these artifacts. Our case of study focuses on a sample of lapidary ornaments from the Zacatenco site located in the Basin of Mexico. We have applied analyses such as X-ray energy dispersion spectroscopy and traceology, and the results have helped us to review the proposals that exist about the interaction networks that were developed during the Formative period.

Overcoming Centralization in the Ancient Sierra Nevada de Santa Marta: Toward a Novel Model of Indigenous Low-Density Urbanism in Northern Colombia

This paper develops a novel model to understand the social organization of landscapes and urban settlements in the Sierra Nevada de Santa Marta. This region's history mainly stems from the imposition of European categories to interpret the sociopolitical organization of Indigenous communities, often suggesting that the very chiefs and ethnonyms that emerged in the colonial era had always existed. Said imposition introduced and reified ethnic and cultural categories, such as Tairona, Taironaca, Betoma, Posigüeica, and Carbón. Later, scholars drew on these colonial documents and often proposed that "the Tairona" were the most powerful chiefdom in the Sierra Nevada, concealing the other communities and peoples throughout the area. This account led archaeologists to expect evidence of political centers from which wealthy elites presided over smaller villages and subject populations. In consequence, and despite earlier reports of hundreds of ancient stone settlements beneath the tree canopy, most archaeological research has largely focused on Teyuna-Ciudad Perdida and Pueblito. This paper presents evidence from recent surveys, mapping, architectural analysis, and excavations that reveal a different scenario: a multi-centric or even noncentralized urban landscape, a case of low-density urbanism that redefines theories of this coastal mountain range of northern Colombia.

[127]

Early Occupations of the Mountainous Interior of Puerto Rico

Recent excavations conducted in three cave sites in north-central Puerto Rico have revealed that human

occupation of the mountainous interior of the island took place much earlier than previously thought. The available evidence, recovered from Cueva del Abono, Cueva Matos, and Cueva Ventana, has shown that important developments in the Indigenous history of Puerto Rico such as the origins of food production, pottery manufacture, and the development of rock art traditions were manifested in the central part of the island since its earliest phases of occupation. In this presentation, the evidence that has been recovered thus far will be presented in order to address its implications for our current understanding of the discoverers of the island.

Cutting Through the Networks: An Assessment of the Circulation of Singular Artifacts in Prehistoric Iberia

In this paper, we aim to analyze a collection of singular artifacts recovered from various sites in the Iberian Peninsula, spanning from the Early Neolithic to the Early Bronze Age (approximately 5600–1800 BCE). Our primary focus will be on investigating the patterns of circulation and exchange of polished axes and adornments made on green stone, which made it possible for these artifacts to be distributed across much of the Iberian Peninsula. To achieve this objective, we will conduct a comprehensive analysis of a database containing over 50,000 artifacts. Our analytical approach will encompass a variety of methods, including spatial statistics and network analysis.

Chavín and Its Galleries: An Inside View of the Andean Formative Period

Understanding the unique gallery system at Chavín de Huántar has been one of the PIACCh's primary goals over the past 30 years. Research objectives that began in the mid-1990s with the challenge of simply making accurate maps of these internal spaces, evolved to address broader questions ranging from ancient construction principles and design language to architectural growth and chronology and ritual uses and ideology—and how these changed over time. To investigate these topics the project applied numerous methods including digital mapping, architectural analyses, excavations, remote sensing, digital scanning, chronometric methods such as radiocarbon dating of architectural mortar and optically stimulated luminescence (OSL) dating of construction materials, acoustical studies, and robotic exploration. This paper highlights some of the important results of this work. It then examines a case study of galleries within the main temple building (Building A) as well as the building south of the Plaza Mayor, considering directions for future research. The view from Chavín's galleries reveals profound insights that these enigmatic spaces bring to our understanding of the Andean Formative period, emphasizing their fundamental role in the site's physical and ideological growth while underscoring the need to research architecture as an independent variable and data source.

Tracing Marks in the Dark: Documenting Mud Glyph Cave by Drawing on Methodology of the Past and Present

Since the rediscovery and canonization of Paleolithic and precontact cave art, researchers have grappled with

different ways to document and reproduce sites containing ancient artwork. Early methods utilized hand drawing in situ and, soon after, cave art reproduction included film photography. Later, digital photography became the primary mode of capturing ancient artwork. Contemporary methodology uses photogrammetry, 3D modeling, VR, and AR to transport us to the artwork through digital realities. This paper focuses on the synthesis of traditional methods of drawing, analog photography, digitization methods, and design technology for creating an archive of the Southeast cave art site, Mud Glyph Cave. The artwork of Mud Glyph Cave is comprised of drawings, impressions, incisions, smoothing, and other types of surface preparation that are encased in Pleistocene mud deposits. The simultaneous homogeneity of the surface color and the complexity of surface development in Mud Glyph Cave presents a unique challenge for art reproduction. Drawing on past and present technological methods, this research demonstrates a novel approach to documenting ancient 3D cave art that is created solely in clay.

"Natural" Resources Land Conservation Ignores Archaeological Resources?

Natural resources conservation arrangements, including easements on land, have existed in the US for many years, with origins in the Conservation Movement dating to the time and efforts of T. R. Roosevelt. In recent years, the land conservation movement has grown across the US and often involves support from national, state, and local governments partnering with nonprofit organizations. Factors such as climate change, for example, are increasingly in the mix for the goal to protect land from development that harms plants, animals, and ecology that otherwise would exist as a "natural" system benefiting air, water, and other conditions for sustaining quality of life. In this presentation I will discuss why I occasionally put the term "natural" in scare-quotes, the physical impacts of natural resources conservation, some major players and programs, and why I believe protection of archaeological sites often is on the losing end of natural resources conservation arrangements, particularly where federal funding is involved. I will cite some examples such as from the US Department of Defense and also touch on Native American involvement regarding this issue.

Aquaculture in the Ancient World: Ecosystem Engineering, Domesticated Landscapes, and the First Blue Revolution

Aquaculture is the world's fastest growing food sector and accounts for more than 50% of the world's fish food supply. The significant growth in global aquaculture since the middle of the twentieth century has been dubbed the Blue Revolution. However, it is not the first Blue Revolution to take place in human history. While historically classified as low-ranking, seasonal, or starvation resources in the archaeological discourse, marine foods were vital resources that ancient communities developed and exploited using a vast array of strategies. Among these aquatic strategies was aquaculture. This first Blue Revolution was initiated during the early Holocene, some 8,000 years ago in China, with archaeologists now documenting aquaculture across the globe. This presentation considers the commonalities between ancient aquacultural systems including evidence of ecosystem engineering and the development of domesticated landscapes as production systems. These aquaculture systems were maintained for centuries, if not millennia, and enhanced and diversified key aquatic resources. Worldwide research conducted on ancient aquaculture can provide critical insights into developing more ecologically sustainable, resilient, and diverse marine production systems for coastal communities today, thus achieving industry sustainability and limiting negative environmental impacts to the world's shorelines and overexploited fisheries.

Transiciones en cuerpos y espacios: Acercamiento a las prácticas funerarias desplegadas en Chavín de Huántar a finales del Formativo

Tras el cese del funcionamiento del centro ceremonial de Chavín, el área fue reocupada por los grupos Huarás, Mariash y Callejón, quienes construyeron unidades domésticas en espacios antes considerados como rituales. El punto que llama nuestra atención es la transición entre la ocupación chavín y la implantación de comunidades Huarás. Esta transición debe ser entendida como un cambio abrupto que implicó materialidades totalmente distintas. Así, observamos un enfoque en la desacralización de espacios a través de la reutilización consciente y destrucción de iconografía chavín como parte de un probable programa de “asesinato ritual”. En esta investigación buscamos aproximarnos a las prácticas funerarias ejercidas en un espacio clave y poco usual, la galería 4 al este de Caracolas. En esta estructura encontramos los restos de dos comunidades: una Chavín, asociada a la clausura del espacio; y otra, Huarás vinculada a entierros intrusivos. Esta superposición de contextos formaría parte de la dinámica de posicionamiento de los nuevos grupos quienes emplearon los restos corporales de individuos como vínculos físicos legitimando su presencia mediante la construcción de una memoria corregida. En consecuencia, los cuerpos y las prácticas funerarias desempeñan un papel político al comunicar un nuevo orden y la ruptura con el pasado.

Conociendo a los Paracas del Valle de Chíncha a Partir de la Cerámica Doméstica: El Caso de Pozuelo (Costa Sur del Perú), durante el Horizonte Temprano (500-200 aC)

Nuestro trabajo investiga la función social de la cerámica paracas del sitio arqueológico de Pozuelo. Todo lo que se conocía de este asentamiento es que contuvo la cerámica más antigua del valle de Chíncha denominado como «estilo Pozuelo». No obstante, nuestras investigaciones han demostrado una fuerte ocupación vinculada con el «estilo Paracas» entre los 500-200 aC del Horizonte Temprano. Precisamente, durante esta época en el valle bajo surge una gran explosión de sitios monumentales asociado con una cerámica finamente decorada. Sin embargo, desconocíamos la ubicación de las esferas domésticas que mantuvieron relaciones sociales detrás del consumo de cerámica no decorada. Hasta el momento, Pozuelo es el único sitio del valle que ha evidenciado una alta concentración de cerámica utilitaria o doméstica. En virtud de los resultados ceramológicos y contextos arqueológicos podemos señalar que la cerámica paracas de Pozuelo cumplió la función social para la preparación y consumo de alimentos. Asimismo, el hallazgo de alisadores y platos de alfarero señalan que los núcleos domésticos estarían produciendo cerámica en el mismo sitio y sus formas estarían siendo adoptadas por las elites de habitaron en los edificios monumentales; en tanto, estas similitudes entre las formas evocarían identidad social entre ambas esferas humanas.

Romero, Levi (University of New Mexico)**[84]***Vecinos: The Symbiotic Relationship between Picuris Pueblo and Its Indio-Hispano Neighbors*

This presentation seeks to capture the rewards of a neighboring progression that moves away from past conflicts toward reconciliation forming a new history between the Pueblo and Indio-Hispano people. Inter-communal exchanges between the Spanish and Pueblos helped them to endure droughts, famines, diseases, and the eventual encroachment of a new social system foreign to both of their cultures. The commemoration of feast days in the pueblos and in the villages brought them together in times of plenty and in celebration of the planting and harvesting seasons and other festive occasions throughout the year. Occasions like these forged enduring relationships among individuals and families alike. There are stories that recount the knowledge and wisdom of shared methodologies of agriculture, architecture, food preparation and preservation, religious traditions, rituals, acequia systems, and water harvesting. What has endured through the ages are stories that capture a holistic and balanced life within their shared *querencias*, stories of blessings and offerings, of birthing and of dying, of giving and receiving.

Romero Aranda, Víctor Hugo, and Mari Carmen Serra Puche (Instituto de Investigaciones Antropológicas UNAM)**[214]***Indicadores arqueológicos de la identidad de los pobladores de Xochitecatl-Cacaxtla durante el Epiclásico*

La cuestión relacionada con los grupos que reocuparon el asentamiento de Xochitecatl-Cacaxtla durante el periodo Epiclásico nos permite seguir preguntándonos quiénes eran y su lugar de procedencia, lo cual ha sido atribuido a cierto grupo étnico o a alguna cultura arqueológica definida por diferentes investigadores. Tenemos claro que la viabilidad de cualquier propuesta en torno a una relación filogenética y cultural entre alguna de las regiones de Mesoamérica y el asentamiento de Xochitecatl-Cacaxtla supone demostrar que existió algún tipo de interacción, principalmente al final del periodo Clásico y al inicio y desarrollo del Epiclásico, la cual tendría que manifestarse en ciertos aspectos sociales y culturales identificables en los registros arqueológicos. Por todo lo anterior, en este trabajo presentamos las evidencias arqueológicas que nos permiten suponer que entre el sur de la cuenca de México, específicamente la región de Chalco-Amecameca, y el asentamiento de Xochitecatl-Cacaxtla existieron estrechos vínculos filiales y culturales que nos sugieren acerca de la identidad y del origen de los grupos que reocuparon el viejo asentamiento al final del periodo Clásico y al inicio y desarrollo del Epiclásico en el Altiplano Central.

Romero Padilla, Laura**[320]***Ritual Cave Utilization in the Middle Usumacinta Region: Sociopolitical Implications of Ritual Cave Use at the Maya Residential Sites Associated with Piedras Negras*

In this paper, I will examine the significance of ritual cave use in the emergence and development of Classic Maya polities. Caves are critical settings to understand the diversity of ritual practices and the involvement of such contexts within sociopolitical systems. My work in caves in the Middle Usumacinta Valley will further our understanding of ritual as a powerful venue to negotiate political power between Piedras Negras and its subsidiary minor centers while conflicts were ongoing with neighboring Yaxchilán during the Classic period (AD 250–900). In the summer of 2022, I conducted a field season in Nueva Esperanza Progresista in Chiapas, Mexico. Fourteen caves were mapped and recorded near the secondary center of Budsilhá which was administered by Piedras Negras. My preliminary observations of cave contexts from outlying areas of Piedras Negras and near its secondary centers suggest notable differences in the performance of local practices inside these caves as attested by the presence of rock paintings and unslipped and decorated ceramics. By diachronically investigating cave sites, and by tracing differences in ritual practices, I hope to understand how ritual cave use shaped sociopolitical organization and power dynamics between mid-level groups and major polities in Classic Maya society.

Bending the Urban Narrative: Cyclic Cities in Ancient Greece

The urbanization of human settlements is commonly seen as a relatively linear development beginning in the earliest sedentary communities of the Neolithic and ending with the international megalopolises of the present day. A closer scrutiny of the archaeological record, however, clearly shows that this narrative has little bearing on the factual situation. Using the example of the developments in ancient Greece (700 BC–AD 500), this paper explores the cyclic nature of urban life, and how urbanization and de-urbanization are tightly tied to political agendas and not the given outcome of organic population growth.

Community Archaeology with Descendants of the Enslaved at an Arkansas Plantation

The Hollywood Plantation in southeast Arkansas was a place where over 100 enslaved African Americans labored to improve the land and generate profits for their enslavers for decades following the cession of Indian lands there in 1818. Following emancipation, the enslaver and his descendants converted the plantation into a profitable business exploiting the labor of hundreds of sharecropper and tenant families, the majority of them Black migrants from eastern states. Research conducted over the past two years started with genealogy and connecting with the descendants of this African American community and investigating spaces associated with their ancestors away from the Big House. So far, archaeological investigations have been conducted at two sites: a slave cabin and a sharecropper house. Work has also been done to rehabilitate and interpret multiple Black cemetery and church sites across the historic 12,000-acre plantation property. Investigators also partnered with Fayetteville's Pryor Center to create an online oral history channel featuring the voices of people who worked as sharecroppers on the plantation in the early 1900s. This paper will review the results so far and show how archaeologists can work with descendants to interpret the past in a way that honors their African American heritage.

Deforestation of Pacific Islands Driven by a Combination of Land Use, Fire, and Climate

Remote islands in the Pacific Ocean experienced dramatic environmental transformations after initial human settlement in the last 3,000 years. Human causality of this environmental degradation has been largely unquestioned, but examination of regional records suggests a role for climate influences. Here we use charcoal and stable carbon isotopes from deep soil cores to reconstruct the dynamics of fire activity and deforestation across the Sigatoka River valley on the leeward (dry) side of Viti Levu, Fiji. Fires and pyrogenic patches of grassland predated human settlement by millennia, but the magnitude of fire activity and landscape transformation accelerated with the establishment and expansion of swidden agriculture. Regional comparisons with previous studies in Fiji and elsewhere in Remote Oceania settled between 3200 and 2900 BP reveal a similar pattern of pre- and post-settlement fire activity and landscape change. Pre-settlement fires generally corresponded to droughts, probably driven by El Niño, often correlating with drought-driven wildfires elsewhere in the region. Post-settlement, charcoal and C₄ grasses increased dramatically but nearly all major peaks in charcoal and grasses corresponded to increased El Niño activity. This indicates that fire activity and deforestation were a product of the interaction between swidden agriculture and climate rather than land use alone.

Rorabaugh, Adam (Simon Fraser University; Washington State Department of Fish and Wildlife)**[262]***Assessing Population Dynamics in the Central Salish Sea, Pacific Northwest Coast of North America*

Recent developments in radiocarbon dating have enabled archaeologists to reexamine the question of population dynamism in the Salish Sea. This study expands on prior studies using Kernel Density Estimation (KDE) and an expanded dataset of 538 radiocarbon dates from academic and cultural resource management literature. The expanded sample suggests a pattern of population growth from 3200 to 2800 cal BP in coastal northwestern Washington, with population growth in the San Juan islands during 2600–2200 cal BP. A subsequent decrease in radiocarbon frequencies and large sites suggests shifts in use of the San Juan Islands, followed by peak large-scale occupation from 650 to 300 cal BP. This pattern is robust whether marine or terrestrial dates are considered. However, marine dates are less sensitive to questions at smaller temporal scales. The broad scale radiocarbon frequency patterns observed are also consistent with those observed in southwest coastal British Columbia.

Rosa Figueroa, Jeffrey (California State University, Los Angeles)**[221]***Into the Darkness: Analyzing the Midnight Terror Cave Artifact Assemblage and its Spatial Implications*

From 2008 to 2010, California State University, Los Angeles, working under the Western Belize Regional Cave Project directed by Jaime Awe, investigated Midnight Terror Cave (MTC) in the Cayo District of Belize. At present, MTC is best known for its large human osteological assemblage of over 10,000 bones, which is well documented in the bioarchaeological literature. Less well known is that the survey also recovered a large number of artifacts that have received scant attention. This presentation analyzes the MTC collection within the larger context of our knowledge of Maya cave artifact assemblages to highlight its unique characteristics. Additionally, this research analyzes the spatial distribution of collection within the cave to draw conclusions about the use of artifacts and the function of space within caves.

Rosas Jiménez, Citlali**[273]***Teotihuacán: Retos actuales en la protección de su patrimonio arqueológico*

Desde hace varios años se desarrolla un estado de riesgo de pérdida parcial patrimonial en Teotihuacán. Si bien existe un marco normativo en materia de protección de patrimonio cultural arqueológico para Teotihuacán, este se encuentra desarraigado socialmente, derivado de acciones que muestran principalmente la falta de identidad, apreciación y reconocimiento de los valores culturales por parte de los actores corresponsables de su cuidado. Aunado a ello, la protección legal que sobrevive se enmarca en un estado de falta de mecanismos recientes de protección y/o de actualización de los existentes, elementos esenciales para fortalecer los esfuerzos nacionales de salvaguardia. Adicionalmente, el actor institucional encargado del cumplimiento de los lineamientos en materia de protección combate además un contexto regional de economía informal y de crecimiento urbano descontrolado. Situación que, dentro de los planes gubernamentales aspira a su regularización sin considerar la conservación y recuperación de la armonía patrimonial. Este análisis, producto de los resultados de registro de los procesos institucionales que se operan en Teotihuacán, evalúa el marco de protección considerando la dinámica cultural, política y social actual, de cuyo desenlace resulta exponer la necesidad de reestructurar el proceso de patrimonialización de Teotihuacán encaminado a una salvaguarda efectiva.

Roscoe, Paul (University of Maine)**[263]***Land, War, and Optimal Territorial Size in Neolithic Society: Why New Guineans Rarely Ever Occupied the Territories They Had Conquered*

Not infrequently, New Guinean warriors managed in war to displace or annihilate the members of a

neighboring territory, yet almost never did they then move in and occupy the territory they had won. Instead, they either left it vacant, allowed allies to take it over, or (most commonly) invited the original owners back a couple of years later. This seemingly irrational behavior directs attention to a largely overlooked aspect of neolithic territoriality—the optimal territorial size. In a theater of war, the territorial area that a neolithic polity can control is governed by a trade-off between its capacity to defend members as they move around that territory and the commuting costs incurred to procure the subsistence resources needed to support that defensive capacity. The end result is an optimal territorial size. Neolithic polities have an incentive to maintain this optimum, but should they expand beyond it—for example, by expanding onto a conquered territory—the result is an invidious reduction in defensive strength, a marked increase in subsistence commuting costs, or both.

GlobalID: A New Research Data Infrastructure for Lead Isotope Data

Lead isotope data are an important tool for the reconstruction of raw material provenances of non-ferrous archaeological materials. The quality of the provenance reconstruction depends, among other factors, on the comprehensiveness of the reference data the archaeological samples can be compared with and access to these data. GlobalID aims to develop existing reference data collections, such as OXALID and IBERLID, by further building modern research data infrastructure in a community-driven process. GlobalID's main aims are to create (1) a standardized machine-readable description for lead isotope data from all kinds of objects, (2) an open-access database, (3) a web application providing tools to access the database and to do the most common tasks for working with lead isotope data, and (4) a workflow for the publication of lead isotope data as data publication and a collection of tools facilitating the submission of data and the maintenance of the infrastructure. Apart from building the infrastructure, GlobalID aims to bring the entire community closer together, particularly striving for better integration of colleagues from less wealthy countries. This will be achieved through the organization of training workshops, user meetings, and open educational resources.

The Neolithic Bird Hunters of the Mongolian Gobi Desert

Archaeological surveys in the Gobi Desert of Mongolia have begun to reveal new information about the landscape distribution and seasonal movements of mobile populations in this semiarid steppe environment on the eve of the late Holocene adoption of pastoralism. However, until recently we've had little information

about their campsites and settlement activities due to the very small number of in situ archaeological remains. This made it difficult to understand the trajectories of subsistence pursuits and social organization preceding the shift to herding. The site of Burgasney Enger, located in the Ikh Nart Nature Reserve, Dornogovi Province, Mongolia, is unique in the region. Our recent excavations have revealed an organized settlement with hut circles, elaborately constructed ovens, plant phytoliths, and abundant bird bones indicating traditions of ecological knowledge at a “persistent place” adjacent to an extinct wetland environment. Semi-sedentary settlement there lasted from ca. 8000 to 4000 BP. The information from this site allows us to track adaptations to the increasingly dry environment and address the question of continuity and change in ecological traditions and knowledge.

Toward Establishing a High-Resolution Chronological Record of the Atlatl-and-Dart to Bow-and-Arrow Transition in the Great Basin

The adoption of the bow and arrow by Indigenous peoples was a significant event that had profound social and economic effects. In the Great Basin, researchers have traditionally placed the appearance of the bow-and-arrow weapon system between ~1,800 and 1,500 calendar years ago and assumed that it almost immediately replaced the atlatl-and-dart system. Few efforts have been made to understand when, from where, and how quickly this shift took place. Direct AMS dating of organic weapon components from legacy collections offers a means of addressing these questions. Here, we report dozens of AMS dates on atlatls, darts, bows, and arrows from numerous Great Basin sites. Though much work remains to be done, our preliminary results do not support a rapid transition. Rather, they indicate that the atlatl-and-dart and bow-and-arrow systems were used alongside each other maybe as long as six centuries. As our dataset of directly dated weapon components continues to expand, it will contribute to ongoing conversations about when and why people favored one system over another, and the economic and social effects that such decisions carried with them.

Before There Were Ceramics in Belize

The 10,000 years before ceramics first appear is the longest epoch in the human occupation of Belize, and yet the least understood. Many fundamental cultural developments are first documented in what is now known as the Maya region, including management of tropical forest resources, a reduction in residential mobility, and increased reliance on food production. While relatively few data exist from the Preceramic Mesoamerica,

compared to the subsequent ceramic periods, a significant proportion has been unearthed from the within Belize. In this paper, we briefly summarize previous contributions made by archaeologists working in Belize before the appearance of ceramic containers at ~3000 BP. Early work by Richard MacNeish along with important results documented at Colha and Pulltrouser Swamp are reviewed for their contribution to understanding early occupations of Belize. This is followed by highlights from each author's current field research projects that are contributing new data to understanding the Preceramic. We conclude that archaeologists working within the small modern nation of Belize continue to make disproportionate contributions to understand the ancient Maya region and the larger Mesoamerican world.

Perspectives on Deviance: Exploring Sex-Variance from Bioarchaeological and Contemporary Standpoints

In this talk, we discuss the visible effects of sex-variance on skeletal material and in the modern politico-ethical world, drawing on bioarchaeological, historical, and medical sources. Here, sex-variance includes the overlapping categories of castrates (such as castrati and eunuchs), transgender people, and intersex people. Contemporary political partisanship and religious moralizing have produced “regimes of truth”—in keeping with this session's focus—that have worked to erase or denigrate such variance. Because the techniques and theories that bioarchaeologists and forensic anthropologists use to create knowledge are predicated on an assumption of a sex binary, overlooking “deviance”—a concept we will consider in greater depth—from that binary may be an understandable concession. However, drawing from queer theorizing, we argue that knowledge of such sex-variance in the past (1) eases the burden of invisibility individuals experience in the present and (2) combats the naturalization of a sex and gender binary. We also address the slippery slope—that is, the risk that discussing sex-variance can lead to the medicalization of gender-variance, reducing it to a medically determined and determinable biologically based condition rather than a complex interplay of personal, interpersonal, cultural, social, and biological factors.

Advances in the Understanding and Interpretation of Ceramic Offering Caches in Great Kiva Contexts

Recent investigations at the LA8619 Point Great House Community Great Kiva, have documented a ceramic offering cache of 600 artifacts. Two previous caches were documented in 2016 and 2021, also associated with the Southern cardinal direction in the Great Kiva. Drawing on ethnographic analogy evidence, an economies of destruction political economy theoretical basis, and site-wide novel ceramic analyses, an interpretation of the 2023 cache's ideological and cosmological function within Great Kiva monumental architecture in the ancestral Pueblo world is suggested. Analyses of the ceramic assemblage suggests that the cache is a directed deposition of animated objects that are capable of acting as agents of change. The 2023 offering cache is interpreted to be a closure or decommission event associated with a change in a late AD 1200s cultural tradition influence in the Middle San Juan region of the US Southwest.

Greathouse Springs, Arkansas: Structure and Social Organization of an Archaic Base Camp in the Ozarks

This paper discusses recent investigations at a hunter-gatherer base camp in northwest Arkansas. Excavations at the Greathouse Springs site (3WA569), near Fayetteville in Washington County produced unusual remains of Archaic structures. Included are two elongated rectangular structures, interpreted as communal

cookhouses, and at least four smaller circular structures, interpreted as sleeping huts. These were defined by their hardpacked earth and crushed stone floors and stone-lined posts. Other features are raised platforms with hearths and angled posts. Archaic base camps in the northwestern Arkansas Ozarks were regularly spaced at approximately 25-mile intervals, each with a surrounding cluster of satellite sites. Greathouse Springs provides some of the first detailed evidence of the internal structure and social organization of these base camps.

Millennial Tropical Urbanism in the Upper Amazon

A dense system of prehispanic urban centers has been found in the Upano Valley of Amazonian Ecuador, in the eastern foothills of the Andes. Fieldwork and lidar analysis reveal a deeply anthropized landscape with complexes of monumental platforms; plazas and streets distributed according to a specific pattern; straight, wide roads running over great distances; and extensive agricultural drainages and terraces. Archaeological excavations reveal an occupation from around 500 BCE to 300/600 CE.

Investigating Childhood Metabolic Health during the Rise of the Athenian Democracy

Sociopolitical change, such as that which occurred during the Archaic period in Athens (700–480 BCE), has the potential to increase food scarcity and physiological stress. When dietary diversity is negatively affected, women and children are often the first to suffer the effects of insufficient micronutrient uptake. Thus, investigating metabolic disorders in archaeological populations is essential for understanding both a population's nutritional health and the etiology of early childhood stressors. This study investigates paleopathological indicators of metabolic stress in preadult individuals from Phaleron Cemetery ($n = 75$), ranging in age from birth to 15 years, to understand the potential impact of sociopolitical transition on nutritional insufficiency at Phaleron. In this sample, 81% had at least one indicator of physiological stress that could be related to nutritional deficiencies, and 36% had a suite of stress indicators consistent with scurvy, suggesting significant undernutrition among those who did not survive to adulthood. However, because scorbutic indicators may resemble markers of normal growth, other metabolic disorders, or nonspecific physiological stress, multiple etiologies and possible comorbidities are considered and evaluated. Furthermore, we argue that the presence of these indicators in individuals who would have been breastfeeding may indicate maternal nutritional stress.

Rots, Veerle (TraceoLab, University of Liège) and Justin Coppe (TraceoLab, University of Liège)**[306]***Functional Perspective on the Evolution of Hunting Technology in Africa and Europe*

The development of hunting technology is a key aspect of human behavioral evolution. Many efforts have therefore been made to identify prehistoric projectiles and propulsion modes, especially to determine when long-range hunting weapons were first invented. The African record has been central to such debates thanks to the early dates for stone projectiles and claims made for the first appearance of bow-and-arrow technology in South Africa. Research into the origins of projectile technology suffers, however, from two major setbacks. First, no reliable method exists for identifying propulsion modes, and the present claims therefore largely rely on circumstantial evidence. Second, functional studies have been infrequent, and projectile function has instead been assumed on typological or morphological grounds, Tip Cross-sectional area (TCSA) values being a case in point. Analyses incorporating so-called diagnostic impact fractures have provided more specific data but have sometimes also added confusion. In this paper, we review current projectile evidence for the Middle Stone Age in Africa and the Paleolithic period in Europe and based on our recent experimental and methodological work we propose some avenues that hold promise for future research.

Spanning the early–mid-Holocene and the global climate event at 8200 BP (“8.2 event”), the Late Neolithic (ca. 7000–5000 BCE) is a crucial time for understanding cultural trajectories in southwest Asia. In hyperarid deserts such as that in the Black Desert of eastern Jordan, questions remain about the environmental background and its impact on the behavior of communities. Research over the past decade by the Eastern Badia Archaeological Project has recorded substantial Late Neolithic occupation sites in the eastern desert of Jordan. Although evidence from the Arabian Peninsula and Sahara demonstrated permanent lakes and associated vegetation at this time, until now little evidence was available to place eastern Jordan into this regional perspective. This paper will present evidence from the Black Desert sites of Wisad Pools and Wadi al-Qattafi that suggests that this was a steppic zone crossed by people reliant on caprine herding and intensified hunting. These Neolithic people had contacts outside what we now view as this marginal zone and had increased social and economic interaction beyond the steppic region.

Rowe, Sarah (University of Texas Rio Grande Valley) and Guy Duke (University of Texas Rio Grande Valley)**[161]***Expanding the Archive: Buen Suceso and the Valdivia Tradition in Early Andean Interaction*

The Valdivia tradition of coastal Ecuador (ca. 3800–1450 BC) was one of the first sedentary, agricultural, and ceramic-producing traditions of the Americas. Valdivia holds an important place in regional (coastal) and national imaginings about the origins of Ecuadorian cultures and the Ecuadorian nation. While the modern border between Peru and Ecuador generally serves to silo the cultural traditions on either side of it, connections between Valdivia and traditions in Peru have long been noted, from the pyro-engraved gourd featuring Valdivia iconography found by Junius Bird at Huaca Prieta to similarities in the ceramic assemblages found in El Oro Province and far northern Peru identified by John Staller. Recently identified connections between the Valdivia occupation of the coast and the Mayo-Chinchipe- Marañón tradition of southern Ecuador and northern Peru suggest that further attention to the variety contained within the Valdivia tradition is warranted. We present insights from ongoing research at Buen Suceso (ca. 3750–1425 BC), a

Valdivia site located in the Culebra-Colin (Manglaralto) Valley on the flanks of the Colonche-Chongón hills. Buen Suceso is one of the longest-occupied Valdivia sites and exhibits a unique history and social practices that expand the basis for comparisons of social traditions in Ecuador and Peru.

Urban Renewal, Historical Preservation, and the Erasure of Indigenous Modernity

Indigenous people's urban experiences represent some of latest chapters in their stories of survivance. Yet they remain largely invisible archaeologically because of urban renewal, historic preservation practices, and the myth that US cities do not have modern Indigenous histories. Geographies of race and class underwriting mid-twentieth-century urban renewal and earlier land clearance made the Indigenous inhabitants of Providence its unseen victims. A modest-size city in the Northeast, Providence had the third-largest Native American population in the United States by the first decade of the twentieth century. Structural debris from their homes that city planners considered blighted and often their contents, along with archaeological traces of deeper histories were removed and redeposited, erasing and compromising the Indigenous urban landscape. Historic preservation law designed to address the destruction caused by urban renewal underserve Indigenous communities due to reliance on thematic frameworks that deny that Indigenous people can be modern and urban. Moving forward, urban heritage must be more inclusive and collaborative, and the eligibility criteria for preservation must recognize sites of Indigenous occupation routinely considered lacking aesthetic value or sufficient integrity.

People-as-Animal Comparisons and the Indigenous Experience of Spanish Colonialism in the Andes

Animal metaphors can express conceptualizations of humanity and attitudes about society when referring to groups of people. In Spanish colonial contexts in the Americas, these metaphors often reinforced social hierarchies and denigrated indigenous peoples. Although few, there are first-hand accounts of Indigenous authors subverting these discourses to their advantage. By examining their use of animal metaphors, we can center Indigenous agency in our historical interpretations of the complex processes of colonization. In this project, I explore how the Andean Indigenous author, Felipe Guaman Poma de Ayala, used animal metaphors in his 1615–1616 manuscript through conceptual metaphor theory and social semiotics. Guaman Poma weaved his colonial context into people-as-animal comparisons displaying aspects of human-animal and Spaniard-Indigenous interactions during the first century of Spanish colonization. I also present how similar uses of these comparisons by present-day Indigenous people reveal aspects of the colonial legacy and how investigating the historical origin of these metaphors can improve our understanding of the sociopolitical positions of Indigenous peoples today. This project shows the potential for combining ethnohistorical and ethnographic research with zooarchaeological evidence to reconstruct the Indigenous and animal experience of colonialization and its legacy.

Rubinson, Samantha (Southern Nevada Rep.)**[64]***Discussant***Rubinson, Samantha (Southern Nevada Rep.) and Sarah Miller (Florida Public Archaeology Network Northeast)****[254]***Outcomes of Site Stewardship: Exploring the Vast Archives of Site Preservation*

Data collected through site stewardship programs are unique and provide insights into the long-term preservation of archaeological sites. Stewardship programs across the country are working with communities to document changes over time from environmental and human-driven causes. Site changes are recorded using photography, monitoring reports, mapping, 3D scanning, and site condition assessments. This paper will explore previous, current, and potential research projects using datasets from site stewardship programs. These projects span from the effect of climate change on sites, working with descendant communities to help develop new practices in preservation, tracking the degradation of sites throughout the country and the importance of digital photography recordation as a significant form of preservation.

Knowledge of sawfishes is still scant for Latin America. *Pristis pristis* (largetooth sawfish) and *Pristis pectinata* (smalltooth sawfish) are critically endangered. In the Yucatán Peninsula (YP) these species populated coastal landscapes. We collected 290 surveys of fishers' Local Ecological Knowledge (LEK) with a geospatial component and reviewed 74 literature sources and available archaeological data for the region. Results show the common past presence of sawfishes, their cultural significance for coastal societies, the contemporary absence of sawfishes in coastal areas where they historically existed, sightings of juveniles were only documented by elder fishers, and only two recent narratives mention sawfishes caught incidentally five years ago. Geospatial results prove 52 geographic sites where sawfishes were common in the YP. Results support the development of interdisciplinary research methodologies to study human-nature interactions through time. This matters in the YP, where sociocultural values and landscapes have changed rapidly by increasing tourism development and human migration. This information can help conservation managers understand the past presence and contemporary loss of sawfishes and their habitat and contribute to understanding defaunation of megafauna in the YP. This is critical for tourism and fisheries' ecosystem services on which communities of the YP rely for subsistence.

Rucinski, Hannah (Illinois State Archaeological Survey), Georgia Abrams (Illinois State Archaeological Survey) and Tamira Brennan (Illinois State Archaeological Survey)**[137]***Moving a Monster, Part One: Preserving Illinois' Cultural History in Perpetuity*

In 2022, the Illinois State Archaeological Survey's Curation Section undertook the monumental task of moving its ~24,000 ft³ Illinois Department of Transportation collections to a larger, modified-to-suit facility. These collections include some of the most significant projects carried out in Illinois. This paper addresses our methods for assessing the state of collections and the considerations, logistics, and challenges of

identifying immediate needs to accomplish this task efficiently. Preparations included, but were not limited to, box-level assessments; location control; environmental monitoring across four buildings; identifying an appropriate new facility and upgrading that space with HVAC, fire protection, an alarm system, and high-density shelving units; hiring movers; and physically preparing the collections for moving day. The insights gained in this endeavor illustrate the complexity of moving large collections to better equip other institutions with methods to improve their own collections management plans.

Tracing Tides of Change: Perspectives on Mobility and Materiality in Precolonial Central America

Matters of materiality and mobility across Central America have long been the subject of archaeological investigation concerning its precolonial past. In outlining the spectrum of material movements and their broader sociocultural implications beyond traditional archaeological narratives, this introductory paper seeks to explore the interplay between foreign influences and local integrations of material culture in the Isthmo-Colombian Area. As a precursor to the broader symposium discussions, this paper intends to frame a robust academic exploration of mobility and materiality across and within precolonial Central America, prompting scholars to reconsider its dynamics through the lens of material flows and their transformative impacts on its societies. We particularly want to move beyond some of the more prevailing narratives, including the impact of predominantly external influences on the sociopolitical development of the region. In doing so, we aim to paint a more holistic picture of the mechanisms and dynamics of material trajectories and their effects on matters of migration, filiation, and (social) identity.

Traceología: Identificación de instrumentos sacrificatorios y de manipulación póstuma en el Osario 15 de Toniná

El sacrificio humano por medio del acceso de toracotomía bilateral transversa es una práctica ritual poco documentada a nivel osteológico en el área maya. En el presente trabajo se muestra a nivel microscópico y macroscópico tal evidencia, así como el tratamiento que se les dio a las víctimas posterior al sacrificio. El estudio se llevó a cabo en Toniná, donde se rescataron más de 15 mil huesos humanos con evidencia antrópica, recuperados de la Acrópolis. Se parte de la observación morfooscópica por región anatómica y posteriormente se realizó una selección de una muestra representativa por área anatómica del cuerpo: cráneo, caja torácica, extremidades superiores e inferiores y huesos de las manos y pies. Consecutivamente se revisó a nivel microscópico cada alteración ósea seleccionada, para proseguir con la identificación de herramientas líticas mediante una impronta con polímero replicante para su identificación en el Microscopio Electrónico de Barrido (SEM) y por medio de la arqueología experimental. Este análisis nos aporta datos sobre el tratamiento mortuario y las prácticas tecnológicas referentes a la manipulación póstuma de los cuerpos sacrificados. La finalidad es presentar la evidencia ósea, así como la identificación de las herramientas líticas utilizadas en el manejo de las víctimas.

Reduce, Reuse, Recycle: Small Finds in the Collections of Maya Archaeological Assemblages of the BREA Project in Belize

This presentation addresses data from the Maya “small finds” category in the laboratory assemblage of collected and excavated materials of the Belize River East Archaeology (BREA) Project, which beginning in 2011 has been documenting and researching the cultural and environmental history of the Belize River drainage, comprising Preceramic period land and resource use, Maya settlements and landscapes, Spanish and British colonial contexts, and the Kriol heritage of current communities. Here I focus on material culture studies broadly, and object biographies more specifically, inspecting a range of categories of Maya material production. Among these are objects that have variously been referred to as fishing net weights or net sinkers, as well as objects described in the literature as perforated disks or interpreted as spindle whorls and weft weights. Using insights from ceramic ethnoarchaeology studies, this presentation examines ceramic small finds recycled from pottery sherds within a framework of depositional theory, use-lives of objects, and ceramic reuse behavior. The analysis of processes like discard and recycling within the context of pottery making, fishing technologies, and weaving explores the links between material culture and social practice, with the goal of providing insightful queries into Maya ceramic production and economic specialization.

Risky Research

Sebastian Payne made a lasting impact on zooarchaeology, especially in the Old World, with his 1973 paper outlining age and sex mortality profiles that characterize the prioritization of meat, milk, or wool. Richard Redding was the first scholar not only to suggest that these optimizing models might not be appropriate for ancient societies but to provide a rigorous alternative model that foregrounded another factor: risk reduction, or security. This was an important intervention, one that started me thinking about other factors that prehistoric herders might have considered as they made culling decisions, such as wealth value. Redding made many contributions to zooarchaeology; I would argue that this is the earliest major one and one of the

most enduring.

Enhancing Ceramic Petrography through Deep Learning

Clay recipes reveal information about the local geology and the inclusion of different additives that make up a vessel, which in turn reflects the social, environmental, and technological context of ceramic manufacture. Ceramic petrography has long been instrumental in shedding light on key manufacturing techniques, identifying unique mineralogical signatures, and assessing patterns of cultural exchange among diverse communities. However, traditional methods used to characterize and quantify petrographic thin sections can be labor-intensive and time-consuming, making it difficult to meet the increasing demand for large comparative datasets. Here, we present recently developed machine-learning algorithms to enhance the efficiency, accuracy, and accessibility of these intricate analyses. We review the basic steps for conducting these approaches and illustrate their practical application for being incorporated into a petrographer's standard toolkit. Streamlining petrographic workflows through machine-learning techniques will open new avenues for the quantitative and qualitative assessment of ceramic technology and its broader implications for past societies.

When the Earth Was New: Memory, Materiality, and the Numic Ritual Life Cycle

This paper explores the critical subject of indigenous oral traditions in California and the Great Basin. Using an interdisciplinary approach that considers Numic oral teachings relative to place-based data in ethnography, ethnohistory, archaeology, and geology, the author interrogates traditional narratives encoding some of the earliest forms of scientific observation among Numic speaking communities. This research explores multigenerational memories of recorded localized geological knowledge within oral teachings. These teachings, expressed in the form of narratives, songs, rock art, and material culture, provide opportunities to explore memory, ritual, materiality, and potential convergences between science and indigenous ways of knowing.

Dorset through Their Own Eyes

The Dorset Paleoinuit (Tuniit in Inuit traditional knowledge) are a culturally extinct group who lived throughout much of the eastern North American Arctic between about 2,500 and 700 years ago. They are best known for their art, primarily 2D and 3D carvings, which range from highly naturalistic to highly abstract. Ubiquitous among the carvings are representations of human and near-human faces with a variety of expressions suggesting emotions including surprise or alarm, sadness, joy, peace, and anger. The faces appear on a variety of handheld objects extending from the utilitarian (harpoon heads) to the esoteric ("wands"), as well as at three petroglyph sites. Researchers have offered a variety of interpretations for why the faces were made, usually linking them with shamanistic practices including human-animal transformations and ancestor reverence. However, there is sufficient variation between faces to indicate that a large range of individuals, likely real people, were being depicted. At the same time, certain faces appear to repeat again and again,

across time and space, suggesting specific stories or individuals were being referenced as cultural touchstones. Using collections at the Canadian Museum of History, this presentation investigates the variability and possible meanings underlying Dorset representations of themselves.

Human-Environment Research at the Crow Canyon Archaeological Center: The Legacy of Dr. Karen R. Adams
Initiated by Dr. William Lipe and Ian (Sandy) Thompson in the late 1980s, the goals of the Environmental Archaeology Program at the Crow Canyon Archaeological Center are to study the effects of human occupations on the natural environment, how people socially mediate environmental change, and to contribute to discussions of how past behaviors can inform environmental education, policy, and practices in the present and future. Dr. Karen R. Adams's decades-long career plays a significant role in our understanding of human and environmental interactions in the central Mesa Verde region from AD 500 to 1300. This paper summarizes Dr. Adams' contributions to archaeobotanical and paleoethnobotanical research in the northern Southwest and celebrates her substantial legacy.

A Pipeline Project: Navigating through Diverse Perspectives Surrounding the Line 3 Replacement Pipeline
Enbridge's crude oil Line 3 Replacement Pipeline cuts through 337 miles of Ojibwe Treaty lands in Northern Minnesota and has been in operation since October 2021. It is the most recent installment of a historic petroleum infrastructure tradition in the state of Minnesota that extends back over 70 years. Oil pipelines do not only enter the purview of archaeological attention due to their capacity to harm buried archaeological material along their route but also as contemporary archaeological features that have direct implications for the many communities with whom they come in contact. This contemporary infrastructure, like all its historic developments, is not only a matter of immediate concern but also serves as an example of the continued presence of materiality that violates Indigenous sovereignty that likewise requires archaeological attention. In this paper, I discuss the challenges of obtaining narratives and engaging with a variety of stakeholding community members, such as Water Protectors, law enforcement agents, and archaeologists. My research demonstrates the importance of including diverse perspectives that each emphasize varying understandings of environmental, material, and social impacts of the Line 3 replacement pipeline and presents a unique and holistic approach currently missing in the archaeological literature.

Collaborative Archaeology and Heritage Management at the Malcolm X House, Inkster, Michigan

This presentation reflects on the process and contributions of collaborative archaeology involved in the Malcolm X House Project in Inkster, Michigan. The 800-square-foot home was where Malcolm Little was living in 1952 when he assumed leadership roles in the Nation of Islam, changed his name to Malcolm X, and rose to international prominence as a civil rights leader. In 2020 the Inkster-based nonprofit Project We Hope, Dream, Believe partnered with local archaeologists and historic preservationists to secure funds to purchase and restore the derelict house into a museum and community center commemorating Malcolm X's

legacy. Archaeological investigations were deemed by the nonprofit to be an integral component of the project. We detail how collaborations between the nonprofit, local residents, and archaeologists succeeded in navigating historic preservation and fundraising efforts and empowered an underrepresented community to establish leadership roles in the preservation of civil rights heritage sites locally and statewide.

Tidemarks, Waterlines, and Shifting Sands: Perspectives on Aquatic Landscapes in the Plata Basin

Characterized by hydrological variation and shifting shorelines, rivers, wetlands, and coastal areas of the Plata Basin have historically formed interactive cultural landscapes, dynamic resource and communications geographies, and globally vital ecosystems. Using fluctuating contact zones with water as a theoretical and methodological point of departure, the paper outlines considerations for multidisciplinary approaches to their reconstruction. This is anchored in a diachronic discussion on circulation, exchange, and praxis of waterside communities, centering on the Goya-Malabrigo Archaeological Entity and the Guaraní, the “Phoenicians of the Precolumbian world” (Métraux 1928: 207), also with reference to their maritime extension. Due to the dynamic interplay of natural and anthropic factors, the archaeological record of the islands, beaches, and promontories that formed loci of aquatic lifeways is often fragmentary. In terms of landscape reconstruction, this accentuates the importance of further research on periodically and partially submerged zones, past and present; infrastructures and implements related to aquatic resource exploitation; navigation adapted to specific conditions; and the analysis of bioindicators from aquatic and shoreline environments. Together, these inform questions of scale in historical ecology and the regional archaeology of waterways, also indicating avenues for the study and mitigation of climate change effects.

Acknowledging Behavior and Process in Early Caribbean Stone Tools: The Case of the Ortiz Site, Cabo Rojo, Puerto Rico

Since the 1930s, scholars have examined variation in early lithic assemblages across the Caribbean archipelago. Long-held explanations for the genesis of these assemblages (and the differences among them) include cultural/stylistic factors, aspects of raw material availability/quality, or the intended type(s) of activities of specific tool types or industries. Lamentably, such attempts have often served to relegate lithic toolkits to being mere deterministic responses to external stimuli. Analysis of the lithic assemblage from the Ortiz site, an early (2340 cal BC–cal AD 310) habitation site in Cabo Rojo, Puerto Rico, examines the sustained and contemporary manufacture of both blade and expedient flake technologies. We present here the results of morphological, experimental, and use-wear analyses which sought to gain a more comprehensive understanding of the decisions ancient stone tool makers and users made as they undertook processes of lithic procurement, reduction, and use. Using Ortiz as a case study, our hope is to (re)situate the behaviors and processes of lithic procurement and manufacture in the early Caribbean within the hands of ancient knappers whose assemblages were, above all, products of conscious choices, and far more complex than caricatures of their purportedly “simple” hunter-gatherer way of life.

History and Future of the Kerr Photographic Archive of Maya Ceramics

The Kerr Archive constitutes the largest photographic collection of Maya ceramics, including rollouts and

stills of more than 5,000 unique artifacts from museums, private collections, and archaeological excavations. Devising their own numbering system, Justin and Barbara Kerr created more than just an archive. “Kerr numbers” have become persistent identifiers for Maya ceramics and are today more widely used in the scholarly literature than the designations and collection numbers of the actual repositories. This paper will revisit the history of Justin and Barbara Kerr’s contribution and how the Kerr Archive became the framework for organizing our knowledge of Ancient Maya ceramics. We will provide an update on the work currently done at Dumbarton Oaks to preserve the data from the Maya Vases Book and Mayavase.com, while re-cataloguing the collection in HOLLIS Images and making the images searchable through the Dumbarton Oaks website. We will discuss implications from the Kerrs’ work for future generations of scholars and pose relevant questions to which the papers in this session will respond.

NAGPRA Data Management Plan

It has been over three decades since the Native American Graves Protection and Repatriation Act (NAGPRA) was signed into law on November 16, 1990. NAGPRA was passed in a different information environment than the one at present; electronic documents are now ubiquitous and legislative mandates require a transition from paper documents to digital formats. With this new climate comes new challenges to preserving the integrity of documentation both for security and in respect to stakeholder communities. A particularly relevant subject area is the issue of redaction, which requires an adaptive approach when decolonizing legacy collections. A new path must be forged to develop a model of best practices, to ensure the integrity of the information gathered, and communicate among various entities to ensure that the spirit of the legislation is upheld. As part of a NAGPRA repatriation project, I developed a data management plan to comply with legal requirements and worked to devise a redaction policy, with the specific aims to consider the unique challenges posed with electronic storage and the conversion from older formats. It is hoped that this work will promote a reconsideration of information policies that ensure the utmost effort to secure sensitive information.

From Colonization to Complexity and Beyond: David G. Anderson and Big Picture Archaeology in North America

David G. Anderson’s contributions to the field of archaeology are beyond measure, both in number, scope, and significance. These include substantive contributions to Southeast prehistory, from the peopling of the Americas to the historic period, and from academia to the field of cultural resource management (CRM). David has also had an impact on numerous individuals, via publication, mentorship, and education. In this presentation, I will highlight a number of the ways that David has been an inspiration and enduring influence on my own life and career as an archaeologist in the US Southeast. In particular, I will discuss a sample of his own work and how it has guided my own research in the field of archaeology over the past two decades.

How to Characterize in visu Mountains’ Shape and Its Significance in Inca Culture?

Beyond geomorphology, mountains are complex cultural entities. In Inca culture, they embodied powerful social agents, *wak’as*, and constituted meaningful places in the territories that composed the empire. Early colonial chronicles, as well as ethnological heritages, offer abundant data and analogies on mountains’ cultural

significance, but archaeological evidence is scarcer. It mainly consists of *capacochas* sacrifice remains on very high-altitude summits, of rare examples of miniature representation, and of the architectural devices of mountains scenification (e.g., a window and/or the site location) and their common association to astronomical phenomena. Researching how mountains appear from these devices can allow us to assess if certain summits' characteristics were especially significant in Inca culture, as stated in some chronicles. This talk will present a 3D modeling approach to characterize and statistically compare summits' in visu appearance and relation with astronomical events. This approach, based on horizontal visualization and measurement of a digital terrain model, is applied to the study of Vilcabamba Cordillera, a mountain range close to Cuzco, whose impressive density of snow-capped peaks may have played a significant role in the selection of this region for the implantation of royal estates instead of its planning as a classical imperial province.

Archaeological Study of Sources of Slate Stone Clubs from the Late to Final Jomon of Central Hokkaido

Slate stone clubs created as prestige technologies were frequently found in *shuteibo* (a type of communal cemetery characterized by a circular embankments constructed in the latter half of the Late Jomon of central Hokkaido) burials suggesting that they were regalia of the dead. This paper explores sources of the stone clubs to better understanding trade networks of these artifacts and the Late Jomon political economy. To do so, (1) this research conducted reconnaissance of stone raw materials in the southern Kitagami Plateau in the Tohoku region, which is well known for its fine slates; and (2) examine techniques of the stone club production processes at production sites in the Plateau. Similarities of raw materials and techniques used for slate stone clubs between the Plateau and central Hokkaido suggest that many of these stone clubs were imported from the Plateau via long-distance trades as part of prestige economy. Such trade goods could be used to enhance and reinforce the status of elites as part of an aggrandizer strategy. Trade involving these stone clubs among elites associated with rituals and feasts probably accelerated a high degree of interaction between regional groups in Tohoku and central Hokkaido.

Reconstruction of the Site History of the "Zip Code Site," a Large Virgin Branch Puebloan Site at the Mt. Trumbull Area in the Arizona Strip

The goal of this study is to gain a better understanding of the settlement patterns among the Virgin Branch Puebloans, who were small-scale farmers living in the marginal environment at the Mt. Trumbull area in the Arizona Strip. The Zip Code Site (131BLM) is a large site with multiple pueblo structures at least 200 m long. One of the hypotheses for this large site is that it was a late aggregated village. Previous studies, however, mention the very few corrugated sherds, thus implying that this site was occupied relatively early during the late Basketmaker III or Pueblo I period. Both the radiocarbon dates and the optically stimulated luminescence (OSL) dates range from AD 476 to 1350. Thus, it is hypothesized that, instead of being an aggregated village, this large site is the result of long-term occupation and not all of the structures and rooms were used simultaneously. Between 2018 and 2023, several rooms were excavated to better understand the history of the site's use. In this poster, we will present the results of the chemical compositional analyses of the soils using pXRF from different depths in a few rooms, combined with OSL dates, to investigate the history of site's occupation.

Salas, Megan (Denver Museum of Nature & Science)**[13]***Objects Conservation and Materials Analysis at Pañamarca*

In addition to the painted architectural surfaces recently unearthed at Pañamarca, a wide array of objects have been found in recent excavations. The objects found at Pañamarca demonstrate that the site has an excellent preservation environment. This paper will present conservation approaches to some of the different types of objects—such as metals, organic materials, and ceramics—encountered in the 2023 season. The presentation will highlight the importance of preventive conservation efforts like packaging in ensuring the survival of these materials post-excavation. The successful block lift of a large artifact will be presented as a model for further work at the site. This paper will also present preliminary analytical findings on pigments from the wall paintings. Pigments were analyzed in situ with a handheld X-ray fluorescence spectrometer and samples were taken for further laboratory analysis.

Salazar Chávez, Victor Emmanuel (George Washington University) and Jeffrey Blomster (George Washington University)**[128]***De quelites me como un taco: The Importance of Secondary-Growth Plants in Polyculture-Based Farming Strategies and Food Traditions at Etlatongo, Oaxaca*

Whenever we think of Mesoamerican foods, it is easy to imagine maize. It is particularly true during the Early Formative period, when the first sedentary villages appear in the region. Maize has been used almost exclusively to explain and understand early Mesoamerican diet and subsistence. This has left out a more comprehensive understanding of people's foodways. In Etlatongo, an Early Formative community in the Mixteca Alta of Oaxaca, the largest macrobotanical sampling for the period has been examined, and it provides both essential and new information about people's foods beyond maize-centered views. Several types of plants, such as edible weeds, shrubs, and cacti, were identified. The evidence suggests that they were crucial to the community's food traditions, as well as to the development of polyculture-based agroecological systems. These largely undervalued plant species for archaeologists were rather key to social and cultural development at Etlatongo, and their study offers more nuanced ways to understand one of Mesoamerica's most significant episodes, the emergence of sedentary and sociopolitical complex societies.

Saldaña, Gabriela (Independent Researcher) and Elizabeth Graham (University College London)**[226]***Revisiting the Polychromatic Stucco of Lamanai, Belize*

A significant assemblage of Late to Terminal Classic stucco was discovered at the archaeological site of Lamanai in northern Belize. Originally forming a frieze adorning the upper facade of the palatial Structure N10-28, the stucco fragments are remarkable for their overall preservation and their extensive polychromatic pigmentation. In 2023 a new phase of documentation was initiated, following up on earlier efforts undertaken between 1998 and 2000. This ongoing study aims to explore the potential of photogrammetry for cultural heritage management purposes, and for reconstructing the original pictorial registers of the frieze in a 3D environment. The study focused in particular on (1) photographic and photogrammetric documentation of selected pieces, (2) chromatic documentation and determination of color values of the pigments, and (3) iconographic and epigraphic analyses of the figurative and glyphic stucco. The preliminary analyses of the iconographic frieze reveal sections of a highly detailed narrative scene, which furthers our understanding of ancient Maya pictorial expressions at Lamanai.

[285]

New Observations on Ancient Maya Ceramic/Textile Composites: A Technological, Conceptual, and Contextual Reappraisal

In 1993, a previously unknown composite material made of layers of finely woven cotton fabric saturated in ceramic slip were recovered by the Petexbatun Regional Cave Survey in the Cueva del los Quetzales, Petén, Guatemala. An analysis of the sherds was conducted by the Smithsonian Institution's Conservation Analytical Laboratory (now the Smithsonian Center for Materials Research and Education [SCMRE]) in 2004. A recent revisiting of the materials included micro-CT scan imaging that has led the authors to question the established position that the technology used to produce these sherds was highly specialized, and that they were made exclusively for the elite. This presentation chronicles our reanalysis and rethinking of these rare artifacts.

Changing Curation Practices When Indigenous Voices Are Included

Curation practices changed at museums as human remains and funerary objects went from being seen by practitioners as scientific specimen to individuals. When this happens, how the individuals are handled and cared for changes as well. Consulting with Tribal Nations about the care of individuals allows culturally appropriate methods to be developed and put in place. Our consultations have led to the writing and regular updating of our "Traditional Care & Handling Guidelines" at the Museum of Anthropology, University of Missouri. Along with changes in care of individuals, the museum has made changes in the care of other artifacts as well. And consultations have led to more complete stories being told in the museum as the museum and Tribal Nations work together.

Daily Life Rhythms: Narrating Milpa Landscapes in Mexican Mountains and Sustaining Agroforestry Practices in Brazil

This paper highlights the importance of agroforestry communities in Latin America as guardians of ancestral knowledge related to plant cultivation and ecological practices that have shaped the region's landscape and cultural heritage. These communities celebrate the interconnectedness between people and the environment, resulting in a chain of social practices that permeate their daily lives. This paper explores the transmission of this knowledge and the articulation between ancient and new techniques in traditional communities in Mexico and Brazil. Over generations, these communities have integrated food into complex and sustainable ecosystems, as exemplified by maize production in Baxtla, Mixtla de Altamirano, and the managed areas in the Atlantic Forest by the Tupiniquim of São Paulo to achieve food self-sufficiency. By reclaiming this interconnectedness into narratives of everyday life, we emphasize the persistence and engagement in the exchange of knowledge in various times and places.

"I Had a Reindeer Called Onni . . .": Reindeer Stories, Memory, and the Continuation of Reindeer Herding Culture in Northern Fennoscandia

In recent years, ethnoarchaeological research combining archaeological evidence and traditional knowledge of reindeer herders has added considerably to our understanding of cultural meanings of various reindeer herding practices traceable through the archaeological record. One important aspect brought forward by participant research among present-day reindeer herders is that the relationships with reindeer—particularly working reindeer—are continuous over several seasons and years, the reindeer individuals becoming integrated into people's lives over the long term. This continuity is created in frequent contact with the reindeer, the herders always being mindful of the reindeer, their location, pastures, and well-being, but also their individual life histories and characteristics. The long-term relationships with reindeer individuals are also integrated into memories and stories, which link generations of animals and humans together in the long continuation of reindeer herding culture. In this paper, we will present a few reindeer stories told by the herders. We will examine how these stories reflect various aspects of human-reindeer relationships in reindeer pastoralism today, how they can be used to understand its cultural meaning in the past, and ultimately, what do they mean for the continuation of reindeer pastoralism as a livelihood and way of living in Northern Fennoscandia.

Ceramics and Political Dynamics of the Manteño Culture on the Coast of Manabí, Ecuador

An association between the intricacies of sociopolitical complexity and the diversity in pottery production has been discerned within precolumbian societies. To illuminate the facets of the Manteño sociopolitical framework, this study undertakes a comparative analysis of pottery assemblages across Manteño Julcuy, Cabo Pasado, Nuevo Manta, Puerto Cabuyal, Picoazá, and Cerro Hojas Jaboncillo—all settlements inhabited by the Manteño people prior to the Spanish colonization. Through an examination of the composition, nine primary pottery types and four corresponding subtypes, each exhibiting a total of 36 variations, were catalogued. Simultaneously, the artifacts exhibit a series of recurrent decorative characteristics that transcend all six examined locations. This suggests a notable complexity in Manteño Socio-Political Organization, thereby implying a minimal range of ceramic variation within this context.

Culture Contact and Gender Dynamics in Early Iron Age Southern Italy

While both gender archaeology and culture contact studies have well-developed bodies of theory, the intersection between these is undertheorized, especially outside more recent and better-documented historical archaeology. This is problematic, since any process of interaction potentially implicates divergent gendered expectations and norms and can upset previous balances by altering resources and demography in a community. In this paper, I propose a theoretical framework for studying gender in situations of culture

contact by exploring the gendered entanglements between local southern Italian communities and Aegean newcomers in the ninth–sixth centuries BC. This was a period of intense social change in southern Italic prehistory, eventually leading to the creation of Greek colonies along its shores. This process entailed the close and direct involvement of local communities, both as trading partners and, later, as co-habitants within the same settlements. However, the impact of this trajectory of interaction on the gender organization of local and (later) mixed communities has yet to be fully understood. Here, I draw from feminist perspectives and culture contact theory to reconstruct how these encounters unspooled several parallel processes of interaction across genders, class, and geographical origin.

From Municipal Dumpsite to Private Liberal Arts University: Insights into the City of San Antonio from a Nineteenth-Century Midden

The modern-day campus of Trinity University is located on a nineteenth- and early twentieth-century municipal dump site on what was then the margins of the city of San Antonio, Texas. The land also served as a limestone rock quarry for the Alamo Cement Company (1884–1931), a community baseball diamond, and a lover's lane. The university bought the land and began construction in the 1950s, promptly ending the site's previous uses. A recent archaeological surface collection of the site, currently used as a frisbee golf course and walking track, has recovered thousands of artifacts. Laboratory analysis and archival research into these objects has provided insight into the daily life of low-income and working-class San Antonians during this early occupation. In addition to discussing the ever-changing history of the space, we will discuss our findings on artifacts such as Gebhardt Chile Powder bottles, Ball Mason jars, Vaseline containers, porcelain baby dolls, and opium vials.

Diagenesis and Preservation of Pb Isotopes in Ancient Human Tooth Enamel Using Multiple Samples from the Same Tooth

Complications with diagenetic contamination of ancient human tooth enamel is of primary concern for Pb isotopic studies. While conducting a study of a Caddo skull-and-mandible cemetery in southwest Arkansas (in collaboration with the Caddo Nation), it became clear that many samples were contaminated by soil Pb. Additional samples from the same teeth were subsequently run with different methods. These methods successfully removed the diagenetic Pb content from the teeth. A comparison of multiple samples, their trace elemental concentrations, and their Pb isotopes show clear patterns associated with diagenesis and the lack thereof. The grouping of individuals in clusters provides additional clarity as to what patterned effect diagenesis has on Pb isotopic signatures. The differences between the original and successful methods that led to the removal of contamination will be discussed. While successful, these methods led to the reduction of Pb concentrations in the tooth enamel, making obtaining valid Pb isotopic data more difficult.

Maritime Settlement of Fuego-Patagonia Archipelago: New Archaeological Records from the Middle Holocene (6300–5000 BP) at Navarino Island, Chile (55° S / 67° W)

In the context of research reassessing the chronology and distribution of early evidence for maritime settlement at Patagonia and Tierra del Fuego, we have developed surveys in different areas of the archipelago to expand the geographical scale of the search, thus allowing us to incorporate aspects related to the

geographical directionality of the process. The work that we present reports new findings detected in Navarino Island. They correspond to the sites Ensenada Villarino 61 and Wulaia 15, located in the north and west coast of the Island, whose dates place them between 5000 and 6300 BP, respectively. The main characteristics of the technological assemblages (lithic and bone) and the subsistence strategies deployed are reported, comparing these records with other sites of this period in the region. This presentation is funded by grants: FONDECYT 1211976, FONDECYT 1200727, ANID/BASAL FB210018.

Conservación de la arquitectura en tierra y pinturas murales de Pañamarca

La Conservación de la arquitectura en tierra y pinturas murales del proyecto “Paisajes Arqueológicos de Pañamarca” en las temporadas 2022 y 2023, se desarrollaron en paralelo a los trabajos de excavación, teniendo en consideración la vulnerabilidad estructural así como la fragilidad de los murales pictóricos, que desde su construcción hicieron frente a distintos factores de degradación trópicos y antrópicos, además de la exposición a una nueva realidad climatológica al momento de su descubrimiento. La metodología abarca la investigación integral e interdisciplinaria establecida a partir de la necesidad de los sectores intervenidos que han demandado diferentes acciones de acuerdo a su grado y tipo de patología, partiendo de las actividades preliminares (antes de la excavación), la conservación preventiva estructural y pictórica (durante la excavación) y finalmente las actividades de protección (después de la excavación) garantizando que evidencias arqueológicas estructurales y pictóricas, perduren en el tiempo. La conservación no solo es responsable de garantizar la protección y preservación del patrimonio cultural como tal, va más allá del aspecto físico, se trata de proteger un legado histórico, el cual se refleja en la identidad de su comunidad la cual permite el desarrollo socioeconómico a partir de su protección y difusión.

From the Varrío to the Academy: Chicano Perspectives in Indigenous Archaeology

As a first-generation scholar from a low-income campesino background, the lived experience of socioeconomic inequality, racism, and other issues influence teaching, research, and scholarship. While the varrio, or “hood,” is often associated with negative connotations, positive aspects, such as community, respect, and convivencia, are overlooked and underappreciated. These collectivist cultural values are distinct from Western norms, highlighting independence and individualism. In this paper, I highlight how BIPOC scholars, especially those from the varrio, may gravitate to archaeological research that supports collaborative and community-based research practices like those found in Indigenous archaeology.

Aproximación al estudio de forma-función de la cerámica de contextos rituales en dos sitios con arquitectura monumental en el Valle Central de Costa Rica: 750-1150 dC

Trabajos pormenorizados a nivel de forma-función para la caracterización de actividades y espacios sociales

son raros en las investigaciones arqueológicas intra-sitio en el Valle Central de Costa Rica, incluyendo asentamientos complejos y con construcciones monumentales características del 750 al 1550 dC. Para el caso de los sitios Chagüite (C-151Ch) y Agua Caliente (C-35 AC), excavaciones llevadas a cabo por el Museo Nacional de Costa Rica recuperaron depósitos nutridos de fragmentos de vasijas cerámicas insertos en los complejos arquitectónicos y en proximidad a áreas funerarias muy bien delimitadas por lo que se presume que eran vertederos originados por fiestas o celebraciones de carácter público y funerario. Alrededor de este supuesto, se propone un análisis no instrumental de cerámica para lo cual se contemplaron tres contextos distintos buscando examinar la representatividad de distintos tipos funcionales. Este tipo de estudios también debe cimentarse en rigurosos análisis de huellas de uso y de propiedades tecno-funcionales de la cerámica, por ahora, el aporte principal que se espera de este ensayo es el de proveer de información comparativa que sirva para una mejor definición y caracterización de los espacios sociales en asentamientos complejos tardíos del Valle Central de Costa Rica.

[230]

Water Mountain, Ritual, and Maya Community Cohesion at Mensabak, Chiapas, Mexico

Maya established communities at Mensabak, Chiapas, instead of other adjacent lakes because of its impressive water mountain on an island where a major river is born. People traveled and pilgrimaged up the Tulijá River to live near Mirador Mountain (Chakaktun “red-hollow stone / cave-of water” in Lacandon Mayan) where they constructed multiple shrines and terraces to communicate with powerful spiritual forces residing there. Mirador is a high mountain that contains several caves and cenotes, in addition to a red-stained limestone cliff on its east side. Preclassic (ca. 200 BCE–200 CE) and Late Postclassic (ca. 1300–1600 CE) Maya aligned their buildings with this impressive landscape feature. Mirador Mountain became an important symbol of community over time and has been the location of collective rituals that united people in the region. Today, the Lacandon Maya state that Mirador is the center of the world and home to important local gods, who are consulted for community health, subsistence, and transition to the realm of the dead of its members. The archaeological and cultural information indicates that Mirador Mountain has been an archetypical Maya version of Nahuatl *altépetl*: a water mountain that represents a people, polity, and ritual landscape.

Geographically Broad Social Networks in Southwest Europe during the Solutrean: The Origin of Siliceous Rocks Exploited at Peña Capón (Central Spain)

The Solutrean of southwest Europe (~25,000–20,000 cal BP) is an outstanding case for studying human mobility and social networks within harsh environmental conditions, given its coincidence with the Last Glacial Maximum. However, little is known about these topics in the inland territories of the Iberian Peninsula. Although it was assumed that humans avoided the Iberian hinterland during the coldest periods of the Last Glacial, recent research has demonstrated that some interior regions were recurrently settled. Thus, investigating networks connecting these regions with other areas is essential for understanding population dynamics and human-environment interactions. We present results on chert sourcing and mobility patterns of hunter-gatherers occupying the Peña Capón rockshelter (central Spain) during the Solutrean. We conducted macroscopic, petrographic, and geochemical analyses by means of LA-ICP-MS. The statistical treatment of data has allowed connecting different archaeological chert types with a specific geological source. Then, we used GIS tools to establish the least cost routes potentially connecting the archaeological site with the rock sources. Results show that siliceous rocks exploited at Peña Capón come from a wide variety of regions, including areas well beyond inland Iberia, thus demonstrating the existence of long-distance contacts during the LGM.

[230]

Women Elites in the Royal Court of Tonina, Chiapas

New hieroglyphic and iconographic evidence allows us to preliminary reconstruct women's political hierarchy inside Tonina's royal court during the Late Classic period. As it is well known, parentage statements are very scarce in the inscriptions of Tonina and limited to maternal ancestry. Aside from the importance of local female nobility, there is evidence of the arrival of powerful female foreigners: this is the case of the mother of "Ruler 8" who was from Pomona's royal court in the Tabasco region. The recent discovery of funeral monuments related to female elites bearing the *ix sajal* title is of the greatest importance to understanding women's participation not only in the political affairs inside the royal court of Tonina but also beyond the kingdom as provincial governors. Therefore, visualizing their participation in the courtly life of the site is essential to avoid gender bias in the reconstruction of Tonina's history. And, overall, to promote a study of Classic Maya society from a more integrative approach.

Recuperando la memoria hidrosocial y arqueológica de la Meseta de Marcahuasi: Un enfoque hacia el desarrollo sostenible en la Sierra de Lima

En tiempos prehispánicos, las comunidades ubicadas en la Meseta de Marcahuasi (San Pedro de Casta, provincia de Huarochirí, Lima) manejaron las estaciones lluviosas y secas de su territorio mediante el uso de sistemas de siembra y cosecha de agua para el abastecimiento de una sostenible economía agrícola. Con el tiempo este manejo del "paisaje hidrosocial" se ha ido perdiendo. Las migraciones, el cambio climático y un turismo desligado de las tradiciones locales han provocado la pérdida de saberes ancestrales, la degradación del patrimonio y la dependencia económica externa. La pandemia y el confinamiento evidenciaron aún más estos problemas de autosuficiencia y desconexión tradicional. Con el turismo y la agricultura afectados por la falta de agua, el municipio y la comunidad de San Pedro de Casta buscan recuperar la memoria hídrica de Marcahuasi como modelo de desarrollo sostenible. En el presente año, un equipo multidisciplinario de arqueólogos y arquitectos venimos trabajando un reconocimiento de los sitios arqueológicos y proponemos estrategias para complementar las actividades locales de gestión hídrica en paisajes arqueológicos, reivindicando los conocimientos tradicionales y potenciando un modelo turístico sostenible para el beneficio de la naturaleza, la sociedad y la preservación del patrimonio cultural.

The Deconstruction of Technical Behavior: Assessing the Significance of Low-Cost Technologies in the Upper Paleolithic
Expedient technologies are linked to low-cost behaviors, aimed at producing stone artifacts with low technical complexity and minimal temporal requirements. Traditionally, these have been associated with assemblages characterized by simple production systems mainly geared toward obtaining flakes. In recent years, these attributes have been described in Lower and Middle Paleolithic assemblages. However, their presence in Upper Paleolithic contexts remains notably limited. This is because industries associated with *Homo sapiens* have primarily focused on lithic specialization and the increase of technical complexity, masking the existence of expedient behaviors. In this study, we analyze Upper Paleolithic assemblages from Cova Gran de Santa Linya (NE Iberia) and Vale Boi (SE Iberia) to detect and discuss the occurrence of expedient behaviors. The study of these industries can serve multiple purposes: (1) extending our understanding of expedient behavior and low-cost technologies associated with *Homo sapiens*, (2) exploring diverse manifestations of expedient behavior from a diachronic perspective, (3) elucidating the role played by expedient technologies in technically complex assemblages, and (4) providing new insights to understand the aim of low-cost behaviors and their significance from an evolutionary and adaptive standpoint.

Assessing the La Playa Projectile Point Assemblage

More than 300 projectile points have been collected from the La Playa site. The vast majority were found on the surface without archaeological contexts. The site begins to be used continuously from the middle Holocene (ca. 7,000 years) by Archaic hunter-gatherer/forager groups as a locality included in their residential mobility rounds. During the early and middle Holocene, the Boquillas river floodplain was an important locality to find water and prey and collect mesquite seeds, wood, and herbs with seed near the river. Around 5,000 years ago better weather returned to the Sonoran Desert, and the Boquillas River was an oasis where a sedentary community with a much larger population could settle and farm corn that they obtained from their neighbors from the south. Here we present a cultural history of the site using projectile point styles. We also offer some demographic data and interaction data for the Archaic and Early Agricultural period peoples in the Sonoran Desert, comparing the La Playa points with other studied sites in the Plains of Sonora.

Reanalysis of the Aterian Lithic Assemblage from Layer 6 of Mugharet el'Aliya: Specialized Activities in a Cave Context during the Middle Stone Age of Morocco

The cave of El'Aliya on the Atlantic coast of Morocco contained a Middle Stone Age (MSA) occupational sequence that produced Aterian lithic assemblages (i.e. with tanged tools) dated to Marine Isotope Stage 3 (Layers 6 and 5). The site was excavated during the late 1930s and 1940s, and the lithic assemblages from the MSA deposits were originally described by Howe in 1967 and later by Bouzouggar et al. in 2002.

Comparative analyses of the lithic assemblage from layer 6 and those from other MSA sites in Morocco

conducted in 2022–2023 indicate that potential collection bias introduced during excavations was not extensive and that the assemblage contains: (1) a strikingly high representation of bifacial foliates and other pointed tool forms, some exhibiting potential impact fractures and other types of damage; (2) incomplete reduction sequences suggesting that many of the stone tools were not manufactured on site; and (3) retouched artifacts that show unexpectedly high rates of reduction. The association of this lithic assemblage with a zooarchaeological collection reflecting specialized and intense hunting of gazelle, suggests that Mugharet el'Aliya may have been used by groups of highly mobile foragers as a specialized location for the processing of animal resources hunted in the surrounding landscape.

The Transformations of the Sacred Spaces Linked to the Ancestors in Mitla, Oaxaca: A Historical and Phenomenological Perspective

This paper presents an investigation on how the transformations of rituals and spaces linked to ancestors have occurred in San Pablo Villa de Mitla, Oaxaca, from the Late Postclassic to the present. The spaces known as the Grupo de la Iglesia and Grupo del Calvario are addressed, both with antecedents from prehispanic times, as places where sacred rites are performed today that allow communication with the ancestors. This study is enriched with ethnographic work carried out from a vision and dialogue with the local Zapotec culture. The work is carried out by two researchers, from a phenomenological, historical, and archaeological perspective. In parallel, the phenomenon of cultural commercialization and its local social consequences are exposed, it also helps to raise new elements to rethink economic development initiatives that can be in dialogue with the protection and conservation of the cultural heritage of Mitla.

Refining Haudenosaunee Site Sequences in the Cayuga Lake Region

In this paper, I refine fifteenth- and sixteenth-century village relocation sequences for Haudenosaunee sites located on both the eastern and western sides of Cayuga Lake (in what is today central New York State). This area is the traditional homeland of the Cayuga Nation. First, I present information on Cayuga sites, including data on settlement types and recovered artifacts and ecofacts. Next, I review the conventional perspectives on regional site sequences. Then, focusing on the seven radiocarbon-dated Cayuga sites, I evaluate recently-run AMS radiocarbon dates and employ Bayesian chronological modeling to test and refine

occupation dates and relocation sequences. I conclude by presenting a refined site sequence for this region. Assessing chronological models alongside settlement and artifact data, I provide new information about fifteenth- and sixteenth-century Cayuga settlement patterns, mobility, resource use, and exchange.

Source Analysis of Cascade Points from the Connley Caves, Oregon (35LK50)

Researchers commonly use X-ray fluorescence (XRF) to source lithic tools and their associated byproducts made on obsidian and fine-grained volcanic toolstone. The results of such studies can be used to reconstruct lithic conveyance patterns, which in turn can tell us about hunter-gatherer mobility, territoriality, and/or exchange. In this study, we report XRF data for the Cascade projectile points from the Connley Caves (35LK50) in central Oregon. The results provide new insights into early and middle Holocene lithic conveyance in the northern Great Basin.

Baobabs, Caves, and Towns: An Alternative View of Island Urbanism in Precolonial Zanzibar

Studies of urbanism in East Africa have tended to focus on the medieval “stone towns” that dot the coast.

However, studying these more traditional expressions of urbanism produces an incomplete picture of the settlement patterns of precolonial East Africa. In islands such as Zanzibar, settlement patterns are unique due to the presence of limestone caverns with access to freshwater. These caverns, which number more than 500, have served as dwelling places for humans for millennia. Further, forager camps, fishing stations, and seasonally occupied locations cannot be ignored. I argue that the activities of town dwellers, cave dwellers, mobile foragers, fishers, and seasonal visitors intersected in creative ways that challenge traditional understandings of urbanism and force us to look beyond traditional settlements to a landscape of practice across which different human groups interacted in a variety of ways.

Legacy Collection from a Mid-Columbia River Village Site Reveals Surprising Late Precontact Focus on Terrestrial Mammal Hunting and Processing Bone and Stone Items for Use and Export

Archaeological data and collections from the Chiawana Park site, a precontact village on the Columbia River in Washington State, were analyzed decades after its original excavation. Archaeological excavations conducted in 1967 produced huge assemblages of animal bones, bone tools, and stone tools.

Geoarchaeological, faunal, and technological artifact analyses address methods and challenges faced when analyzing legacy collections. The archaeological materials appear to date primarily within the last two millennia and are associated with a possible mat lodge. Results of faunal analyses suggest an emphasis on hunting pronghorn but surprisingly little evidence for salmon fishing. Extensive bone tool manufacturing and use is represented especially by bone spear points and awls. Stone tools are dominated by simple flake tools and specialized tools for bone and wood working. Projectile points for both bow-and-arrow and for dart-and-atlatl weaponry are present along with evidence for processing local toolstones to produce bifacial blanks for exports. The data gathered during the reanalysis fill in important details that were absent from the original excavation reports.

Rethinking Egalitarianism and Segmentarity from Archaeological Analysis

For a researcher raised on a political-economy archaeological tradition, the assertion that the origin of inequality is not the relevant point in anthropological research is a shake. But after a careful reading of *The Dawn of Everything*, we are still persuaded that social relations of production remain the heart of the matter. The aim of this communication is twofold. We will present an overview of Spanish social theory on archaeology to show to what extent it is coherent with the book's proposals. Clastres's ideas and peasant societies are both at the core of many Iberian Peninsula archaeological researches. We will also describe the archaeology of Iron Age northwestern Iberia in order to foster the discussion of egalitarianism as an historical construction, and not as an "state of nature" or primitive fiction. Two issues are especially relevant for us: the assertive agency against hierarchization and the existence of egalitarianism in complex agrarian social formations.

Archaeology of the Upper Yukon River Canyon Riparian Zone: Alaska and Yukon Territory

The Upper Yukon River Canyon traverses the international border between Alaska and the Yukon Territory. We consolidate over 60 radiocarbon dates among numerous sites and develop a first-approximation model spanning the Chindadn to Dene Traditions in Eastern Beringia. The radiocarbon date series is ordered temporally in 10 discrete Bayesian probability density plots. Consolidation of available radiocarbon dates among over 40 components, associated lithics, and the geomorphology of the Yukon River contextualize cultural patterns in a geographic area that is underrepresented in the archaeological literature. Observed cultural patterns include dated components with sourced obsidian from geographic areas peripheral to the UYRC that span a broad geographic range. Two dated early Holocene Denali microlithic components support the hypothesized movement of microblade technology from central Interior Alaska to the central and southern Yukon Territory. A relatively large number of radiocarbon dated components in the late Holocene span the two regional White River volcanic eruptions that differentially blanketed the UYRC study area with tephra. A novel assemblage of southern sourced obsidian with the initial dated copper at the time of the eastern lobe of the White River eruption suggests an expanded social network following the volcanic event.

Mapping the Mayordomo's Procession: A Study of Ritualized Movement in Oaxaca

Ritualized movement such as processions are one way in which people in Oaxaca, both past and present, interact with and shape the landscape. To better understand the sacred landscapes of Postclassic communities in Oaxaca, this project examines ritualized movement through the analysis of a modern procession as described in James Greenberg's ethnography, *Santiago's Sword*. This procession route is used by the mayordomo or host of a ritual fiesta on the first of a 13-day period leading up to that fiesta. Using the descriptions and names of stops given in the text in Chatino, Spanish, and English, the stops were located and mapped in a geographic information system. Then, existing pathways and roads were utilized to map possible routes between each stop. Mapping this procession provides insight into the types of stops visited and paths used during a procession in a modern Chatino community, which can be used to form hypotheses about processional paths and the stops along them in past communities and increase understanding of human interaction with the landscape in the Postclassic.

Examining Dental Wear of Mongol Period Elites from Khövsgöl Province, Northern Mongolia

The purpose of this study is to explore the social status and daily lives of Mongol-era (twelfth to fourteenth centuries CE) “common elites.” Common elite is a general term used in this region to describe a group of high-status people that were not in the immediate lineage of Chinggis Khan. We investigated whether cultural activities such as food preparation, food consumption, and occupational tasks were reflective in individuals’ dental wear patterns. The data presented in this study consists of skeletal material salvaged from looted and undisturbed tombs ($N = 20$) spanning across three mountainsides in Khövsgöl Province, Northern Mongolia. Tooth occlusal wear was scored using Smith’s (1984) crown scoring system. We hypothesize that the degree and location of dental wear may elucidate dietary and cultural practices including occupational activities. We will also investigate whether dental wear delineates occupational and dietary patterns pertaining to gender and age. Future work includes using dental and skeletal data from these field seasons along with previous excavations of “high-status elites” from Khorig, Northern Mongolia to explore if differences in dental wear can be identified between these two groups.

A United Europe of Things: Similarities and Differences in Small Finds across Later Medieval Europe

The idea of “unity of culture” in medieval Latin Europe is well known in historical texts, especially when it concerns the so-called “Europe north of the Alps.” Scholars have often suggested that due to long-distance trade, widespread knowledge of Latin, and shared religious ideas, we can observe cultural similarities throughout late medieval Europe. For the past five years, we have been testing the extent to which this bold statement is true in terms of the “unity” of material culture, especially small finds, by holding sessions at the annual conference of the European Association of Archaeologists. The results led to an overview publication and the creation of the European Medieval Finds Network focused on supporting research on small finds going beyond the usual national and regional limits. In this presentation, I intend to discuss the opportunities and challenges of studying this group of specific medieval artifacts from the pan-European perspective on an example of later medieval dress accessories (thirteenth–sixteenth centuries). This specific group of artifacts illustrates how innovations in production technology correlate with social change and can be traced in archaeological material across the whole continent.

Daily Life Outside the Monument: Recent Excavations at the La Banda Sector, Chavín de Huántar

Chavín de Huántar is a very important Formative period site located in the Conchucos region of north-central Peru. It has unique monumental architecture, which includes a series of buildings with complex galleries and canals, as well as finely crafted stone sculptures. Although substantial research has been conducted on Chavín iconography and architecture, much less is known about the people who lived and worked outside of the monumental core. In this talk we will discuss our recent excavations at the La Banda sector in 2022 and 2023, located across the river from the monumental core, to interpret the material evidence left by the people living here. This sector appears to have been heavily occupied as evidenced by the number of rooms and the occupation sequence. There is evidence of ritual activity: parts of animals and worked tools were deposited under some constructions. Formal canals, similar to some of those found in the monumental core, were also excavated in La Banda. The results of some of the analyses, including bone

artifacts and radiocarbon dates, will be presented and discussed during this talk to better understand the daily lives of the people who supported the activities at the Chavín temples.

Chacoan Roads and Landscape Archaeology in the Eastern Red Mesa Valley, New Mexico

Chacoan culture is well known for its examples of communal building projects and monumental architecture. Chacoan roads, apart from great houses, are perhaps the most well-known yet enigmatic examples of such. In the Red Mesa Valley of western New Mexico, we examine how several newly identified road segments manifest themselves on the landscape as well as how they relate to and served to integrate the larger local Chacoan Community.

Defining the Spatial Structure of Rock Art in 12th Unnamed Cave, Tennessee, through 3D Modeling and GIS

Twelfth Unnamed Cave is a dark-zone cave art site in Tennessee that contains over 300 individual petroglyphs. Like many cave art sites in the American Southeast, the locations of the art within the cave appear to be structured. However, traditional spatial analytical methods have made it difficult to understand the distribution of artwork across the morphologically complex site. This study uses a 3D photogrammetric map of 12th Unnamed Cave to study the locations of petroglyphs from a new perspective. Various 3D GIS tools are utilized to measure the glyphs' locations from prominent cave features, the volume of the chambers in which they are located, and their visibility from different vantage points. Results suggest that experience and perception played dominant roles in determining where certain motifs were prioritized, and that 3D modeling is a powerful tool for quantifying these phenomenological variables.

Past Particles: Palynology at Poverty Point

The first pollen work at Poverty Point was conducted by Sears at the request of Ford and Webb in the 1950s. Since then, more evidence has been collected, leading to alternate interpretations of the site and resolving some matters while raising new questions to explore. This paper reviews palynological work, past and present, and the implications of these projects. Issues that will be addressed include the origin of sediments used in mound building, local vegetation changes over the past 5,000 years, microscopic charcoal and its relation to fire records, and comparisons to pollen results from other Archaic sites.

Shifting Bioarchaeological Perspectives in Alaska: Community-Centered Projects with Indigenous Partners and Project Participants from Descendant Communities

This presentation is focused on highlighting the value of conducting bioarchaeological research that not only works with descendant communities but is driven by the questions they want answered and adheres to their goals and management expectations surrounding their ancestors. Bioarchaeological projects that partner with Alaska Native communities are unique among the growing pool of collaborative archaeology in the United States and are useful in assessing what currently facilitates successful partnerships with the communities whose heritage and ancestors we work with, and how those successful partnerships culminate in research processes and outcomes. We will discuss projects within Alaska that work with and for these communities, and the effect of increased descendant inclusion and agency in our and others' bioarchaeological work.

Childness, Humanness, and Violence among the Precolonial Maya

Over the past decade or so, bioarchaeologists working in the Maya area have called attention to how permanent alterations of the body transformed immature bodies into fully realized humans. Among these alterations were cranial and dental modification, painful practices that were not without risk of injury or even death. While some children were cultivated into human adulthood, others were selected for premature death as evidenced by sculptural and painted imagery, as well as archaeologically recovered human remains. This paper reflects on the role of violence in making humans out of some children, but not others, while also considering when children themselves became violent actors.

Impacts of the Coronado Expedition on Social Networks at Piedras Marcadas Pueblo, New Mexico

Between late 1540 and early 1541, the Vázquez de Coronado expedition laid siege to the Southern Tiwa ancestral community of Piedras Marcadas and fought the Pueblo's residents. Eventually, the Coronado expedition left the Rio Grande Valley and moved north and east to the Plains. Piedras Marcadas was occupied for about 250 years prior to the siege, and occupation continued in much reduced form until the early 1600s. In this poster, we explore the social networks reflected in trade relationships of pottery both before and after the siege. Do these social networks change with this event, or do they stay the same? The entire Rio Grande Glazeware sequence, from 1300 to the early 1600s CE, of pottery types (Glaze A to Glaze F) is found at Piedras Marcadas. Petrographic analysis of the temper and paste characteristics can tell us what other communities or regions the village residents interacted with and if the siege impacted those social networks.

Molding Bricks and Making Place: Earthen Architecture in the Cañoncillo Archaeological Complex

The built environment of the Cañoncillo Archaeological Complex in the northern coast of Peru is dominated

by earthen architecture constructed and modified within a span of 1,800 years. Although the sites within the Complex—Jatanca (500 BCE–100 CE), Huaca Colorada (650–950 CE), and Tecapa (800–1100 CE)—were each constructed out of materials sourced from their shared landscape, the stark stylistic and structural contrast observed between these sites reveals essential differences in the conception of place-making and place among the communities that inhabited each site. Thus, Cañoncillo serves as an ideal lens to interrogate the ways in which people across time made places that produced distinctive earthen architecture in terms of form and fabric. A close inspection of these processes of making earthen architecture offers an important vantage point to understand unique conceptions of space and time within the communities that built and dwelled within each site, mutually constitutive relationships between people and the Cañoncillo landscape, and interdependencies among cogent political communities. In this paper, I mobilize the preliminary results of morphological, material, and geoarchaeological analyses carried out between 2018 and 2020 to reconstruct meaningful, site-specific processes of making earthen architecture within the Cañoncillo Archaeological Complex and to consider their implications for understanding intercommunal dynamics.

It Takes a Village to Defend a Village: Women, Elders, and Children in Indigenous Resistance during the Contact and Colonial Periods of Central New Mexico (1539–1696)

Warfare and conflict are almost always described in terms of male-centered actions. But it is clear in many cases, such as those during the contact period in the Western Hemisphere, that conflict often involved entire communities thrown into struggles for their freedom and survival. This was quite evident during the first explorations of the American Southwest by outsiders, principally Spanish-led expeditions. The frequently rebellious nature of these encounters is a prominent feature in written descriptions, as is the complete involvement by all members of impacted societies. While the term “noncombatant” is sometimes used, it was unusual for any remaining members of a community to not be part of their active resistance. Women, elders, and children are often described as having been present at, and in some cases directly participating in, the conflicts that ensued. Examples of these groups and their participation in acts of self-defense and resistance are presented in case studies from central New Mexico for the period starting with the Vázquez de Coronado expedition and ending with the last of the Pueblo Revolts (1539–1696).

From Fontaneda to Archie Carr: Sea Turtle Zooarchaeology and Conservation in Southeast Florida

In southeast Florida, sea turtles (Chelonioidae) are both a major focus of conservation efforts and a hallmark of local zooarchaeological assemblages. Despite this abundance however, little work to date has been done to connect these archaeological turtle remains to contemporary sea turtle ecology and conservation. In this paper, I both offer a synthesis of regional sea turtle zooarchaeological literature as well as report the

preliminary results of three analysis methods trialed with sea turtle long bones recovered from the Stock island Midden (8Mo2). The results of these analyses provide data on both the species and age demographic of turtles targeted by ancient hunters, providing possible insights into both hunting methods and seasonality. Furthermore, such data facilitates direct engagement with modern turtle ecology studies. In doing so, this work seeks to demonstrate both the utility zooarchaeological turtle remains hold to local conservation efforts, as well as the importance of properly curating and studying these invaluable sources of ancient ecological data.

Classic Mimbres Period Aviculture at Elk Ridge, New Mexico

People in the ancient Southwest domesticated, tamed, or managed several species of birds. The Late Pithouse and Classic Mimbres (AD 750–1000) archaeological site of Elk Ridge provides a rare example of ancient aviculture in the Mimbres area of southwestern New Mexico. Excavations by Human Systems Research Inc. at Elk Ridge in the upper Mimbres Valley revealed one parrot tarsometatarsus (one of only six positively identified in the Mimbres area) and over 500 turkey bones, including at least 20 individual turkeys found as bone concentrations or partially articulated on or near the floors of excavated rooms. Turkey (*Meleagris gallopavo*) bone measurements and evidence for healed injuries along with contextual data from excavations provide insights into how turkeys were raised at this village, a practice not documented at other sites from this area and time period. Variability in turkey size, age class, and healed injuries are consistent with managed birds, despite minimal evidence for pens. Identification of the parrot bone along with other parrots (*Amazona* sp. and *Rhynchospitta* sp.) in the Southwest is also discussed, with implications for how far these birds were transported in the ancient Southwest.

From One Jar, Many Selves

Red-on-Natural jars, characterized by nearly identical forms and decorations, were used by people of all ranks who lived in the adjoining Naco, middle Chamelecon, and lower Cacaupala valleys of northwest Honduras from CE 600 to 1000. These vessels' ubiquity suggests that those who used them participated in a community of practice that transcended the realms centered on each of the three basins. The different techniques and resources used to shape, fire, and decorate these containers, however, constituted multiple distinct communities of practice enacted in the ceramic workshops operating in each of the valleys. We draw on fieldwork conducted within these production locales together with INAA, petrographic, XRF, and LA-ICP-MS analyses of 424 sherd and clay samples to describe these production-based communities of practice. The research highlights the many ways that social identities can be instantiated as people make and use even

very similar items in regularly recurring routines. It also stresses the importance of attending to the contexts of use and manufacture through which we come to know ourselves as we manipulate things.

Technological Studies of Blade and Bladelet Production in the Aurignacian at Geißenklösterle Cave (SW Germany)

Geißenklösterle Cave has played a central role in assessing the timing of the beginning of the Upper Paleolithic in Central Europe and in contextualizing the origins of Aurignacian technological innovations. The Aurignacian of Geißenklösterle is comprised of archaeological horizons II and III dating to between 42,500 and 35,000 cal BP. The site provides a well-stratified and well-dated record from the Aurignacian of the Swabian Jura. In this paper we present current research on the lithic technology used by Aurignacian stone-knappers at Geißenklösterle. We combine techno-typological analyses with numerous lithic refits to identify different operational chains in lithic production. Spatial analyses reveal how and where the inhabitants of the site produced, used, resharpened, recycled, and discarded stone artifacts. Building on the innovative publications on operational chains during blade production by Joachim Hahn and colleagues, we present new results documenting multiple cycles of blade and bladelet production at Geißenklösterle. This work shows how knappers produced bladelets from carinated cores, burin-cores, and regular cores on cobbles and flakes.

Settlement and Political Ecology in the Lower Lacantun River Landscape

Over three field seasons, the Lower Lacantun Archaeological Project has examined the political organization and settlement of the region surrounding the confluence of the Lacantun and Usumacinta Rivers in Chiapas, Mexico. This riverine landscape is unique in the Western Lowlands, presenting risks and opportunities related to seasonal and long-term flooding of the alluvial plain. During the Classic period, this region was likely associated with the poorly understood Lakamtuun kingdom, known from inscriptions from Piedras Negras to Ceibal. This paper addresses recent work in the region, namely the documentation of monuments at the sites of Benemerito de las Americas Primera Seccion, El Palma, and San Lorenzo; the identification of a

ceramic workshop at Benemerito de las Americas Primera Seccion; test excavations at El Palma and Yaxun; regional survey; and ongoing community outreach to develop a long-term project with the modern community of Benemerito de las Americas. These efforts have also included the analysis and ground verification of several lidar datasets, particularly focused on agrarian landscapes and drained fields. Future work will involve additional drone lidar data collection and the generation of a predictive model to locate households and agrarian features based on local knowledge, survey, and ecology, contrasting uplands and floodplains.

Seven Millennia of Wood and Reed: A Preliminary Chronology of Weapons Systems from the West Texas Region

The arid west Texas region has a wealth of large perishable assemblages offering unexplored research potential. This talk focuses on weapons systems recovered from both recent excavation work and existing collections from this area. We provide an overview of the diversity and age of the weapons from these contexts and then place them within other well-dated regional examples. These results provide one of the longest nearly continuous records of weaponry from any region, enabling us to build a high-resolution chronology. We use this chronology to offer initial thoughts on changes in design, materials, hunting strategies, prey choice, and key technological transitions in projectile weaponry.

The Wisconsin Dugout Canoe Survey Project

Efforts to trace 80 dugout canoes reported from Wisconsin resulted in the identification and documentation of more than 66 and the recognition that six had been destroyed or lost. Wisconsin dugouts range in age from 4,000 years old to the early twentieth century. Dugouts were made from a variety of types of wood and those that date to the last 2,000 years correlate with the nineteenth-century vegetation in the regions where they were found, while the wood choice for older canoes likely reflects the ecological impact of mid-Holocene climate change. The assemblage also records temporal and cultural variation in style and manufacturing techniques.

To Build or Not to Build: An Historical Archaeological Examination of Fort Louise Augusta and the Role of Sovereign Perceptions and Interests in the Construction and Maintenance of Danish West Indian Fortifications

Colonies, as discontinuous frontiers, may be more or less integrated into the homeland, resulting in distinct fortification patterns across time. The former Danish West Indies (DWI) was one such discontinuous frontier, separated from Copenhagen by more than 7,500 km yet a key part of the Danish economy. By examining changes and continuities in the construction and repair of fortifications across two distinct phases of Danish occupation of the West Indies through the excavation and radiometric dating of construction phases in Fort Louise Augusta, St. Croix, DWI, this paper sheds light on how sovereign perception and the shifting primacy of sovereign and imperium interests in discontinuous frontiers influence colonial fortification.

Large-Scale Analyses Show Flexible Paths of Aurignacian Lithic Production at Vogelherd Cave in Lone Valley

The Aurignacian marks the beginning of the Upper Paleolithic in southern Germany. During this time blade and bladelet production became the central focus of the stone knapping. Lithic technology of the Swabian Aurignacian is nowhere better documented than at Vogelherd. Here Riek's original excavation in 1931 and Conard's excavations in the site's backdirt (2005–2023) have produced by far the largest lithic assemblage from this technocomplex. However, diverse core typologies and views on lithic reduction make characterizations and comparisons of Aurignacian assemblages difficult. In this talk we provide an overview of multiple modes of lithic reduction documented at Vogelherd. With such a large lithic assemblage we are able to place various types of cores within a fluid system of reduction. Due to the exceptionally large number of artifacts from Vogelherd, we are able to identify important characteristics of the Swabian Aurignacian that were previously considered marginal features. To gain insights into the *chaînes opératoires* from Vogelherd, we analyze the cores, tools, all debitage products, raw material units, and hundreds of lithic refits. This enables us to look beyond typological categories and to gain a much more comprehensive understanding of reduction processes, which should facilitate regional and interregional comparative analyses.

Reconstructing Vanished Midwestern Wetlands: Insights from the Aquatic Fauna of the Middle Grant Creek Site

The same glacial processes that produced Lake Michigan in midwestern North America also produced numerous wetlands of many types at the southern end of the lake. A diverse wetland matrix of smaller lakes, rivers, streams, ponds, marshes, swamps, bogs, and fens was once found throughout the region. Many of these wetlands have been destroyed or altered by urban and agricultural development. Wetlands were essential to Native Americans who inhabited the area prior to European colonization. The Middle Grant Creek site, an early sixteenth-century Huber phase agricultural village, has produced abundant, diverse, and well-preserved remains of fauna from aquatic ecosystems. The faunal remains can be used to determine the types of wetlands that were present in the vicinity even if they no longer exist. They can also be compared to those from other sites in the region to understand Late Prehistoric patterns of wetland exploitation. We examine the habitat preferences of the species that were used by the inhabitants of Middle Grant Creek to

determine what types of wetlands were once present nearby and compare the past distribution of wetlands to the current wetland-impooverished landscape. Such studies are important for those who wish to understand or reestablish vanished ecosystems.

Shellscape Communities of the Ten Thousand Islands, Florida

The Ten Thousand Islands of Florida contain the vestiges of massive shellscape communities constructed by fisher-hunter-gatherers. This paper explores two of the largest shellworks—Pumpkin Key and Turner River. Each community constructed over 40 massive shell midden mounds that comprise some of the most complex shell architecture worldwide. With reference to other shellwork site characteristics (temporality, shapes, sizes, and constituents), new interpretations are offered on the past histories of these two unusual sites.

Engaging with NAGPRA at the Veterans Curation Program

The Veterans Curation Program (VCP) is a US Army Corps of Engineers (USACE)–funded program with a dual mission to rehabilitate USACE administered artifact and document collections and provide temporary employment and vocational training to veterans. Since its inception in 2009, the VCP has trained more than 790 veterans who have worked with collections from 25 USACE Districts. At the start of each term, veterans receive training in many anthropological topics, including NAGPRA and how it affects Indigenous communities within the United States. VCP contractor staff continue to refine the teaching of sensitive issues, like NAGPRA, to non-archaeologist veteran technicians, including incorporating Indigenous knowledge and educating them about modern and historical Tribal Nations local to each lab. Additionally, document collections related to archaeological excavations are cleaned, organized, and digitized in a standardized way, which allows the records to be accessible without having to physically view them. Through this process, over 1,800 linear inches, or 150 feet, of documents have been rehabilitated and are now searchable, not only for research purposes but also for aiding USACE and Tribal communities in the NAGPRA process.

(En)Gendering Cure: An Exploration of Gender Construction at a Twentieth-Century Southern Asylum

In this paper, I explore the way gender is conjured at an early twentieth-century North Carolina Asylum through its organization of space and patients' movement in this space. I consider the way that gender is maintained, reified, and produced through archival research on the Raleigh State Asylum of North Carolina. The built landscape of the Raleigh State Asylum functioned as a medical technology for its patients and was entangled with projects of cure that sought to transform patients into suitable North Carolinian subjects. In many cases, as this research demonstrates, this entailed a gendered transformation. I argue that the hospital's gendered landscape was an integral medical technology operationalized at the Raleigh State Asylum. This paper relies on critical archival research and offers an alternative to excavation-based investigations into materiality and meaning.

Schwartz, Erin (Thomas Jefferson's Poplar Forest)**[45]***Physical Trowels and Digital Teapots: Developing Accessible Toolkits for Archaeology Learners*

The COVID-19 pandemic necessitated broad shifts in the ways archaeologists excavate, analyze, and communicate with each other and the public. Although we have largely returned to in-person teaching and research, these experiences in designing and implementing new remote and hybrid modalities offer several potential solutions for making archaeology education more accessible. This poster outlines various questions explored, strategies employed, and solutions developed for undergraduate students learning archaeological laboratory analysis during the pandemic. More specifically, this work outlines the roles of technology and collaboration (even when far apart) in creating both physical and digital spaces where all are welcome and supported. While this poster highlights creative strategies developed for teaching lab methods, potential strategies for teaching and outreach outside the lab are also examined.

Schwartz, Glenn (Johns Hopkins University)**[212]***Discussant***Schwartz, Soul (Indiana University) and Ryan Kennedy (Indiana University)****[199]***Comparing Multiple Methods of Fish Size Estimation Using Sheepshead Remains from New Orleans, Louisiana*

Size estimation of archaeological fishes has been employed by zooarchaeologists to address a number of topics, including past fishing methods, commodification of fishes, and overfishing. Although the development of regression formulae describing the relationship between fish length and skeletal measurements is the most common method employed by zooarchaeologists, direct comparison of archaeological fish remains to bones of modern fishes of known sizes has also been used. In this poster, we compare these two methods using modern sheepshead skeletons collected from southeast Louisiana and archaeological sheepshead remains from sites in New Orleans, Louisiana. We note relative advantages and disadvantages of each method, including the upfront time costs incurred while building regression formulae, the need that particular skeletal landmarks be present, and limitations caused by broken or pathological comparative specimens. We also present the first regression formulae for size estimation of sheepshead, which should be useful in coastal archaeological contexts throughout the Gulf of Mexico and East Coast. Ultimately, we suggest that there is no one-size-fits-all solution to size estimation, but rather that the most appropriate method for any given project should be determined by factors including project timeline, skeletal part representation, and relative fragmentation rate of fish remains at a site.

The Tomb of the Known Unknown Soldier: Identifying the Remains of Confederate Soldiers Buried near the Williamsburg Powder Magazine

In an ironic twist, while the names of the Confederate casualties of the Battle of Williamsburg have been remembered and memorialized, literally carved in stone, the physical remains of the soldiers were lost and forgotten until we accidentally exposed their burials while excavating near the Williamsburg Powder Magazine. In this presentation, I will demonstrate how Williamsburg's racial divide and the goals of the Lost Cause movement created this discontinuity and how these historical circumstances affected the goals and outcomes of our research. By combining the results of the archaeological excavation of the remains, investigations into the materiality of the artifacts affiliated with the deceased, documentary research in the National Archives, and osteological analysis of the four complete skeletons recovered from the Magazine we have taken the first steps toward reassociating these skeletal remains with their names and identities.

***Images of human remains and funerary objects will be shown in this presentation.

Beneath the Field of Battle: A Summary of Previous Archaeological Investigations at Vicksburg National Military Park
The Vicksburg National Cemetery, established in 1866, and Vicksburg National Military Park, established in 1899, were created to commemorate the 1862–1863 siege, to honor those who had fought and died here and to preserve these significant places on the very grounds on which these actions occurred. While great efforts were made to create and perpetuate a contemplative landscape rich with monuments and interpretive signage, relatively little systematic archaeological investigations have been conducted over the past century. Nevertheless, and in spite of large-scale alterations to much of the park's landscape over the past century, archival research combined with recent and ongoing archaeological investigations point to the existence of potentially significant archaeological deposits indicative precontact, historic period Native American, and colonial Spanish occupations that in many ways are foundational to what happened at this Civil War-era battlefield.

Network Analysis of Magdalenian (Upper Paleolithic) Perforated Disks

The Magdalenian (ca. 20,000–14,000 cal BP) of western and central Europe witnessed both a rapid expansion of Upper Paleolithic human populations after the Last Glacial Maximum and the creation and circulation of an unprecedented abundance and diversity of portable decorated items. The materials, design details, and chrono-spatial distribution of these visual displays suggest changes in the types and patterns of social

connections among hunter-forager groups as they navigated postglacial landscapes. Using similarities and differences in the decorative elements of one particularly common form of visual display—perforated disks—we employ formal network analysis to test hypotheses about Magdalenian social networks. Quantitative and graphical analyses of node-tie relationships at multiple scales reveal a complex social landscape that was influenced not only by geographical distance, topography, and local environments but also by the reinforcement of social identity through manipulations of visual displays at multiple social scales. Our results illustrate both the promise and pitfalls of using Paleolithic archaeological data for network analysis.

Quartz Microcores and Bladelets in Southern New England: Gulf of Maine Archaic Tradition Sites and the Rise of Quartz Technology during the Early Holocene

Sites containing Early Holocene Gulf of Maine Archaic Tradition (GMAT) components have been few and far between in the New England region. Given the lack of diagnostic tools associated with the industry and the general rise in quartz use during the Archaic period in the Northeast, these sites have often been misattributed to Late Archaic period occupations; more commonly referred to as Narrow or Small Stemmed. However, increased study and recognition of the Quartz Core and Uniface Industry, the principal suite of technology utilized at GMAT sites during the Early Archaic period in northern New England, has led to a subtle boom in identified GMAT sites throughout the region, including sites in southern New England. In fact, sites with quartz microcore and bladelet technology have been increasingly identified throughout the northeastern United States and Canada, indicating a wider technological adaptation during the Early Archaic period than originally proposed. In this presentation we discuss recently identified GMAT sites in southern New England, the potential for GMAT as a technological response to environmental change, and the further implication for the extent of this overlooked industry.

Reconstructing the Life Use of a Medieval Friary from Its Fragmentary Remains

The Dominican friary in Trim, Co. Meath, Ireland, was established in AD 1263 by Geoffrey de Geneville, then Lord of Trim. Located just outside the town wall, the Black Friary was an important institution during the late

medieval period, as indicated by its large size and double cloister as well as its use for ecclesiastical and governmental meetings. By 1540, as part of the dissolution of the monasteries, the commissioners of King Henry VIII suppressed the friary and sold its land, buildings, and goods. The buildings then gradually fell into disrepair before being demolished in the 1750s. Unlike similar sites in Ireland, the Black Friary was never significantly reoccupied or built over, providing a unique opportunity to investigate the growth and decline of a medieval friary over the course of five centuries. Ongoing archaeological excavations since 2010 have recovered evidence of building works throughout the use-life of the friary. The primary medieval occupation saw the addition of a south aisle to the church, refurbishment of the east window above the altar, and the extension of the chapter house. Later, following the dissolution, modification of the buildings in the west range document partial reuse of the site for farming activities.

Strontium ($^{87}\text{Sr}/^{86}\text{Sr}$) Isoscapes for Mobility and Migration: The Way Forward

Applications of $^{87}\text{Sr}/^{86}\text{Sr}$ in studies of paleomobility and migration have developed in an interdisciplinary space at the intersection between archaeology, geochemistry, and ecology. The approaches taken have depended on the home discipline of the lead researchers. Differences in approach and criteria in the many, very diverse studies now in the literature are confusing, and a barrier to potential new users. Three main areas of concern are (1) sampling; i.e., developing datasets for building isoscapes; (2) mapping and modeling, or how best to synthesize $^{87}\text{Sr}/^{86}\text{Sr}$ values and associated information into isoscapes; and (3) interpretation, or the use of isoscapes for provenance. This talk will offer some comments on challenges such as: Which approaches are likely to be best for different applications? What are the costs and benefits of different options? How do we handle uncertainties? Some of these points may be applicable also to other isotope systems, such as lead and neodymium.

Sacred Landscape and Ceramic Ritual Production in Cobán, Guatemala

An accidental discovery by bulldozer of an ancient Maya ceramic workshop has created a post-civil war chapter of exploration in central Alta Verapaz. The site of Aragón lies at the base of a mountain, near the headwaters of what becomes the Usumacinta drainage. Its Late Classic-Terminal figural contents represent a range of ritual and daily objects that are markedly different from those manufactured in communities of the lowland Petén riverine zones. This unique production zone permits new insights into aspects of ritual representation and practice.

The Ontological Mammoth Body: Varieties of the Human-Mammoth Ritual Drama Mediated by Cultural Interactions with Mammoth Remains in Pavlovian Moravia and Mezinian Ukraine

Ethnohistoric sources show hunters burnt the bones of prey or hung them on trees, heaped them on piles, deposited them in bogs, etc., in order to propitiate nature spirits such as the “Master of Animals” for game resurrection and renewal. Animals were not mere prey but partners to hunters. Animal body parts could be used to attain spiritual potency and even increase human fertility. In the highly cooperative society of hunters, everyday life included festivities and rituals, an important part of which might have been the deposition of as wide a sample of bones from the kill as possible. Nevertheless, archaeozoologists persevere in ignoring these facts. However, we see the Mammoth Steppe of the Moravian Pavlovian (32–22 ky BP) and Ukrainian Mezinian (20–13 ky BP) as a “shamanistic” landscape for the ritual drama of the hunt and ontological interplay between humans and mammoths with evidence for religious beliefs and acts in a vast array of material cultural correlates; many of these in the form of modified mammoth remains, including monumental architecture, that comprise one of our species’ most ancient, elaborate religious complexes, and serve as a model for the interpretation and reconstruction of religious doctrines and ritual in archaeological societies.

The Sociopolitical Impacts of Agricultural Intensification and Water Management in Classic Maya Society

A central issue for our understanding of Classic Maya society is how it managed to flourish despite scarce water resources, and limited access to agriculturally productive soils. More recent investigations confirmed that the adaptation strategies, which the prehispanic Maya developed to overcome these obstructions, were less defined by cultural traditions than by the requirements of the local environment. Consequently, the agricultural and hydraulic features of the Maya Lowlands are remarkably well adjusted to the different geographic regions. These highly customized and carefully constructed installations indicate large amounts of labor input and high levels of experience, which suggest and a long-standing tradition in the development of these features. The presentation shall provide an overview of the landscape history and the different geological and climatic areas of the Maya Lowlands and explain the development and functionality of the adaptation strategies and their interaction with the local settlement landscape. Since the sociopolitical effects of these landscape transformations remain poorly understood, this lecture will explore how and to which extent (intensified) agriculture and water management influenced a process of social stratification and demonstrate the economic and sociopolitical relevance of prehispanic adaptation strategies during the formation, florescence and collapse of Classic Maya society.

Seetah, Krish (Stanford University)**[245]***Chair***Seetah, Krish (Stanford University)****[245]***Ecological and Cultural Impacts of Colonialism on Mauritius*

The colonization of Mauritius exemplifies the role played by humans in altering the ecosystems of remote islands. Previously uninhabited, it now has the highest population density of any African nation, and despite scant natural resources, also has one of the continent's highest GDPs. Mauritius serves as an ideal case study for islands where the chronology is well attested historically, but remains poorly assessed archaeologically, specifically within the context of demographic and cultural flux. This presentation outlines the rate and scale of ecological change, modeled against prevailing demographic and imperial transitions: once colonized, how did different culture groups contribute to environmental modifications? Through archaeological and anthropological studies conducted in Mauritius, this presentation reveals the different phases of colonization and transformation that led to the current multicultural populace and environmental degradation that typifies Mauritius.

Sefton, Jahleen, Ian Freestone (University College London) and Laura Adlington (University College London)**[170]***Interpreting Recycling in the Roman Glass from Colchester*

By the time of the Roman invasion of Britain in AD 43, the Roman glass industry had reached its height, largely due to the development of a glass-blowing technique which allowed glass vessels to be produced in greater quantities and variety of shapes contributing to its wider use. Antimony, a decolorizer used in the glass industry of Egypt, produced the most brilliant colorless glass in the empire. However, over the Roman period the use of antimony gradually diminished until it was completely replaced by manganese (an alternative decolorizer) in the fourth century AD. Along with the development of glass was the industry of recycling, which produced new glass objects from discarded material. Antimony and manganese concentrations of 101 samples from sites within Colchester dating to the Roman period were analyzed. Using the Olympus Delta pXRF, one can measure quantities of antimony and manganese in transparent naturally colored and decolorized colorless glass. These measurements reveal if concentrations indicate a deliberate separation of antimony-decolorized glass and manganese-decolorized glass in the recycling process. By understanding the various compositional groups and comparing them against the typological groups and dated context, a more detailed picture of the recycling behaviors and socioeconomy of the area has emerged.

Seidemann, Ryan (Louisiana Department of Justice) and Christine Halling (Louisiana Department of Justice)**[131]***Navigating Neutrality and Bureaucracy among Property Owners and Descendant Communities as Government Representatives in Matters of Cemeteries and Human Remains in Louisiana's River Parishes*

Louisiana's River Parishes between Baton Rouge and New Orleans, alternately known as "the Industrial Corridor" or "Cancer Alley," has long been a place and landscape with clashing interests of industrial uses, economic development, environmental justice, and historic and archaeological preservation. This area is home to vast communities of descendants of enslaved peoples from the antebellum plantations that lined this historic highway of commerce. To and through the 1980s, the interests and concerns of descendants took a backseat to industrial and economic development, with massive international corporate plants—producers of pesticides, petroleum products, and innumerable other chemicals—being constructed on former plantations. Beginning slowly in the 1980s and reaching unrivaled heights today, communities have gained traction in bringing historic, prehistoric, and especially cemetery sites directly into the crosshairs of judicial and extrajudicial disputes with local, state, and federal governments, and corporate interests. From the perspective of governmental employees, we attempt to examine the intersection of legal issues, archaeological resources, and community interests. Recent case studies in the Louisiana legal system highlight areas intended to advance guidance and efforts of all stakeholders as relationships, however tenuous, may continue to build protections that serve the interests of the many rather than the few.

Multivocal Approaches to Sustainability in the Rejuvenation of the Archaeological Tell Site, Vésztő-Mágor

Too often the conservation, visualization, and management of archaeological sites are afterthoughts of excavations. Heritage preservation and presentation are only considered after the trowels leave, with site managers working within the confines of what they've been given and the public viewing what is left. Excavation decisions—whether knowingly or not—remove the agency of post-excavation site specialists, impacting site preservation, visualization, interpretation, and ultimately sustainability. The team working to reinvigorate the archaeological site of Vésztő-Mágor, Hungary, recognizes the benefits of blending interdisciplinary perceptions of value in their approach to safeguarding the site. Rather than a single archaeological narrative, the team looks to contemporaneous articulation of multiple values. Drawing insights from archaeologists, conservators, engineers, site managers, and local communities, the project aims to create a dialogue of meaningful presentation strategies for the site to ensure its preservation as a thriving center for local identity, regional congregation, and tourism. This paper discusses the Mágor Conservation and Exhibition Project, and how preservation of this unique prehistoric tell is happening "at the trowel's edge." Whereby sustainability and authenticity are embedded in the planning and execution of excavation, conservation, and visitor interpretation at the largest tell on the Great Hungarian Plain.

Islands in the Stream: Fort Pulaski's Shifting Shorelines and Rising Groundwater

Excavations at Fort Pulaski's Workers' Village have uncovered evidence of how the fort's builders adapted to their barrier island environment and coped with hurricanes. Past fort personnel had their own version of the National Park Service's Resist-Accept-Direct Framework: resisting by constructing a breakwater, accepting by abandoning buildings, and directing through a ditch-and-dike system to drain the marshy island. Today's archaeologists also had to adapt to their barrier island environment, which is rapidly changing due to climate change. Archaeologists occasionally struggled with seeing direct evidence of hurricanes in the archaeological

record, especially while their units filled with groundwater, but the cultural adaptations to the climate and storms were evident in the stratigraphy of this anthropogenic landform and in the remaining traces of structures.

Long-Term Spatio-Temporal Dynamics of Sámi Reindeer Husbandry on the Northern Shore of Europe

Reindeer hunting, reindeer husbandry, and nomadic pastoralism form a significant part of the history of Sápmi, and the whole northern Fennoscandia from the late Iron Age to modern times. Sápmi, situated on the northern shore of Europe, is the transnational homeland of Sámi people, Europe's only Indigenous group. Recent multidisciplinary studies have clarified our understandings of the development and significance of reindeer herding through time, e.g., as part of the international trade and contact networks. This presentation examines the changes in reindeer husbandry in space and time, based on the radiocarbon dates obtained from the Sámi reindeer herder sites in whole Sápmi, and assesses how these relate to the wider historical context. The Sápmi-wide chronological perspective offers a wider view on the past developments, as the previous temporal reviews have been based on regional case studies. The latest results from our multidisciplinary studies, e.g., zooarchaeological, aDNA, anthropological, and ethnoarchaeological research, are reviewed alongside the spatio-temporal analysis. The aim is to give a sweeping overview of the development of Sámi reindeer husbandry throughout Sápmi from its beginnings in the (Late) Iron Age to the twentieth century.

Emergencia de poder e interacción interregional en la sociedad del Periodo Formativo: Una perspectiva de la Sierra Norte del Perú

El objetivo de esta presentación es analizar la relación entre la sierra norte del Perú y la región ecuatoriana en el proceso de emergencia de poder del periodo Formativo peruano. En las excavaciones en el sitio Pacopampa se han recuperado varias tumbas con objetos de oro que datan de 700-600 aC. El descubrimiento de tumbas similares en el sitio Kuntur Wasi nos ha llevado a argumentar que surgieron diferencias sociales durante el periodo Formativo Tardío (800-500 aC). Para ello, se ha centrado la atención en los objetos rituales y sus materias primas, que se basan en el intercambio interregional. Conchas marinas como *Spondylus* y *Strombus*, que probablemente fueron traídos de Ecuador, eran los recursos importantes para asegurar posiciones de liderazgo. Este punto puede deducirse de la "Tumba del Sacerdote de los Pututus" descubierta el año 2022 en el sitio La Capilla ubicado cerca de Pacopampa, donde el individuo descansaba sobre 20 *Strombus* acompañado de un gran número de cuentas de concha y piedra. Dado que esta tumba es varios cientos de años más antigua que las tumbas reparatadas anteriormente, sugiere que existió una profunda conexión con la región ecuatoriana durante más tiempo del que se pensaba.

Orientation of Tsukuriyama Kofun Tumulus: Examination from Lidar Survey

The Tsukuriyama Kofun in Okayama is a massive burial mound from the fifth century that spans over 350 m and ranks third-largest in Japan. The Okayama University team used lidar to survey the mound and integrated the data into arcAstroVR, a visualization software for archaeological remains and celestial bodies. The mound's scale and layout resemble the Ishizugaoka Kofun in Osaka, sharing an axis deviation of 29° from the true north. From this, it can be inferred that the two burial mounds built 154 km apart shared the same basic design, including the method of determining the axis of the mound. One suggested reason for this directional choice is the "Token" Big Dipper alignment in the fifth century. Another perspective posits that a 90°-rotation of this angle would nearly correspond to the sunrise direction during the winter solstice. Ground-penetrating radar surveys and partial excavations have unveiled a parallel alignment between the axis of the central burial structure within the rear circle and the overall mound axis. Current investigations aim to determine if the mound's placement was influenced by the "Hokushin Faith," a belief from that era centered on the North Pole of Heaven in China.

Burt Lime Production in the Eastern Puuc Region

This talk will present an overview of the Bolonchen Regional Archaeological Project's contributions to the study of Maya burnt lime production, drawing on a mix of excavation, archaeometric, and spatial data. As part of their extensive Kiuic-Labná intersect pedestrian survey, Tomás Gallareta Negrón and Rossana May Ciau identified hundreds of distinctive annular structures in the study region in the early 2000s. Vertical and horizontal excavations of a sample of these structures in the mid-2010s demonstrated that they were used as pit-kilns to produce burnt lime. Subsequent lidar flyovers of the study region in 2017 and 2022 identified hundreds more of these annular pit-kilns. Comparisons of the BRAP spatial data with those from lidar flyovers in other regions of the Maya lowlands suggest that the eastern Puuc was the epicenter of the annular pit-kiln method for burnt lime production. The high frequency of pit-kilns is likely connected with the distinctive demographic and architectural construction trajectories of the Late Classic eastern Puuc. In addition to providing an overview of pit-kiln mechanics, this talk will discuss the socioeconomic and ecological implications of burnt lime production in Classic Maya communities.

Replicating Stone Tools for Use in Experimental Archaeology: The Case of End Scrapers

This study evaluates the value of porcelain slip casting for the replication process of prehistoric end scrapers. The method when used in conjunction with 3D scanning and printing has already proven successful in making nearly exact replicas of prehistoric projectile points and their preforms. Many functionally identical copies can be made from a single mold (useful for building large sample sizes in experimental archaeology), and these copies can be resharpened or retooled in ways that mimic their stone counterparts. Due to the shrinkage of porcelain as it is fired, porcelain replicas cast in molds made directly from artifacts result in copies that are smaller than their originals. By digitally scaling and 3D printing a larger model and creating molds from the print, one can circumvent the shrinkage issue. Porcelain lithic replicas made by this method can be manufactured to similar dimensions of original artifacts or scaled to different sizes as desired. We applied this protocol to the creation of exact porcelain replicas of prehistoric end scrapers and tested them to see if the edges of the porcelain objects behaved similarly to the originals. The results and the potential applications of the process are presented here.

Excavation and Ceramic Analysis Results from a Moderately Sized, Eleventh- through Early Fourteenth-Century Pueblo (LA135004) near Taos in North-Central New Mexico

Chronicle Heritage recently excavated part of a moderately sized, multicomponent site, LA135004, in advance of development near Taos in northern New Mexico. The prehispanic component, dating AD 1050–1300, consists of at least one room block with features, extramural cooking pits, and thousands of ceramics, flaked and ground stone, and other artifacts. Chronicle Heritage excavated four units in the room block's previously disturbed midden and recovered nearly 1,000 sherds, 120 lithics, and one turquoise pendant, among others. In this poster, I summarize the excavation, present the ceramic analysis conducted, and discuss how the results improve the understanding of eleventh- through early fourteenth-century patterning for the Taos area, a time when populations aggregated into a few very large villages. In particular, I compare the midden assemblage to similar dating residential sites in the vicinity. Most contemporaneous sites, and nearly all associated data from north-central New Mexico, are from very large pueblos excavated as part of academic investigations. Consequently, LA135004 provides a complementary dataset from a small residential holdover during this period of population aggregation, demonstrating the need to reevaluate assumptions reliant on prior excavations at the large pueblos.

NAGPRA-Era Collections-Based Research in the Academy: Insights from Investigating Collections at Five Institutions

The passage of NAGPRA in 1990 has had a tremendous impact on archaeological investigations, museum curation practices, and active relationships with Native American communities, notably those federally recognized. Although many archaeologists fretted that NAGPRA would significantly curtail or outright distort archaeological research and interpretations, most view the outcomes as overwhelmingly positive. A less discussed change in the NAGPRA era is the shift from excavation-focused doctoral dissertation research at US universities to collections-based research, something starkly in contrast to prominent publications demonstrating peers attach a higher prestige to the former. In this talk, I present a summary of my doctoral research project during which I analyzed over a dozen site collections, analyzing ca. 80,000 ceramic artifacts, reconstructing excavation histories from field note archives, and dating 20 specimens curated by multiple institutions. I use the outcomes of my doctoral project to address how despite the existing NAGPRA-related restrictions, or already repatriated materials in some cases, these did not significantly curtail or limit. Rather, prior experience working for a tribal cultural resource agency and, separately, toward repatriation efforts informed how I approached and interpreted archaeological materials and ultimately led to more profound implications.

Mogollon Strontium Isotopic Baseline

Recent studies on domestic turkeys (*Meleagris gallopavo*) and exotic scarlet macaws (*Ara macao cyanoptera*) have raised new questions about how prehistoric communities in the American Southwest maintained local avian management practices, developed breeding regimes, and fostered trade networks. While strontium isotopic analysis ($^{87}\text{Sr}/^{86}\text{Sr}$) can be used to define local and nonlocal birds, the lack of localized biogenic strontium baseline studies across the region currently makes pinpointing the origins impractical. Here we present our results from a robust strontium isotope analysis that incorporates tooth enamel and bone from over 115 small mammals recovered from 30 archaeological sites in the Mogollon region. Because strontium isotopes from bone and tooth samples can be used as proxies for local geologic signatures, this dataset helps characterize strontium variability at each site. Our study defines strontium isotopic baselines for a largely understudied portion of southwest New Mexico and southeastern Arizona and identifies the likely origins of turkeys and macaws. This strontium isotopic baseline study will facilitate ongoing research through much of the Mogollon culture area and lay the foundation for future isotopic studies.

A Preliminary Botanical Analysis of the Quinebaug Falls Site in Preston, Connecticut

During the Section 106 process, Heritage Consultants LLC, personnel identified the Quinebaug Falls Site along the Quinebaug River in Preston, Connecticut. Phase II investigations of the site yielded diagnostic cultural materials indicating the presence of Middle and Late Woodland occupations, including a Fox Creek and potential Jack's Reef component. The excavations resulted in the identification of cultural features that yielded botanical materials, as well as a radiocarbon date of 1440 ± 30 BP (1375–1296 cal BP). Middle Woodland sites are rarely preserved and recorded in archaeological literature throughout Connecticut and southern New England, in comparison to other time periods. As a result, this presentation will focus on the botanicals of the Quinebaug Falls Site and will provide a preliminary overview of the information this data adds to the archaeological record regarding Indigenous plant use during the Middle and Late Woodland periods in southern New England riverine environments.

Recent Investigations at the Musgrove Shell Ring (9L12169) on St. Catherines Island, Georgia

In this poster, we present the preliminary findings on recent fieldwork at the Musgrove Shell Ring. Due to the ring's low topography and dense vegetation coverage, archaeologists did not identify the ring prior to the review of new lidar data, which showed an anomaly approximately 60 m in diameter. Fieldwork consisted of a shell density survey and multiple geophysical techniques including gradiometry, electrical resistance, ground-penetrating radar, electrical resistivity tomography, and time domain induced polarization. Additionally, limited excavations of the shell deposits and the center helped confirm a Late Archaic shell ring, making it the third on St. Catherines Island.

Violence and Selected Funerary Treatment: Insights from a Collective Open Tomb of the Upper Nepeña Drainage, Peru (AD 1300–1500)

The recent PARAMa project undertook the excavation of several open sepulcher funerary contexts in the Upper Nepeña Drainage, among which two structures were thoroughly excavated. Their content, predominantly skeletonized and partially mummified human remains, were analyzed, representing the first systematic bioarchaeological study in the region. Here, the authors will discuss the results of this seminal study, focusing on the special case of Intirumi, a communal tomb of the *machay* (rockshelter) type. The context dates to the second part of the Late Intermediate period (AD 1300–1500). In addition to being characterized by a specific funerary selection, the commingled skeletal assemblage recovered shows an exceptionally high rate of lethal and sublethal cranial trauma (92.3%). The integration of archaeological (mortuary patterns), bioarchaeological (demographic profiles), and paleopathological lines of evidence enabled the authors to reconstruct and discuss the biocultural context associated with these traumatic injuries. In turn, it helps shed light on the lived experiences of the people deposited in this tomb, including the types and patterns of interpersonal violence and warfare in the Cordillera Negra region during this period. Finally, the remains highlight the overall significance of this particular open sepulcher context within the funerary landscape.

Xochitécatl-Cacaxtla: Una ciudad dos veces abandonada

El tema del abandono de las ciudades arqueológicas, se ha tratado en muchos estudios, pero en este caso la particularidad es el “retorno”, en Xochitecatl-Cacaxtla se identifican dos periodos de ocupación, el primero de 800 aC a 200 dC, y el segundo del año 650 dC al 950 dC. La causa del primer abandono fue la erupción del volcán Popocatepetl, sabemos hacia donde fueron y se establecieron, pero lo más intrigante es el porqué del regreso después de 500 años a habitar los mismos espacios habitacionales y los edificios del Centro Ceremonial. Tenemos evidencias de casas epiclásicas construidas encima de las ruinas de las del periodo formativo. Vuelven a ocupar la “ciudad” hasta el año 950 dC cuando otra erupción del Popocatepetl destruye el paisaje y nunca más “retornan”.

Composting the Past for the Future in the Bahamas: A Case Study of Contemporary Reuse and Transformation of Historic Spaces

Farmers and gardeners in the Bahamas have long practiced swidden agriculture to replenish the thin soil

layers sitting atop limestone bedrock. These methods recycle the organic materials of the landscape to produce something new and generative. In similar fashion, the historical materials that dot the landscape of rural islands are recycled into new constructions that make life in rural islands like Eleuthera possible. Drawing on DeSilvey's formulation of "compostheritage" (2017), this paper considers how the abandonment and decay of organic materials and the built environment is not a definitive end to the lives and uses of historic places and objects but is part of a process of transformation wherein old things breathe new life into the living landscape of the island. The paper considers the materiality of the early nineteenth-century Millar Plantation Estate and surrounding late nineteenth-century post-emancipation settlements where stone walls once associated with the plantation are deconstructed and reappear in garden walls, road markers, cemeteries, and more. Composting materials ties the past to the present and makes it visible in daily life, but it also has a future-oriented capacity. Archaeological ethnography reveals intersections of past/present/future embedded in the historical and contemporary materiality of this place.

Osteological Evidence from a Civil War–Era Grave and Surgeon's Pit in Colonial Williamsburg

In this paper, we report on the study of human skeletal remains recently discovered near a powder magazine in Williamsburg, VA, the site of a mass Confederate grave. Osteological analysis of four discrete burials and additional remains recovered from a nearby surgeon's pit indicates that these individuals likely served as soldiers. The four individuals were identified as males ranging in age from the mid-teens to the mid-thirties. One individual exhibits an extreme degree of robusticity while two others present with gunshot wounds. Our findings are consistent with documentary accounts of medical knowledge and practices of the day. For example, the lack of "false starts" and small size of the "terminal snaps" observed for amputated leg bones recovered from the surgeon's pit indicates a high level of technical expertise. Additionally, the cutting of healthy bone (evidenced by lack of periosteal reaction) suggests that amputation occurred relatively quickly following a diagnosis of infection so as to avoid its spread throughout the body. These findings and the results of isotopic analysis will inform the proper and respectful reburial of these individuals while also contributing to an expanding social bioarchaeology of violence. ***This presentation will include images of human remains.

Navigating Uncharted Waters: Staying Up-to-Date with New Tools and Best Practices for Underwater Archaeological Survey

This poster highlights surveys by the US Army Corps of Engineers in North Carolina's Outer Banks and Florida's Tampa Bay. These studies illustrate how large-scale surveys and novel techniques are improving our ability to identify submerged resources but are also increasing the need to develop strategies to assess the significance of potential features, in order to maintain best practices for the management of our underwater cultural heritage. In order to safely survey the dynamic, shallow shoals of the Outer Banks, the Corps employed the use of an aerial drone magnetometer. The resulting survey was able to capture data at nearly three times the speed of a boat-towed magnetometer survey, and removed the potential hazards associated with such shallow waters. Lake Edgar, beneath Tampa Bay, is a late Pleistocene/early Holocene freshwater

feature that served as the drainage basin for the various fluvial channels in the region. Surveys for multiple Tampa Bay federal projects have recorded locations of the now submerged paleo lakeshore, thus potentially adding to our knowledge about the paleolandscape of the region and precontact archaeological deposits. Though not currently impacted by the project, effective and efficient assessments of these features is a challenge that requires consideration.

Boundaries and Crossroads, Immigrants and Ancestors: Comparing the Post-Chavín Landscapes of the Moche and Virú Chaupiyungas

The centuries following the disintegration of the Chavín interaction sphere (~500/400–200/50 BCE) were experienced in myriad ways throughout the ancient Andes. In the Moche and Virú Valleys in northern Peru, the late Early Horizon (~500–200 BCE) generally saw earlier traditions of large ceremonial centers fade to be replaced by evidence for fortifications, increased social hierarchies, and a boom in regional demography. However, even these generalized patterns were unevenly distributed across and between the landscapes of the valleys themselves. Situated at the highland edge of the coastal river valleys below, the *chaupiyungas* of the Moche and Virú Valleys witnessed recognizably different trajectories despite occupying similar borderlands in neighboring valleys. In this paper we use two full-coverage survey datasets to compare the post-Chavín landscapes of the Moche and Virú Valley *chaupiyungas* and explore the many ways in which relationships between neighboring and local groups transformed during the late Early Horizon.

Using Ethnographic Skills while Excavating: Exploring the Longevity of a Community Archaeology Project in Western Ireland

Community archaeology brings people from different backgrounds together to investigate the past, and each group contributes to the project in unique ways. While many articles discuss best practices, generic, formulaic approaches do not work in the field. This poster explores the techniques that help archaeologists create community interactions that benefit communities and archaeology, as community-based research is intended to do. Since 2007, the Cultural Landscapes of the Irish Coast (CLIC) project used various methods to build relationships with communities to create long-term partnerships to ensure archaeology benefited multiple interested communities, not just scholars. Through a community-based research project case study on Inishark and Inishbofin, County Galway Ireland, islands about five miles into the Atlantic Ocean, we explore the different approaches used to interact with all the interested groups in community-based research and how to apply methods to other locations and projects.

Shantry, Kate (Washington State University)**[262]***The Osceola Mudflow: Dropping into the Valley and Standing Up Next to the Mountain in Southern Puget Sound*

On the Northwest Coast of North America cultural processes are intertwined with the natural environment. A collapse 5,600 years ago on the northeast slope of Mount təqʷuʔməʔ [Rainier] caused the massive Osceola Mudflow (OM) event and transformed the landscape. In Lushootseed teachings, the Changer genre of stories distinguishes between the present and the past when people and animals were indistinguishable. The research presented here aims to connect land transformations and traditional ecological knowledge through the archaeological record. Local Indigenous notions of place are tied to a mosaic of resources managed by people at various degrees and levels. The post-OM landscape has been and continues to be actively used with cultural continuity. How people used the landscape after the OM is connected to past use, however the pre-OM landscape is less visible, less understood, and underexplored. This study investigates the history of the OM through oral history, geology and the archaeological.

Shapiro, Craig (Ohio State University)**[42]***Building Resilience with Traditional Knowledge in Samoa*

Analyses of lidar datasets have allowed archaeologists to expand the study of archaeological landscapes to study extensively human-modified environments at regional scales with more advanced geospatial methods. In Sāmoa, lidar reveals networks of ditches, terraces, and other earthen- and stone-monumental architectural features that extend from the coast to the remote interior. These precolonial constructed landscapes reflect the traditional ecological knowledge of Pacific Island ancestors. This intimate understanding of adapting to variable island environments and how to engineer those settled landscapes for long-term resilience still serves Pacific communities today. In Sāmoa, these socioecological systems control flooding and consequent soil saturation, support agricultural production, and provide examples of communities building resilience through collective action. Ancestral Sāmoans not only knew how to target specific soils for agricultural production but also recognized the importance of monumental water control features to maximize agricultural production. Revitalizing such traditional ecological knowledge and land management practices may simultaneously draw further connections to related communities, promote an adaptation strategy for other indigenous island and coastal communities preparing for increasingly powerful and more frequent rainfall events due to a rapidly changing climate, and indicate how these precolonial features could be integrated into modern efforts to enhance climate-resilient food production.

Sharapov, Denis (University of Tyumen)**[23]***Im(mobile) Pastoralists of the Central Steppes? Ethnohistory vs. Archaeology*

Due to the heavy influence of sixteenth- to nineteenth-century ethnography, many researchers still consider the Late Bronze Age (LBA; 2100–1300 BC) populations of the Trans-Ural steppe/forest-steppe to be nomadic pastoralists—a situation where most or all of human population is involved in periodic movements between pastures. However, a comprehensive synthesis of data pertaining to settlement architecture, garbage accumulation rates, herd composition, osteological seasonality markers, stable isotopes, the degree of transportability of artifacts, and haymaking activities from 42 archaeological sites points to the fact that the settlements of the Sintashta, Petrovka, Alakul, and Srubno-Alakul cultural types were sedentary; i.e., occupied year-round by at least a portion of the population. This observation, among other things, indicates that the analysis of the LBA populations of the central steppes requires no special approaches that would account for community-level seasonal mobility, thereby opening up the possibilities for focusing on some of the previously understudied aspects of LBA regional demography. In addition, the above finding adds the Trans-Urals to the list of world regions where large-scale sedentism preceded crop cultivation.

Housing the Dead, Assembling Kin: The Construction and Use of Chullpa Tombs during the Middle Horizon in the Callejón de Huaylas Valley, Peru

In the highland Andes, archaeologists often emphasize the late prehispanic era (post-1000 CE) when examining the widespread mortuary tradition of interring the deceased in aboveground tombs known as chullpas. Our understanding of this practice during the preceding centuries, however, remains limited due to the smaller geographic distribution of early chullpas. In this paper, we present findings from excavations at two Middle Horizon (700-1000 CE) archaeological sites in the Callejón de Huaylas—Hualcayán and Jecosh—to assess how local peoples adopted this funerary tradition in different communities. We discuss the material evidence for distinct chullpa-building techniques, their spatial layout and location on the landscape, the feasting and offerings found outside the structures, and the social identities of the deceased interred inside them. As monumental architecture and focal points of ritual interaction, these chullpas were impressive settings where communities of mourners gathered to venerate the dead and ask them to intercede on their behalf. Yet, our data for the use and decommissioning of chullpas points to how communities perceived chullpa tombs as much more than venues for interring and feeding the dead: they may have also considered chullpas to be social actors with personhood and agency, even kin, much like many Andean houses.

Panama Archaeology's Paradigm Shift: A History of Cerro Juan Díaz, Its Excavations, and Ongoing Research

In the late 1980s, the Panama authorities became aware of extensive looting outside the modern city of La Villa de Los Santos. By the time archaeologists had been called to investigate, the area around the hill known locally as Cerro Juan Díaz resembled the cratered surface of the moon. Thus began a decade of intensive excavations by an international group of researchers, uncovering the history of what may have been one of the largest settlements in Pre-Columbian Panama. Occupied from 200 BCE–1600 CE and spanning some 150 ha, Cerro Juan Díaz may have been a ceremonial center, burial ground, and residential community. The exact nature of the settlement is still under investigation, as hundreds of thousands of cultural remains are still under analysis. Dozens of archaeologists were involved in the project over the years, many of whom began their careers at the site. This paper explores the history of the site's discovery and excavations, as well as recent projects and plans for the future. Most importantly, it emphasizes the significant impact Cerro Juan Díaz had, and continues to have, on our understanding of ancient life in the Isthmo-Colombian Area.

Two Decades (Almost) of Regional Clay Surveys by the EAF: Successes, Challenges, and Opportunities

An early and ongoing goal of the EAF was to not only generate compositional data on archaeological artifacts but also to build comprehensive collections and elemental databases of natural materials that had potentially been used to manufacture craft objects. To date, EAF efforts to build collections of geological reference material have focused primarily on clays from Andean South America. Since 2005, EAF collaborators have undertaken numerous semi-systematic surveys of clay deposits in Peru, Bolivia, Chile, and Argentina. LA-ICP-MS analyses of clays acquired during these surveys have produced critically important compositional data, which, when used in tandem with elemental analyses of ceramics, are instrumental in comparative understandings of pottery production and circulation. We concentrate on four of these regional surveys: those undertaken in the Moquegua Valley and the Cuzco region of Peru, the Azapa Valley of Chile, and Bolivia's Department of Cochabamba. We discuss what motivated each survey, the array of scientific, artistic, and community collaborations and methods adopted, and the opportunities and challenges furnished by the distinct geological context of each survey region. We also reflect on how the elemental database of clays from each survey enhances reconstructions of regional pottery traditions and suggest protocols for future surveys.

Reconsidering the Terminal Classic in the Northern Lowlands: A Boom or the Start of a Bust?

After many sites in the Southern Maya Lowlands were abandoned during the major societal transformation known as the "Maya Collapse," settlements in the North grew markedly in size. In the Cochuah region of the Yucatán Peninsula, and elsewhere, some of the largest architecture ever built was constructed. More residences than had been seen before, or since, covered prior occupations and extended across terrain that, at most, had previously only been used periodically for swidden farming. While estimating population counts is problematic, artifact counts and densities similarly reflect this population "boom," long described as a cultural florescence, that was eventually followed by a seemingly puzzling crash of the Postclassic. Reconsidering these major demographic shifts in light of current migrations taking place around the world, it makes sense to not necessarily think about the Terminal Classic as a time when sites in the north thrived, but instead of as a period when society was likely strained by large numbers of people arriving from the south into a drier territory undergoing significant periodic droughts. As with refugees today, there were likely varied responses to the new arrivals.

Middle Horizon Residence and Production at Huaca Colorada: Sectors A and C in Comparative Perspective

Since excavations began at the Late Moche and Middle Horizon ceremonial center of Huaca Colorada (ca.

750–920 CE) in 2009, its expansive residential and production zones have attracted much attention for their ephemeral architecture. Largely located in the windblown sand of Sectors A and C, these structures have been interpreted as encampments where pilgrims from the coast and highlands feasted and crafted a wide range of items from copper alloys, textiles, ceramics, and maybe other materials. However, permanent architecture was also unearthed alongside these encampments, and recent excavations have revealed that many of these large structures undergird the informal residences. Based on stratigraphic data, new chronological models, and statistical analyses of cultural remains, I present sequences of architecture and activity areas in Sectors A and C of Huaca Colorada. I also briefly compare these results to data from other Middle Horizon, North Coast settlements (urban and nonurban) to discern whether Huaca Colorada's residential areas contained rooms and features typical of the region's houses and whether craft production areas were spatially distinct from general domestic activities and, if so, when.

The Privilege of Memory: Segregation within a Plural Long Island Cemetery

The legacy of memory, and who is entitled to it, is an important conversation within post-Contact archaeology. This research examines the local narrative of segregation within Amityville Cemetery, located in the demographically separated Amityville, New York. While White individuals predominately live in the Village of Amityville, the hamlet of North Amityville consists of a majority non-White citizens who claim heritage from enslaved and Indigenous peoples. The two groups' shared cemetery offers a case study of how segregation impacts contemporary settings, with local informants indicating the front of the cemetery was reserved for the White members of the Village of Amityville and the rear portion for the non-White inhabitants of North Amityville. Utilizing a grave marker survey and reviewing historical documents, this research illustrates not only historic racial segregation, but also modern economic segregation, permeated through stratified burial costs and maintenance fees. The findings show that even today, memory serves as a privilege many are not entitled to. This poster will not include images of human remains.

Intrasite Spatial Analysis of the 13,800-Year-Old Component at Shég' Xdaltth'i', Central Alaska

Shég' Xdaltth'i' is an archaeological site (FAI-2043) located about 30 miles south of Fairbanks, Alaska, in the Tanana Flats. Results of archaeological testing and excavations between 2013 and 2022 identified three distinct archaeological components, components 1, 2, and 3, dating to about 13,800 cal BP, 12,700 cal BP, and

5000 cal BP, respectively. While excavating a 25 m² block, approximately 60,000 pieces of archaeological materials were collected in situ with three-point provenience, and most of these come from component I. This paper will discuss the spatial patterning of lithic technological material, radiocarbon dates, charcoal, and fauna material that has been identified at Shég' Xdaltth'í', focusing on component I. We will use spatial analyses, modeling, and qualitative observations to demonstrate different activity areas in component I and to test the discrete nature of all three archaeological components at the site.

Suburban Space Transformed: Investigating Chu Capital's Southern Suburbs before and after Conquests

Research on ancient city sites in Chinese archaeology tends to focus on remains within the city walls, while paying limited attention to the city periphery as a distinct and research-worthy spatial unit. The present paper challenges this prevailing approach by investigating the southern suburban area of the Chu capital in South China. It explores the complex relationship between this suburban space and the urban core to which it was connected. Notably, following events of monumental conquests of the region during the third century BCE, settlements in the southern suburbs underwent restructuring and became the western suburbs of the newly established Nan Commandery under the Qin and early Han empires. Overall, this study aims to offer a fresh perspective that enriches our understanding of the nuanced trajectory of early (sub)urbanization in China.

[19]

The Dynamic World of Ritual: Oracle Bone Divination Practices in East Asia

Oracle bone divination, an ancient East Asian practice for predicting the future, originated in northwestern China during the middle Neolithic period (5000–3000 BCE) and ultimately became a prominent ritual during the late Neolithic and early Bronze Age. Its influence reached the Korean Peninsula and Japanese archipelago around 500 BC, potentially via terrestrial and maritime routes. This divination method significantly shaped the cultures and belief systems of ancient East Asian societies. Long-distance transmission prompted technological and cultural adaptations, revolutionizing religious beliefs and divination practices. Simultaneously, the collapse of ritual traditions and the establishment of new authorities, on the other hand, were miniatures of community politics. The way diviners practice divination as well as their control of related knowledge play an essential role in the emergence of early East Asian states.

The COREX Project: Explaining Patterns of Genetic and Cultural Diversity in Prehistoric Europe

This six-year international interdisciplinary project funded by the European Research Council (2021–2027) is bringing together the increasing quantity of genomic data available for prehistoric Europe and related macroscale archaeological data with the aim of exploring how small-scale processes generate large-scale patterns in genetic and cultural data, and how the two interact. The archaeological core of the project is the BIAD relational database. It currently includes space-time referenced datasets of radiocarbon dates with contextual information, strontium isotope analyses, archaeobotanical and archaeofaunal data, and descriptions of the archaeological context and associations of ancient DNA results, providing links to the genomic data. The space-time referencing also enables links to pollen data in the European Pollen Database. BIAD provides a curated dataset with source references, not a data repository, which can be accessed directly in R to carry out analysis. The talk will outline BIAD and some of the challenges it has had to overcome and present some results of initial analyses.

Anticipating Ruptures: Living with Uncertainty and Undertaking Repair

Drawing on archaeological research on the longue durée of ancestral Lenca society in Honduras, we argue that centuries of resilience provided the tools people needed to understand and respond to periodic interruptions in the normal progress of seasons, lives, and relationships, “failures” of specific forms of social relations most dramatically visible as societal collapse and conquest. We relate this history to Indigenous ontologies in which relations between humans and other forces are in need of constant maintenance—repair—a philosophy that imagines and expects disruption, breaks, and even violence. We log evidence that communities in the ancestral Lenca area dealt with repeated uncontrollable events—extreme flooding, unpredictable impacts of volcanic ash eruptions, and agricultural failures—that provided them with a pragmatic and ritualized set of tools for confronting disasters. We examine changes in ritual action that suggest shifts in underlying philosophies of engagement with the landscape, in particular with the celestial realm, that emerge during the “collapse” of hierarchical social life beginning ca. AD 900–1100, and adjustments made in the face of the most visible catastrophe in Lenca history, the sixteenth-century colonization of the region, arguing that persistence in place resulted from overcoming failures in existing social routines by “repair.”

Archaeology and Community Engagement at Mission Espada, San Antonio TX

This paper presents the findings from two seasons of fieldwork at Mission Espada in San Antonio as well as preliminary results from comparative analysis of the living quarters of the priests and Indigenous living quarters at the mission in the eighteenth century. This comparison is part of a larger multiscale project that examines the lived experiences of Indigenous neophytes at Mission Espada and its associated ranch, Rancho de las Cabras. More broadly, and perhaps more importantly, this project engages with local Indigenous descendant communities in the San Antonio area. Through working with local community members, I have gained better understanding of how sites of such historical significance, like Mission Espada which is both a National Park Service site and World Heritage site in addition to being a fully functional Catholic church, both impact and are impacted by these contemporary communities.

Testing a Possible Feasting Context at an Early Fort Ancient Village: A Zooarchaeological Analysis from the Turpin Site in Southwest Ohio

The Turpin site (33Ha19) reflects the remains of an early Fort Ancient (ca. AD 1000–1300) village located near the confluence of the Little Miami and Ohio Rivers on the east side of modern-day Cincinnati, Ohio. Recent excavations at Turpin revealed evidence of habitation, midden, and possible special purpose contexts. One large pit (Feature 100) dated between cal AD 1223–1276 contained a notably high concentration of artifacts, including the remnants of decorated shell tempered vessels, mussel shells, adornments, and the remains of a variety of animals. The density and nature of these deposits led to an initial interpretation that Feature 100 contains the remains of a feasting event. This project has two objectives focused on examining this hypothesis using animal remains. First, a zooarchaeological analysis is conducted using the Feature 100 assemblage to characterize the species deposited here. Then, this assemblage is compared to an equivalent sample from a contemporaneous midden context to determine whether Feature 100 reflects the secondary deposition of feasting debris or if it is just a larger pit used for everyday disposal. This comparison provides insight into Fort Ancient subsistence practices and has the potential to reveal elements of feasting in an early agricultural village.

Characterizing Lithic Networks during the Archaic Period in the Lower Mississippi River Valley

This research investigates temporal patterns of toolstone acquisition and utilization during the Archaic period in the Lower Mississippi Valley region. Chert assemblages from Middle and Late Archaic, including Poverty Point, sites are analyzed. Whereas Late Archaic and Poverty Point assemblages are known for their diverse lithic materials, Middle Archaic chipped stone assemblages are thought to be predominantly, if not exclusively, comprised of local cherts. The goal is to pinpoint the source locations of these materials and explore whether the utilization of nonlocal toolstones represents a unique Late Archaic/Poverty Point phenomenon or is a continuation of long-standing traditions in the region's prehistory. Nondestructive Visible/Near-Infrared (VNIR) and Fourier-transform infrared (FTIR) reflectance spectroscopy and machine-learning algorithms are employed to examine the chipped stone artifacts. We conclude that both nonlocal and local raw materials are present in all these Archaic assemblages and represent the same reduction stages, regardless of their distance from the source.

Macro and Micro Floor Stratigraphy from Poverty Point Ridge 2 Northwest

Poverty Point's concentric ridges have long been assumed to be residential areas despite an absence of archaeological evidence for houses. In 1991, a field school excavation was initiated based on a core that suggested a possible clay floor buried ~60 cm below the surface. Sixteen 2 × 2 units were opened, but most were not completed, and three of the more informative units lay open for months following the field school. Unfortunately, no final report was produced and many of the records and artifacts are now missing, making it impossible to evaluate the outcome of the excavation. Diana Greenlee recently led a project to reopen two of the completed units to uncover and analyze the ridge stratigraphy preserved in the old unit profiles. In this paper I describe the stratigraphy and micromorphological evidence for constructed and used floors.

Sicán Politics and Population: Nuclear Genomic Perspective

Why are there clustered and dispersed Middle Sicán (900–1100 CE) monumental mounds in the Lambayeque region of northern coastal Peru? What do these mounds reveal about Sicán politics and demography? As one investigative avenue to answer these questions, DNA was extracted from 15 human burials excavated at three mounds of the Sicán capital: Ventanas, Loro, and Lercanlech. It was analyzed using a next-generation sequencer. The entire mtDNA sequences for one specimen each from Ventanas and Lercanlech and the mtDNA haplogroups were identified as A2 and C1, respectively. These haplogroups are unique to indigenous peoples of the Americas. Nuclear genome analysis was possible for the young adult woman from Lercanlech. SNP data was combined with the data from both modern and ancient South Americans, and PCA was performed to clarify the genetic characteristics of this person. Compared to other open-source New World population data, this individual is positioned within those from South America. Indigenous Andeans are known to have regionally distinct genetic characteristics since ancient times. Further analysis may reveal related regional populations. We discuss how the Lercanlech person relates to the modern and ancient South American regional populations and cultural inferences that can be drawn.

Locating Sak B'alam: Preliminary Research on the Last City of the Lakandon Ch'ol

According to the ethnohistorical sources, the Lakandon Ch'ol managed to maintain their independence from Spanish colonialism for over a century somewhere in the forest, after the Spanish seizure of their capital in 1586. They founded a new center called Sak B'alam, which was finally conquered by the Spaniards in 1695. Sak B'alam was renamed as Nuestra Señora de los Dolores but abandoned in 1721. After the abandonment, the location of Sak B'alam has been lost to date. Although archaeologists and historians have long attempted to locate Sak B'alam in Selva Lacandon, Chiapas, there is little written information for the location of Nuestra Señora de los Dolores in the Spanish documents. As part of a new research project focused on the historical and archaeological sites related to salt production in the interior Chiapas by Proyecto Arqueológico Sak B'alam, this paper presents results of preliminary research that employs lidar reconnaissance and surveys to locate potential Sak B'alam. The initial survey explored the area by test-pitting excavations in 2023. Results have begun to reveal some occupations in the preconquest time period.

Not-So-Set in Stone: An Investigation of Rock Art Digitization Methods and Scale of Applicability

Around the world, rock art sites present significant preservation challenges due to their vulnerability to deterioration from natural weathering as well as human impacts. Various forms of digital recordation are frequently presented as a means to preserve rock art images at various sites. The goal is to preserve them as they are before they disappear entirely. While digital documentation methods (e.g., lidar, photogrammetry, DStretch) can be effective in many cases, these technologies may not always be the best or only solution when situated within systems of cultural values and traditional knowledge of affiliated descendant communities. This extended literature review summarizes and theorizes contemporary uses of digital rock art preservation methods, including their effectiveness and impacts on site conditions. In doing so, this work investigates the plausibility of broad-scale application of digital preservation technologies for known rock art sites across the United States. I also explore where digital documentation has been done in collaboration with affiliated descendant communities and public response in these cases. I emphasize the importance of community engagement and the intertwining of archaeological and Indigenous cultural knowledge in pursuit of effective heritage preservation protocols.

Optimization of a Minimally Invasive DNA Extraction Protocol for Teeth

Ancient DNA extraction protocols are inherently destructive and, therefore, are often controversial and problematic. For some communities, destructive processing of human remains could be perceived as a desecration of ancestors. For laboratory scientists, the destruction of samples limits the ability to replicate results. Harney et al. (2021) present a minimally destructive protocol for extracting DNA from human remains that relies on collecting DNA from the cementum of the tooth root, leaving the sample structurally intact with only minimal discoloration in most samples. However, since the cementum is the outermost layer of the root, it is prone to high levels of exogenous contamination, which significantly increases sequencing costs and decreases sequencing data quality. This study explores a potential method to optimize the Harney et al. minimally destructive protocol by adding an additional lysis buffer exchange step prior to incubation.

We tested multiple time intervals for additional buffer exchange and compared resulting library quality statistics (e.g., endogenous content, fragment length, contamination estimates). While the success of protocols always depends on sample preservation quality, the results indicate that an additional buffer exchange step has the potential to optimize DNA yields and quality from ancient and historic tooth samples.

Prehistoric Millet Cuisine: Diversity across Eurasia

Broomcorn millet (*Panicum miliaceum*) was first domesticated in northern China and spread both to east and to west during the mid-Holocene. Recent developments in biomolecular analytical techniques have enabled archaeologists to investigate prehistoric millet cuisines by examining the organic residues absorbed by the pottery. While the detection of miliacin, which is considered as the biomarker of broomcorn millet grains, in the pottery itself, and in charred deposits on the inner walls (foodcrusts), provides direct evidence of millet cooking using pottery, compound-specific carbon isotope analysis on the same extracts also detects other ingredients mixed with the millet, such as animal fats or dairy products. By doing so, this paper highlights the clear regional difference in millet cuisine in Bronze Age–Iron Age Eurasia, from the east in Japan and Korea, and west in Kazakhstan.

Collaborative Decolonial Approaches to Narrative in the Coastal Heritage at Risk Taskforce

Florida stands to lose more recorded sites to sea-level rise than any other state in the region, with nearly 4,000 estimated to be lost to a 1 m rise. For many of these heritage sites, untold stories of Florida history that are currently missing from the public record will also fade into obscurity as destruction occurs due to sea-level rise. Many of these stories are of marginalized groups who encountered violence from the start of Florida state history, and who often had to flee their communities or were forcibly removed by city planners or state military. These sites include the stories of the Underground “Saltwater” Railroad, and the forced removal of Indigenous people to internment camps on the west coast of Florida. The Coastal Heritage at Risk Task Force (CHART) team is a partnership of public, private, academic, and government entities. In this paper, our team will discuss collaborative decolonial approaches to narrative development working with Seminole THPO and the National Museum of the Bahamas. CHART’s aim is to create visibility of at-risk coastal heritage sites and their untold stories in Florida for secondary education classrooms and the public, while also assessing site risk for future adaptation strategies.

Inca Hydrodynamics at the Chachabamba Archaeological Site (Machu Picchu National Archaeological Park, Peru)

The Chachabamba archaeological site in the Machu Picchu National Archaeological Park contains a unique water complex erected by the Incas. Based on archaeological investigations, it has been established that the function of this water complex was strictly ceremonial. The necessity to control water flow in an architectural context is often associated with the need to apply water in a spiritual context. Moreover, hydrodynamic studies of the water supply canals have verified the previous ritual-oriented findings. Due to the complex characteristics of the site, which is overgrown by dense vegetation, we employed a volumetric analysis technique not previously applied in the region. 3D documentation techniques based on lidar and 3D scanning were used to produce hydrodynamic analyses of the site, which facilitated the preparation of models that are key to understanding the function of the entire water system. As there are many potential archaeological sites within Machu Picchu Park where this analytical method can be developed, the presentation aims to share the methodology used and discuss its possibilities and limitations. The research was carried out as part of a collaboration between the University of Warsaw's Center for Andean Studies and the Peruvian Ministry of Culture at Machu Picchu National Archaeological Park.

Archaeology by Experiment, Replicating the Past, and Education: The Classroom and the Waters of the Lesser Antilles

As most archaeologists would agree, we can never know with certainty what really happened in the past given (1) the fragmentary nature of the archaeological record and (2) the intangible aspects of human behavior that may have factored in forming the archaeological record. By integrating emic and etic perspectives we aim to build an accurate/plausible (re)construction of past human behavior and the motivations, selective pressures, and cognitive frameworks that resulted in material patterns identified archaeologically. Archaeology by experiment is one source of observations that has been used to assist in understanding the past since at least the mid-nineteenth century. Experimental archaeology is also a pedagogical exercise to include in program curricula for students to make connections between human behavior and archaeological implications. We discuss (1) an undergraduate course in experimental archaeology offered to mostly Montclair State University commuter students. Working in collaborative teams, students design, conduct, and report on experiments that are doable within the semester framework. Experiments range from lab-based tightly controlled exercises to others that approximate the messiness of the real world; and (2) a long-term public-oriented experimental program in Caribbean maritime travel, including Indigenous canoe construction and engaging the public in negotiating the waters of the Lesser Antilles.

Junius and Margaret Bird at Chiloé: A Review of the First Archaeological Work in the Northwestern Patagonian Coast
 Junius and Margaret Bird's expedition to southern Patagonia is primarily renowned for its discovery of Late Pleistocene occupations within the Magellanic steppe. However, their voyage included two lesser-known stays at the northern margin of the Patagonian archipelagos. During those periods, Junius conducted the first archaeological work at the shell middens of the insular coasts of Reloncaví Sound and Chiloé Island, which he believed to be the birthplace of the canoe-faring societies of the southern Pacific. Perhaps surprisingly, however, his publications only briefly mentioned these sites. Therefore, if not for excerpts from Junius and Margaret's diaries and letters, those excavations and surface collections have remained relatively unknown, despite representing pioneering work in an area that wasn't studied for decades thereafter. In this work, we present results of the first study of the collections held at the American Museum of National History, along with the spatial reconstruction of the archaeological work carried out between 1935 and 1936. The collections include evidence so far unrecorded in the area, such as *Mytilus* shell tools, and a diverse set of ceramic, bone, and lithic assemblages that account for Chilean cultural history from the Middle Holocene to the Spanish colonial times.

Malaria in the African Indian Ocean Islands: Prospects and Challenges for Biomolecular Archaeology

Malaria remains one of the most devastating infectious diseases affecting human populations, with over 200 million cases and 500,000 deaths annually worldwide, most of which focused on the mainlands of sub-Saharan Africa. While malaria is an "old" disease on the mainland dating back tens of thousands of years, its history on the African islands of the Indian Ocean is thought to be much more recent, closely intertwined and impacted by human migrations. In this talk, I will discuss the prospects and challenges for biomolecular studies of the history of malaria on the African Indian Ocean islands. The focus will be the island of Mauritius, where a severe malaria epidemic in 1867 killed some 41,000 people, representing ~10% of the island's total population at the time. I will present results from a pilot paleogenomic study on human remains from the Bois Marchand Cemetery, established in 1867 due to the malaria epidemic.

Using Sediment Chemistry to Define Ancient Activities

Soil chemistry is used in the Maya area to evaluate ancient activities not readily identified through architecture and artifact assemblages. We evaluate ancient activities at Ta'ab Nuk Na salt work, one of the largest underwater sites in Paynes Creek National Park, with at least 10 wooden buildings preserved below

the sea floor. Some of the buildings are salt kitchens that have abundant briquetage from evaporating brine over fires to make salt. Our paper will report fieldwork at Ta'ab Nuk Na to collect sediment samples, results of chemical analyses, and our interpretations. We expected chemical signatures for various activities such as pottery production of salt pots, salt enrichment areas, fishing or salting fish, and temporary or permanent residences for salt workers. Comparisons of 21 chemical elements using inductively coupled plasma–atomic emission spectrometry, notably calcium (Ca), magnesium (Mg), zinc (Zn), phosphorus (P), potassium (K), and aluminum (Al) are compared among between six buildings. The results show variations in elements associated with salt production as well as differences inside and outside of buildings and a residence for the salt makers.

Working for the Dead: The Role of Gravediggers and Their Impact on Burial Practices as Evidence in Transylvanian, Hungarian-Szekler Communities (AD 1050–1800)

Parker-Pearson's (1999) oft cited phrase, "the dead do not bury themselves," has led to decades of broad investigation surrounding the created social perception of an individual in different contexts and at different scales (family, military, celebrity). However, little research exists on the last individual to physically place the dead. Gravediggers have an extended relationship with the deceased and the mortuary landscape through initial placement as well as secondary placement when the initial grave is disturbed, as was common in medieval European cemeteries. This poster discusses the lived experience of gravediggers in medieval Europe through investigation of social expectations, folk accounts of the gravedigger experience, and bioarchaeological evidence of gravedigger actions. The Papdomb archaeological site in Transylvania, Romania (AD 1050–1800) acts as the archaeological case study and includes broad burial types (semi-disturbed graves, ossuary, grave shaft modifications) indicative of gravedigger choice and action. Correspondence analysis was run to compare burial type with age, sex, and location of each individual. The poster explores several possible interpretations ranging from the individual gravedigger's experience to community expectations in an attempt to highlight an important but overlooked step in medieval mortuary practices.

[223]

Before the Dig: The "Archaeologizing" of Peruvian Heritage Sites Prior to Formal Research

The contemporary southeastern Peruvian towns of Chinchero and Urquillos sit atop Inka population centers and are connected by the Urquillos Valley. Now occupied by family farms and walking routes, this steep valley also hosts former Inka roads and several understudied archaeological sites that survive in various stages of integration with small agricultural plots, protection by the Peruvian Ministry of Culture, and overgrowth by local ecosystems. Three of the many small sites within the valley—known as Inkaq Mallquin, Apiypanki, and Choquekasantuy/Trapichi—present a set of case studies for the processes by which Inka archaeological sites in the Cusco area are transformed before intensive governmental action but after their recognition as potential tourist sites. In this poster presentation, I demonstrate how the potentials of the archaeology-tourism nexus in the Urquillos Valley reconstitute these sites in materially lasting ways prior to formal governmental intervention, archaeological excavation, and reconstruction. I develop this analysis from ethnographic, ecological, and architectural studies carried out during two months of residence with local Indigenous families in Chinchero. Findings from this study have actionable implications for understanding how contemporary pressures are transforming the analyzable records of archaeological sites throughout Peru.

Tallgrass Prairie Archaeological Landscapes Project: Investigating Occupational Histories within a US National Grassland through GIS

The Tallgrass Prairie Archaeological Landscapes Project (TPALP) was established to identify the dynamic settlement lifeways within the current boundaries of the Midewin National Tallgrass Prairie in Will County, Illinois. Previous CRM-based projects identified 214 sites spanning the Archaic to historic periods across 18,094 acres (73.22 km²) of this US National Grassland. Current research at the Langford-phase site 11WV1280 has consisted of a combination of Phase I survey in 2021–2022 and Phase II testing in 2023. Situated along Prairie Creek, the preliminary data recovered from this site provides new insights for developing models of human settlement, cultural transformations, and land use within the Upper Illinois River Valley region. Incorporating these results with a GIS compiling all site data recovered from Midewin, this poster presents the first long-term overview of occupation and addresses Jeske's argument that Langford settlement patterns are tied to resource exploitation associated with drier prairie/forest landscapes. The broader implications of this work provide a perspective on regional patterns of interaction during the Mississippian period.

The Geography of Precontact Native American Rock Art in the American Southeast

In recent years, a large number of precontact Native American rock art sites, including caves and open shelter localities, have been recorded in the southern Cumberland Plateau. Cave sites contain pictographs, petroglyphs, and mud glyphs. Most open sites are pictographs or petroglyphs painted or engraved into upland sandstone shelters and bluffs. The subject matter of these sites varies, but abstract symbols, geometric shapes, human figures, and animal images dominate. Chronological information is limited but indicates a long sequence of rock art production beginning 6,000 years ago. With nearly 300 proveniences currently known, southeastern rock art sites can now be examined from a geographic point of view. Using GIS, we assess the spatial relationships among the varied forms of rock art and identify patterns that may reflect shared site selection criteria, including cardinal orientation, elevation, and landform associations. We also use GIS to examine possible dimensions of variation that have a chronological basis.

[325]

Decolonizing Deposition

Archaeologists view deposition as existing at an interesting crossroads: it is both fundamental to our basic understandings of site formation and easy to dismiss as unintentional or of secondary importance. Detailed discussions occur most frequently either to explain away issues with the archaeological record (poor preservation, looting, etc.) or to highlight highly structured and deliberate occurrences (burials, layering of colored sediment, etc.). While these discussions are clearly important, a large amount of social understanding is overlooked when everything between the extremes is chalked up to casual activities, unremarkable accumulations, or “trash.” In particular, the extension of ontological categories, such as trash, can obscure the identification of important cultural patterns when applied to non-Western contexts, such as Indigenous

North America. In this paper, we discuss the ways significant depositional practices have been overlooked by archaeological classifications of fill through a case study of ancestral Sugpiaq sites on the Kodiak archipelago.

[116]

Son of a Son of a Sailor: Island Life and the Colonization of Cyprus

For years the Mediterranean islands were considered devoid of much Neolithic or earlier occupation. That no longer is the case, with Cyprus being one island where recent research has rewritten the prehistory of the Mediterranean. We now know that its colonization was not a one-time “Noah’s Ark” event, but rather that the sea was a highway instead of a barrier, resulting in multiple voyages. This means that the first explorers and permanent residents of Cyprus must have had skilled sailors in their midst to make these voyages. I have investigated these early phases at three sites from Late Epipaleolithic pygmy hippo hunters, to deer hunters, domestic herders, and farmers in the Aceramic Neolithic. These studies have been productive, notwithstanding current political issues on this divided island. The studies have contributed to our understanding of how and why people become islanders. The early colonizers likely originated from several Levantine and Anatolian locales and were skilled seafarers with the ability to transport not only people but domestic animals and other resources. These skills were passed down through the generations, ensuring continuous voyages and resulting in a unique island identity that persists today.

Simmons, John (Western Michigan University)

[153]

Up in Smoke: Dating Pipe Stem Fragments from Fort St. Joseph

Clay smoking pipes fragments proliferate archaeological sites in colonial North America. Clay pipes were in regular use, did not last for very long, and were often replaced. Pipe bowls and stems found at sites across New France not only provide evidence of daily life on the frontier, they also introduce and strengthen occupational data garnered from the archaeological and historical record. Stem fragments from Fort St. Joseph, an eighteenth-century mission, garrison, and trading post complex located in present-day Niles, Michigan, will be evaluated to reinforce the post’s occupational date range and offer additional lines of evidence to date areas and features of the site. This study aims to provide a more detailed understanding of time at the fort and the daily lives of those who participated in the smoking culture.

Microstratigraphic and Biomolecular Identification of Seaweeds in the Mesolithic of Atlantic Iberia, SW Europe

Mesolithic shell mounds are prominent testaments of the prehistoric coastal adaptations along the Atlantic shores of Europe. In the Iberian Peninsula, postglacial hunter-gatherers largely turned to coastal regions and lived successfully with a broad-spectrum economy fostered by Early Holocene environmental changes. While mollusk shells are the most striking component of their foraging activities, an array of other marine resources were available, including seaweeds. In this paper, microstratigraphic investigations on Mesolithic shell mounds yielding novel evidence of seaweeds are presented. The microscopic remains of seaweeds were optically identified and associated with specific microstratigraphic layers highly rich in organic matter, burned within combustion features, and in disposal deposits. These observations suggest the processing of seaweeds as

other dietary components. To further investigate the significance of these finds, lipid biomarker techniques were applied to identify the n-alkanes and fatty acids of marine origin in the sediments from the same contexts. In parallel, an experimental program on controlled burning of current seaweed species was also carried out to tackle the lipidic burning signal in the archaeological samples. This paper discusses the significance of these invisible coastal resources as paleoenvironmental proxy, dietary component, and indirect evidence for foraging dynamics and specific fishing or harvesting techniques.

The “Cracking the Code” Project: Markers of Culture and Networks in Early Iron Age Stamna, Greece

In Stamna, Greece, ceramic art is the focal point of investigation. This research reveals questions about the symbolism on the decorated surfaces of 709 Protogeometric funerary vessels discovered in 500 graves excavated in the 1990s. Our objective is to show how different theoretical perspectives on ceramic interpretation can be explored through both qualitative and quantitative analyses, employing modern digital methods. The distribution of decorative motifs across the Aegean and the Eastern Mediterranean are mapped with GIS. Correlation and density calculations of the motifs focus on their related positions and statistical significance. A network analysis attempts to reconstruct travel routes and social connections, shedding light on both overland and overseas movements. However, successful digital applications require well-organized databases, not available when studying old excavations. In this paper, we present the challenging steps in digitizing analogue datasets. Interesting gaps are revealed in the transition from descriptive excavation diaries to fully quantifiable records. By assigning new temporal and spatial categories of our datasets we establish connections, and we test intra- and intersite similarities. Then, through GIS, we attempt to rewrite the narrative of the people who produced this material culture.

[307]

Research Fatigue in South Greenland

Western views (mindsets), practices, and methodologies have dominated all scientific enquiries, including archaeology, which is inherently colonizing because they assume that Western knowledge is superior to Indigenous knowledge (Smith 1999). Such approaches have led “scientists” to merely take knowledge from local communities without truly including or understanding them. This approach has caused what is now known as “Research Fatigue” (Way 2013). In Qaqortoq, Greenland, people are beginning to begrudge cooperating with the “scientific” outsiders who take local knowledge and never give anything back to the community. We need a shift. Adopting Indigenous and decolonizing methodologies does not only ensure inclusivity; it enriches research outcomes, providing deeper insights and holistic understandings rooted in local traditions and wisdom (O’Connor 2016). Researchers should work hand in hand with local communities, respecting their culture, language, and needs. In Kujataa (UNESCO World Heritage Site), we aim to guide researchers into involving local perspectives, crafting their methods to fit unique local contexts. By doing so, we can ensure research benefits for communities under focus and strengthen trust. In presenting this paper, we aim to share a blueprint for a more inclusive, enriched, and respectful way of conducting archaeological research.

Simpson, Diana (University of Nevada, Las Vegas)**[189]***Violence or Funerary Ritual? Performances of Life and Death in the Middle and Late Archaic Period of North Alabama*

This study takes a holistic biocultural approach to reconceptualize the forms and patterns of violence taking place at two neighboring Archaic period shell mound sites on the Tennessee River in north Alabama, Mulberry Creek (ICT27) and Little Bear Creek (ICT8). Bioarchaeological documentation was supplemented by archival records in an attempt to reconstruct identity, mortuary treatment, and site use over time. This allowed for a nuanced consideration of individual experience and community norms. Ultimately it is argued that patterns of trauma and mortuary practice in the Middle and Late Archaic periods indicate variable identities for victims and perpetrators of violence, as well as specialized rituals surrounding postmortem alteration and burial of such individuals within these communities. This indicates that inflicted injury likely had diverse intentions and perceived meanings in the past, and that certain forms of violence taking place were not deviant or maladaptive. Rather, it reinforces the argument that certain forms of ritualized violence likely served to foster community identity, group cohesion, and even lend stability during times of environmental and cultural change within these ancestral Native American communities.

Sinclair, Anthony (University of Liverpool, UK)**[63]***Moderator***Sinclair, Anthony (University of Liverpool, UK)****[173]***The Citation Process in Archaeology*

Citation counts are a significant source of data for the evaluation of research by institutional managers and research grant providers when looking at projects and individual scholars. Raw citation counts, however, are inappropriate for this purpose except when seen in the context of comparative publications. This is usually accomplished by the normalization of citation counts within a discipline or subject area—as recognized by the major bibliometric databases. This process of normalization is problematic for archaeology since these same databases recognize just two types of archaeology in either the arts and humanities or the sciences, while specialists writing in archaeological publications recognize as many as 50 different types of archaeological research. This poster will explore the nature and variability of referencing practices within archaeological publications since 1970 that are the source of citation data. Specifically, it will explore variation in the patterns of references made by the various subfields examining the spread of references made to other research areas, the referencing of publications of different ages, and differences in citations received between men and women and scholars by seniority. It will present a more detailed discussion concerning the limitations of citation counts in the evaluation of archaeology.

Goin' on Forever: A Retrospective on Karen Adams and Relationships with Maize

For over three decades Dr. Karen R. Adams has been at the forefront of research on the origins and long-term evolution of maize (*Zea mays* subsp. *mays*) in the US Southwest and northwestern Mexico. Dr. Adams has approached untangling the complex and oft convoluted histories of maize in a collaborative and multidisciplinary fashion. Among her immense research contributions are collaborative, controlled grow-outs of native maize varieties with agronomists, soil scientists and Indigenous farmers, detailed analyses and experimental studies examining modern and ancient maize morphology, and the major environmental and cultural influences on the attributes of maize most commonly preserved in the archaeological record, studies of nutritional content of Indigenous maize varieties, and the documentation of thousands of archaeological maize fragments spanning over three millennia prior to Spanish contact. We explore the voluminous contributions Dr. Adams has made to our understanding of ancient maize in the greater Southwest/Northwest over the course of her career and chart a path forward for studies of ancient maize inspired by her work.

How to Carve Ivory and Drill Holes in Mammoth Ivory Beads

Researchers have often called the Swabian Aurignacian the Ivory Age, and in fact, this term is entirely fitting due to the great number and diversity of ivory artifacts. These artifacts include a wide variety of both tools and symbolic artifacts including beads, figurines and flutes. Here we address which stone tools were used to make ivory artifacts. Based on experimental research and comparisons with archaeological material, we discuss techniques used for carving, marking and drilling. We also examine the prospects of identifying specific signatures of individual ivory craftspeople. While we employ a range of macroscopic techniques, our focus lies on how high-resolution microscopic, techno-functional studies can contribute to these questions.

Sink, Taylor**[265]***Establishing Lithic Site Profiles for Joshua Tree National Park*

Despite nearly a century of archaeological investigations in Joshua Tree National Park, a history of arbitrary and inconsistent nomenclature for lithic materials has precluded any sort of landscape-level assemblage comparisons. To address this, I have assembled a dense catalogue of all visually-distinct lithic raw materials and their relative frequencies at a variety of sites across the northwestern portion of the park. I propose that this reference will enable the systematic recordation of lithic assemblages in the future and eventually allow for the evaluation of these assemblages as part of a cultural continuum, rather than as isolated sites. Even the preliminary findings of my fieldwork are already highlighting sites with anomalous raw materials or ratios of materials, suggesting that these methods may aid park management in identifying sites with greater data potential or elevated management sensitivities

Tracking Kelp-like Marine Seaweed Fuel in the Archaeological Record of Atacama Desert Coast through Raman Spectroscopy: Insight from the Analysis of Macro- and Microremains of Charred Particles

The use of seaweed as fuel has been mentioned in ethnographic sources from different world regions. Still, the archaeological record of seaweed burning is limited to contexts where preservation is exceptional, and the macroscopic discrimination of charred remains is possible. In the Atacama Desert coast (northern Chile), the unusual preservation conditions of organic remains provide direct evidence of charred remains of kelp-type seaweed in at least 10 archaeological contexts. Based on this high-quality record, we developed a methodological tool using Raman spectroscopy, which is particularly relevant in contexts with poor preservation of charred particles. Combined with a machine-learning approach, this tool can robustly discriminate between seaweed and terrestrial plant chars in the archaeological record. The method is effective for macroremains and potentially for chars observed in micromorphological thin sections. In this presentation, we discuss the application of this new methodology to charred macroremains and those observed in micromorphology thin sections. These charred particles were sampled from several Atacama Desert Coast shell midden sites from the Early to the Late Holocene. Bringing together this evidence, we further discuss the long-term use of seaweed fuel by Atacama Desert Coast communities.

Connected Then, Connected Now: The Archaeology of One Plantation within New Orleans's Plantation Country
Just upriver from New Orleans, Evergreen was just one of the several hundred plantations that flanked both sides of the lower Mississippi River. We have begun archaeological investigations into the lives of the enslaved at Evergreen, but it has become increasingly clear that this work extends beyond this plantation and the Antebellum. In this presentation, I lay out several theoretical considerations that may help archaeological approaches to plantation contexts become necessarily multidimensional. In order to understand life on plantations such as Evergreen, archaeologists must take a broader regional approach that incorporates other plantations, other free and enslaved Black communities, and what is happening in New Orleans. A multi-temporal approach is also critical as there is no clear-cut end to many of the phenomena occurring during enslavement as these legacies persist to the present day; thus, we as archaeologists are responsible for understanding how our actions play into these dynamics.

Pilgrimage Centers as Persistent Places: Spiritual Magnetism, Affects, and Atmospheres

Pilgrimage centers and shrines are persistent places due in large part to spiritual magnetism, defined as the power of a place of pilgrimage to attract devotees. Most scholars, following James Prestons's original treatment of the term, believe spiritual magnetism comes from and is conferred by humans based on cultural, social, or historical factors or events that are associated with certain places. However, I contend that spiritual magnetism is better viewed as the unique and lasting affective qualities or atmospheres that emerge at a place due to the intermingling of various phenomena, human and otherwise. In this paper, I examine how the intersection of natural features, bodies, objects, substances, memories, and emotions at two famous Christian pilgrimage centers—*Lourdes* and *Santiago de Compostela*—generates meaning, power, and efficacy and ultimately is what draws people to these places. Moreover, I suggest that because affective qualities and atmospheres are contextual and ever emergent, these places will remain potent and continue to draw visitors for years to come.

Ancient Landscapes of South Texas, an Educational and Engagement Initiative for the Earth and Social Sciences

In July 2019, the award-winning Community Historical Archaeology Project with Schools [CHAPS] Program at the University of Texas Rio Grande Valley embarked on a bold initiative demonstrating how the purposeful integration of locally focused earth and social sciences could radically alter K–12 education and engage the broader community in their historical “landscape.” COVID slowed the process but with funding from the

Roberts, Summerlee, and Houston Foundations the CHAPS Program created a unique far-reaching program for educational and community engagement which integrates the earth and social sciences. They include K–13 lesson plans developed by Native American, natural, and social science educators aligned with Texas Essential Knowledge and Skills educational standards. To support teachers in the classroom are educational teaching trunks, an augmented reality enhanced projectile point poster, a popular book, and a 45-minute documentary film. A bilingual tour map, bilingual web page, and bilingual traveling exhibit supplements the classroom experience and are platforms for broader community engagement. The Ancient Landscapes of South Texas initiative template is expandable and has the promise to make archaeology's position within STEAM (Science, Technology, Engineering, Arts, Math) education more accessible and less aspirational.

A Simpler Time: Archaeological Excavations and Assessment at Juukan Gorge 2008–2014

This paper discusses the archaeological excavations at Juukan Gorge in 2008 and then in 2014. We present a Late Pleistocene and Holocene chronology for the Gorge (see Slack et al. 2009), indicating that Aboriginal people first occupied the interior of the Hamersley Plateau in Western Australia over 46,000 years ago. Human settlement in the region continued throughout Marine Isotope Stage 3 (MIS3) and Stage 2 (MIS2), including the height of the Last Glacial Maximum (LGM) ca. 23,000–19,000 years ago. The archaeology of the Juukan 2 site is presented in detail, a record of thousands of stone artifacts, bone implements, organic material, and sacred items unrivaled by any other Australian arid zone site. The results show unequivocally how the Juukan Gorge sites were of international significance and should never have been disturbed.

The Dry: A Case Study of Collaboration between Archaeologists and One Descendant Community

The Dry, an early twentieth-century Black homesteading community, offers a long-lasting example of collaborative public archaeology. Thanks to generous grant funding, we practiced inclusive teaming with the descendant population, from project conception through every stage of our work, even beyond completion of the project. The extent and depth of what we learned at The Dry was only possible through direct partnership with the descendant community. The project was featured in multiple newspaper and radio stories while the work was ongoing, but even after the project was finished, information about The Dry continued to garner public interest, leading to a comprehensive story and interview on Colorado Public Radio, and finally culminating 10 years later in a beautiful and poignant photo exhibition that opened in Colorado's state history museum in 2023 and remains on display today.

Dynamic Heritage as a Path to Collaborative Knowledge Production in Tahcabo, Yucatán, Mexico

The focus of archaeological work has shifted in recent decades to collaborative frameworks that allow for sharing of knowledge production among local and descendant communities. Drawing on the work of Laurajane Smith, we argue that recognizing heritage as a dynamic social process rather than exclusively an artifact or archaeological site is an important element of shared knowledge production or democratizing heritage. The perspective of heritage as a process moves beyond conventional understandings of archaeological sites as static

remnants of past activities and instead highlights how sites hold diverse meanings in the present. Drawing on the use of oral histories to investigate a church in Tahcabo, Yucatán, Mexico, as a case study, this paper demonstrates how previous approaches to colonial architecture, which interpret colonial buildings as temporally inert remnants of colonial powers, contradict local understandings of these structures.

The Forest Foods of Ancient Arenal, Costa Rica

Paleoethnobotanical investigations at two different domestic structures in Arenal, Costa Rica, reveal the plant resources utilized by past peoples living in this volcanically active setting from 1500 BCE to 600 CE. Over 100 different genera of trees have been recovered and identified between the two sites, over half of which produce edible fruits, leaves, or vegetative material. These results demonstrate that the people of ancient Arenal were knowledgeable arboriculturalists who did not rely heavily on agriculture for their subsistence practices and would have been able to collect from a variety of trees for their subsistence needs. While cacao is a prominent tree within the wood charcoal assemblage at both sites, other notable fruit trees include achioté, avocado, cashew, cherry/plum, fig, guava, hogplum/jocote, mamey, nance, palms, ramon, sapodilla, and soursop/guanabana. Trees would have been able to withstand minor volcanic eruptions, whereas low-lying vegetation such as milpa agricultural fields would not have survived such conditions. The macrobotanical results suggest that the ancient inhabitants employed mixed strategies for subsistence and may have preferred food resources that would have remained accessible during times of ecological stress.

Life and Death by the Lake in Pomerania: Introducing the Late Medieval Cemetery at Żelewo Site 1-3

The late medieval cemetery in Żelewo is in northwestern Poland, near Miedwie Lake, on the moraine hill named Catherina's Hill. Excavations began in 2019 and continued in 2023 as a salvage archaeology project. The site is part of the Kołbacz Monastery's estate—founded in 1173—the oldest Cistercian monastery in Pomerania. The cemetery is related to the as-yet undiscovered village of Jaśnica, known only from fourteenth-century writings. Cistercians were known for efficient management of cultural and environmental landscapes. Therefore, this project aims to (1) help rebuild the lost history of the region while mitigating site damage, (2) trace medieval cultural and environmental changes, and (3) investigate the Cistercian's role. Graves excavated during 2023 and 2019 included at least 28 adult and 16 nonadult individuals, from prenatal/infant to older adult. Most burials were oriented west–east, consistent with Christian practices. Recovered grave goods included one bronze belt buckle. Individuals evinced a range of pathologies and trauma, including unique patterns of dental caries and antemortem tooth loss. Traces of previous occupations included flint tools from the Late Paleolithic, Middle to Late Mesolithic, and Late Neolithic, and Roman Iron Age graves and metal artifacts. These findings illuminate potential lifeways in the region.

Ancient Lifeways but Not Archaic Approaches: Theoretical and Methodological Contributions from Researching the Earliest Record of the American Southeast

We review contributions of archaeologists studying the Pleistocene and Early Holocene records in the American Southeast. Researchers expand on a variety of theoretical approaches, including the evolutionary theories of human behavioral ecology and cultural transmission, technological organization, and gender archaeology. While still rooted in processual archaeology, great efforts have been made to build and test relational analogies, and major contributions of this work include experimental approaches to technology and the gathering and modeling of paleoenvironmental data. This work has implications for understanding climate-induced site destruction and resilience and social implications for connecting with and respecting ancestral histories of indigenous communities.

Defensibility, Cooperation, and Centralization: A Comparative Analysis of the Interrelationship between Warfare and Sociopolitical Organization in Late Intermediate Period Peru

This research advances the current theoretical agendas of warfare scholars, overcoming the limitations of earlier social evolutionary theories and examining the interrelationship between warfare and sociopolitical organization in the Huamanga Province of Peru during the Late Intermediate period (LIP; AD 1000–1450). Only through the analysis of this interrelationship can scholars begin to understand warring societies across time and space. The LIP is an ideal period to study this relationship, as it has often been characterized as a time of violent conflict and social transformation. More specifically, this paper presents the final results of archaeological surveys carried out at 14 sites in the Huamanga Province. These surveys included extensive mapping of all standing architecture, surface artifact analyses, and GIS-based spatial and visibility studies. First, focusing on the 14 sites, this paper evaluates local (site-level) relationships of community cooperation and power and associated practices of defense. Then, incorporating all known LIP sites in the region, it considers how sociopolitical interactions between LIP settlements (regional-level relationships) relate to defensibility practices.

Unearthing Difficult Histories: The Delicate Balance of Public, Community, and Campus Archaeology in West Philadelphia's Black Bottom

This paper discusses the conception, implementation, and ongoing results of Heritage West, an archaeology project co-developed by academic archaeologists at the University of Pennsylvania and community stakeholders. Heritage West delves into the intertwined narratives of migration and urban renewal in the Black Bottom—a historically Black neighborhood razed in the 1960s by the Philadelphia Redevelopment Authority to facilitate the expansion of UPenn and Drexel. This project is simultaneously an attempt to mobilize community archaeology to assist former Black Bottom residents and their descendants' objectives of preserving their history, a public initiative to highlight the role of archaeology for understanding the recent past in an urban context, and a campus project entailing an undergraduate field school during the fall 2023

semester. Our discussion explores the challenges and intricacies of such multitiered engagement, showcasing how a synergy of community interaction, oral history, and urban archaeology can illuminate the everyday lived experiences of Black Bottom residents between 1850 and 1960.

Diachronic Domestic Spaces at Torre d'en Galmés: Results from the 2022–2023 Seasons of the Menorca Archaeological Project

The Menorca Archaeological Project (MAP) investigates the site of Torre d'en Galmés on the Balearic Island of Menorca (Spain). While the site is primarily known for its prehistoric Iron Age remains, it was also home to a small Medieval Islamic farming community, primarily in the twelfth and thirteenth centuries AD. Built atop and between the Iron Age structures, MAP is dedicated to the excavation of the entirety of Torre d'en Galmés' history, taking an explicitly multi-temporal approach to the understanding of both the Iron Age and medieval habitations of the site. Since 2021, MAP has excavated multiple Islamic house compounds that have provided evidence of a population that had to quickly establish themselves in an abandoned prehistoric site after being removed from other parts of Spain as part of the Christian conquest. The excavations have also shown that these Islamic structures preserve the Iron Age remains underneath them, illustrating the benefits of taking a multi-temporal approach. This paper will discuss the results of the 2022–2023 seasons specifically focusing on our understandings of the Islamic village and the excellent preservation of the Iron Age remains beneath it.

Canid Diets and Social Roles in Ancestral Maya Communities in the Eastern Maya Lowlands

For millennia dogs (*Canis familiaris*) have fulfilled various biological, functional, and companionship roles, yet their use and significance in Mesoamerica varied substantially through time. Previous studies of dogs in the Maya lowlands argued that human-canid relationships involved high levels of dog consumption, though zooarchaeology and epigraphic sources also suggest important ritual roles beyond food. This study explores the social role of dogs in the Belize River Valley region of western Belize from the Preclassic through Terminal Classic period (~1000 BC–AD 900/1000) through dietary reconstruction based on stable isotope analyses of dog bone collagen and apatite ($\delta^{13}\text{C}_{\text{co}}$, $\delta^{15}\text{N}_{\text{co}}$, $\delta^{13}\text{C}_{\text{ap}}$). Results indicate a spectrum of diets reflecting differences in human-canid relationships. Some dogs consumed lower proportions of C_4 foods like maize, suggesting they likely spent time away from human settlements and possibly served as forest hunting companions. Dog remains from Classic period (AD 300–900/1000) ceremonial deposits typically have a stronger C_4 signal compared to those from domestic or monumental settings, perhaps suggesting purposeful feeding of animals included in ritual activity. Classic period management may be linked with the increasing importance of dogs as symbolic ritual agents instead of serving as food.

Beyond the Birds of Paradise: A Geoarchaeological Investigation of Large Ancient Maya Linear Wetland Features

Growing scholarship since the 1980s has focused on ancient Maya–wetland interactions after raised field agriculture was revealed in northern Belize. From this, mounting evidence indicates extensive reliance on seasonal and perennial wetlands for ancient Maya farming, aquaculture, and water retention across the region.

These systems would have served as major sources for food production and oases against the seasonal wet/dry hydroclimate and episodic long-term drying of the neotropics. The Birds of Paradise (BOP) wetland fields of NW Belize are one such system with use starting in the Late Preclassic, ~2000 BP, and lasting through the Postclassic (after 1000 BP). Lidar imagery from 2016 and 2022 revealed a group of linear wetland features downstream of BOP that span more than 730 m and may have been fed by runoff from nearby wetland canals. Our goals here are to test multiple hypotheses for these features by dating with AMS, identifying connections to waterways through hydrological modeling, and detecting evidence of construction and use through soil chemistry, isotope geochemistry, particle size analysis, and aDNA. Our early results show evidence for complex constructions throughout the region connected to a network of transportation corridors and the wetland fields, canals, and broader watershed.

Establishing Institutional Partnerships that Reunite Communities through Joint Repatriation

The Florida Museum of Natural History at the University of Florida, Florida State University, and the Florida Bureau of Archaeological Research have a shared institutional history. This long-standing interconnection has resulted in intertwined holdings, which create numerous split-and-share issues for NAGPRA compliance. To resolve these issues and better facilitate full community returns, we have committed to full partnership across our shared repatriation efforts. This partnership entails the inter-agency sharing of archived documentation and related inventories, collective consultation with Tribal nations, and joint submissions to National NAGPRA. We are together in our commitment to shared consultation decisions for disposition and repatriation and our willingness to coordinate the physical transfer of ancestors and their belongings in accordance with recipient nations wishes. We cooperatively support other institutions that may also retain portions of these collections and, through open communication, ensure that we do not inadvertently create new split situations when accessioning. This collaborative approach to repatriation aims to comprehensively, respectfully, and expediently unite and return ancestral communities.

Teaching Archaeology to Change the Status Quo

When we were students there were few Aboriginal archaeologists—and no Aboriginal faculty employed to teach archaeology at a university. When we became university teachers we worked to change this situation. This presentation outlines our teaching strategies and the efforts undertaken by our peers who also sought to change the status quo. It details our challenges, successes, and failures. Over time, it has become clear the vision of an Aboriginal archaeology peopled by Aboriginal archaeologists has to be enacted across generations of teachers. While there are now more Aboriginal archaeologists, there are still too few. We finish this presentation with our key learnings: cultural safety, culturally appropriate support, and the importance of community.

Smith, Erin (Eastern Washington University)**[36]***Chair***Smith, Erin (Eastern Washington University) and Colin Grier (Washington State University)****[36]***The Conscious Midden: An Indigenous Ontological Approach to Mound Building, Environmental Sustainability, and Other-Than-Human Selfhood in the Pacific Northwest Coast Salish Sea*

The Salish Sea is a region speckled with coastal shell mounds. Often these places are the remnants of winter villages occupied over generations. Mounds were built with intention and foresight to leach nutrients into the surrounding ecosystem, sustaining the environment for generations. Millennia ago, Indigenous peoples understood through transgenerational knowledge how these features contribute to the renewal of beings—or, what contemporary Western science colloquially calls Earth's biogeochemical cycles. Some shell middens were understood as conscious and composed of beings that agreed to being caught/harvested. In taking an ontological approach to mounds, we utilize ethnographic and archaeological data to explore human-environment relationships and the role of Indigenous Ecological Knowledge. Grounded in perspectivism and an ecology of selves, this approach allows for a deeper understanding of selfhood among other-than-human beings, the relational association of beings in mounds, and the larger ethos of environmental sustainability. This paper is also a critical call to protect conscious middens from accelerated erosion due to climate change and the onset of harsher winter storms. Preserving conscious middens thus extends beyond the realm of archaeological preservation; rather, it is tantamount to conserving ecosystems and biodiversity, and reflects a renewed relationship with the diverse beings of the Salish Sea.

Smith, Geoffrey (University of Nevada, Reno)**[219]***Chair***Smith, Geoffrey (University of Nevada, Reno), Richard Rosencrance (University of Nevada, Reno) and Katelyn McDonough (University of Oregon)****[219]***Revisiting the Western Stemmed Tradition Component of Last Supper Cave, Nevada*

Last Supper Cave (LSC) is located in the rugged High Rock Country of northwestern Nevada. Thomas Layton excavated the cave in 1973–1974 under the auspices of the Nevada State Museum. He recovered a diverse assemblage of lithic, fiber, and wooden objects including a number of Western Stemmed Tradition (WST) points. Radiocarbon dates and time-sensitive projectile points suggested that people used the cave for much of the Holocene. Despite the assemblage's potential to address a range of questions, it was never fully analyzed. Beginning in 2008, researchers from the University of Nevada, Reno, and Nevada State Museum began reanalyzing the collection—work that continues today. Here, we present new radiocarbon dates from cultural features that provide a better understanding of when people visited the site, with a particular focus on the late Pleistocene and early Holocene. Our work draws on Bob's many contributions to our field in the areas of radiocarbon dating, lithic technology, and hunter-gatherer archaeology.

A Multicomponent Archaeological Site at Spring Lake, San Marcos, Texas

In the 1970s, researchers recovered fluted points that appeared diagnostic of Clovis technology in Spring Lake, the spring-fed headwaters of the San Marcos River located along the Balcones Escarpment in Central Texas. Although recovered in mixed stratigraphic contexts, this evidence suggests that Ancestral Peoples may have visited the site for over 13,000 years. Since then, several research teams have confirmed that the site provides evidence of consistent human use throughout the early Holocene, Archaic, and Historic periods and remains significant in the traditions of contemporary Indigenous Cultures. In this poster, we summarize results of previous archaeological and geoarchaeological investigations and the archaeological problems that continue to drive research at this important cultural resource and on the site's artifact collections. Discussion will highlight how ongoing investigations by our team of Texas State University researchers and students are addressing problems concerning access to and the integrity of stratified cultural deposits, diachronic and synchronic variation in prehistoric peoples' activities around the lake, and our understanding of Ancestral lifeways practiced in Central Texas.

Decolonizing Mohenjo Daro: A Participatory Approach to Archaeology in Pakistan

Expanding the geographic coverage of the Collaborative and Community symposium to the Global South, this presentation covers the 25 years of community-based and participatory work done in South Asia, with a particular emphasis on the last five in Pakistan at the World Heritage Site of Mohenjo-Daro. Our archaeological collaboration is run under the Laboratory of Integrated Archaeological Visualization and Heritage (LIAVH.org) at the Pratt Institute. LIAVH makes connections between technology, archaeological data management, and heritage practice. For a century, Mohenjo-Daro has been excavated, photographed, drawn, mapped, and written about, and yet, there is still so much we cannot quite figure out about the ancient city. In this presentation, we will highlight the 2023–2024 winter field season focused on a program of photogrammetry using both drones and hand-held cameras. A key component of this research is pedagogic and participatory, specifically focused on building capacity through teaching workshops and including local and regional specialists and students of archaeology. Rather than pursuing archaeology as an extractive exercise, this research engenders generative modes of knowledge production and sharing.

Continued Work on the Ray Robinson Collection: Preliminary Investigations into the Clont's Farm Site, John's Farm Site, and Other Nearby Sites in the Safford Basin of Southeastern Arizona

As investigations continue into the Ray Robinson Collection by its dedicated team of volunteer researchers, we return our attention to the poorly documented Safford Basin of southeastern Arizona. In addition to the preliminary data previously presented based on Ray's investigations on the Cork and Elmer's Farm sites, we

have completed our preliminary research on the Clont's Farm site and the John's Farm site (AZ CC:2:2 ASM) near the eastern end of the Basin and the nearby sites of Melvin's Farm and Cottonwood Canyon in the western portion of the Basin. Clont's Farm site is a room block with 30–50 structures on private land. The settlement dates to the late eleventh and early twelfth centuries and is one of very few sites investigated from this period. The John's Farm site dates primarily to the later Salado period during the fourteenth century and comprises area near the residence and in the adjoining fields owned at the time by the Paul John family. This paper will share the results of documentary research conducted using Robinson's notes and will present a detailed inventory of the artifact assemblages from each as well as ceramic typological and obsidian sourcing analyses.

Applied Systems Engineering Can Help See into Non-contiguous Debris Zones with New Eyes

Finding the lost ships of Tristan de Luna's fleet is a high-priority historical challenge. Florida archaeologists discovered three of the lost ships in Pensacola Bay. Applied systems engineering can help see into non-contiguous debris zones with new eyes. A 1559 hurricane destroyed ships associated with Pensacola's first settlement. Three ships were found in bay (1992–2016) near downtown Pensacola. The others were reported to have run aground, wrecked on sandbar, or landed intact ashore. Pensacola Bay has 30 miles of shoreline and hosted lumber and brick industries. Applied systems engineering can reconcile physics-based assumptions, topography, and mass analytics. Conservation of mass predicates that ballast, any high-density cargo, and some wood will not disappear. Topographical clues from historical record describe several discernible land or water features. Wood debris is relatable to time. Physics-based clues in littoral zone, consistent with record, can illuminate areas for further study. Noncontiguous debris zones are contaminated by lumber and brick industries. Carbon 14 is radioactive isotope used to determine time since tree was alive. Mass analytics complement wood genus identification using ¹⁴C radiocarbon dating. Wood dates older than 460 years before present may correlate to shipwreck. Results forthcoming of analyses of driftwood collected from possible shipwreck area.

Use of X-Ray Fluorescence for Elemental Analysis and Resolution of Commingled Remains with the Arch Street Project
During early excavations of the Arch Street Project collection, remains were commingled. Reassembling commingled remains is a long, difficult, and technically advanced process that can take years if not decades to

complete. This study uses XRF on eight individuals from the Arch Street Project to assess the validity of using elemental analysis to reassociate commingled remains and identify what can be learned from a nondestructive analysis technique such as XRF rather than a traditional destructive method. The analysis identified 15 elements within the eight individuals. The XRF results identify a single unique individual and trends within certain elements. One individual, G-41, contained mercury, along with two other toxic heavy metals, arsenic, and lead. Strontium showed very consistent levels within an individual but distinct, although slight variation between individuals. Lead showed a high degree of variation within and among individuals but also a high degree of clustering. Overall, XRF is a useful method of elemental analysis but is not as accurate as destructive methods. While trends and individual variation were present during analysis, XRF did not have sufficient variation among individuals to resolve the mock commingling.

Isotopic and Paleogenomic Evidence of Maya Persistence at Late Postclassic and Early Colonial Chactemal (Santa Rita Corozal), Belize

Santa Rita Corozal, hereafter known as Chactemal, is a Maya site located in what is now northern Belize on the coast of Chetumal Bay. Chactemal was home to some of the earliest known Maya peoples in northern Belize during the Middle Preclassic (~800–300 BCE), was continuously occupied throughout all subsequent phases of Maya chronology, grew to become an influential Postclassic Maya capital, and was the site of the earliest Spanish colonization in Belize (1531 CE). Ethnohistoric records indicate that Maya people fled Chactemal before Spanish invasion and launched guerilla-style attacks that prevented permanent Spanish settlement in the region. However, no prior archaeological evidence exists that the Maya people returned to Chactemal during the sixteenth century. In this study, we generated radiocarbon, stable isotopic, and paleogenomic data from 17 Maya Ancestors at Late Postclassic Chactemal to refine the settlement chronology, migratory history, and biological relationships of the final interments at the site. We present evidence that the Maya people returned to Chactemal after Spanish occupation and that their return was shaped by memories of their ceremonial and kinship ties to the ancient city. This study was approved by the Belizean Institute of Archaeology and conducted in partnership with Maya communities in Corozal.

Surveillance at Ancient Hillforts of the Titicaca Basin, Southern Peru: Insights into Social Dynamics and Defensive Strategies

In this paper we model visibility and movement in and around ancient hillforts or *pukaras* across the highlands of southern Peru. During the Late Intermediate period (1000–1450 CE), communities moved to hilltops where houses were often tightly packed together within the confines of large defensive walls. The coalescence of large populations at these sites, sometimes reaching over 1,000 people, would have been a novel experience where new social roles and relations would have had to be quickly forged among unfamiliar faces and tightly confined spaces. While studies have investigated *pukaras*' views of the outside landscape including other *pukaras*, monitoring one's neighbor within these large sites may also have been important. Architecture is often still intact at these sites, revealing original pathways, plazas, houses, tombs, and storage structures. We rely on recent site mapping at several *pukaras* to better understand the use, design, and movement through these built spaces with an emphasis on private versus public spaces. While previous research provides little evidence of centralization or political control at *pukaras*, our analysis reveals the construction and design of spaces which could result in highly visible and intimate living arrangements, contributing to a shared identity, cohesive communities, and stronger defensive coalitions.

Archaeobotany Foodscapes

There is more than one way to gain insight about past Native American use of plants. The conventional approach is to collect archaeobotanical samples during archaeological excavations. Another perspective is to inventory the environments surrounding sites and communities to understand the foodscape that might have been accessible to people. Karen Adams was one of the first Southwest archaeobotanists to apply the landscape-scale resource approach to examine prehistoric subsistence strategies. She expanded this ecological research through contract projects and inspired the next generation of archaeologists and archaeobotanists. In this presentation, Karen's field school archaeobotany module from the Rock Art Ranch is summarized and a foodscape archaeobotany example from Ajo, Arizona is presented.

Exploring Biological Affiliations and Cultural Perspectives through Dental Morphology at Cerro Juan Díaz, Panama: A Preliminary Study of the Early Burials (30–650 CE)

Burial space reuse and prolonged interaction with the dead were common practices in the Isthmo-Colombian Area, dating back to at least the Early Ceramic period. However, it is unknown whether the individuals interred in disturbed, multiple burial contexts shared biological or social ties within their communities, or whether they pertained to multiple communities that transported their dead to a shared cemetery space. We explore possible intra-cemetery biological affiliations through a biological distance analysis at the site of Cerro Juan Díaz in Panama, estimated via dental metric and non-metric traits present in individuals recovered from multiple burial contexts from the first mortuary horizon. Inter-individual differences compared across burial group, age, and sex showed broad similarities between the three burial contexts. Significant differences in biological distance were found only when the pooled data were compared by age (adults aged 15+ years to nonadults). Nonadults also showed a significantly higher intragroup phenotypic heterogeneity when compared to adults. Our results are largely consistent with previous notions of Cerro Juan Díaz's function as a community burial ground. Infants and children may have been brought to the site for burial from nearby villages, perhaps following specific mortuary traditions governed by age group.

Hawaiian Archaeology and Disasters: (Re)unification with the Land to Build a Resilient Future

Hawai'i is a dynamic landscape with a unique archaeological record. The archipelago's relatively short physical history has been subject to various disasters, including sea-level rise, tsunami, wildfire, and drought. Predictions indicate that anthropogenic drivers of climate change will increase the frequency and severity of disasters in the Pacific. In the wake of Maui's devastating wildfires, Native Hawaiians are again forced to confront their identity and the destruction of their identity. The natural resources and beauty of the land, once enabling precontact Hawaiians to flourish, have been subjected to colonialism and contemporary tourism. This exploitation and misuse of the islands' resources has resulted in overall uncooperative relationships with the land, increasing the likelihood of disasters. Throughout Hawai'i's precontact archaeological record, there is evidence of Native Hawaiians throughout the islands. The native Hawaiian worldview embodies the concept of interdependence between people and their land. This research explores archaeologists' crucial role in safeguarding and unveiling the Hawaiian worldview found within the archaeological record and how this worldview can enhance today's human-landscape relationship, promoting cooperation with the land for a more disaster-resilient future.

Death Undone: The Contextual Importance of Human Skeletal Remains in an Analysis of Diachronic Mortuary Practices at Mesambria Necropolis, Bulgaria (ca. 400 BC–AD 1400)

This study addresses the contextual importance of human skeletal remains in identifying diachronic changes and constants in mortuary practices from the Mesambria necropolis, on the banks of the Black Sea in modern Nessebar, Bulgaria. Skeletal remains are the central element of mortuary practices but are often excluded from archaeological interpretation, just as burial context is often disregarded during osteological analysis. By considering both archaeological and osteological assessments, a more comprehensive image of diachronic mortuary practices and corresponding cultural shifts is created. A sample of 538 graves was assessed based on the physical characteristics of interments via photographic, archaeological, osteological, and historical evidence. Notable variation was observed in grave type, degree of preservation of skeletal remains, orientation and positioning of the skeletal elements, and artifact deposits. Utilizing multicomponent interpretation methodology increases the contextual information available for mortuary practices in the Black Sea region through a vast temporal range.

Migration and Mitogenomes: Analysis of West Mexican Populations to Better Understand Their Place in the Larger Mesoamerican Social Landscape

The world has always been connected through the movement of people, exchange of goods, and sharing of cultural traits; thus, evidence of such can be found within the genomes of individuals, as well as the archaeological sites they leave behind. The present research is comprised of multiple lines of inquiry that address questions of gene flow, genetic variation, migration, trade, and interaction among societies in West Mexico and outlying areas to the east and south. Whole mitochondrial DNA genomes (mitogenomes) have been sequenced from individuals in order to address the main research hypotheses from a variety of sites in the region, including Amapa and Peñitas in the Aztlán core zone in Nayarit, and Tizapán el Alto in the Jalisco highlands. Additional investigation into the relationship between individuals at the coastal sites and the contemporaneous highland sites will also be investigated, particularly in relation to how this may then be related to larger regional migration and trade routes.

The Negotiation of Status: New Insights into a Late Classic Household at Las Ruinas de Arenal, Belize

There has been a long history of settlement and household archaeology in the Belize River valley that has added significantly to our understanding of everyday people in the Maya lowlands. This research has allowed us to examine questions related to broader cultural norms and traditions, as well as better understand the distribution of settlement across the varied landscape of this region. In this paper, I present new data from a Late Classic household group at Las Ruinas de Arenal, Belize. This non-elite household was built just southeast of the site's Preclassic ballcourt and E-Group complex. Preliminary data from a combination of horizontal and vertical excavation both on and off the platform suggests that the location of this household, as well as the production activities of its occupants, played a role in the negotiation of a more privileged status within the larger Las Ruinas de Arenal community. Through the invocation of social memory and broader timescales of connection with historic places and peoples, the notion of status can be complicated beyond synchronic sociopolitical or economic relations.

Political Complexity and Gendered Violence in the Andes: A Bayesian Approach

The nature of violence in the premodern past remains an enduring question in anthropological research. In this study, we investigate the potential relationship between sociopolitical organization and the frequency and type of violence experienced by adult males and females in Andean archaeological contexts. For this study we establish four broad categories of sociopolitical organization: foragers, early agriculturalists, 'soft' hegemony, and states. Drawing on a database of over 6,700 individuals from over 115 sources and 130 sites, we then

construct a multinomial logistic regression using Bayesian Hamiltonian Monte Carlo methods to fit our model. Our findings indicate that odds of encountering antemortem or perimortem trauma were low for both sexes, but consistently slightly higher for males than females across all categories. However, there are clear differences in the odds of trauma among the four societal categories. Additionally, societies with soft hegemonic influence show higher odds of trauma and atypically similar odds of perimortem trauma for the sexes, suggesting differences in the nature of violent encounters in these societal categories. Our study complicates the notion that increasing sociopolitical complexity leads to decreasing interpersonal violence and highlights the different ways that males and females in the Andes were likely to experience interpersonal violence.

Beyond the Biface: Revisiting Cobble Tool Use during the Cascade Phase at the Kelly Forks Work Center Site, Idaho
The Cascade Phase, spanning roughly 9000–5000 years BP, is defined by distinctive lithic technology and edge-ground cobbles. Archaeological data suggests mobile foragers temporarily camped in resource-rich areas during this period. Despite its recognition as a unique cultural period, our understanding of Cascade Phase lifeways, particularly resource use and subsistence strategies, remains incomplete. While previous research heavily emphasized hunting-related biface technology, the presence of cobbles with edge-grinding features remains enigmatic. These cobbles have been hypothesized to represent various plant and animal food processing activities, yet few focused studies provide data supporting these hypotheses. This has left a significant gap in the literature regarding the Cascade Phase toolkit and an incomplete picture of site activities and resource utilization. To bridge this knowledge gap, this research employs macroscopic use-wear and plant microfossil analysis of cobble tools from a well-documented, substantial Cascade Phase cobble feature at the Kelly Forks Work Center Site in traditional territory of the Nez Perce (Nimíipuu) Tribe located in the Nez Perce-Clearwater National Forests, Idaho. This research aims to shed light on the unexplored aspects of Cascade Phase lifeways, the role of cobble tools in resource exploitation, and connections to traditional subsistence practices of the Nez Perce (Nimíipuu).

A Geoarchaeological Analysis of the Site Formation Processes at Brown Hole and WR-1.

WR-1 and Brown Hole are two submerged archaeological sites in the West Run of the Aucilla River. This thesis utilizes a geoarchaeological approach to evaluate the depositional sequences of these sites as well as their potential for further archaeological investigation. The sedimentary histories of the sites represent adjacent depositional facies within a single environmental locus. WR-1 and Brown Hole have limited additional archaeological potential, Brown Hole having more than WR-1. However, the sites present evidence of a freshwater source and a point of access to that source that has been proven to have been used by humans in the past.

The Origins of the Capacocho Victims: Results of Stable Isotope Analyses of Individuals Sacrificed at Ampato, Misti, and Pichu Pichu Volcanos

Capacocha was one of the most important rituals performed in the Inca Empire and involved the sacrifice of children and young women. The victims were selected from the provincial elite based on their beauty and health. They were gathered from across the Empire and brought to the capital, Cusco, in order to be sacrificed during important events associated with the life of the royal court, natural disasters (earthquakes, droughts, volcanoes, and epidemics), and cyclical holidays (e.g., summer and winter solstices). This paper presents the results of the analysis of stable isotopes related to the diet (carbon $\delta^{13}\text{C}$ and nitrogen $\delta^{15}\text{N}$ isotope ratios) and mobility (strontium $^{86}\text{Sr}/^{88}\text{Sr}$ and oxygen $\delta^{18}\text{O}$ isotope ratios) of teeth and bones from 13 individuals sacrificed at Ampato, Misti, and Pichu Picchu volcanos. Isotopic analysis of the tooth enamel revealed that the children had mixed origins, while examination of the bone and teeth of the victims from Misti showed that the diet of some of them had changed in the last years prior to their death. This suggests that the children may have been taken from their place of origin as hostages or *acllas* long before they were sacrificed.

[22]

Beasts and Feasts in Late Medieval Ireland: The Case from Mcdermot's Rock

The twelfth-century Anglo-Norman conquest of Ireland triggered a complex swirl of changes that presage dynamics of European colonialism in modern times. One key pattern is the emergence of divides between Anglo-Norman (colonizer) and Gaelic (indigenous) identities. Negotiating differences between “being Anglo-Norman” and “being Gaelic” was vital to implementing and resisting colonial projects in medieval Ireland. Anglo-Norman perspectives on such divides are relatively well known. Gaelic attitudes are not. This paper uses zooarchaeological data from ongoing excavations at McDermot’s Rock—an island retreat in County Roscommon—to compare foodways at a Gaelic high-status site with those from Anglo-Norman castles in eastern Ireland. Colonialist texts tend to denigrate Gaelic foodways as disorderly and bestial. The large and well-preserved faunal assemblage from McDermot’s Rock provides an unparalleled opportunity to discover how animals were used in feasts and other activities to build a Gaelic society.

Beyond Teotihuacan: The Decline of Teotihuacan's Sociopolitical System

Toward the end of the sixth century AD, a great fire destroyed the ceremonial center of Teotihuacan, capital of the largest urban development in Mesoamerica. This event was the culmination of a long process of disintegration of Teotihuacan’s macroregional system, a process that began during the ancient city’s apogee. This presentation will reflect on the stimulus that regions outside the Basin of Mexico received by participating in Teotihuacan’s economic and political system. This situation would have led to the sociopolitical complexity of these regions and eventually their independence from the larger system, with the consequent weakening of the center. The simultaneous apogee of several sites, at the time that the Teotihuacan Valley began to experience unfavorable changes, is evidence of a concatenated phenomenon. A long-term macroregional perspective allows contextualizing the decline of the iconic city, which, despite its collapse, remained the largest settlement in the Basin of Mexico during the years to follow.

[269]

Exploring Thirteenth-Century Settlements on the Hopi Mesas

Recent collaborative fieldwork on Hopi tribal lands is yielding a new archaeological perspective on settlement during this key time period when migration to the Hopi Mesas accelerated. Newly recorded and redocumented sites include citadel-like structures built up the sides of rocky outcrops, defensible sites atop discrete, steep-sided landforms, and plaza-oriented pueblos. The number and scale of these communities indicates that the Hopi Mesas and their peripheries were more heavily settled in the AD 1200s than previously realized. This poster outlines some of these patterns and explores archaeological perspectives and Hopi traditional history of this key time period.

Coastlines, Mountains, Linguistic Diversity, or Subaltern Trade Networks: Hypothesizing Sources of Language Isolates in the Isthmus of Oaxaca

As a linguist and specialist in the languages and cultures of the Isthmus of Tehuantepec and Oaxaca, I have long considered that one of the most intriguing hypotheses Dr. Pohl has presented has been on potential maritime networks which might explain the presence of language isolates (Chontal and Huave) in the Isthmus and the settlement patterns along the Pacific coast of Mesoamerica. The current paper investigates this hypothesis in light of more general hypotheses around the diversification of languages (and subsequent decline in linguistic diversity) and the location of language isolates (Nettle 1999; Urban 2021; Van Gijn et al. 2022) and patterns more specific to the northwest Amazon. In fact, similar to findings by Epps (2020) we find that in the case of the Isthmus of Tehuantepec in particular, linguistic diversity, while a good predictor for the presence of language isolates, fails to predict the actual reasons behind the presence of these two isolates. Similarly, geographic explanations also fail. In general, other factors such as the trade networks proposed by Dr. Pohl with the corresponding sociocultural importance of the subaltern nature of said networks may provide better and deeper complementary explanatory power.

Replicating Plant Processing: Insights into Ancient Diets and Perishable Technologies

Investigating plant processing in the archaeological record is challenging due to the perishable nature of plant materials and their associated technologies, which are rarely preserved. We examine tools used for grinding and pounding, providing insights into the transformation of plant organs before their consumption. To address this, we have developed and tested a multiscale methodology for analyzing wear patterns and related residues on stone surfaces. This method is validated through replicative experiments, tailored on the evidence recovered from Brînzești I, a Moldovan cave site, where 114 putative ground stones were found in the cultural layer III (32–18 cal ka BP). Our methodological approach has been fine-tuned through replicative sequential experiments, following a standardized protocol that includes Plant Selection: Choosing plant species based on Upper Paleolithic Moldovan biome compatibility, as well as ethnographic and archaeological evidence; Tool Selection: Identifying stones resembling archaeological samples via petrographic analysis; and Detailed Documentation: Employing imaging techniques at various magnification levels, from macro to nano scales to document wear formations and the entrapment of use-related residues. The creation of a reference collection has been pivotal in understanding ancient gestures, timing, and resource productivity, enabling us to gain insights into past exploitation methods.

Early Evidence of the “Mississippianization” of Late Woodland Communities from the Upper Tombigbee River Drainage, Mississippi

In the southeastern United States, the genesis of Mississippian societies circa AD 1000 is often referred to as Mississippianization, or the process whereby regions were incorporating general Mississippian traits. This process involved the spread of a broad cultural horizon that influenced many aspects of life, including how people built their homes, ate their meals, buried their dead, and performed acts of worship. While the cause of this phenomenon has been debated over the years, the spread of practices has been suggested to be the result of the introduction of ideas and ways of doing, an influx of migrants, and/or the arrival of traded goods. To date, the spread of Mississippian practices has not been thoroughly examined in the communities of the Upper Tombigbee River drainage in Mississippi and Alabama. To understand the transition in this region, this study aims to investigate the ceramic practices of the preceding Late Woodland (AD 650–1000) period using ceramic compositional analyses, including petrographic and LA-ICP-MS approaches. I use these data to understand ceramic craft production during this period, as well as to analyze any regional craft traditions that hint at the early incorporation of Mississippian practices.

[14]

Experiencing Trade and Exchange: Teaching Archaeological Concepts through Role-Playing Games

When teaching about archaeological concepts on trade and exchange, typically, theoretical models dominate the classroom lecture and discussions. Traditional theoretical discussions limit explanations to biological, social, environmental, or religious reasons. Although lectures and discussions are useful, they limit student understanding of concepts related to trade and exchange. Interactive role-playing games in the classroom offer students a first-hand experience of the various aspects of decision-making and agency within trade and exchange that are not necessarily within the realm of traditional theoretical discussions. For instance, students might engage in trading with another group in retaliation to a third group. The interactive role-playing game allows students to reflect on their decisions while experiencing the emotional and empathetic side of trade and exchange.

Sosa Ruiz, Mónica (Escuela Nacional de Antropología e Historia)**[290]***Chair***Sosa Ruiz, Mónica (Escuela Nacional de Antropología e Historia)****[290]***The Children of the Fire*

Fire is an important part of ceramic production; nevertheless, it is usually taken for granted when studying and analyzing ceramics. Ethnoarchaeology, experimentation, and sensory archaeology allowed us to grasp a better understanding of the relationships entangled between fire-using potter and pottery. An extensive compilation of myths, sayings, and words in *p'urhé* allow us to identify ways of thinking and therefore ways of making. This paper will show the connections found between the information told to Spaniards and compiled through text and that preserved through traditional knowledge and making. These connections strongly relate makers with their making, imprinting on this last one's part of the former one's ways of being.

Sotelo Santos, Laura Elena**[83]***Tiempos de cera y miel: Iconografía, ecología y sacralidad de las abejas nativas en el Códice Madrid*

La evidencia escrita más completa sobre el cultivo de abejas en el mundo maya procede del libro jeroglífico prehispánico denominado Códice Tro-Cortesiano. En los almanaques de las abejas que están en las páginas 89b y 103 a la 112 hay abundante información sobre diversos aspectos de la meliponicultura: las abejas, identificadas como *Melipona beecheii*, colmenas y colmenaras, así como su manejo, desde el traslado de las colmenas silvestres, la "siembra" del jobón y la cosecha; los armadillos como depredadores, los árboles melíferos, las deidades protectoras de las abejas y las ofrendas empleadas. Esta ponencia tiene como objetivo revisar las secciones de abejas del Códice Madrid desde una doble perspectiva: etic como la evidencia escrita más antigua, detallada e integral del manejo de las abejas xunan kab, a través de las categorías conceptuales occidentales contemporáneas (iconografía, taxonomía, zootecnia, ecología) y emic, para acercarnos a los distintos pasajes temáticos del código, como vías de comunicación con el mundo sagrado, identificando los actores (dioses y ¿sacerdotes?) y elementos rituales, principalmente ofrendas. El punto de partida de este trabajo es la analogía etnográfica, y también se recurrirá tanto a fuentes arqueológicas e históricas, pues esta práctica maya parece remontarse más de dos milenios.

Soto, Victoria (Fondecyt 11200857), Consuelo Huidobro (Fondecyt 11200857) and Josefina Macari (Fondecyt 11200857)**[282]***Exploring Obsidian Hafted Scraper Use-Wear Patterns through Experimental Hide-Working in Southern Patagonia*

Ethnographically, three types of hafted scrapers are found in Patagonia: northern Tehuelche, southern Tehuelche, and Selk'nam. However, due to environmental conditions, hafting materials rarely survive in the archaeological record, hindering our understanding of these tools. To address this gap, we conducted experimental research to characterize the use-wear on obsidian scrapers used for hide-working. Our primary goal was to create reference points for hide-working and particularly for hafting traces using obsidian scrapers. We modeled our experiments on ethnographic tools and conducted scraping trials on fresh and dry sea lion and penguin skins, incorporating additives as part of hide-curing, replicating local resources used by marine hunter-gatherer societies in the Strait of Magellan. We also examined two ethnographic Selk'nam-type glass scrapers. Our traceological analysis of experimental obsidian scrapers revealed distinct patterns in the

distribution of use-wear depending on the scraper type, and notable differences between fresh and dry skin experimentation. Even in the case of fresh skin, significant abrasion was observed. These findings provide valuable insights into the functioning of Patagonian scrapers, shedding light on their use in hide-working activities. By comparing our experimental results with use-wear on ethnographic instruments, we contribute to a deeper understanding of Patagonian tool technology.

Network Analysis in the Tairona Chiefdoms: Settlement Patterns and Social Interaction in the El Congo Microbasin, Sierra Nevada de Santa Marta, Colombia

This paper seeks to present the results of network analysis for the case of the chiefdom communities that inhabited the northwestern slope of the Sierra Nevada de Santa Marta from AD 400 to 1600 in the El Congo microbasin. Through the use of statistical algorithms in R language and databases in geographic information systems, this paper seeks to present how network analysis can provide information on settlement patterns at a regional scale and how the spatial distribution of small local and supralocal communities, together with their social interaction networks, allows an evaluation of the strength and direction of relationships between social units in economic and political terms. Using quantitative methods oriented to investigate measures of centrality, this paper also aims to be a case study for archaeological research regarding the emergence of chiefdom communities in the Intermediate Area, by pointing out how network analysis in archaeology and the study of settlement patterns allows the identification of demographic centers that originated complex socioeconomic relationships that determined decision-making in precolumbian chiefdom communities.

Maternal Marginalization and Infant Mortality in Dunedin, New Zealand, 1850–1940

New Zealand was the “poster child” for relatively low infant-mortality rates in the nineteenth and early twentieth centuries compared with other OECD countries; however, little is known about how social disadvantage may have increased the mortality rates for marginalized groups. We investigate the causes of death and age at death of infants (one year of age and younger) of married and unmarried mothers buried in the two main cemeteries of historic Dunedin (Northern and Southern Cemeteries) between 1850 and 1940 using death records. Of 4,653 burials, 354 (7.6%) were born to unmarried mothers. This is higher than expected as the ex-nuptial birthrate hovered around 4% at this time. Causes of and age at death differ between the babies of married mothers and babies of unmarried mothers. The inextricable link of infant and maternal health meant that babies born to unmarried mothers may have had poorer health outcomes than babies born to married parents. We argue that unmarried mothers faced structural violence in colonial New Zealand through official legislation and social structures preventing equitable access to the care and support necessary to provide a healthy life for their child.

A Report on a Late Woodland Period Dugout Canoe from Cape Porpoise, Maine, USA

In 2018, the Cape Porpoise Archaeological Alliance (CPAA) located a dugout canoe during a surface survey of the Cape Porpoise tidal flats in Kennebunkport, Maine. A sample of the canoe dated to between 1275 and 1380 cal AD making it the oldest known from the region. Professional archaeologists and volunteers excavated the canoe from the intertidal in the summer of 2019 for analysis and conservation. This research provides new insight into precontact watercraft technology in the Far Northeast and emphasizes the promise of citizen science initiatives for identifying and recovering delicate archaeological materials that are exposed and under threat from rapidly changing coastlines.

Spahr, Tim (Cape Porpoise Archaeological Alliance)**[317]***Discussant***Spanbauer, Jeffrey (Illinois Valley Community College)****[153]***Cultural Identity and Remembrance at “French” Fort Chartres*

Built between 1754 and 1765 in southern Illinois, Fort de Chartres has been interpreted as a French settlement in historical and archaeological interpretations and reconstructions. This continues to be the case, despite a large British garrison and attached civilian workforce and traders who have been erased or villainized. This obscures any nuanced discussions of identity and the cultural affiliation of material goods, and flies in the face of a rich British documentary record that illuminates quantities, styles, and producers of these goods. As such, previous interpretations of the cultural affiliation of artifacts are compromised, and a recent reexamination of the assemblage suggests a better proxy argument for a British affiliation, especially when considering the impacts of geography, trade, and historical events. This assemblage, when corroborated with documents, reveals the intricate negotiation of identity that emerges from intersectional categories that aim to parse a culture of production of materials from a culture of use.

Speer, Charles (Idaho State University) and Stance Hurst (Texas Tech University)**[86]***Folsom Hunter-Gatherers May Have Ignored Local Raw Material Sources*

The Adair-Steadman Folsom site (41FS2) functioned as a lithic workshop and campsite between 10,800 and 10,300 RCYBP and is situated ~5 km away from an Edwards chert quarry (41FS12) in the Southern Plains. This research aims to determine potential sources of Edwards chert Folsom artifacts at Adair-Steadman through LA-ICP-MS. The outcomes of this study, combined with a technological investigation, may yield valuable insights into Folsom mobility patterns. A previous investigation into the Adair-Steadman Folsom preforms (130), channel flakes (287), and projectile points (58) suggested knappers were gearing up for future hunts. A minimum analytical nodule analysis determined that knappers were likely not using the quarry at 41FS12 for the manufacture of Folsom projectile points. However, a preliminary assessment of the geochemical analysis of Adair-Steadman artifacts combined with previous research at 41FS12 suggests that Folsom knappers may have utilized Edwards chert from alternative sources potentially 50 km or further away. The selection of nonlocal Edwards chert sources may fit within other Folsom knapper constraints of landscape and ecological zones and/or raw material quality encountered during logistical forays. This is to be confirmed by comparison of geochemical data from raw material and artifacts from 41FS12 with the Adair-Steadman artifacts.

Kotið: An Integrated Geoarchaeological Investigation

The site of Kotið, in Skagafjörður, northern Iceland, consists of several interposed components ranging from medieval outbuildings to a small dwelling from the first period of settlement in the region (ca. 870–930 CE). To understand how the inhabitants of Kotið constructed and reconstructed the buildings there and impacted site deposits (both inside as well as outside of formal structures), an integrated geoarchaeological project has been initiated employing diverse methodologies ranging from soil coring to soil micromorphology to geochemical analysis. This poster presents the preliminary results of the geoarchaeological investigations at Kotið.

The Buffalo Hill Quarries Site: Investigations of an Ancestral Maya Quarryscape in the Mountain Pine Ridge Forest Reserve, Belize

The Rio Frio Regional Archaeological Project (RiFRAP) 2022 Mountain Pine Ridge Forest Reserve regional survey resulted in documentation of the Buffalo Hill Quarries (BHQ), the first recorded ancestral Maya granitic rock quarry with a ground stone implement workshop site. Preliminary investigations indicate a complex multicomponent quarryscape with extraction pits and cut faces surrounded by debitage piles spread out over an area of at least 16 ha. Debitage piles contained discarded items, granite flakes, preforms, and production tools, including quartzite hammerstones. Regional aerial lidar data later received revealed the BHQ is at least three times larger than our initial surveys indicated, and that two other multicomponent quarry sites are in the region. Our RiFRAP returned to the BHQ in the 2023 season to ground truth the lidar results and to conduct systematic excavations of a quarry pit to investigate extraction techniques. Results confirm the site is approximately 45 ha in size, but many components are invisible in the lidar data, indicating the need to employ multiple remote sensing solutions and fieldwork for documenting such sites. We also present findings of our investigations into how granitic rock was quarried and survey results identifying the raw material source for hammerstones.

Colonialist Biases in Historical Markers in Detroit

Applying a feminist intersectionality theoretical perspective in close readings of historical markers in Detroit reveals their intersecting colonialist racist and sexist biases. Of Detroit's 265 historical markers, 89% include men, 63% include White men, but only 26% include women, of which 71% are White. Native American men

are included on 6% of Detroit's historical markers, none of which mention Native American women. The biases show that these historical markers were very predominantly erected by Euro-American men from the viewpoint of European male colonists. The historical markers at colonial sites are very predominantly about White European men at military sites, religious sites, and home sites of enslavers. The few historical markers that include Native Americans mostly commemorate battles they lost, or mention land Native Americans "sold" to White men. These historical markers justify the conquest and settlement of the land by Europeans and the forced removal of most of the Native Americans to reservations further west. Very few White women are mentioned on historical markers for colonial sites, including Cadillac's wife and the wife of a slave owner. Suggestions are made for the inclusion of more information about minorities and women, especially Native Americans, on existing or new historical markers.

Domesticating Earth: Rethinking the Origins of Agriculture

The origins of agriculture have long been depicted as one of the greatest innovations of humanity, a humanist approach that rose to prominence in archaeology during the latter half of the twentieth century. During this time, a wide range of push and pull models for the origins of agriculture were developed, all of which were formulated as responses to the question of "why humans invented farming." This conscious view of agriculture continued to dominate discourse despite scholars, such as David Rindos, presenting coherent alternative narratives, which relied on ecological principles. Over the past 20 years the prevailing views have drastically changed, and in 2009, Dorian Fuller declared that a paradigm shift was under way. Despite the recognition of an overarching change in views, there have been few discussions regarding what this new "paradigm" entails and what aspects of the origins of agriculture debates should be rejected or retained. While most of the scholars embracing the ecological perspective would agree that the process was unconscious and protracted, discussions over the great why question still persist. In this talk, I will look at some of the assumptions that persist from the view of farming as a great innovation.

"Half-way up a hill, at the foot of which we camped": Archaeological Investigations of the 1781 Rochambeau Camp #5, Bolton, Connecticut

In 2023, the Connecticut Office of State Archaeology directed a new archaeological investigation of the 1781 Rochambeau Camp #5, in Bolton, Connecticut, as part of the Connecticut State Library's Digging into History Program for high school students. Camp #5 is one of several stops along the route taken by French forces under the command of Jean-Baptiste de Rochambeau, as they made their way across Connecticut and into New York to join the Continental Army before proceeding to Yorktown, Virginia. The Camp #5 site,

now a town preserve, was historically used as farm and pasture land, and retains much of its eighteenth-century character. An archaeological metal detecting survey conducted the 1990s identified a scatter of military artifacts, demonstrating the site's potential. The current archaeological investigation included geophysical survey, metal detecting, and limited excavations. Despite extensive plowing in the nineteenth and twentieth centuries, much of the camp site appears to be intact. Metal detecting identified concentrations of artifacts, including regimental buttons, tools, and personal items and the remote sensing work identified the truncated remains of several likely camp features. The results suggest that a combination of survey techniques provides the strongest methods for documenting and interpreting such short-term military sites.

The Calamitous Fourteenth Century and Its Influence on the People: A Case Study from Ypres, Belgium

During the fourteenth century in Europe, challenges like climate change, crop failures, and the plague affected the people significantly. Such events bore great consequences for people's health and their everyday lives forcing them to adapt. The inhabitants of Ypres, present-day Belgium, were no exception. During the high medieval period (eleventh–thirteenth centuries), the city expanded into one of the largest in northwestern Europe. Yet, during the fourteenth century, natural disasters and sociopolitical unrest resulted in a strong population decline and lifestyle changes. Multi-isotope analyses on human remains document human past and provide information on people's health, movements, and social interactions. However, as historical sources are not always available or difficult to interpret, connecting isotope data to historical events remains challenging. How to link information from isotopes to other disciplines such as environmental, medical, or archaeological studies, and how to improve future studies? Over 1,500 multi-isotope datapoints obtained from 185 humans and 52 animals from medieval Ypres are discussed in their historiographical context. Their implications are not only relevant for the medieval population of Ypres but also for isotope analyses studies in general.

An Overview of Ancient Funerary Practices in Oriental Amazonia: A Regional Bioarchaeological Approach for Amapá, Brazil

Archaeology and ethnology have shown that the relationship between the living and the dead in Amerindian societies in Amazonia is a fundamental element for understanding their lifeways in the past and present. Archaeological research on funerary practices in the Amazon region has revealed a variety of body treatments and burial patterns over the last 2,000 years. In the coastal region of Amapá (Brazil), this diversity is evident in the human burials constructed across different landscapes, in natural or artificial monuments, with ceramics of different styles. The ongoing research aims to identify the spatial distribution and the patterns in archaeological human burials to provide a comprehensive overview of funerary practices in the region through the analysis of the deposition patterns of human skeletons at archaeological sites in three regions of Amapá: (1) Atlantic coast, (2) estuarine coast and the mouth of the Amazon River, and (3) southern inland. We excavated burial urns at the laboratory and analyzed the human remains and associated artifacts to provide an initial description and characterization. The data produced so far confirms that the precolonial cultural diversity in the region—often associated with the abundance of archaeological ceramics—is also observed in the funerary practices.

Investigating the Residential History of the Esplanada Mass Graves at Phaleron, Greece

Cemeteries are spaces in which social and political identities are publicly negotiated between the living and the dead. Three mass graves, termed the “Esplanada,” at the Phaleron cemetery, Greece, are a clear and public statement that has captured significant attention since they were first uncovered. A total of 79 individuals were buried in long rows and bound with metal shackles, calling into question who they were, where they came from, and why they were given nonnormative burial treatment. This study investigates the residential history of 47 of these individuals using strontium isotopes ($^{87}\text{Sr}/^{86}\text{Sr} = 0.709777$, standard deviation = 0.003944) and proposes a novel method for interpreting radiogenic strontium results to better handle the complex geological variability in the Aegean. From the bioavailable range of values, the authors generate a probability that individuals in the study spent their early life in this area, allowing for an estimation of locality when bioavailable strontium ranges overlap between adjacent areas. Each individual will have a likelihood of locality assigned that will aid in determining residential history. Refining the interpretation of strontium isotopic values by adding probability will thus enable more nuanced interpretation of the mobility and social identities of those buried in the mass graves at Phaleron.

Testing and Improving Interlaboratory Comparability of Tooth Enamel Carbonate Isotope Analyses

Carbon and oxygen isotope ratios of human tooth enamel carbonate are frequently used to reconstruct past diet, movement, and environmental conditions. Despite a long legacy of research, samples are prepared and analyzed using a remarkably broad range of protocols, and this methodological heterogeneity raises questions about the comparability of isotopic data across studies. We report a systematic comparison of isotope delta (δ) values for 10 “modern” faunal teeth (obtained from field recoveries) measured in two different laboratories. Our tests included comparisons of enamel powder subsamples that were chemically pretreated using commonly adopted protocols and subsamples that received no pretreatment. We also evaluated δ values generated with and without (1) standardizing the reaction temperature used during isotope ratio mass spectrometry and (2) baking the samples and vials to remove moisture before analysis. The results showed that δ values from the two

laboratories were systematically different when samples were chemically pretreated, but that differences were smaller or negligible for untreated samples. Standardization of reaction temperature and baking also improved comparability. We suggest that the widely adopted practice of oxidant and acid pretreatment of enamel samples is largely unnecessary and may compromise the accuracy of stable isotope analyses.

Gulf Ballgame Viewership: The Ballgame and Center Functions

In south-central Veracruz, higher-level centers during the Classic period had ballcourts. The prevailing “low-density urbanism” and a distributed urban network pose challenges for sociopolitical integration. How well did the ballgame accommodate at least nearby populations and contribute to social integration? We examine test cases to assess viewership versus population. Previously we compared game viewership to the people accommodated in the central plaza. Here we ask a different question: how well did viewership serve the immediate surrounding population? We then compare the ballgame to other urban services in Gulf centers.

Place-Making, Fire, and the Praxis of Becoming Angkor

The ninth- to fifteenth-century Angkorian state was premodern Southeast Asia's earliest large-scale collective, and its roots extend back to an early first-century CE polity described as Funan, and then to a confederation of successor states called Chenla. Place-making was intrinsic to Angkorian rulership: rulers formalized transportation and communication routes linking the capital to its peripheries and inscribed their acts on sandstone stelae embedded in state monuments. Angkor's capital swelled to 750,000–900,000 residents at its twelfth- to thirteenth-century peak, yet Angkorian citizenship did not require urban residence at the capital. Multisite archaeological fieldwork across Cambodia suggests instead that Angkorian Khmers constructed state places through their monuments and intangible sites of memory. Ritual practice in the Angkorian world merged indigenous animist beliefs with Brahmanical and Buddhist ideologies to require new ways of moving through the Angkorian world and harnessing pyrotechnologies to produce and use iron goods (including architectural) and stoneware ceramics across the empire. This paper explores how Angkor's citizens engaged with deeply historized places, transitioned local tutelary spirits in small shrines to sculpted gods in sandstone temples, and created a sense of collective belonging through the manufacture and consumption of unique objects forged through fire.

Assessing Mobility among the Medieval Makurian Individuals Interred in Crypts 1–3 on Kom H at Old Dongola, Sudan

As the capital of the medieval Kingdom of Makuria, in what is today Sudan, Old Dongola was a central location of administration and culture; Old Dongola was also the seat of a bishopric. Such factors would have made Old Dongola a key location for mobility, with various pull factors from economic, social, and religious, including monastic. Numerous questions remain about the population of medieval Old Dongola and mobility to the site. During excavations of the monastery on Kom H at Old Dongola, three burial crypts (Crypts 1–3) were uncovered. The identification of the epitaph of an archbishop Georgios in proximity to these crypts suggests that Georgios may have been interred in one of the crypts along with other, likely, social elites of Dongolan society. The use of Crypts 1–3 on Kom H bring forth questions about burial space use and mobility among different social segments in Makurian society. This study presents the results of strontium ($^{87}\text{Sr}/^{86}\text{Sr}$) isotope analyses of dental enamel from 19 individuals buried within these three crypts to assess potential mobility to the area of Old Dongola.

Assessing the Nature and Pace of Platform Mound Construction in Cahokia's Ramey Field

First detected by Charles Bareis in 1969 in Cahokia's Ramey Field tract, Mound 17 (the Bareis Mound) was partially exposed beneath artificially mixed plaza fills, immediately west of the palisade wall that bounds the eastern extremity of the site core. Following an analysis of Bareis's collections from the 1969 field season in 2019, two consecutive field seasons were undertaken to understand the nature, timing, and spatial extent of Mound 17's construction. Using multiple geophysical prospection methods, soil probing, targeted excavations that expanded from Bareis's original trenches, micromorphological sampling, Bayesian modeling of sampled AMS dates, and the analysis of contextually associated artifacts, Mound 17's construction sequence was determined with attention to micromorphological clues and Bayesian modeled AMS dates, in order to accurately assess the cultural context and pace of mound construction between the eleventh and twelfth centuries CE. Bayesian modeled AMS dates indicate a 19-year construction span for Mound 17, and micromorphological thin sections that lack evidence of construction surface weathering indicate that construction occurred within a few weeks. Considering experimental labor estimates and local meteorology in west-central Illinois, Mound 17's construction is evaluated as a punctuated event in Cahokia's history, repeated at varying scales during Cahokia's overall occupation.

Plants and Environment: A Paleoethnobotanical Analysis of the Vosburg Site (21FA002)

Recognized archaeologically by their distinct material culture, Oneota sites exist in many ecological zones across the Upper Midwest. Consequently, the sites are hardly homogenous. Across localities, Oneota groups are recognized as late Precontact food producers who grew *Zea mays* (maize), *Cucurbita pepo* (squash), and later *Phaseolus vulgaris* (bean). The utilization of other wild and domesticated botanical resources across localities is not as well documented. While extensive paleoethnobotanical analyses have been completed for the late Precontact period in southeastern Minnesota and southwestern Wisconsin, little is known about plant utilization by Oneota groups on the Minnesota prairie. The Vosburg site (21FA002) is a late Precontact (ca. 1300–1400 CE) Oneota site located within the woodland-prairie transitional ecotone of Minnesota. The macrobotanical remains from half of a large, culturally significant feature from the Vosburg site were analyzed and compared to those of previous paleoethnobotanical studies from contemporaneous Oneota sites in the Upper Midwest. Moreover, this study provided a more accurate understanding of the environment of southern Minnesota ca. 1300–1400 CE. This study is a significant contribution to archaeologists' limited understanding of diversity in Oneota plant assemblages and of the Blue Earth phase of Oneota in southeastern Minnesota.

Steere, Benjamin (Western Carolina University)**[124]***Heritage Management at the Cherokee Town of Noquisiyi (Nikwasi) in Franklin, North Carolina, USA*

The Noquisiyi or Nikwasi Mound, a monumental earthen platform mound located in the town of Franklin, North Carolina, was first constructed during the Mississippian period (AD 1000–1600) and marks the location of an important Cherokee mother town. In this paper I consider the history of the preservation of the mound as a case study in the evolution of cultural heritage preservation in the ancestral Cherokee territory of western North Carolina. Drawing on insights from Indigenous studies, I suggest that the town of Franklin initially preserved and interpreted the site as monument to Cherokee absence, rather than a symbol of Cherokee resilience. This narrative still haunts current discussions about the site. However, recent efforts at more collaborative interpretations of Noquisiyi, which include the use of concepts from Cherokee language and cosmology and frequent visits to the site by Cherokee cultural organizations, provide examples of a more expansive and equitable concept of heritage. Those involved in the preservation and interpretation of Noquisiyi have an opportunity to reclaim the site as an active part of the Cherokee cultural landscape, but doing so will require all involved to push back against archaeological interpretations that separate living Indigenous people from their past.

Steeves, Paulette (Algoma University)**[7]***Discussant***Steeves, Paulette (Algoma University)****[258]***Weaving Paths to Healing and Human Rights: Creating Tsunamis of Systemic Change in Archaeology*

Substantive practices for a just future in archaeology require an acknowledgment of the history of discrimination and marginalization within American archaeology. Equity is not achieved through policies supporting marginalized communities within the discipline. Substantive practices and equity are addressed through action. Discrimination within archaeology against marginalized groups includes both settler and Indigenous populations. Transformation of an academic field begins with discussion, including testimony from impacted communities to the harms inflicted by systematic discrimination within the field. If we are to create a just and equitable future in archaeology, we must first listen to marginalized people and communities and together weave paths to healing and transformation within archaeology and the communities whose histories and lands are central to the work archaeologists do. From an Indigenous perspective and lived experience, I discuss the harms inflicted on Indigenous communities and on settler archaeologists whose work leapt beyond the enforced time frames of the initial peopling of the Western Hemisphere (the Americas). It is an honor to acknowledge archaeologists who suffered the wrath of the archaeological status quo and to acknowledge the groundbreaking work they have done over the last century, supporting deep Indigenous links to the lands of Turtle Island.

Maya Lithic and Metal Technologies in Belize

Over more than a century, archaeological research in Belize has contributed greatly to our understanding of past Maya stone and metal technologies. From the preceramic through the colonial periods (~11,000 BC–AD 1700), the analysis of flaked and ground stone tools recovered from excavations in Belize has provided critical insights into Maya subsistence and socioeconomic and ideological behavior, while incorporating studies about raw material sources, quarrying, tool production, trade and exchange, tool function, ritual, and symbolism. In contrast to the ubiquity and longevity of stone tools in the archaeological record of Belize, metal objects appear in small quantities and at select sites relatively late in time (ca. AD 1200/1250–1700). Metal never “replaced” stone at Maya sites, and because Belize has no known metallic ore deposits, copper-based ornaments rather than tools were either imported from elsewhere in Mesoamerica or they were produced by recycling metal objects that had been imported earlier in time. Here we provide an overview of the major themes addressed in lithic and metallurgical studies in Belize, with an emphasis on the contribution of lithic studies in Belize to understanding big picture questions about resource acquisition, tool use, and socioeconomic and ideological behaviors throughout the Maya region.

White Iron and Red Gold: How to Identify Tin, Copper, and Bronze Derived from Rooiberg Mineral Deposits, South Africa

Tin and copper ores around Rooiberg, South Africa, were exploited from 1000–1300 CE until about 1840. Geologists estimated that around 1,000 tons of the tin mineral cassiterite, equivalent to 792 tons of metallic tin, were mined there. Archaeological survey showed only a small amount of evidence for tin smelting near Rooiberg. Therefore, the ore deposits appear to have been an open resource, with tin carried away to sites near and far for smelting. Isotopic and chemical analysis of bronze and tin metal from archaeological sites across southern Africa has established that Rooiberg was the primary source of tin for the manufacture of bronze in South Africa, Botswana, Zimbabwe, and southern Zambia (the latter about 800 km from Rooiberg). Missing from this discussion is the possibility that copper was also moved long distances from Rooiberg. In this presentation, we establish the isotopic and chemical signature of copper from Rooiberg. Our results prove that copper from Rooiberg was distributed around the region, and we use these data to reconstruct networks of mobility and interaction in the southern African Iron Age.

Sterling, Kathleen (Binghamton University)**[124]***Vive la différence? Comparing American and French Approaches to Heritage*

What do archaeologists mean when we talk about heritage? That depends in large part on our often-shifting positionality within broader heritage discourses. Western archaeologists often investigate what we might describe as our own heritage as well as that of others, both within our own nations and elsewhere. When we discuss “heritage” in the United States, it is often with a feeling of personal and patriotic connection to the past. Heritage work is about stewardship, pride, protection, and specific kinds of expertise for the benefit of all. France provides a complementary and contrasting example. The United States and France are both Western states that share a standpoint of national exceptionalism, and we point to our histories to justify that. Both nations have World Heritage sites within their borders. However, the differences between a settler-colonialist state and a colonial state, coupled with very different racial dynamics, means that American heritage and French *patrimoine* bear only superficial resemblance to each other for the producers and consumers of archaeology, arts, and history.

Luis Barba is the 2024 Fryxell Award honoree, in recognition of his excellence in interdisciplinary research contributing significantly to American archaeology. Luis started his career with academic degrees in chemical engineering, geology, and anthropology. His research interests and over 200 publications focus on archaeogeophysical prospection, chemical residues on archaeological floors and vessels, and the integration of multiple noninvasive geospatial datasets indicative of human activity. He has worked extensively in Mexico but also in Spain, Chile, Turkey, Italy, and Israel. He has done much to strengthen the infrastructure of archaeological science within Mexico and elsewhere. He was a co-organizer of the biannual International Symposium of Archaeometry (ISA) in Mexico City in 2000 and was also on the local organizing committee of ISA 2018 in Mérida. He has served on the Standing Committee of the ISA since 2000 and has been a longtime chairperson of the field techniques symposia. He was head of the Applied Sciences Network for Cultural Heritage Research and Conservation (Mexican National Council for Science and Technology). Luis Barba has participated in many international collaborations. He has mentored a bevy of younger colleagues and students. All of this was done with professionalism, collegiality, creativity, and a joyful work ethic.

Sternner, Katherine (Towson University)**[228]***Chair***Sternner, Katherine (Towson University)****[228]***Use and Sources of Ohio Hopewell Fossil Shark Teeth*

Fossil shark teeth recovered from Ohio Hopewell sites represent a quintessential example of an exotic good representative of the Hopewell Interaction Sphere. As with most artifacts, the primary questions asked of fossil shark teeth in archaeological contexts are (1) what were they used for and (2) where did they come from? Answers to date are that these objects were primarily decorative or catch-all ceremonial in function, with more recent consideration of additional utilitarian functions. Several sources have been considered for fossil shark teeth recovered from Ohio archaeological sites: the lower Mississippi Valley, Florida, the Gulf Coast, the Carolinas, and the Chesapeake Bay region. Sourcing evidence typically relies on factors such as proximity to the proposed sources, the presence/absence of other participants in the Hopewell Interaction

Sphere, the presence of Ohio-sourced materials in the proposed shark tooth source location, the presence of waterways for transportation, and proximity to fossil shark teeth. This study applies use-wear analysis to samples of fossil shark teeth from Florida, Ohio, and the Chesapeake Bay, to determine if teeth were used in a similar manner between regions, and if such overlap may indicate the primary source of Ohio fossil shark teeth.

Glass Windows and Vessels from Bir el Knissia, an Early Byzantine Church in Carthage

Excavations at the site Bir el Knissia in Carthage from 1990 to 1992 recovered large glass assemblages from the site of an early Byzantine cemetery basilica, constructed by the mid-sixth century CE and destroyed by fire in the mid-seventh century. These artifacts include vessels (especially lamps, beakers, and goblets) and substantial quantities of glass windowpanes. Visual examination of glass coloration reveals significant differences among vessels, equally distributed between colorless, light green, and bluish-green glass, and the windowpanes, made overwhelming of bubbly bluish-green glass. Elemental analysis of approximately 100 glass vessels and windowpane fragments has been carried out to elucidate the reasons for the variation between the vessels and the window panes. We present preliminary results of analysis from Bir el Knissia and consider the implications for glass trade, glass workshop organization, and glass recycling in early Byzantine Carthage.

A Geoarchaeological Investigation of an Early Holocene Soil Feature at the Page-Ladson Site (8JE591)

Florida State's 2022 field school excavated into Page-Ladson's stratigraphic unit (SU) 5, a stratum that spans the terminal Pleistocene and early Holocene with Bolen period occupation and exposed a sediment feature. It was unclear if the feature was cultural or natural. The soil transition was diffuse but there was an increase in charcoal and faunal content. Limestone and wood were ambiguously scattered. Several Late Paleo/Early Archaic projectiles surrounded the feature. This research reconstructs the environmental context of this early Holocene feature and associated SU and determines its cultural or natural origins. Several geoarchaeological methods were employed to identify whether this soil feature is the result of a cultural or natural process with two possible conclusions: the feature is a hearth or a natural water feature. The materials around the soil feature are reminiscent of a hearth, but no materials were visibly thermally altered. An alternative explanation is that the arrangement of materials are the result of a debris line at the margins of a pond. The following methods were applied: $\delta^{15}\text{N}$ and $\delta^{13}\text{C}$ isotopic analysis, Loss on Ignition, Magnetic Susceptibility, pollen analysis, and faunal, charcoal, and lithic distribution. The results indicate that this is a cultural burn feature.

Augmented Curiosities: Virtual Play in African Pasts and Futures

Technologies inspire the creation of new subjectivities—changing our points of perspective and augmenting the ways in which we perceive. Through our ever-expanding applications of innovation, humans recontextualize realities. We use the tools of the present to formulate our visions of the future and our understandings of the past. Along these explorations of meaning, we apply interfaces of magic upon the seemingly mundane to educate and entertain. *Augmented Curiosities* engages our technological entanglements through the emerging, immersive, and experiential visualization techniques of augmented reality (AR) and

virtual reality (VR). Critiquing the colonial dynamics of the “cabinets of curiosity,” which significantly influenced Western museum practices, *Augmented Curiosities* provides opportunities for intimate and playful interactions with African material culture from Northwestern University’s Herskovits Library of African Studies Collection. Through this digitally tactile experience, we exhibit synergies of the technical and the tangible as a community-oriented framework for future museum curation.

I Know as I Relate: Reimagining Relationships of the Deep Past

Framed within Eurocentric materialism, economic theory of the deep past has largely formed a world of “natural resources” ready for extraction, exploitation, and management. Conversely, Indigenous-based economies of North America-Turtle Island widely see an animate universe in which all creations have agency and tradition all their own. Such economies are place-based, relation-based, and future-based, with many added values that are neglected in neoclassical economic theory. In this paper, I begin the process of reimagining Indigenous Peoples’ relationships with beyond humans (i.e., Plant and Animal Persons) in the Deep Past of the Archaic period. I examine how various Indigenous groups observed their social brothers and sisters, like Tree- and Deer-Persons, and worked to maintain relationships with these beings for millennia.

NAGPRA Practice as Death Work: Determining a Need for Grief-centric Training for NAGPRA Practitioners

NAGPRA practice entails working with death. This occurs when practitioners are engaging with the Dead, the circumstances of their occurrence in collections, and the wider scope of systemic violence that prompted the need for NAGPRA. NAGPRA practice is a type of death work. However, in the institutions that comply with NAGPRA, practitioners do not receive preparation to cope with their own grief brought on by their work or the grief of their Native American partners. Meaningful NAGPRA practice involves interpersonal relationship-building and interactions that broach potentially traumatic conversations. Having a foundation in grief-centric training would allow NAGPRA practitioners to not only practice self-care in their own work but also amplify the pursuit of healing which is the spirit of NAGPRA. This study surveyed NAGPRA practitioners, individuals who are responsible on some level within their institutions for the implementation of NAGPRA. Using likert scales, the participants were prompted with questions about the relationship between their practice and grief, their confidence and ability in approaching the grief of their tribal partners, and their perceived need for additional training that is grief-centric. The results help estimate a need for grief-related training or preparation for NAGPRA practitioners.

The Middle Stone Age Goes Alpine: Preliminary Results of New Excavations at Ha Soloja Rockshelter, Lesotho, Africa

While settlement of the world’s high plateaus represents a final chapter in *Homo sapiens*’ global colonization, there were surprisingly early dispersals into high mountain systems. Africa possesses evidence for an early hominin presence in such settings, yet the processes by which human-highland engagements unfolded remain

obscure. This paper introduces a new project to understand when, why, and how humans began exploiting southern Africa's highest mountain system, the Maloti-Drakensberg. We present the preliminary results of renewed excavations at Ha Soloja (2,300 m asl), a large rockshelter in the uplifted Sehlabathebe region of southeastern Lesotho. We opened two new trenches at Ha Soloja, data from which form one prong of a multidisciplinary program of rockshelter excavation, paleoenvironmental reconstruction, landscape survey, and heritage valorization. From the uppermost levels we obtained infinite radiocarbon dates, suggesting the entire ~3.2 m Ha Soloja sequence predates ~50 kcal BP. The cultural material recovered is heavily dominated by flaked and fire-cracked stone artifacts. Low artifact densities, high rates of retouch, and abundant small flaking debris suggest that the site was recurrently a short-term logistical camp, lending preliminary support to our hypothesis that Ha Soloja functioned as a deep time high-altitude hunting station.

Interpreting the History of Stolen Land: A Collaborative Project between the New Mexico State Land Office and New Mexico Highlands University

The New Mexico State Land Office (NMSLO) manages over nine million acres of land that was stolen from the Indigenous and Hispano peoples as a condition of US statehood. This land was allocated to New Mexico under the Ferguson Act of 1898 and the Enabling Act of 1910 in order to generate funding for schools and hospitals. While acknowledging this history, the NMSLO is devoted to the principle of stewardship and the responsible care of cultural resources. The establishment of the Cultural Properties Protection Rule and creation of a new division, the Cultural Resources Office, have increased protections and adhere to a complete avoidance practice. To highlight this shift toward caretaking management strategies and increased consultation with descendant communities, students from New Mexico Highlands University's Media Arts & Technology Department created interpretive materials for the public spaces in the NMSLO building located in downtown Santa Fe. This project contrasts the colonial beginnings of the land office with aspirations of the current administration.

Toxic Taphonomy

We are living through an era that has been described as "the apotheosis of waste," a globe brimming with greenhouse gasses, mountains of tailings, lagoons of pig-shit, and hangars of acidic sludge. The massive scale and persistence of industrial waste has not only transformed the air, water, and soil that we live on, it has hijacked the taphonomic processes of decay. Rather than a process of undoing, the decay of industrial waste is toxic, uneven, and hidden. As it decays, industrial waste not only materially remakes the bodies, communities, and environments that live in its shadow, it transforms humanity's capacity to know and act in the world. Drawing from excavations of a 1930s mining community that lived downwind of lead tailings, this paper explores how the immigrant miners and their families lived were unevenly exposed to these tailings and their harms. Beyond focusing on the material harms themselves, I am interested in the ways these harms played at the limits of the legibility and in doing so unsettled the community's local practices of resilience in the face of exploitation.

Stewart, Rebecca (Brockington & Associates Inc.)**[324]***A Flash of Silver in the Swamp: The Identification of a B-24 Crash Site from World War II in the Lowcountry of South Carolina*

On Dec. 15, 1944, a B-24 took off on a night navigation mission from Chatham Air Field in Georgia, headed to Florida. The crew of nine were training to patrol the East Coast for enemy submarines. Fifteen minutes into the flight, engine #1 caught fire. The bomber crashed less than five minutes later into swampland in the Lowcountry of South Carolina. This paper discusses the identification of the crash site, the condition of extant wreckage found as part of an intensive cultural resources survey in 2021 and provides a narrative history of the incident based on information obtained in the Army Air Force crash report. This site highlights the significant loss of life which occurred within the US as a result of training accidents during World War II. It is an unusual archaeological site type, and it has few, if any, precedents within the southeastern US. Of the 561 fatal Army Air Force crashes recorded in South Carolina and Georgia during World War II, this is the first to be recorded formally as an archaeological site. Using Phased Aviation Archaeology Research (PAAR) methodologies adopted from the UK as a guide, the wreckage of Plane 42-50992 has been mapped, photographed, and analyzed.

Stojanowski, Chris**[241]***Phenotypic Perspectives on Biological Variation at Phaleron*

Phaleron is an important site in the history of ancient Athens and preserves a unique record of life in the past. One of the more compelling aspects of the site is the range of mortuary treatments documented there, including multiple groupings of nonnormative burials, a series of co-interments buried in shackles, as well as pit and jar burials. Given the variation of mortuary treatments, and in particular clear evidence of violent death for some individuals, one question to address is how these different burial subsets relate to each other in terms of biological variation. Dental morphological data were collected from approximately 600 burials using the Arizona State University Dental Anthropology System. These kinds of data have been repeatedly shown to reflect patterns of biological relatedness at different scales of analysis and serve as useful proxies for neutral genetic variation. As such, they complement more direct genomic approaches and generally use larger sample sizes and are nondestructive in their implementation. Data were cleaned using standard trait registration techniques and subjected to multivariate biological distance analysis. Patterns of variation are compared among Phaleron subgroups as well as with published data from other sites in Greece that reflect suitable broad-scale comparative outgroups.

Exploring High-Elevation Mobility in the Sierra Sur Mountains Past and Present

Much like their ancestors did in the past, people in the Sierra Madre del Sur mountains still travel largely on foot to reach places, such as milpas or grazing land, that are completely inaccessible by car. These trips can take hours, following trails that easily cover 500–1000 km of vertical movement over rugged terrain. However, the Least Cost Path (LCP) analyses used to model travel both in the present and the past frequently fail in mountainous landscapes because of built-in biases against high elevations. This presentation explores the spatial data collected during walking tours with local guides and what these results tell us about how people actually move through rugged, high-elevation mountain landscapes. Ultimately, the spatial and ethnographic data together will provide a more holistic picture of movement in mountain landscapes and help archaeologists understand more in-depth the history of occupation and movement in the Sierra Madre del Sur mountains.

Genomic Contributions to Understanding Early Caribbean Settlement

In the Caribbean, archaeological and linguistic research have contributed a wealth of knowledge to our understanding of human settlement, yet many issues surrounding dispersal trajectories, adaptation to island environments, and population dynamics over time are still debated. In recent decades, genomic findings have begun to transform our understanding of regional population dynamics and address long-standing questions. Additionally, ancient DNA (aDNA) has quickly become a promising method for exploring human population origins and dispersals in island systems. Despite these advances, the application of paleogenomic techniques for studying ancient Caribbean peoples has primarily focused on individuals dating to the last ~2,500 years and from a small number of islands. Here, we discuss the potential contributions that paleogenomics can make toward elucidating the origins of the earliest Caribbean inhabitants and past interactions between contemporaneous and later island communities. Additionally, we will present preliminary results of an aDNA study of human Ancestors from the Ortiz site located in southwestern Puerto Rico, currently the oldest dated from the island. We will discuss how these data, when contextualized with existing archaeological and bioarchaeological evidence, shed light on the lifeways of Puerto Rico's earliest known inhabitants.

Community-Engaged Bioarchaeology: Decolonizing Research

Bioarchaeology as a field of inquiry aims to bring forward the life histories of individuals through the analysis of skeletal markers of disease, trauma, and activities, at the individual and population level to better understand the experiences and identities of people that came before. A recent and important shift in the bioarchaeological approach has been the inclusion and consideration of descendant groups. In this paper, I consider the slow pace of, and sometimes resistance to, intertwining Indigenous and descendant community knowledge within bioarchaeological research. My goal here is to underscore the need to rethink traditionally colonial research questions and modes of inquiry, and to revision bioarchaeological practices that are community engaged and intertwined with Indigenous/descendant knowledge of their ancestors. A community-engaged bioarchaeological project begins by bringing in Indigenous people and/or descendants from the very beginning of the project, centering their questions and bringing forward their knowledge of the past provides grounding and inclusion. Shifting away from solely the analytical goals of bioarchaeologists to those of the community creates a shared vision of the past that is co-created by invested descendants and bioarchaeologists. This process looks different and develops differently across projects but is an important step in decolonizing bioarchaeological practices.

Evaluación del desarrollo de urbanismo en el Valle de Tepango entre los Periodos Formativo y Clásico

El urbanismo, en gran parte de las tierras bajas del Golfo, exhibe un patrón de crecimiento continuo desde el período Formativo hasta el Clásico. En muchas regiones, las ciudades más antiguas del Formativo se convirtieron en las ciudades más grandes e influyentes del Clásico con centros más pequeños alrededor. A menudo se supone que un patrón de centros pequeños rodeando a centros grandes representa una jerarquía política, en donde el centro grande controla sus alrededores. Las investigaciones realizadas en el Valle de Tepango han sugerido precisamente este patrón de crecimiento, siendo Totocapan el asentamiento más grande desde el Formativo Medio hasta el Clásico Tardío. En el pasado, he propuesto que Totocapan integró políticamente el Valle por un breve tiempo desde el Clásico Medio hasta el Clásico Tardío; sin embargo, esa conclusión se basó principalmente en una comparación entre las diferencias de tamaño que existen en la arquitectura monumental de los sitios. En esta presentación, reexamino la distribución de estilos cerámicos y los patrones económicos de producción e intercambio durante la transición del Formativo al Clásico en el Valle de Tepango para probar la naturaleza de la interacción entre los centros político-rituales de la región.

One Step at a Time: Preliminary Evidence for Human and Megafauna Trackways Located along the Ancient Shorelines of Lake Lucero, White Sands Missile Range

In 2006, human trackways were discovered at White Sands National Park along with the trackways of giant Sloth, Dire Wolf, Camel, and Columbian Mammoth. Upon the mapping and excavation of these prints in 2018, small preserved ancient grass seeds (*Ruppia cirrhosa*) were revealed that provided calibrated dates of 22,860 (± 320) and 21,130 (± 250) years ago (Bennett 2021). Considering this unique discovery, and its proximity to portions of White Sands Missile Range (WSMR) the cultural resource team at WSMR has embarked on a unique project to conduct a large-scale (16 km²) aerial drone mapping project to identify additional human prints. This study will utilize numerous new digital technologies in coordination with targeted pedestrian survey to map large areas of the ancient shoreline of Lake Lucero. The expectation based on preliminary observations (several human trackway locations have already been identified) is that hundreds of human and megafauna trackways will be located. The implications for future research on these exciting new discoveries could provide interesting new perspectives on the peopling of the North American continent.

St-Pierre, Éloïse (Université Laval) and Jacques Chabot (Université Laval)**[126]***Expedient Tools from a Functional Angle*

In almost every culture of the world, expedient tools are present. They are “tools of the moment.” These flakes were crafted quickly with semi-improvised techniques, then used for a short period of time and discarded. The use of flakes as tools may not only indicate reuse or recycling of debitage waste, but also the existence of a real intention to manufacture blanks for immediate use. Expedient tools are not the most “glamorous” artifacts found on archaeological sites; they haven’t been as studied in comparison to formal tools. This is true from both a technological and a functional standpoint. The main challenge in order to diagnose the function of ad hoc tools is to decode their discrete use-wear traces by high magnification traceology. This can be possible thanks to an experimental reference frame. As a case study, we will talk about Saint-Pierre-et-Miquelon’s prehistory. The French archipelago is located south of Newfoundland and was occupied by Paleoeskimo and Amerindian populations for 5,000 years. Recently, we performed traceological analyses on formal tools found on the island and in a forthcoming project we aim to study the use-wear patterns of expedient tools in order to compare subsistence activities.

Pioneering genomic analyses of bone and dental calculus from the 19,000-year-old Magdalenian “Red Lady” skeleton in El Mirón Cave, along with DNA from other Late Upper Paleolithic human remains provide critical information supporting the archaeologically based theory of human range southward contraction and northward re-expansion in response to the major environmental changes of the LGM. The existence of refugia during the Solutrean followed by recolonization during the Magdalenian, as proposed by Jochim and Straus, is confirmed genetically, with the addition of novel information on gene flow among the Balkans, Italy, Belgium, France, and Iberia, reinforcing the archaeological evidence of interregion relationships, especially during the Magdalenian. Details on the oral biome of the El Mirón adult female, including connections to long-extinct Neanderthals provide insights into the lives of Late Glacial humans in northern Spain that complement classic evidence from artifact, faunal, and human paleontological analyses. DNA analyses of salmon and red deer—key food resources for Solutrean and Magdalenian foragers—confirm the role of the Cantabrian region as a refugium during the LGM and Oldest Dryas. The paleogenetic revolution led by Pääbo has both confirmed archaeological models and provided extraordinary details on key aspects of Upper Paleolithic population history in Europe.

The Northern Question: The Kaanu'l Kingdom and Its Legacy in Yucatán

The historical importance of the Kaanu'l (Kanul) dynasty and its political networks is now well established. Dzibanche and Calakmul were its two principal centers over the course of the Late Classic period, and the sources we use for reconstructing its history come from many surrounding sites in the southern lowlands. In this paper, I look northward, into the political landscape of northern Quintana Roo, Yucatán, and Campeche, in order to assess Kaanu'l's presence and influence in those regions. The sources at sites such as Coba, Okop, and Edzna are scarce by comparison, yet point to a close series of interactions, perhaps different in than what is evident with Kaanu'l's aggressive alliance-building the Petén and beyond. Looking beyond the Classic inscriptions, I propose a historical connection between the Kaanu'l dynasty of the Classic period and the Canul lineage of Postclassic Yucatán, members of the Mayapán confederacy who later established their own polity in northern Campeche not long before the Spanish invasion. Historical, geographic, and linguistic factors raise the possibility that Kaanu'l (Dzibanche) was a Yukatekan-speaking center, raising important implications for interpreting the broader ethnic and political landscape of the Maya lowlands in the Classic period.

Experimental Archaeology and the Theory of Experience: A View from Medieval Archaeology

The theoretical foundation of experimental archaeology is often left implicit. Some argue that the primary value of experimental archaeology lies in scientific experiments to investigate specific and non-theoretical questions about ancient technology. This paper will address the experiential aspect of experimental archaeology and how that can make a significant and valuable contribution to better interpretations of the archaeological past. The role of human action and behavior is central to anthropological studies, and interacting with the material world is a central part of human action. Experimental archaeology can make a step toward recreating past behavior and material interaction rather than just replicating technology. Examples from medieval archaeology in Europe, specifically food and ceramics, will be used to illustrate the value in experiential experimental archaeology.

The Enduring Practice of Dental Modification in the Ecuadorian Past

Dental modification has been well documented from the coast of Ecuador, with practices including elaborate

dental inlays and incisions. However, few examples come from recently excavated or well-provenienced sites, making the antiquity and changing significance of dental modification unclear. Additionally, it is unclear whether this practice originated in Ecuador or was imported from Mesoamerica through well-established trade routes. This poster presents evidence of dental modification from Buen Suceso, a coastal Ecuadorian site with two occupational histories. First, we present what may be the oldest examples of Ecuadorian dental modification from two Valdivia burials (3800–1450 BC). These two individuals, a female adult and a nonadult, both presented a single incised line on each of their central incisors. Notably, these individuals predate the existence of known trade routes with Mesoamerica. Second, we present evidence of Manteño (AD 700–1500) dental modification from two individuals and an associated stone bead artifact modified to look like a tooth. These modifications were more elaborate, with several horizontal and vertical incised lines. We argue that these examples of modification demonstrate the enduring and autochthonal practice of dental modification in Ecuador and the significant connection between dental modification and power over time.

Understanding the Forecasted Labor Shortage: Undergraduate Views of Archaeological Careers

There is a projected dearth of qualified archaeological professionals in the coming decade. As such, it becomes essential to discover the underlying causes of a lack of interest in pursuing a career in archaeology among individuals otherwise interested in the field. Social cognitive career theory posits that self-efficacy, expected outcomes, and goal mechanisms lead to a student's career-relevant interest leading to their career aspiration. Could a deficiency in these factors caused by marginalization be affecting interest? Using a mixed-methods approach, we explore the career interests of undergraduate students taking introductory archaeology courses to understand perceptions of careers in archaeology with students, both majors and nonmajors, enrolled at a regional comprehensive institution in the Midwest. Participating students completed surveys at the beginning and end of these courses. Some students volunteered to be interviewed regarding their class experience, career interests, and perceptions of archaeology. Survey results reveal that there are no significant changes in career interest from the beginning to the end of an introductory course in archaeology. Interview data indicate that taking the course gave students a better appreciation for archaeology and none of those interviewed felt less likely to pursue a career in the discipline.

Interdisciplinary Research, Zooarchaeology, Electronic Databases, and the Impacts of Struever's Vision

Struever's passion for multidisciplinary archaeological research in the lower Illinois River valley (LIV) attracted both authors to Northwestern University and to our specializations in zooarchaeology. Struever's primary interest was in anthropological interpretations of subsistence, settlement, and social systems, and he encouraged us to go beyond the natural history orientations of our zoology colleagues in our zooarchaeological research. Research on LIV Archaic and Woodland subsistence considered the influences of climate and environmental change and also of cultural factors such as settlement function and cultural traditions. Standard use of screening and flotation yielded large collections of faunal remains, and to make sense of them, we developed some of the earliest coding formats for computer-assisted analyses of faunal data. The electronic databases we generated and the methods we used facilitated systematic comparative research. Regional zooarchaeological research demonstrated the early importance of aquatic animals and the increased importance of fish as gardening and larger settlements emerged. Struever's perspectives, our interdisciplinary experiences, commitment to analysis of small-scale remains, and development and use of

electronic databases have been foundational in our careers and in our recent synthetic zooarchaeological research documenting the great variability in human use of fauna across the midwestern and interior eastern United States.

How Were Stones Used in a Bronze Age Society? A Case in the Middle Yangtze River

Numerous previous archaeological discoveries and studies have shown that rulers from the Central Plains during the Shang Dynasty (ca. 1600–1050 BC) were motivated to systematically construct settlements and operate in the Jiangnan Area of the Middle Yangtze River drainage at least in part in order to control metal resources in the middle and lower reaches of the Yangtze River. Some recent studies are also revealing this; for example, some scholars found that the Middle Yangtze River Valley is tentatively identified to be the provenance of the copper used at the Early Shang Capital in Zhengzhou by studying lead isotopes in crucibles and a metal droplet unearthed in Zhengzhou. But, to what extent these same rulers affected the exploitation of other resources is an open question. I will investigate whether we can see evidence of top-down centralized control of ubiquitous resources necessary for everyday life in the region by focusing on the acquisition and use of stone raw materials used in this region.

Interwoven Networks: Obsidian Exchange and Overlapping Economies among the Ancient Maya of Western Belize

Studies of ancient Maya commodities have focused on elite control of economic institutions, yet goods were mobilized at different levels of the social hierarchy to support the growth of broader economic institutions. Here we present the results of portable X-ray fluorescence (pXRF) analyses of over 4,000 obsidian artifacts from Preclassic to Terminal Classic period (ca. 900 BC–AD 900/1000) contexts from four sites across the Belize River Valley region of the Maya lowlands (Baking Pot, Cahal Pech, Lower Dover, Xunantunich) to reconstruct economic networks within and between communities. Geochemical sourcing data are integrated into formal network analyses to explore to what degree ancient Maya obsidian economies were centralized, the extent to which they overlapped, and how these trends transformed through time. Commoner households possessed more homogeneous assemblages with fewer sources, likely obtained through decentralized exchange relationships. In contrast, more diverse assemblages with more sources of obsidian from higher status contexts reflect the development of more formal economic institutions during the Classic period. This study has broad implications for understanding differences in distribution and consumption of commodities between apical elite, intermediate elite, and commoners, and the transformations of their relationships in the Maya world over the *longue durée*.

Suarez, Nicholas [283] see Messinger, Emma

Suárez, Rafael (Universidad de la República, Uruguay)**[306]***Temporal Persistence of Spear-Thrower Use in Uruguay: Evidence from the Late Pleistocene and Late Holocene*

The plains of Uruguay are an appropriate place to investigate different aspects of lithic projectile technology used with spear-thrower and bow and arrow. During the initial settlement, we have recorded an interesting cultural diversity with at least four different designs of projectile points: Fishtail, Tigre, Pay Paso, and triangular non-stemmed, which must have been used with a spear-thrower. The chronological evidence suggests the beginning of this weapon system around the late Pleistocene (ca. 12,900 cal BP) and their extended during the early Holocene (ca. 10,300 cal BP). There is also direct evidence of spear-thrower use in Uruguay during the late Holocene (ca. 1800–1000 cal BP); some atlatl bone/antler hooks or spurs have been recovered in archaeological contexts, which are presented and discussed here. In addition, there are data that indicate the use of manufactured projectiles to be used with bow and arrow. It is not yet clear how the latest weapons system enters the region. This presentation discusses the broad temporal persistence, possible cultural transmission, and invention-reinvention of spear-throwers in Uruguay.

Suárez Calderón, Amanda (Dumbarton Oaks)**[188]***The Emergence of Social Complexity in the Precolumbian Socio-ceremonial Center of Java in Southern Costa Rica*

The settlement of Java is a precolumbian socio-ceremonial center located on a hilltop in the Coto Brus Valley, in southern Costa Rica. An intensive survey of the site revealed that the main occupation of the site occurred several centuries earlier than previously thought. Java is one of the largest settlements from the Aguas Buenas period, with an area of approximately 40 ha and a population between 400 and 800 people. In spite of the copious amounts of stone sculptures, petroglyphs, and possibly residential earthen mounds, the ceramic and lithic remains have the characteristics of a domestic assemblage and they show very little variation across the different sectors of the site. In other words, there are no indications of inequalities based on wealth accumulation or access to fine ceramics or specialized tools, which are often interpreted as status markers. Finally, the concentration of the population on the hilltop, the privileged view of the valley, and the clearly delimited layout of the settlement indicate a potential concern about the threat of violence. These results question long-held assumptions in the regional archaeology about the relationship between hierarchy and monumentality.

Suarez Gonzalez, Nathalie (Université Libre de Bruxelles), Lawrence Owens (University of Winchester), Gontran Sonet (Institut Royal des Sciences Naturelles de Belgique) and Peter Eeckhout (Université Libre de Bruxelles)**[53]***Characterization of a Multiple Burial Context from Pachacamac, Peru: Complementarity between Bioarchaeology and Molecular Archaeology*

Pachacamac is a major precolumbian site located on Peru's Central Coast. Covering approximately 6 km², the site was occupied for over a thousand years before the Spanish conquest in the early sixteenth century. In 2012, the Ychsma Project discovered a unique Late Intermediate period (AD 900–1470) multiple burial ("Cx4") made of two funerary chambers with a vegetal roof structure, containing over 110 intact and fragmentary deceased together with numerous grave goods. More than 60% of the individuals are subadults whose sex cannot be assigned using osteological observation. Among the adults, 23 females and 20 males were identified, and the sex of the remaining four individuals couldn't be assigned with certainty. We aim to fully understand the sociobiology of the Cx4 population, including biological sex, using a combined bioarchaeology and molecular archaeology approach. Despite significant human modern contamination and low amounts of endogenous ancient DNA, our results show that sex could be assigned genetically in >70% of the cases, including subadults. Sex identification of infants, children and adolescents is crucial to fully understand this complex context and its funerary recruitment, and to perform an integrated and holistic analysis of all associated data.

A Zooarchaeological Reconstruction of the Grand Feast of Plaza of the Columns, Teotihuacan

Offering D1 represents the residue of an extravagant feast, involving a plethora of artifacts, over 25,000 ceramic fragments, and more than 50,000 animal bones ceremoniously “killed” and discarded in a pit excavated in an old plaza floor. We present the zooarchaeological report of this assemblage, focusing on trying to understand the scale of public feasting at Teotihuacan. The volume and properties of the ceramics tells us this event was a state-sponsored feast that included many foreign diplomats, likely special guests, to commemorate the completion of the construction of Structure 25C, one of the three major pyramids at Plaza of the Columns. As most of the trash from this grand feast seems to be sealed in this offering cache, it provides an opportune context to reconstruct ancient cuisine and the role of feasting in alliance building, power negotiations, and social identity construction.

Materialization of Time, Space, Nature, and Societies Denoted by New Lidar Maps at Teotihuacan

Primary archaeological data indicate that the current reconstruction of the city of Teotihuacan was apparently built with a master plan around AD 200. Three major monuments were harmoniously integrated into a rigorously calculated city layout with functional and/or symbolic units including the Avenue of the Dead, plazas, administrative facilities, or residential compounds. We have mapped, excavated, and consolidated buildings since the 1990s, recording architectural features, sculptures, or murals with total stations, drone-mounted lidar, Slam-lidar, 3D scanners, and photogrammetric devices. To explore architectural principles, artistic aesthetics, and integrated ideological factors like worldview or concepts of time and space, we analyze populous urban zones, surrounding cultivation lands, and mountaintop areas of Cerro Gordo and Patlachique, where Teotihuacanos left their concerns to landscape and astronomy. Taking advantage of ArcAstroVR, a new astroarchaeology program built on Stellarium, we reconstruct ancient skylscapes with masonry buildings precisely defined by our maps and analyze the city’s standardized orientations, dimensions, and spatial distributions, often reflecting astronomical phenomena of particular periods and time. We particularly test previous interpretations of the city’s N-S and E-W axes and argue in archaeological contexts the sociopolitical implications of advanced astronomical knowledge and the invention of Mesoamerican calendar systems blueprinted at Teotihuacan.

Results of the Multiyear Study of the Ancient Maya Lithic Production Community of the Took' Witz Group at El Palmar, Campeche, Mexico

This paper presents the results of a multiyear research project at the lithic production community of Took' Witz, a hinterland group located near the ancient Maya city of El Palmar (Campeche, Mexico). Our research explored the large-scale utilitarian lithic production that occurred at the site, as well as the activities and material cultures at three individual households—the West, East, and South Plazuelas. We use these datasets to examine the impact that different degrees of involvement in lithic production activities had on the socioeconomic status of each household. The presentation will detail the 2023 excavations within and around the three plazuelas in conjunction with the data from previous surveys, shovel testing, and excavations at the group. We will report the construction sequences and the activities that took place in each household. Finally, the results of all these archaeological investigations at Took' Witz allow us to demonstrate differences in the production activities and spatial proximities to production areas corresponding to distinct economic statuses of each household.

Late Classic Marketplace Pottery Exchange in the Three Rivers Region

The understanding of Maya marketplaces has long been hindered by the lack of archaeological data to support their identification. The ceramic data presented here serves as one aspect of an overarching project that uses a configurational approach and a set of cross-cultural marketplace indicators to investigate the presence of an integrated regional market system in Three Rivers Region (TRR) during the Late Classic. The regional focus of this project provides for a more global view of artifact exchange. An important aspect of this research is to examine the comparability of goods among regional sites and households to identify supply chains. Neutron activation analysis (NAA) of selected sherds can provide an independent way of determining the potential existence of a market as well as a means of cross-verifying the data obtained from other types of analyses. In this paper, we discuss our hypotheses and preliminary analyses regarding the exchange of utilitarian as well as high-quality ceramic types between various sites in the TRR.

Cooking and Colonialism: Identifying Cultural Values and Identities in Consuming “Foreign” Goods in the British Atlantic World

Consumption, as a shared material practice, has frequently been examined by archaeologists to understand

the cultural dynamics in the distinction of groups that inform status, class, and identities. In the increasing integration of global exchanges across the Atlantic in the eighteenth century, this paper seeks to understand how nonlocal colonial goods were perceived, valued, and consumed in British colonies. This interest arises out of ongoing research that compares cultures of colonialism in the histories of two Atlantic ports: Spanish St. Augustine, FL, and British Charleston, SC. Given the contested and overlapping histories between these two cities in the North American Southeast, this preliminary research is interested in identifying how British colonists may have consumed Spanish goods in the eighteenth century, with implications for how the process of colonialism changed British colonists themselves. A survey of contemporary cookbooks, style guides, and personal correspondences can identify discourses on how Spanish goods (such as wine and chocolate) were considered and consumed in Britain and in Charleston, SC. The implications found in the consumption values of foreign goods are considered in comparison to the archaeological studies of the eighteenth-century British colonies that often emphasize a close adherence to their metropolitan influences.

Late Classic / Early Postclassic Chiapanec, Zoque, and Maya Socioeconomic Interaction in and around the Chiapas Central Depression: Further Interpretations of the Results of an Instrumental Neutron Activation Analysis of Clay Sources and Paste Recipes in Fine Orange Ceramics

The Late Classic through Postclassic transition in Central Chiapas, ca. AD 750–900, was a time of dynamic change in population, social, and political organization, some of which was incurred by the entry of the Chiapanec people into the Central Depression. The Spanish conquistadors, arriving in the area some six centuries later, described the Chiapanec as dominating their Zoque neighbors and in frequent conflict with Maya groups in the neighboring highlands. This paper investigates the socioeconomic organization of people in the Central Depression and their relationship to neighboring groups at the Late Classic–Postclassic transition, through an instrumental neutron activation analysis (INAA) of fine orange pottery samples. We interpret variation in paste recipes as the result of craft production using a variety of local clay sources, and occasional exchange of vessels from the Jovel Valley. The results of this analysis suggest some interesting features in the socioeconomic organization of the region during this period.

Grain Size Variation and Culinary Traditions: Insights into Prehistoric Food Globalization in Eurasia

Over the past 15 years, research into prehistoric food globalization has shed light on the timelines, routes, and tempos of crop diffusion across the Old World. This diffusion not only involved the spread of plants but also the reproduction and transformation of cultures, technologies, and ideologies associated with staple crops in diverse ecological and socioeconomic settings. Recent studies have delved deeper into this complex process, exploring culinary traditions, agricultural strategies, and labor organizations, among other factors. In our study, we examined published morphometric data on foxtail and broomcorn millets, wheat, and barley from the late fourth to the first millennium BC. Our findings reveal a consistent cross-taxonomic trend in grain-size changes along a longitudinal axis. Grains tend to compact when moving eastward and enlarge when moving westward across Eurasia. We argue that this phenomenon reflects profound differences in culinary traditions between Eastern and Western regions, rooted in Upper Paleolithic practices. Western Eurasian

culinary traditions historically favored larger grains for grinding and baking, whereas Eastern Eurasian culinary practices preferred smaller grains suited for steaming and boiling. This culinary preference likely played a crucial role in shaping the observed grain size variations across Eurasia in our study.

Settlement Construction and Craft Production: Recent Discoveries at the Panlongcheng Site

The Panlongcheng site was the largest urban settlement in the middle Yangtze River during the Xia and early Shang period (1500–1300 BC). In recent years, the joint archaeological expedition has carried out archaeological excavation at the Yangjianwan North and Wangjiazui locus of the Panlongcheng site. The new discoveries in the two loci reveal the shift of the core of the Panlongcheng settlement from south to north and different settlement patterns. Meanwhile, through typology, petrography, and X-ray fluorescence analysis, we explore the craft production in Panlongcheng, especially relating to its cultural characteristics, to identify the choices of technique and resources for pottery we excavated. The new discoveries of Panlongcheng site provide clues for recognizing the structure and changes of the urban settlement in early Bronze Age, researching pottery production and its associated cultural interaction.

Jeanne's Legacy and Indigenous Archaeology at Tlaqayamú (CA-SCRI-330)

Jeanne's excavations at tlaqayamú (CA-SCRI-330) yielded detailed information about bead-making on limuw (Santa Cruz Island, CA) in the centuries before Spanish colonization. Two of the important classes of artifacts that underpinned the conclusions she presented about life at tlaqayamú include shell-bead production detritus and sea grass cordage. Today, a multi-tribal Chumash group draws on her work analyzing these materials to revitalize indigenous knowledge there, exploring craft production and the occupational history of the site. Excavation in the fall of 2022 recovered sea grass cordage and shell artifacts from a cliff-side test unit. Analysis and interpretation is ongoing at Cal State Channel Islands. This talk describes the process of incorporating Jeanne's methods and conclusions to address community-based questions, of designing the excavation methods to recover material from a delicate location at the site while preserving its integrity, and of the rich possibility for future indigenous archaeology across limuw enabled by Jeanne's meticulous approach and uncompromising standards for analysis.

Papa's Work Is Not Fathering

Stereotypes and concomitant expectations for priority setting in archaeological careerism exist in tension with deep anthropological drives to understand and embody family ideals. Archaeologists, long confronted with the idea that “engendering archaeology” (cf. Conkey and Gero 1991) meant we must grapple with the ways we pigeonhole actors in the past as well as agents of present theory and practice, have made tremendous strides with the former but little progress with the latter. Rather, unspoken gender ideologies persist and are policed in our discipline, constraining potential expansions of how we define and value nurturing roles filled by its practitioners, and continue to afflict role-modeling for the next generation of archaeologists. Personal reflections of a father seeking to chart a career in archaeology and not lose sight of what's most important include critical interventions by colleagues, friends, family, and community partners via coalition building and support networks at home, work, and in the field. Possibilities and potential for “Papa's work” are grounded not only in where one is from but also anchored in family and community futurities.

Chimú-Era (AD 1000–1450) Child Sacrifices from Pampa la Cruz-Montículo 1, Episode 3, and Pampa la Cruz-Montículo 2: Biodistance Comparisons with Other Chimú Sacrifices and Regional Skeletal Populations

In recent years, hundreds of Chimú-Era child sacrifices have been discovered at locations to the north of the Chimú's capital—Chan Chan—by the Programa Arqueológico Huanchaco. Here we report on biodistance results for 22 recently excavated child sacrifices from Pampa la Cruz-Montículo 1, Episode 3 (~AD 1220–1300), and 39 individuals from Pampa la Cruz-Montículo 2 (est ~AD 1000). Population structure and biodistance analyses indicate that the children from these contexts, like those previously reported from Pampa la Cruz-Montículo 1 Episodes 1, 4, and 5, are highly variable and unrelated to a local Chimú-era sample and seven additional comparative samples from the region. However, temporal trends in the data suggest that the children represented by these samples became increasingly variable through time. We discuss the implications of these results as they relate to the Chimú Empire's expansion and their ritual expressions of power and dominance over conquered peoples.

Life and Death of a Middle Preclassic Individual from Aguada Fénix, Tabasco

We explore a Middle Preclassic skeleton from the site of Aguada Fénix, Tabasco. It is one of the scarce cases of the early temporality in the Maya area. We first describe in detail its archaeological context and osteological sex and age-at-death and infer the individual's social role. We evaluate his oral and skeletal pathologies and compare them with two later Classic burials found at a nearby site, El Tiradero. We found his megalithic use based on these assessments. Finally, we examine the post-sepulchral alteration according to the distribution of the skeletal elements in the burial context.

Social Connections Near and Far: The Role of Local and Exotic Goods in the Emergence of Complexity on Cyprus during the Prehistoric Bronze Age

The presence of international goods has long been a signifier of social complexity on Cyprus, but the accumulation of local goods and interregional imports may be equally as important for understanding the formation of hierarchical social networks during the Prehistoric Bronze Age (2400–1700 cal BC). This period marks the transition from undifferentiated social systems to urban, hierarchical systems with higher levels of wealth inequality. Studies have shown that though Cyprus is small, regional differences appear in the material culture, and trade is apparent between communities on the North Coast, Central Plain and South Coast. This paper explores the role of local goods as a proxy for differential control of resources within a community, and interregional imports as a proxy for participation in intra-island trade networks in the emergence of social complexity on Cyprus during this period. These proxy data obtained from mortuary contexts are statistically analyzed to determine the scale of access to local resources and participation in trade networks, and the results are used to determine the network models that best describe the social system. In approximating social network configurations, the role of local and imported goods in the emergence of complexity is determined.

Ancient Genomics Is Archaeobiology

Archaeo- or paleoethnobiology is the study of how humans interact with their environment; the most extreme and intimate expression of this relationship is domestication. Domesticates are not only a biological organism, with their own unique evolutionary trajectories that they bring into domestication, but they are also a cultural artifact, their genomes shaped by millennia of human values and practices. Genomic analysis, incorporating ancient samples, allows us to infer past networks of trade and exchange, human movements and the cultural values and practices of the people who shaped modern agriculture.

The Aesthetics and Poetics of Infrastructures in Ancient Andean Urbanism

Social scientists have stressed the invisibility of modern infrastructures, whether roads, irrigation systems, or hidden electrical wires and plumbing. They have argued in turn that as a system of interconnected substrates, infrastructures recede to the background and become the subject of conscious reckoning primarily when they fail or breakdown. However, infrastructures in both pre-industrial and contemporary societies often form critical nodes of larger religious landscapes, and they become key sites of urban spectacle. Inspired by the theories of Rancière, Larkin, Lefebvre, and others, this paper examines the seamless interconnection of architecture, religious aesthetics, and infrastructures in Ancient Andean cities and elsewhere. It also critiques the archaeological tendency to ignore the performative aspect of construction projects—often highly visible, politically charged, and protracted affairs. In the end, infrastructures played a central role in the constitution of ancient urban subjects not simply by prescribing movement or controlling access to resources but by wedding the aesthetics of place with religious cosmology, imagination, community self-esteem, and sentiments of empowerment.

Kura-Araxes Herding Practices in Early Bronze Age Armenia

In this paper, I present an analysis of Early Bronze Age (EBA) faunal remains from field investigations conducted between 1998 and 2018 in the Tsaghkahovit plain of northern Armenia by the joint Armenian-American Project for the Archaeology and Geography of Ancient Transcaucasian Societies (Project ArAGATS). The vast majority of Project ArAGATS's EBA fauna was recovered from the well-documented site of Gegharot. Excavations at Gegharot revealed an agropastoral village, with other lines of evidence indicating a minimally differentiated social structure. This paper examines Kura-Araxes egalitarianism from the perspective of Gegharot's faunal data. Identification of differential status may be possible through context specific analyses, e.g., comparing between houses or areas of the site and identifying consumption of limited parts of the animal vs. consumption of whole animals, or by consumption of hunted animals vs. reared animals. The site includes well-defined Early Bronze stratigraphic layers, distinguished by distinct Kura-Araxes ceramic complexes, allowing for the investigation of change over time in herd composition and management. I specifically examine the data for distinct herding practices between and within taxa in order to assess whether distinct herds of animals can be identified in the faunal record.

Negotiating with Empire: The Chancay as "Intermediaries" in the Inka-Chimú Conflict

During the Late Intermediate period, the north-central coast of Peru was inhabited by a number of small but dynamic polities, or *señoríos*, that were actively engaged in interregional networks of trade, intermarriage, and warfare. However, even though the north-central coast was sandwiched between the Chimú and Inka, we know relatively little about how the *señoríos* who inhabited this region interacted with or were incorporated into these late prehispanic empires. This paper argues that, rather than be passively absorbed into the Chimú or Inka's rapidly expanding spheres, at least some of these groups actively negotiated their own terms of engagement with these growing imperial powers. Specifically, the author examines how one of these *señoríos*, the Chancay, may have leveraged their position as merchants to at least partially resist both Chimú and later Inka advances. Using recent excavation data from the Chancay site of Cerro Blanco in the Huanangue Valley, Peru, as well as ethnohistoric data from the Justicia 396, and the *Historia Anonima de Trujillo*, this paper examines the ways in which this small, but potentially ambitious community of merchants may have been drawn into the wider Chimú-Inka conflict and yet emerged unscathed through advantageous alliances on both sides.

Macrobotanical and Microbotanical Evidence for Plant Use and Consumption at Gede, Kenya

Over the last several decades, excavations at numerous Swahili period sites along the East African coast have yielded a wide variety of data on economic and cultural practices during the last millennium BP. The results of intensive flotation recovery of macrobotanical remains from pit latrine sediments at housing structures are

presented, providing direct evidence of the consumption of a variety of plant types by elite populations at Gede during the fifteenth–eighteenth centuries CE. We further provide data from pollen/phytolith washes of ceramic remains associated with elite burials at Gede, which suggest not only the presence of goods interred with the dead during this period but also offer insight into the symbolic importance of specific food types in funerary practices at this location.

Using Paleoenvironmental Data to Learn about Past Inuit Societies: A Case Study from the Rising Whale (KTZ304) Site at Cape Espenberg, Northwest Alaska

To precisely contextualize and date climate variations and practices related to living spaces at the onset of the Little Ice Age, archaeoenvironmental analyses were conducted within a winter dwelling (Feature 21) at the Rising Whale site, Cape Espenberg. Two high-resolution datasets were employed: tree rings and insect and plant macrofossils, both benefiting from exceptional permafrost preservation. In this tundra landscape where driftwood from interior Alaska is the main wood resource, a 1,000-year-long tree-ring 1940s legacy chronology for northwest Alaska remains the yardstick for dendrochronology and paleoclimatic inferences. Tree-ring dating of 19 white spruce architectural elements in combination with high-resolution radiocarbon wiggle-matching yielded seven precise calendrical dates, refining and confirming that the construction and occupation of F-21 fell after AD 1265. Identified seed (archaeobotany) and insect (entomology) remains from within the house established local resource use(s) and space management within this refined chronology. The accumulation of necrophagous and detritivorous insect remains indicates storage spaces or dumps areas for organic matter of animal and plant origin consumed by the inhabitants, while the presence of characteristic tundra insects and plant seeds indicates local resources collected in summer and eaten or used in the construction and maintenance of the dwelling.

Puffin Heads and Albatross Limbs: An Examination of Avifaunal Usage from the Rat Islands, Alaska

Human groups have used birds in a variety of ways, from food, to raw material for tools, to clothing. In addition to their more practical usages, birds often play a significant role in cosmologies and myths. However, due to poor preservation and excavation bias bird remains have only recently begun to be studied in depth. The archaeological sites of the Aleutian Islands have very large avian bone assemblages due to excellent taphonomic conditions which allows rigorous study from which we can study not only local relationships with birds but also develop models for other times and places. Comparing the patterns of archaeological skeletal part representation with oral histories and ethnographies reveals the interplay of the symbolic and 'material' aspects of the relationship between birds and the residents of the Aleutian Islands. This presentation will examine a case study from KIS-050 and RAT-31 to examine how skeletal part representation can vary greatly even within island groupings and can reveal cultural and environmental changes. Specifically, the presence of puffin heads at KIS-050 versus the abundance of albatross head/parts at RAT-31 illustrates how avian use varied between the islands due to cultural factors and site usage.

Biogeography of Hunter-Gatherer Diet

Anthropologists have long recognized latitudinal pattern in hunter-gatherer diet, where plant use increases toward tropics. However, causes of the dietary variability remain unclear reflecting the fact that ecology in general lacks robust theory for predicting geographical variation in the balance of plant and animal foods that omnivores consume. Here, we use large ethnographic data to gain insight into the causes of global-scale variation in hunter-gatherer diet composition by analyzing its relationship with environmental variables that reflect the availability of resources and with metrics of population pressure. Our results show that climate and other environmental factors are clearly more important than demographic factors in explaining large-scale diet variability. We also compare the patterns observed in hunter-gatherers to patterns of diet composition among other mammals. Our results show that a latitudinal gradient of increasing plant use toward lower latitudes is a general phenomenon among omnivorous mammals. Furthermore, we find that geographic variation in hunter-gatherer diet mirrors patterns in the functional composition of mammal communities globally. Together, our findings indicate that the environmental factors shaping the feeding ecology and distribution of mammals generally have been a dominant force in driving resource use in hunter-gatherers.

Talley, Dania (Oakland Museum of California)**[15]***“Too Hood for This”: Navigating the Profession of Archaeology and Finding My Place*

I found my roots in archaeology in undergraduate school during an archaeological excavation at the Stewart Indian School in Carson City, NV. It was an empowering experience. It was the first time I witnessed a BIPOC community having autonomy over their historical narratives. It also brewed a sense of rootlessness in me as an African American from the hood. Indigenous history, knowledge, and lifeways can be unearthed anywhere in the United States, but this is not the case for African Americans. The archaeological experience I had in Nevada encouraged me to pursue archaeology if it meant that I, the African American, could have a voice in the historical narratives of Black people. This collaborative experience was enticing, but it isn't always the reality of archaeology and I found myself being “too hood” for the profession. But my personal experiences and professional experiences have influenced how I approach my work offering nuanced ways of thinking and taking archaeological practices back to the streets and into BIPOC communities.

Tamez-Galvan, Evan [13] see Ochatoma Cabrera, Jose

Tamura, Kohei (Tohoku University)**[308]***Macroscopic Comparative Studies of Archaeological Data: Spatiotemporal Variability in Lithic Technology of Paleolithic Asia*

Comparative studies using archaeological data on a broad spatiotemporal scale can provide an overview for investigating significant questions in human history and can promote discussions among scholars from different disciplines. This talk will present the results of a quantitative analysis of lithic technologies from the PaleoAsia Database, developed as a part of the “Cultural History of PaleoAsia” project. The database comprises information about the presence or absence of 24 distinct lithic technologies across 895 lithic assemblages spanning from 130 to 20 ka, along with spatial, temporal, and other archaeological information. Our analysis identified and visualized spatiotemporal variations in lithic technologies, potentially linked to the dispersal of modern humans. For instance, the frequencies of blade/bladelet production and microlithic tools concurrently increased primarily in the north of the Himalaya Mountains, even though the occurrence of these technologies exhibited a mosaic pattern in northern China. However, large-scale comparative studies have various limitations, including issues in developing a unified coding scheme and sampling biases. We will further present our attempts to address these issues, including geometric morphometrics and simulations using data from the Japanese archipelago.

Tang, Yiyi (Dartmouth College), Jiajing Wang (Dartmouth College), Liu Li (Stanford University) and Wei Chen (Hubei University)**[51]***Local Adaptation and Subsistence Strategy of Yangshao Migrants in Northwestern Sichuan in China during the Middle Neolithic (5300–4700 cal BP)*

Migration is a frequent phenomenon in human history. Previous studies mainly used migration as a general term to explain any cultural changes observed in migrant communities. Recent studies, however, have recognized that migration is embedded in both environmental and social contexts, thus making it necessary to study the consequence of migration on a case-by-case basis. To better understand the changes associated with migrational processes, this case study investigates the subsistence pattern of a Neolithic site, Liujiazhai, in Northwestern Highland Sichuan by employing microbotanical residue analysis on pottery vessels. Our results contain millet phytoliths and thus contribute to the overall picture of millet agriculture in Yangshao and Majiayao migrant communities and enrich our understanding of how varying crop patterns in Neolithic western China are likely a consequence of migration. In addition, we suggest that Liujiazhai migrants adapted to the high-altitude environment by adopting more local wild plant resources. This study shows that, although Yangshao migrants were still connected to their homeland in terms of material culture, relocating to the challenging environment in

NW Sichuan required adaptive strategies that distinguished the Yangshao migrants, including those at Liujiazhai, from their home culture. Hence, this study exemplifies how migration is an agent of change.

Cerro Malabrigo y el resurgimiento de la monumentalidad prehispánica en Chicama, Costa Norte del Perú

Desde el año 2020, el Programa Arqueológico Chicama (PRACH) ha realizado prospecciones sistemáticas y excavaciones en el valle de Chicama y área relacionadas. El objetivo principal es explicar la historia de la ocupación humana y los fenómenos sociales vinculados a tales poblaciones. Nuestras investigaciones han demostrado que una serie de temas y fenómenos sociales todavía quedan por investigar y comprender. Un ejemplo de ello es la presencia de monumentalidad arquitectónica prehispánica. De este modo, en esta ponencia describimos nuestra investigación sobre una de las estructuras monumentales prehispánicas más antiguas en el Cerro Malabrigo, ubicado al norte del valle Chicama. Este sitio es representativo de un proceso previamente poco teorizado del resurgimiento de la arquitectura monumental en el área de Chicama a principios del período Intermedio Temprano (200 aC-600 dC). Presentamos los resultados de nuestras excavaciones, incluido un análisis del inventario de artefactos, y fechados radiocarbónicos de esta estructura monumental. Finalmente, discutimos una serie de correlaciones sociales y temporales, así como la relevancia de Cerro Malabrigo dentro del proceso histórico precolonial.

Stingless Beeswax in Mesoamerican Investment Casting Processes

Mesoamerican metal objects have been studied in-depth in terms of alloys and production techniques, but little work has focused on the foundry materials used in the prehispanic casting process. In modern foundry practice, synthetic waxes, paraffins, or processed European honeybee wax (from the *Apis* genus) are commonly used as pattern materials for lost-wax (or investment) casting. In the Florentine Codex, Sahagún describes a copal-wax mixture as pattern materials of the Aztec. This paper evaluates the combination of various species of stingless beeswaxes and copal species, in terms of thermal, mechanical, and rheological properties of these blends, and their applicability in casting. *Melipona beecheii* is a genus known to be cultivated by the Maya, but other stingless bee genera—like *Trigona* and *Frieseomelitta*—also inhabit the Maya area. Ethnohistorical sources describe widespread meliponiculture in prehispanic Mesoamerica at Spanish contact. Meliponiculture was common in Northern Yucatán where its products, honey and beeswax, were exchanged as commodities and used to pay provincial taxes. Archaeological evidence suggests that lost-wax casting formed an important component of Postclassic period Maya metallurgical technologies at the urban centers of Mayapán and Lamanai, including metallurgical ceramics and production debris. Beeswax was a prerequisite to developing these technologies.

Tarrant, Damon (Simon Fraser University)**[236]***Chair***Tarrant, Damon (Simon Fraser University), Laura Yazedjian (British Columbia Coroners Service) and Michael Richards (Simon Fraser University)****[236]***Application of Dietary Isotopes to Questions of Medicolegal Significance*

Isotopic analysis of human remains has been used in archaeological and forensic contexts to examine diets, mobility, and the geographical origin of individuals (Bartelink and Chesson 2019). We applied dietary isotope analysis, a method more commonly applied in archaeological science research, to 30 unidentified human remains from British Columbia, Canada, to explore whether this relatively inexpensive method can be used to separate out archaeological and modern (forensic) human remains. This project was on behalf of, and in collaboration with, the British Columbia (Canada) Coroners Service. We extracted bone collagen and measured carbon, nitrogen, and sulfur isotopes in the Archaeology Isotope Laboratory, at the Department of Archaeology, Simon Fraser University, Canada (Longin 1971; Brown et al. 1988; Collins and Galley 1998). Using K-means cluster analysis, the results clustered into two distinct groups; archaeological or contemporary. Radiocarbon dating was then used to confirm the findings of the isotope analysis and to ensure the correct attribution to the modern or archaeological clusters. Cases considered to be archaeological are returned to local communities for reburial, while those determined to be contemporary indicate possible forensic cases. This study shows the utility of applying methods mostly used in archaeological science to forensic research.

Tarry, Sarah, Reagan Hoehl and Erlend Johnson**[104]***Exploring Kisatchie's Deep Past: Findings from Site 16VN3416*

This poster presents the findings and analysis of artifacts from a 2 × 2 m excavation unit at site 16VN3416 in the Calcasieu Ranger District of Kisatchie National Forest. A large number of diagnostic lithic artifacts were recovered from this unit, spanning the millennia from the late Paleoindian period (10,000 BCE) through the Woodland period (1200 CE). The excavation encountered significant soil disturbances, bioturbation, and long-term taphonomic processes that complicate interpretations of archaeological contexts. Nevertheless, the density and diversity of diagnostic lithics from this unit can contribute to an understanding of 12,000 years of Native American lifeways in this region of western Louisiana. The fieldwork at site 16VN3416 also highlights the ongoing effects of tree falls and fires in Kisatchie National Forest, events that are likely to be worsened by climate change.

Tartaron, Thomas (University of Pennsylvania)**[17]***Linking Multiple Scales in Time and Space: Small Worlds and World-Systems Analysis*

This contribution proposes that world-systems analysis could benefit from greater consideration of a local-scale, or "small world," perspective. These maritime and terrestrial small worlds, defined by face-to-face interaction and often deeply embedded social and economic ties, are building blocks that can illustrate key aspects of how local-scale entities are constituted and how they might operate within a world system. Particularly, at this scale, we can observe the variability in the way that small worlds operate internally (e.g., hierarchically or heterarchically) and how they form linkages to external worlds, using a network approach that identifies the strong ties that bind them and the weak ties that link them to other (often larger) networks. It is also to be recognized that many small worlds within zones, such as the Aegean, that are engaged in the interactions that define a world system, are marginally or not at all integrated into those world systems. Several examples from the Bronze Age Aegean illustrate potential insights that might be derived from the small world perspective.

Concealed Archaeology of Kazakhstan: An Early Neolithic Burial from Koken

The period prior to the emergence of agriculture and pastoralism is one of the most understudied and least deciphered time periods in Eurasian steppe archaeology. A shortage of stratified or well-preserved early Holocene campsites means that our knowledge of this period heavily relies on lithic assemblages not always with associated ¹⁴C dates. Contrary to this norm, our excavations at the site of Koken in the semiarid steppe zone of eastern Kazakhstan recently uncovered stratified Stone Age deposits underlying a Bronze Age settlement. Within these earlier layers, our team has further discovered a paired human burial dating to the mid-sixth millennium BC. The Koken burial represents the earliest known, and directly dated, human remains within all of Kazakhstan, and hence offers scholars an exclusive opportunity to examine hunter-gatherer dispersals, lifeways, and population composition prior to the appearance of food producing economies in the region. In this paper, we consider the Koken site layout and contents as well as consider its potential utilization and social networks with other hunter-gatherer complexes of Eurasian. On a preliminary basis we position the early Neolithic burial from Koken within the thin landscape of its regional contemporaries in Baikal and Mongolia.

Use-Wear Insight into the Chipped Stone Plant-Processing Toolkit in the Lower Pecos Canyonlands

The focus of this research was to analyze potential plant-processing chipped stone tools from several rockshelter and terrace sites in Eagle Nest Canyon within the Lower Pecos Canyonlands of southwest Texas, excavated by Texas State University from 2013 to 2017. The chipped stone tool assemblages' evidence heavy plant polish on both informal and formal tools. Archaeological evidence and ethnographic accounts from the greater Southwest and Mexico show that sotol and agave lechuguilla were important plant resources, processed in intensive earth oven facilities and used as a major fiber resource. However, the Lower Pecos lacks a formalized identification and analysis of the chipped stone tool assemblages associated with these plant-processing activities. Is there a correlation between informal or formal tool type and tool function? Were tool types used for singular or multiple activities? I will present a use-wear analysis of these plant-polished tools, analyzing wear patterns from experimental and archaeological assemblages in order to provide insight into the prehistoric chipped stone plant-processing toolkit.

Un balance crítico del estudio del género en la arqueología peruana

¿Ha sido el estudio del género un campo de estudio sistemático dentro de la arqueología peruana? ¿Cuáles han sido los enfoques teóricos y metodológicos empleados? Y ¿qué tipos de contexto arqueológico se han empleado para dichos estudios? Por medio de la siguiente ponencia planteamos hacer un recorrido analítico sobre cómo ha sido abordado el estudio del género en el Perú prehispánico e identificar su impacto dentro de las interpretaciones realizadas por lxs arqueologxs sobre e las poblaciones prehispánicas. En esta ponencia buscaremos generar una visión historiográfica sobre como esta corriente teórica ha impactado en nuestra arqueología y como se ha reinventado en mano de arqueologxs locales y extranjeros.

Culturally Appropriate Collections Stewardship: Creating an ICC Guide

For centuries, museums and academic institutions have acquired and amassed Indigenous cultural items for their own use and benefit with minimal consideration from descendant communities. The values expressed in stewarding those collections resonate throughout an institution. The Indigenous Collections Care (ICC) Working Group, established in 2021, advocates for stewardship approaches that privilege Native American knowledge and center concepts of culturally appropriate care for items in institutional collections. To meet these goals, the ICC Working Group is creating a guide, which will be a reference tool for institutions that interact regularly with indigenous collections. The guide will not teach museums how to specifically care for each item, since these vary among each community. It will instead offer achievable considerations and templates for implementation, advocacy, and creation of policies and procedures. This guide does not replace consultation or the repatriation process—instead, it is meant to help guide those conversations and provide a framework. The ICC Guide is contributing to and amplifying a fieldwide reimagining of how, and for whom, collections are stewarded.

Early Domestic Horse Exploitation in Southern Patagonia: Archaeozoological and Biomolecular Evidence from Chorrillo Grande I, Argentina

The introduction of domestic horses following Spanish colonization transformed Indigenous societies across the grasslands of Argentina, leading to the emergence of specialized horse cultures across the Southern Cone. However, the relatively late establishment of permanent European settlement in Patagonia means that the dynamics of this introduction are poorly chronicled by historic records. Here, we apply archaeozoological and biomolecular techniques to horse remains from the site of Chorrillo Grande I, located in the Río Gallegos middle basin in the steppes of southern Argentina. Osteological and taphonomic analyses of these

horse remains suggest that horses were raised and used for food by Aónikenk people before the onset of permanent European settlement in the region, as early as the mid-seventeenth century. DNA-based sex identifications suggest consumption of both male and female horses, while residues from a ceramic sherd also show consumption of guanaco products. Sequential isotope analyses on dentition from the oldest specimen in the assemblage reveals an origin for the animal in southern Patagonia and, within this region, suggests the movement of these animals between the Río Coig (Coyle) and Río Gallegos basins. These results reinforce emerging evidence for extremely rapid and Indigenous-mediated dispersal of the domestic horse in the Americas.

Ambiguous Archaeology: Eating and Ceramic Styles in the Early Modern Caribbean

This paper underscores “ambiguity” and duality as pervasive factors in archaeological research through a case study of coarse earthenware from La Soye, Dominica. Within this framework, I concentrate my approach on syncretic foodways and ceramic productions, which blend, confound, and subvert straightforward interpretations. Using the material culture as a guide, I explore the fuzzy multitudes of Indigenous and colonial life. Specifically, I analyze local ceramics from three coastal loci—each within 1 km of La Soye Point. Early modern Dominica was an illicit colonial frontier and free Indigenous stronghold, making it an ideal space to analyze cultural ingenuity and maintenance in ambiguous environments. While our exact interpretations of the La Soye complex are in flux, the first locus is a probable Indigenous trade center occupied in the mid-seventeenth century. The second locus is a village site contemporaneous with the aforementioned trade center, and the third is a much earlier site from the late Saladoid or early Troumassoid period. The historical depth of these loci allows me to assess the impact of Kalinago, African, and European culture on Caribbean cuisine while understanding the power of ambiguity in frontier spaces.

Life, Death, and Renewal: Examining the Significance of Lowland Maya Sweat Baths in the Belize River Valley

Although sweat baths were an integral form of architecture in ancient Maya communities, these special architectural features have received limited attention from Maya scholars. In this poster, we address this omission through the examination of four recently discovered sweat baths from the sites of Baking Pot, Cahal Pech, Pooks Hill, and Xunantunich in the upper Belize River Valley. To understand the significance of sweat baths in this lowland Maya subregion, we address the following questions: What is the spatial context of sweat baths in western Belize? What were the sociocultural and ideological significances of sweat bath use in ancient Maya society? How do the uses of sweat baths in the Belize Valley compare to those in other regions of the Maya area? The value of this regional approach, as well as the sample size (four sweat baths), provides a more informed understanding of the significance and use of sweat baths in the upper Belize Valley specifically, as well as in the lowland Maya area in general.

Terlep, Michael**[264]***Conjoined Twins or Alternative Personas: An Analysis of Polycephaly within Southwest Rock Imagery*

Researchers, most recently Crown and colleagues (2016), have long highlighted the significance of polydactyly (having more than five digits on a hand or foot) within rock imagery and material culture across Mesoamerica and the American Southwest. Anthropomorphic and zoomorphic figures displaying polycephaly (multiple heads) is another frequent depiction across Mesoamerica and American Southwest rock imagery and material culture. While we currently lack paleopathological cases of polycephaly and/or conjoined twins in North American prehistory, such individuals would have likely held considerable importance and status. Globally, medical reports and artistic renderings of polycephaly/conjoined twins date back at least 2,000 years and were often incorporated into mythology. Alternatively, polycephalic depictions may reflect dual or multiple symbolic or pragmatic roles, genders, or personas of individuals within a community. This presentation explores depictions of polycephaly within Southwest rock imagery and proposes that such imagery reflected actual or allegorical accounts of conjoined twins or alternative personas.

Terrell, John (Field Museum of Natural History)**[323]***Archaeology, History, and Modeling the Past: Neglected Assumptions*

For archaeologists, finding something from the past is more than its own reward. When what they have “recovered” can be interpreted as playing plausible roles in convincing historical narratives, they have reason to believe they are doing something extraordinary: fleshing out our ignorance of history with factual evidence of what may have truly happened. For several decades now, some archaeologists have championed using social network analysis (SNA) to tease out statistically how the relative spatial positioning of things, places, and people may have informed what could (or couldn't) have happened in the past. Last year my colleagues and I introduced an alternative strategy for using relational analysis in archaeology and other historical sciences. Instead of reconstructing spatial ties as the principal goal, we argue that relational thinking can be used to develop testable hypotheses about covariation and causal patterning. While the hypotheses considered can be about how differing spatial relationships could have been instrumental in the past, they need not be. Using the modeling strategy we call dynamic relational analysis (DYRA), they can also be about relationships—causal contingencies—of many forms among things, places, and people.

Xochicalco and Teotenango: New Approaches on Their Interactions (750–1150 CE)

Since the 1950s, Xochicalco (Morelos) and Teotenango (state of Mexico) have been constantly compared and assumed as two Epiclassic cities. The hypothesis of their contemporaneity and interaction is derived from their similarities in terms of location, visual culture, sculptural style, and glyphic system. However, upon reviewing and approaching the data provided by archaeological research in a more systematic way, there is a remarkable series of differences in terms of chronological sequence, spatial organization, and ceramic and lithic material, among others. The examination of the available visual and material culture leads us to consider that, if there was an interaction between these two sites, it was in the Xochicalco–Teotenango direction and, furthermore, other sites in the southern region of the State of Mexico and the Toluca Valley (such as Santa Cruz Atizapán and Malinalco) had a fundamental role in these relationships. Xochicalco and Teotenango shared features that are present in several city-states that were part of the Epiclassic network of the central Altiplano, such as Cacaxtla-Xochitécatl and Tula Chico, but also toward the east and north.

Partnering with Descendant Communities: Investigating the Dorsey Site, an 1874 African American Farm in Sugarland, Maryland

The current symposium explores how professional archaeology is changing. In the past 25 years, we have increased partnerships, and collaboration, with descendant voices changing the practice of archaeology. Toward that end, in 2020 the Sugarland Ethno-History Project (SEHP) leadership initiated the investigation of the Basil and Nancy Dorsey's 1874 smallest farm in Sugarland. Sugarland, Maryland, is one of the best-documented historic African American communities in the county. Founded in 1871, Sugarland once boasted a church, a community hall, a US Post Office, a grocery store, and a school. In 2020 the SEHP published its history in a book and the following year published the first Dorsey Site Archaeology Report, a virtual exhibit and walk-through, as well as an Archaeology Curriculum Module for K–12 teachers. Working closely with the SEHP Board and Sugarland Descendants, I was able to incorporate their voices into reports and curriculum. Working together meant we imparted to young people the realities of thriving in an early African American community. By interpreting the Dorsey Site, we enhance Sugarland's written history and broaden the conversation to include contributions African American people made to society.

Extending Teotihuacan's Past: Ceramic Insights from Lidar-Based Surface Survey

In this presentation, we will explore the density patterns of ceramics in the Teotihuacan Valley, from the Patlachique phase to the Mexica occupation. Our research is based on an initial ceramic analysis conducted using a recent lidar-based surface survey. To manage and visualize the density maps more efficiently, we integrated the collected data into a geographic information system. We aim to offer a fresh perspective on the relationship between the distribution of ceramics and the topography of the Teotihuacan landscape, given that the collected materials are linked to the lidar map. We have already tested the Patlachique Phase, and we observed a shift in the occupation's elevation during that phase, followed by significant variations in subsequent ones. The close connection between the collected materials and the lidar map offers new

information that may not have been clear previously. With the lidar map covering most of the Teotihuacan Valley, our vision extends beyond the ancient city's core area, allowing us to reinterpret the connection between the central area's primary occupation and its peripheries.

Thacker, Paul (Wake Forest University) and Carlos Periera (Câmara Municipal de Rio Maior) [29]

Castros and Cordage: Recognizing Contextual Evidence of Iron Age Practice at São Martinho

Castro settlements, prominent from the Late Chalcolithic through the Iron Age in western Iberia, are often described as hillforts or defensive hilltop villages. The delineation of sites as *castros* often influences archaeological interpretations, bolstering focus on the strategic advantages of the geographic settings for population and herd protection, resource and network access, landscape control, or projections of political power. Excavations at Castro de São Martinho in central Portugal have revealed that spinning and cordage production were important components of the everyday secondary products economy, findings that challenge the potential reductionism of location-driven narratives. While direct recovery of fiber artifacts is extremely rare due to basalt-derived sediments, spindle whorls were found in most excavation blocks at São Martinho. This presentation explores the context of a spindle whorl set associated with a large firepit feature that included abundant macrobotanical remains of inedible, poor-burning flowering and shrub plants. Local ethnographic investigation and experimental replication indicate that some of these plant tissues are suitable for manufacturing adjective dyes. The São Martinho case illustrates the benefits of considering past cordage and textile practices during hypothesis formulation and the need for developing understandings of archaeological features resulting from fiber processing and dyeworks.

Mapping Human Migrations, Past and Present: Developing Environmental Isotope and Trace Element Maps of Mexico and Central America

Thousands of clandestine migrants die every year while traversing the hostile terrain of the US-Mexico border. Most of these individuals go unidentified, leaving families in a desperate search for answers regarding their loved one's whereabouts. Rural counties along the South Texas Borderlands lack resources for full forensic documentation, investigation, and identification of poorly preserved human remains. In such cases traditional methods and even DNA studies are unproductive. Our team is developing a dual-language, open-access, geospatial database of environmental isoscapes and trace element distributions that will facilitate the research of future archaeologists, public health researchers, wildlife ecologists, conservation scientists, and innumerable other Latin American scholars. Our goal is (1) to advance modern forensic investigations and humanitarian repatriation of human remains from Texas and other US border states and (2) to accelerate scientific studies of past and present human migration, health, and landscape transformation.

Paris I-Panthéon Sorbonne)****[307]***Studying Past Iñupiat Legacy Collections from the Kobuk River, Northwestern Alaska: Challenges and Benefits of Developing an Integrated Database*

Iñupiat collections from archaeological sites located along the Kobuk River, excavated by J. L. Giddings, D. Anderson, and C. Hickey in the 1940s and 1960s, are held at the University of Alaska Museum of the North and the Brown University Haffenreffer Museum of Anthropology. Their joint study requires detailed cataloguing of artifacts and all associated contextual information (site and feature descriptions, maps or photographs, field notes, and other existing archival documentation), thus generating vast amounts of heterogeneous yet interconnected data. With basic technical and programming knowledge and limited means, we use free, open-source, and institutionally supported software to build a database able to support large datasets of various natures and allow complex queries. One of our goals is to standardize the terminology used to designate and describe past Iñupiat archaeological artifacts, revisit conventional functional classifications, and reconsider assemblage variability within and between sites. Combined with a dating program and settlement patterns analysis, our research aims to ultimately provide a better understanding of the last 600 years of precolonial occupation in and around the Kobuk River region.

Thompson, Amy (University of Texas, Austin)**[74]***Discussant***Thompson, Amy (University of Texas, Austin) and Adrian Chase (University of Chicago)****[301]***Whose Land? Governance of Land Tenure, Property, and Inequality in the Maya Lowlands*

The role that governance and property regimes play in the everyday life of citizens is something we grapple with, actively or passively, every day. In the archaeological record, these topics often prove challenging to evaluate without written records. However, using robust survey data from settlements and civic-ceremonial/administrative architecture in conjunction with high-resolution and multiproxy dating and spatial analysis, we address these questions in the Maya region while considering bottom-up and top-down approaches at multiple scales. We evaluate the role of governance on economic, political, and environmental inequality among more than 40 Classic Maya cities. We bolster this broader survey with two case studies, one from the large Maya city of Caracol in central Belize and the second from the medium-sized cities of southern Belize, discussing the dynamic interplay among settlement selection, governance, and differential access to resources as these communities developed, persisted, and declined over hundreds of years. Our work highlights the heterogeneity of ancient Maya sociopolitical landscapes and the implications of changing governance and communities.

Thompson, Jordan (Washington State University), Rachel Horowitz (Washington State University) and John Blong (Washington State University)**[265]***A Reanalysis of the Weitas Creek Site (10CW30): An Early Nez Perce Upland Hunting Camp*

The Bitterroot Mountains mark both an ecological and social margin between the Southern Columbia Plateau and the Plains region. The Nez Perce (Nimiípuu) Tribe traditionally followed a seasonal subsistence cycle routinely crossing these ecological and social boundaries, referencing long-term landscape and resource knowledge while negotiating complex social interactions. The Weitas Creek site (10CW30) is situated along the North Fork of the Clearwater River, in north-central Idaho, within the ancestral homelands of the Nimiípuu at the western edge of the Bitterroots. Weitas Creek was previously interpreted as an upland hunting camp containing Windust and Cascade phase technologies, estimated to be 12,000 or more years old. Because of the lack of radiocarbon dates and coarse-grained excavation methods, the original analysis divided the site's occupation into four broad phases, and roughly estimated their age based on the lithics recovered. This poster presents a reanalysis of the site through limited fine-grained excavation, chronometric dating, geoarchaeological analysis, paleoethnobotanical analysis, lithic analysis, and nondestructive geochemical sourcing of stone artifacts. These analyses provide a refined understanding of the chronology and antiquity of the Weitas Creek site and help to explore changing landscape and resource use in the context of social dynamics in a liminal territory.

A Comparative Consideration of the Institutions of Governance of the Native American Polities of Florida

Florida once encompassed a vast landscape of Native American polities prior to and after the arrival of European colonizers. More northern groups in the region relied on fishing, hunting, and gathering, but also practiced maize agriculture to varying degrees. Further to the south, the vast majority of people living in these areas relied solely on fishing, hunting, and gathering to support large Indigenous populations that lived in small settlements and densely occupied urban environments. The geopolitical landscape of Florida was not static but rather a dynamic place of alliances, cooperation, and conflict that ebbed and flowed at different spatial scales. In this presentation, I compare institutions of collective action across the Florida political landscape. Specifically, I consider institutions of governance (e.g., councils, longhouses, confederacies, tributary town, royal marriage, etc.) at both intra- and inter-settlement levels among the different polities in the region. This comparative analysis demonstrates that political complexity in the region was not dependent on agriculture and that similar institutions emerged among different groups under a variety of economic systems. That said, there are key differences among these peoples that suggest how collective action was organized to solve varied societal challenges across the landscape.

Dietary Evidence for the Timing and Diversity of Mesoamerican Turkey Husbandry

In the absence of morphological changes, clear genetic markers, and pen structures, the archaeological evidence for turkey (*Meleagris gallopavo*) husbandry and domestication in Mesoamerica relies primarily on identifying dietary shifts in ancient turkeys. As in the American Southwest, captive Mesoamerican turkeys exhibit greater consumption of maize than their wild counterparts. Although this general pattern has been identified, emerging isotopic work has also documented diversity in past turkey diets, which may indicate complex and varied husbandry practices across space and through time. Current isotopic datasets are also skewed toward later time periods (Classic-Postclassic) and lack adequate coverage of the Preclassic period, which is critical to understanding the origins of Mesoamerican turkey domestication. The stable carbon ($\delta^{13}\text{C}$) and nitrogen ($\delta^{15}\text{N}$) isotopic dataset presented here provides expanded geographic and temporal coverage of Mesoamerican turkey husbandry and domestication and informs our understanding of past human-turkey interactions in this region.

Salmon Wars: Medieval through Early Modern Land Tenure and Social Change in Northern Conflict Landscapes
 Into the earlier, local common pool resource systems of Iron Age and early medieval Scandinavia, the increasingly incompatible taxation and land tenure concepts of developing state governments were imposed on Arctic and peri-Arctic populations. This paper examines the archaeological and historic record of conflicts, disputes, and uprisings that unfolded around fishing rights along rivers and coasts, as royalty, aristocrats, priests, and commoners of both Indigenous and Nordic extraction squabbled and clashed over control of salmon and salmon-fishing infrastructure. The Swedish tradition, in which legal negotiation between peasants and the state was the norm, persisted through periods of extreme autocracy and militarism as well as eras in which property and other rights were more equitably apportioned.

Application of Archaeometric Methods to Forensic Anthropology Casework to Resolve Medicolegal Significance
 Human remains cases processed through the medicolegal system come from a variety of different circumstances. Protohistoric and prehistoric human remains are often submitted to law enforcement, and these remains often lack burial context and provenience. This presents a problem not only for law enforcement, who curate the remains as an unresolved case, but also for tribal communities who want ancestors repatriated. If the remains are Indigenous, lack of resolution means that the ancestors of a tribe are not rightfully reunited with their people. In forensic anthropology casework where it is suspected that remains could be archaeological, a triage method is needed for determining medicolegal significance. Archaeometric methods, such as radiocarbon dating and stable isotope analysis, can provide information that can resolve these cases and lead to successful repatriation. Radiocarbon dating can determine whether remains are ancient, historic, or modern, whereas stable isotope analysis can be used to provenance remains to possible regions where they originated. We report on four case studies from California that demonstrate the use of these methods to resolve forensic anthropology cases that were not of medicolegal interest.

[69]

Power or Privilege? Parallel Gender Hierarchies in the American Southwest
 This poster explores the concept of parallel gender hierarchies as applied to the Hohokam culture of the American Southwest. Bioarchaeological work in regions adjacent to the Hohokam area has revealed evidence of sexual inequality within multiple sites, presenting as poor health and less elaborate burial treatment for females compared to males. More nuanced analysis reveals that the impacts of these inequalities were distributed unevenly between females, indicating an intersectional aspect to this marginalization. Among the Hohokam, archaeological evidence for sexual inequality also exists, though comparing osteological data is difficult, due to the widespread practice of cremation. Instead, sexual differentiation in mortuary assemblages and the existence of some high-status female burials have been interpreted as evidence for complementary gender roles resulting in parallel hierarchies for men and women. Because social divisions by sex are often considered “horizontal” rather than “vertical,” it is implied that these separate hierarchies were essentially equal. By contrast, investigations of intersectional inequality can explore gender as a vertical class system interacting dynamically with other statuses and identities. Such an analysis presents a compelling alternative

explanation for the fact that, when treated as an undifferentiated group, Hohokam females display less evidence for wealth, power, or prestige than males.

The “Hands of God” as Instruments of Death and Creation: Physicality, Embodiment, and Symbolism of Sacrificial Knives in Mesoamerica

In this talk, we shall analyze sacrificial knives in Mesoamerica’s (bio)archaeological record, among written sources, and iconography. Our survey emphasizes the diversity of cutting weaponry through time and cultural spheres. By combining forensic evidence with the material study of sacrificial knives, swords, and blades, put into perspective the implements with particular practices of laceration and penetration of the human body during and after sacrificial immolation. Their representations in codices and especially the specimens in museums allow us to approach the study of the handles, some with a rich iconography. We also find deities in the form of knives such as Itztli and Iztapaltótec in the codices and a large corpus of knives with divine attire in the ritual deposits of the Templo Mayor. Thus, deities such as Quetzalcoatl, Tlaloc, Xiuhtecuhtli, and Xochipilli were represented as flint knives with different characteristic attire. The symbolism of flint is linked to sacrificial death but also to the birth of gods from knives represented in codices and illustrated in myths and to concepts of fertilization. For all of the above, the flint knife materializes one of the main significations of human sacrifice: to generate life from death.

The Curse of Classic: Rethinking the Agency of Maya Ceramic Production

Rooted in the Eurocentric concept of Classical antiquity, the “Classic” period is considered to have epitomized Maya civilization, standing in contrast to the developments that characterize the periods that came before and after. This dichotomy not only frames the way we categorize ceramic assemblages—the most abundant evidence in the archaeological record—but also influences how we interpret the agency behind ceramic production and consumption. In this paper, I will draw from two case studies to demonstrate that a high level of skills and specialization in the production of fineware ceramics was not a feature exclusive to the Classic period. The first case study focuses on the polychrome vessels from Nakum dating to 100/50 BCE–300/350 CE (Protoclassic period); the technology used to make these locally produced vessels exhibits clear signs of potters’ effort to increase their production with both social and economic value. The second case study highlights the central role played by the potters in making manufacturing decisions in the production of fineware ceramics in the Central Maya lowlands during 800/850–1200/1250 CE (the transition from Classic to Postclassic period), even though the mode of specialization evolved through time.

Chullpa Use in in the Ancash Region of Peru: Insights from the Discovery of Multiple Rare Developmental Conditions at Marcajirca (AD 1000–1650)

Situated on a steep-sided mountain slope on the eastern side of the Cordillera Blanca in the Ancash region of Peru, the Late Intermediate–early colonial period (AD 1000–1650) site of Marcajirca consists of residential, public, and funerary areas. Interment contexts include 35 aboveground walled tombs (chullpas). While it is logical to suggest these open sepulchers were used by kin groups, such suggestions of tomb use and prehistoric social structure tend to be based on colonial records and ethnographic analogy, and less frequently on the human remains themselves. Archaeological testing of eight tombs produced an MNI of 250 adults and 110 subadults. Among the remains, two rare heritable developmental conditions were observed among multiple individuals from different tombs: brachydactyly (MNI=3, 2 tombs) and Madelung's deformity (MNI=2, 1 tomb). Given the rarity of each of these conditions, it is likely the individuals were related. This presentation will consider these findings in the context of understanding chullpa use. These cases offer insight into cultural practices, suggest the continued use of the site over time by an extended kin group, and underscore the importance of identifying rare developmental conditions in the archaeological record as their presence may indicate genetic relationships within or among archaeological cemeteries.

Yankwik Mexiko: Contributions of Mesoamerican People to New Mexican History

Mesoamerican contributions to the state of New Mexico are often overlooked within mainstream “hispano” historical narratives. What little information is shared is usually relegated to trade routes and modes of exchange during the prehistoric period. The European invasion and subsequent colonization of New Mexico saw an influx of Mesoamerican peoples from various cultural groups. These individuals played an impressive role in shaping the cultural landscape of the New Mexico we know today. By exploring the various ways in which modern Chicano/Nuevomexicano identity was influenced by the Mesoamerican progenitors, we will help shed light on a history that is all too often ignored.

Kaanu'l Lords in Quintana Roo: New Data from Dzibanche and Resbalón Monuments

Redocumentation and analysis of inscribed monuments from the archaeological site of Dzibanche and its vicinity have revealed new details of the history of the Kaanu'l polity during the Classic period. The presentation centers in particular on the narratives recovered from the hieroglyphic stairways of El Resbalón, which contain one of the earliest known attempts to contextualize the rise of Kaanu'l—as seen by its political allies and clients—within a broader historical framework stretching as far back as the fourth century BC. The inscriptions of El Resbalón also suggest previously unknown kinds of roles that subordinate and allied lords may have played at the Kaanu'l royal court.

Water Management from the Maya Lowlands: Implementing Archaeology in Mutual Aid

The capitalist world system in place today has caused resource insecurity and social vulnerability for groups all over the world, pushing people to depend on bureaucratic leaders to solve these issues. The archaeological record, as well as some responses to recent disasters, shows the benefit of mutual aid–style networks of action allowing communities to survive in spite of the hierarchical systems that push to dissolve their autonomy. Looking to the future of our communities and our planet, it is important to create sustainable infrastructure networks to meet the needs of communities without relying on governmental aid. In this presentation, I discuss the example of the so-called Maya “collapse,” and how elite leaders fell while small farming communities have survived to this day. In particular, I focus on the water management networks utilized by Maya communities of different sizes and outline the biosphere reservoir as a potential method of attaining both social and ecological sustainability. The goal of this presentation is to highlight the use that archaeology can bring to conversations of capitalism and resistance, as well as how archaeology can provide examples of potential sustainable systems for autonomous communities to put in place.

Conclusion: Living within and with the Wetlands

Wetlands are valuable ecosystems for many animal species, but they also present critical ecosystems for humans. By protecting against floods, erosion and improving water quality, wetlands present a valuable source for human food procurement and activities. In this paper, I exemplify the role of wetlands from the Southern Carpathian Basin by presenting settlement evidence for the human-wetland interaction during the Copper

(4500–2700 BC) and Bronze Age (2700–1500 BC). By showing how different communities utilized wetlands for over 2,000 years, I stress the importance and coexistence with such ecosystems in the region in the past. To conclude, this paper will also stress how society undermined wetlands' importance from the nineteenth century onward. Seen in lieu of recent natural disasters, climatic changes, and lack of water management practices, this study hopes to emphasize the importance of such ecosystems and advocate for the maintenance of those still remaining.

Camelid Pastoralism in the Wari Empire and Its Political Implications

The South American camelids had tremendous importance for basic subsistence, social life, and religion in all prehispanic Andean societies, but implications of herding domesticated llamas and alpacas for broader political systems have received less academic attention. This study uses the camelid remains as a proxy to study pastoral traditions within the political apparatus of the Wari Empire (ca. 600–1100 CE, modern-day Peru). The overview of current evidence from southcentral Wari territories combined with novel zooarchaeological and isotopic (C, N, O, and Sr) results from northern Wari sites implies that herding strategies were strongly influenced by preexisting local practices of animal husbandry, which led to different political consequences in each subjugated province. This research suggests that camelid herding was an indispensable tool in the Wari imperial repertoire, reflecting practices of ecological engineering and trajectories of regional governance.

Remote Sensing and Ground Truthing: Revisiting the Middle Khabur, Northeastern Syria

Between 1986 and 1994, the Yale University Khabur Basin Survey Project (KBP) carried out archaeological surveys of the middle Khabur region of northeastern Syria and recovered ceramic and lithic artifacts from 257 sites dating from the Paleolithic to the Ottoman period. Following these ground investigations, in 1998, Nicholas Kouchoukos used Landsat images to assess environmental variables for the sites that had been discovered for his dissertation. Subsequently, Smith carried out a comprehensive analysis of CORONA images from the 1960s and 1970s for his 2015 PhD dissertation, identifying potential archaeological sites over this large region. From 2020, Tonoike and Hole, as part of the final report of the KBP, used a combination of GPS points, hand-marked sites on topographic maps, field notes, and Google Maps satellite imagery in an attempt to plot all sites in the survey area. This paper compares the results of these various survey methodologies and interpretations and emphasizes the efficacy of combining diverse remote-sensing data together with ground truthing and experiential knowledge of the regions to provide a holistic view of a complex archaeological landscape.

Toombs, Garrett (Washington State University) and Rachel Horowitz (Washington State University)**[282]***An Experimental Analysis of Water Content on Stone Raw Material Quality*

It is well known that heat treating chert and other cryptocrystalline silicates improves the stone's quality for knapping. However, ethnographic texts report that Indigenous knappers from around the world evaluate a stone's moisture content as a marker of the stones' quality for flaked tool production. Contemporary Euro-American flintknappers make similar claims. Despite the shared discussions by Indigenous and Euro-American flintknappers on toolstone moisture content, previous studies of flaked stone materials have not been conducted to evaluate the proposed relationship. This study utilizes a flintknapping experiment to quantify the impact of moisture content on raw material quality for tool production by measuring the length of pressure flakes removed from materials with varying moisture content. This poster provides an experimental evaluation of the role of moisture content in flaked stone tool production and integrates Indigenous perspectives on stone into lithic studies. We find that added moisture increased the length of pressure flakes removed of knapping. These findings are particularly important for experimental knappers who use raw materials which were previously extracted from the ground, and who may wish to rehydrate the toolstone before knapping.

Torquato, Melissa**[224]***Data Inconsistency and Multi-site Analyses: Using Multilevel Modeling to Transform Archaeological Data*

For over a century, the proliferation of archaeological excavations in the United States has generated a large amount of archaeological data. Much of this data is published in archaeological reports that are housed in state-run archives. These archives offer a wealth of information for scholars who explore research questions that require multisite analyses. However, the lack of consistency in reporting can make it difficult to combine data from previously excavated sites. Specifically, if data is reported in different units (e.g., weights vs. counts), it can be difficult or impossible to use in the same analysis. To explore this issue, I present a case study that examines using botanical remains to study dietary trends in the Interior Eastern Woodlands. I use multilevel modeling to transform weight data from count data for seven nut types, providing a stable basis for comparison across sites. This analysis explores how statistical methods can be used to address reporting inconsistencies between sites, thus allowing previously excavated data to be used in multisite analyses.

Individualities have been difficult to identify in Classic period Teotihuacan, as this multiethnic urban culture presents itself as a faceless society where inequality must be addressed with new perspectives and methodologies. In this poster, we explore whether this inequality is perceptible through biological sex differentiation in mortuary evidence, e.g., burials and sacrifices, at Teotihuacan. We analyze this hypothesis through a machine-learning approach. The results of our research indicate that graves do not present differential patterns by biological sex. However, biological sex was an important factor in the sacrificial burials of the Temple of the Feathered Serpent. These results offer a deeper insight into social inequality and individual roles at Teotihuacan, highlighting the potential of computer science to understand human interactions in a complex social network of plural identities underrated in the archaeological record.

Those Flowering Waters: Reconstructing 1,200 Years of Human Adaptation to Hydroclimatic Changes in Central Nicaragua

Central Nicaragua is highly susceptible to hydroclimatic variations, which are affecting the subsistence economies of local populations. To what extent hydroclimatic changes impact prehispanic adaptation strategies in the Mayales River Valley (MRV)? This presentation will show the final result of the Interdisciplinary Archaeological Project Finca Santa Matilda (PRISMA), which integrates the geoarchaeological analysis of Roberto Amador site (RA: AD 900–1250) and the multiproxy palynological analysis of a 1,200 yr core from El Tigre-Asososca lake (León). Prehispanic human responses to the incidence of inundations is evidenced in RA by a strategic use of the site landscape and differentiated use of alluvial terraces. The inundation that affected the site around AD 1250 ultimately likely led to its abandonment and unveils how the human communities living in the MRV used adaptive settlement strategies to relocate when exposed to major fluvial changes. By comparing the archaeological data from RA to the paleoclimatic record produced by the authors, it is possible to correlate this inundation to regional hydroclimatic developments. This study shows that human communities of the MRV had a constant and dynamic relationship with the fluvial environment of the valley, unveiling how rivers are active forces that intimately shape human societies.

[24]

Strings of the Past: Revisiting the Lapidary Industry of Poverty Point

The Poverty Point culture has long been recognized for the abundance and variety of stone beads that can be found at both large mound centers, like Poverty Point and Jacketown, and smaller sites, like Slate. Tubular, barrel, disc, and effigy beads that depict owls and other birds are found at Poverty Point affiliated sites throughout Louisiana and Mississippi, and even as far away as Florida. Beyond simple admiration for the artistry evidenced by the beads, a close examination of the manufacturing wear suggests makers utilized different toolkits and processes to achieve their results. By documenting variation in bead production and mapping the distribution of bead styles across the landscape, we can begin to gain insight into cultural identity, exchange, and interaction among communities of the Lower Mississippi Valley and Gulf Coast.

[246]

The Question of Permanence: Understanding Head Shaping as a Process

Recent conversations about body modification demonstrate that alterations to human form are experiential and are not solely oriented toward a final product. In thinking of prehistoric head shaping practices—practices engaged in with the bodies of infants—archaeological perspectives are frequently necessarily focused on the marks of the practice on the adults. In contrast, placing attention on the process of head shaping as part of the acts of child-rearing moves discussion into a consideration of infancy, parenthood, and the actions that inform what is deemed proper child-rearing. Shifting focus from an archaeologically visible aesthetic to one that is structured around the appropriate ways to treat an infant moves the discussion away from a focus on the practice as inherently having an end goal of permanence. To that end, here I consider approaches to permanence from architecture and art history to shape our understanding of the body as a dynamic thing. I present a broad appraisal of cranial vault modification from ~1,700 individuals who lived in northern Chile before the colonial era, arguing that perhaps permanence is a modern fixation, and that final shape may not have been what was important for the people who bound their child's head.

Torres, Hilda (Texas State University)**[335]***Lithic Attribute Analysis for Blydefontein Backed Blades and End Scrapers*

Attribute analyses are common in the field of archaeology for categorizing and analyzing artifacts. In this study, the Later Stone Age end scrapers and backed blades from Blydefontein Rock Shelter in South Africa undergo an attribute analysis using an objective attribute guide. The guide combines common terms from previous studies along with new terms for typology to provide an efficient attribute analysis of the Blydefontein backed blades and end scrapers. The guide divides variables of the artifacts into attributes to identify differences between lithics not commonly used when conducting a general typological analysis. These variables include tool type, blank type, blank shape, dorsal scar patterns, lateral trimming, platform type, raw material, measurements, dorsal surface cortex proportion, and color for both end scrapers and backed blades. End scrapers also include variables of lateral trimming side, ventral surface flaking, bit measurements, and bit morphology. The attribute analysis of the Blydefontein Rock Shelter lithic assemblage will aid in the selection of lithic artifacts to be studied through use-wear analysis by predetermining manufacture, use, and postdeposition attributes.

[158]*Fishing Weirs, Docks, and Cholchénes in the Patagonian-Fueguine Archipelago: Confluence of Different Maritime Cultures on the Coastal Edge*

The intertidal zone, as part of the coastal landscape, is the territory of transition between the terrestrial and marine environments. In the southern fjords (between Chiloé and Cape Horn), it is a space of social construction that reveals multiple culture-marine ecosystem relationships, based on the interaction between different cultural groups with strong links to the sea, such as indigenous nomads, chilotes, and huilliches, and currently artisanal fishermen, among many other actors. Over time, the intertidal zone has accumulated material features of the activities of these populations, such as fishing weirs, pirenes weirs, docks, and *cholchénes* (*vivideros*, or mollusk beds), among other uses, accounting for the economic and sociocultural strategies of these groups, but also of their worlds (ontological dimension) and what can and should be done in this space and the things that populate it (cosmogonic dimension). This research presents the results of the study of several structures found in different areas of the Fuegian and northern Patagonian archipelago, from an archaeological and ethnographic perspective, respectively. The study allows us to discuss the wide knowledge and use of the geographical space of this vast region, considering the continuity of cultural practices throughout time.

[53]*Embodied Lives: Bioarchaeology of the Moche Valley Chimú*

During the late 1970s to early 2000s archaeologists studying the Chimú of the northern coast of Peru created a foundation in the archaeological literature. This research helped us understand Chimú chronology, general functionality of the empire, and technological advancements made by the society. While these contributions to the Chimú literature are fundamental, a bioarchaeological investigation provides researchers with a more nuanced understanding of the lived experiences of people during the Chimú reign. The Chimú cemetery excavated at the Huacas de Moche site outside of Trujillo, Peru, is one of the largest samples of non-sacrificed individuals available for study. We analyzed 126 individuals who were interred in Plaza I of the Huaca de la Luna archaeological complex. We provide an analysis of the mortuary practices, demographics, and overall health of the Chimú individuals buried in Plaza I terraces 1 and 2.

Creating Ties: Co-responsibility between Government and Community for the Safeguarding of the Prehistoric Caves in the Central Valleys of Oaxaca, a World Heritage Site in Mexico

During the last four years, in the UNESCO World Heritage Site Prehistoric Caves in the Central Valleys of Oaxaca, effective relationships have been strengthened and created between the ejido commissary and the cultural managers of the National Institute of Anthropology and History (INAH). Through constructive dialogue, knowledge sharing, and joint actions with other governmental instances, the collaboration offered a better way to guard the site despite external limitations, thanks to inclusive spaces and the support the community and the institute find between them. The feeling of pride, belonging, and co-responsibility led to an archaeological project, national exhibition fairs, and cultural diffusion of the area where local worldviews, norms, and values were the base for co-creation processes. The union built has the potential to advance so that diverse cultural expressions can flourish and add to the protection and safeguarding of the World Heritage Site.

The Linguistic-Epistemic Uprising behind the Teaching of the Atacamenean Language

This paper examines the insurgent practices of the people of Atacama who seek to teach Ckunza, a language that is extinct according to experts and the Chilean state. The Atacameños created the academy of the Ckunza language and teach the language in the community. Thus, they revive Ckunza, decolonizing the episteme imposed by the neoliberal state and taking up their linguistic and educational self-regulation. Finally, they are recovering ancestral knowledge through Indigenous research and legitimizing the representation of identity through their language (research funded by FONDECYT N. 11220225).

Creating a Digital Reference Collection for the La Quemada-Malpasos Valley Archaeological Project

A long-running project in West Mexico, the La Quemada-Malpasos Valley Archaeological Project (LQ-MVAP), has entered the final stage of the data life cycle with a shift from long-term curation and analysis of the physical materials to an open-access digital archive with training guides for data reuse by future researchers. In this paper, we describe our NEH-funded collaboration with the Digital Archaeological Record (tDAR) to create the LQ-MVAP Digital Reference Collection (DRC), which will allow users to search images, attribute

data, reports, and field notes for information about specific artifact classes, chronological periods, or intrasite locations, as well as explore queries designed around project themes such as human-environmental interactions, craft production, exchange, and ritual practice. We also discuss the varied ethical considerations that arise from the digital curation of a multi-decadal and international project, as there are constraints to be addressed regarding the authority to control and disseminate online datasets and images. A bilingual web portal for the LQ-MVAP DRC will provide digital enhancements for a forthcoming edited volume and educational resources for all ages to engage the public in a dialog about this important archaeological site and its significance to local and descendant communities in Mexico and around the world.

Pompeii's Pitfalls: The Vulnerability of Water Supply in the Wake of Natural Disasters

The Roman water-supply system of Pompeii, Italy, has provided numerous insights into resource management and urbanization in the ancient Mediterranean world. It also provides a unique parallel for understanding the impacts of climate change and natural disasters on urban infrastructure today and in the past. Prior to the eruption of Mount Vesuvius in 79 CE, a series of earthquakes caused significant damage to Pompeii, Herculaneum, and nearby towns. As evidenced at Pompeii, this damage greatly impacted the water-supply system, requiring repairs and necessitating changes to the distribution of water at the site. This paper synthesizes the current research on Pompeii's aqueduct-fed system focusing specifically on the advantages and pitfalls of Pompeii's approach to dealing with interruptions in water supply and damaged infrastructure that resulted from a series of natural disasters in the Bay of Naples region from 62 to 63 CE.

Accessing the Inaccessible: Late Intermediate Period Chachapoya Collective Mortuary Practices at Diablo Wasi, Peru

The complexity in mortuary traditions across the Chachapoyas region ranges from single individual interments to large, commingled mortuary caves, as well as including constructed sarcophagi and shared open chambers high on cliff faces. Variation within sites and across funerary complexes demonstrates individuality in construction and may reflect not only markers of identity but specific ideological purposes. Explorations at Diablo Wasi using vertical rope access techniques allow us to characterize the variation at this site and nearby La Petaca. While constructed masonry chambers are found on the lower, easy-to-access base, other platforms and chambers are built on narrow ledges located in the center of the escarpment. Unique to Diablo Wasi are the masonry-enclosed natural grottos with more elaborately designed decorations around the entrances. The selection of natural small caverns parallels larger cave systems, but the added façade encloses them in a similar fashion to open sepulchers. Due to challenges in accessibility, these vertical sites have been less damaged by taphonomic processes and retain more materials for analysis. These mortuary contexts present significant challenges in accessibility, both during construction and use, but also for archaeological practice. These raise questions about the nature of risk associated with interring the dead and Chachapoya eschatology.

Cultural Collaborations among Ritual, Economy, and Social Organization: Recent Investigations at the Site of Dos Hombres, Belize

Evidence from the site of Dos Hombres in northwestern Belize is presented from multiple contexts revealing the cultural collaborations with ritual, economic, and social expression/s as they are manifest in and necessarily tied to material aspects of everyday life. Ongoing previous research has been concerned within the northern plaza, a space of public activity. Essential to the understanding of economic activity at the site, however, necessarily involves the identification and analysis of possible market locales within the site which includes all three plazas and/or the liminal spaces between them. These recent studies were conducted through an NSF grant. Although analysis is ongoing from the recent NSF data collection, preliminary data, architectural construction sequences, activity residues, and ritual and economic deposits collectively reveal much about the ancient city specifically the interconnected nature of important aspects of daily life, public and private activities of economic, religious, and social significance. Material culture associated highlights the interwoven nature of ritual with economic production, social activity, and commerce and the importance of cultural collaborations among them. The extent of market based economic activity and its integration with ritual and social expression are critical perspectives in understanding the nature of ancient Maya life at Dos Hombres.

Meeting Needs in the Ancient Maya Forest: A Model of Food and Shelter at El Pilar

Maya land-use strategies, based on traditional agricultural methods documented by the Spanish conquerors and oppressed during the colonial period, have demonstrated a staunch resilience into the modern age. The milpa forest garden cycle demonstrates dynamic regeneration via an asynchronous cycling of open fields with annual crops, perennial succession providing domestic products, and mature forests for fruits and construction materials such as thatch and wood framing. This poster outlines our method of using spatial analysis techniques, remote-sensing data, and traditional ecological knowledge from living Maya forest gardeners to identify areas suitable for traditional practices. Using settlement data and Lidar to quantify slope thresholds for milpa cycle agriculture, and identifying mature and managed forests, we examine the landscape of El Pilar under a lens of product fulfillment. We estimate the food and shelter needs of an ancient Maya population using agricultural productivity data and required materials for house construction as outlined by Maya forest gardeners. In turn, we investigate the potential of the land at El Pilar to provide the necessary resources for life in this tropical environment. The results guide a discussion of the sustainability and sufficiency of the milpa forest garden cycle within the Maya forest.

Trebouet, Florian (Northern Arizona University)**[181]***Discussant***Trejo, Claudia (INAH Mexico)****[152]***Chemical Analyses of Activity Areas at Cueva de las Varillas in Teotihuacan*

We present the chemical analysis of human activities in a cave occupied during the Epiclassic and Postclassic periods (AD 600–1500) at Teotihuacan. The archaeological context is formed by different cultural occupations within the same space, but during different periods of time. Due to the cultural and temporal diversity, we implemented a methodology based on the 3D association of the data through a digital model. With this procedure, a total of 11 superimposed occupations were detected, three from the Aztec period, two from the Mazapa, and six from the Coyotlatelco. A total of 395 samples were analyzed to establish phosphate, carbonate, and pH values of each activity area excavated. The results define the types of activities and the use of space in each occupation, while differentiating the activities carried out in each chamber of the cave. It was observed that in all occupations, both daily and ritual activities were carried out. To corroborate the results, the chemical data were contrasted with general data from the associated lithic and ceramic materials. This made it possible to integrate the results within a broader interdisciplinary project and promote the generation of more precise explanations about the use of these caves in prehispanic times.

Trepal, Dan (Michigan Technological University)**[62]***The Hamtramck Historic Spatial Archaeology Project: Integrating Archaeological Collections into Historical Spatial Data Infrastructures*

The Hamtramck Historic Spatial Archaeology Project, launched in 2021, is an active digital, web-based, public, collaborative deep-mapping project for the city of Hamtramck, an industrialized city completely surrounded by Detroit. The primary focus of the project is to create and launch a digital, web-based, publicly accessible deep map linking information from written records and historic maps with archaeologically recovered objects or building remains associated with the same location. This paper describes our recently launched deep map (www.mappinghamtramck.com) and the ways a public, urban archaeology project can make more effective use of the interplay between the historical and archaeological records and also better collaborate with heritage-making efforts on the part of the community. Finally, we present our project as a model that can be replicated in other urban communities through partnerships between universities and local heritage organizations.

[13]*Pañamarca through Time: Before, during, and after Moche*

Although it is now best known for earthen architecture bearing iconic wall paintings in late Moche style (ca. 600–850 CE), Pañamarca was a monumental center of great importance in the lower Nepeña Valley of north-coastal Peru from at least 150 BCE through the 1400s CE. In this paper, we present the evidence for this expanded understanding of the site's history and its monumental transformations and reconfigurations—from the Final Formative period until the eve of Spanish colonization—including data from stratigraphic excavations and dozens of new AMS dates. This diachronic view of Pañamarca has important implications for local and regional archaeology, as well as for enduring relationships between the site and its neighboring contemporary community of Capellanía.

Aguada Fénix and the Middle Usumacinta Region: Interregional Interactions and Social Transformations in the Middle Preclassic Period

The recently discovered site of Aguada Fenix in eastern Tabasco, Mexico, is one of the largest monumental constructions in Mesoamerica. It was built in a standardized architectural pattern that we call the Middle Formative Usumacinta Pattern (MFU). Its earliest construction phases date to the beginning of the early Middle Preclassic, around 1100 BC. This complex represents an altered landscape of a scale and complexity that was previously unknown for Mesoamerica. The overall layout of the ceremonial space clearly represents a vision of the cosmology of the people at that time. Remarkably, this cosmology, exemplified in this very standardized pattern, was not only present in the Middle Usumacinta drainage, but it was shared over a very large region from the Usumacinta Basin to western Veracruz. So far, we have identified 478 of these formalized complexes along the Mexican Gulf Coast. The widespread use of the MFU shows extensive interregional interactions during the early Middle Preclassic among people that were probably of different ethnic groups and spoke different languages. These new discoveries and data lead to new insights into the processes involved in the formation of Maya civilization and other early Gulf Coast groups.

A Dong Son Community: Connecting Communities through a Shared Bronze Tradition

The Dong Son culture (ca. 700 BCE–AD 200), at its simplest, is a collection of a group of sites and artifacts that are characteristic of a particular group or region in northern Vietnam. Their most defining characteristics are their burial practices (i.e., the boat coffins) and their sophisticated bronze tradition seen from artifacts like weapons (e.g., swords/daggers, spears, crossbows, etc.) and prestige goods (e.g., bronze drums, thap, etc.). The presence of these shared practices, specifically the bronze tradition, suggests a community of craftspeople that regularly interacted and shared knowledge to develop their craft; otherwise known as a community of practice. This poster will focus on the way the production of these bronze artifacts can impart social meaning within the Dong Son community, and how that social meaning can be distributed and

eventually shared; thus, creating a Dong Son community of practice. By exploring a Dong Son community of practice through the production of bronze artifacts, this research could provide insight in understanding how craft production can influence the relationship between intra-regional and possibly even interregional communities.

A New Paradigm for South Asian Glasses: Mineral Soda Alumina Revisited

The Elemental Analysis Facility at the Field Museum has been at the forefront of global research into distinctive South Asian glasses, technically termed “Mineral Soda Alumina” glasses. In celebration of 20 years of field-defining research, this paper presents the results of a major review of m-Na-Al glasses the author has conducted in collaboration with Laure Dussubieux. This paper presents the new paradigm and classificatory method for defining and understanding compositional groups in m-Na-Al glasses, and it will demo a new software platform designed to make such analysis easier to conduct. It will present new paradigm-changing results from North India, based on results from the site of Indor, excavated by the author, regarding what they reveal about cross-craft currents of glass supply and exchange both within and outside South Asia. Finally, this paper presents a review of in-group variation and reviews its promise for specifying particular exchange networks from South Asia to the Swahili coast, mainland and island Southeast Asia, and toward the Levant and Europe.

Collections Rescue in Washington, DC: “Can we have our garage back?”

“Can we have our garage back?” The person asking this was storing 50 boxes of collections from data recovery at the 1786 Forrest Marbury House in her garage. Compliance investigations in 1986 were not reported because of a legal loophole, and curation was not funded. DC lacked a curation facility so many of our collections were parked with whoever could be convinced to house them, including developers. After 35 years, we have a curation facility and this legacy collection now has a permanent home, but it remains unreported. Locating and rescuing legacy collections requires doing the archaeology of archaeology. Legacy collections that lack technical reports are appealing to researchers and graduate students looking for collections-based data for papers, theses, and dissertations. Most collections in search of authors were professionally excavated with extant field records, and photo catalogues. Collaboration with young researchers is mutually beneficial. They apply current/contemporary analytical frameworks and methods to create new data, approaching questions of class, ethnicity, heritage, gender, and occupation in ways unapproachable in the 1980s–1990s. They learn collections management best practices, and we receive inventoried, analyzed, curation-ready collections; technical reports; and all the data. We showcase several examples herein including some in need of authors.

Trubitt, Mary Beth (Arkansas Archeological Survey)**[176]***Continuity and Change in Contact Period Caddo Communities in the Ouachita Mountains*

For ancestral Caddos living in the Ouachita Mountains of west-central Arkansas, the two centuries between AD 1450 and 1650 saw both continuity and change. An extended period of drought in the 1450s and contact with outsiders beginning with the Spanish in 1541 would have stressed local farming communities. Responses may have included increasing interactions with neighboring communities within the region that preceded seventeenth-century relocations. Excavations at a village site in the upper Ouachita River valley gave an opportunity to examine persistence, responses, and changes. In particular, two large refuse pits excavated in domestic areas of the site—one dating to 1500 and the other to 1650—provide a wealth of data about material culture, foodways, and chronology. These are key contexts for the definition of a new archaeological phase in the Ouachita Mountains and interpretations about the history of ancestral Caddo communities that lived there.

Trujillo, Judith (Universidad de Los Andes, Researcher Gipri Colombia) and Sonia Archila Montanez (Los Andes University)**[112]***Rock Art Landscapes: Identification of Rock Art Distribution Patterns at Different Spatial Scales in La Lindosa, Guaviare, Colombia*

This presentation shows an initial approach to rock art landscapes in Nuevo Tolima, Serranía of La Lindosa, based on a systematic study of rock paintings. The analysis supposes that multiple human activities left traces currently visible in the rock art landscapes derived from that human agency. These traces can be observed, for example, in the quantity and distribution of motifs on the bedrock, the frequency and variety of motifs on the rockshelters, the size of each of the painted murals, among others. To realize this spatial experience, it is considered important that the observer perceives the rock landscape at different scales, sees each mural as a whole, and in turn as a part of the mountain range. By moving through the tepui to visit the rock murals and observe the particularities of each of the painted murals, certain patterns of their distribution and production can be identified.

Trujillo-Hassan, Daniela, Julie Wesp (North Carolina State University), Sebastián Rivas (System of Culture, Art and Heritage Center) and Ethan Hyland (North Carolina State University)**[201]***Dietary Practices of the Muisca at Nueva Esperanza Archaeological Site during the Late Muisca Period (AD 1000–1600)*

This study analyzes the impact of environmental stressors on dietary practices within the Muisca society at the Nueva Esperanza archaeological site in the Cundiboyacense highlands during the Late Muisca period (AD 1000–1600). This coincides with climatic changes associated with the beginning of the period known as the Little Ice Age, which was a general cooling of the environment that impacted food production around the world. This research combines analysis of stable isotopes ($\delta^{15}\text{N}$, $\delta^{13}\text{C}$), phytoliths in dental calculus, and identification of skeletal pathologies associated with nutrition to examine the effects of these climatic changes and cultural responses to the reduction in food resources. We analyzed individuals from two different occupations during the Late Muisca period; cut 4 ($n = 13$, radiocarbon dated to AD 1024–1155) and cut 13 ($n = 22$, radiocarbon dated to AD 1429–1522). The results suggest that while this is a hierarchical group, their distribution of resources was more egalitarian than other chiefdoms.

Tsai, Che-Hsien (National Taiwan University)**[315]***Unraveling Neolithic Cultures in the Taipei Basin through Pottery Technology at Tzufakung*

The Taipei Basin holds archaeological significance, particularly in illuminating the Neolithic era in Taiwan. The sites of Yuanshan and Botanical Garden each represent distinct Neolithic cultural phases. However, the coexistence, contemporaneity, or transition between Neolithic cultures has been a subject of debate. The nationwide site survey, commissioned by the Ministry of the Interior, unveiled extensive sites across the Taipei Basin. Unfortunately, due to a lack of excavation, most materials gathered lack well-defined contexts. The Tzufakung site, strategically positioned between the Yuanshan and Botanical Garden sites, assumes particular importance in elucidating the relationship between these two distinctive cultures. The extensive surface collections encompass pottery sherds from both cultures, rendering it an ideal case study. This research employs typology, thin-section petrography, X-ray fluorescence (XRF), and scanning electron microscopy (SEM) to examine pottery technology at Tzufakung. Its primary objectives are identifying the origin of pottery, and characterizing production techniques to shed light on interaction and cultural influences. The results explore the potential of pottery and its production to address enduring debates among Neolithic cultures and lay the groundwork for the application of scientific methodologies to other uncontexted pottery to enrich our understanding of technological development and cultural exchanges during this period.

Tsang, Roxanne (University of Papua New Guinea)**[263]***Chair***Tsang, Roxanne (University of Papua New Guinea)****[263]***Rock Art As Place-Making Strategy: A Papua New Guinea Case Study*

Rock art and its ethnographic study provide important insights to understand people's connection to place. In this research, formal and informed methods were used to analyze four stenciled rock art sites in Auwim village, East Sepik Province, Papua New Guinea (PNG). One thousand and seventy-seven rock art motifs were identified while the ethnographic data results show that Auwim people's use of rock art production and its role through time has changed from ritual functions to mundane activities of place-marking. The variation in the subject matter of rock art production, the two to three layers of production and the tentative four-phase sequence model also show change in people's choice from using human appendage design forms to the stenciling of significant long-distance trade and exchange goods and local weapons, and then the stenciling of European-introduced tools. The results of the rock art motif analysis also show links to other existing archaeological sites and objects of significance, revealing regional links with the Austronesian Painting Tradition model in PNG and the broader Indo-Pacific region. This suggests that Auwim rock art could have been made over a long time, but its production continues today.

[32]*Early Monuments at the Maya Archaeological site of El Palmar, Campeche, Mexico*

El Palmar has garnered considerable attention from researchers, primarily due to its numerous carved monuments. In 1936, Sir Eric Thompson's exploration initially reported 44 stelae and several altars at its Main Group. However, despite sporadic studies conducted by Tatiana Proskouriakoff and others in subsequent decades, systematic research was lacking, impeding a holistic understanding of the significance of those monuments in ancient Maya society. This paper centers on the three earliest monuments found at El Palmar. Our epigraphic and iconographic analyses of these early monuments provide new insights into Maya dynastic history. Since 2007, the El Palmar Archaeological Project has relocated or newly recorded 38 stelae, 16 altars, a panel, and a hieroglyphic stairway. The studies of Stela 46 suggest that the El Palmar dual-royal titles, *sakho'ok wak piit ajaw*, can be traced back to at least 125 CE. Stela 20, erected in 514 CE (9.4.0.0.0), documents that the seventeenth successive ruler stood as *k'uhul ibil*, "holy bean," an enigmatic title possibly linked to regional political authority. We conclude that the El Palmar dynasty managed to endure a sociopolitical crisis that unfolded during the Protoclassic period.

The Legacy of the Foraging Spectrum and Mikea Ethnography: Do We Need Hunter-Gatherer Studies Anymore?

One way to view the twentieth-century history of hunter-gatherer studies is as a long attempt to evaluate Victorian notions of foragers as primitive relics with actual data from real foraging peoples. This history came to a fiery climax during the Kalahari history debate of the 1990s, when researchers argued whether hunter-gatherers represent a special type reflective of past lifeways or whether they are oppressed rural proletariat like other peasants. Robert Kelly's Foraging Spectrum offered a third road, one based on empirical data documenting the diversity of hunter-gatherer experiences; and Mikea people walk this road, conforming to and confounding forager stereotypes. Accepting that "foragers" are a diverse bunch, does it make sense to keep the category and continue to devote special study to it? I offer a cautious yes. First because past lessons haven't been learned, and scholars continue to offer homogenized primitives, in other clothes. Second, because the political history of treating some people as hunter-gatherers has made them so. Third, because contemporary and historical foraging activities continue to teach us about human-environment interactions. One legacy of the Foraging Spectrum is a spectrum of new research trajectories.

The Ceramic Chronology of Vista Alegre: An Updated Typological Assessment

The ceramic sequence developed for Vista Alegre, a Maya port site on the northern coast of Quintana Roo, Mexico, demonstrates both the site's persistence through time and its extensive trade relationships across the Maya world. The Proyecto Costa Escondida (PCE) team has synthesized an official site chronology from an ongoing analysis of the ceramic materials, revising Vista Alegre's site history into six ceramic complexes. The earliest Middle Preclassic materials link Vista Alegre to the Gulf Coast and Belize, and the ceramics from subsequent time periods continually expanded this initial geographic range. Vista Alegre's ceramic collection shows ceramic affiliation with various large city centers over time, though without direct external control. The northern Maya Lowland regional trends of Terminal Preclassic incised bichromes and Late Classic slatewares are strongly represented, as well as smaller amounts of southern Lowland-produced ceramic types starting in the Early Classic period. The number of ceramic types found to date shows a remarkable variety as

compared to the nearest inland sites and regional city centers. Vista Alegre's ceramic diversity and volume are indicative of a well-connected, long-lived, and resilient trading port, and its ceramic collection continues to enhance our understanding of ancient Maya maritime exchange.

[209]

Integration of Resilient Bodies in Pathological Narratives around Disability

Bioarchaeology's epistemological history is closely tied to that of paleopathology and medicine. Accounts of disease, injury, and death in the archaeological record are steeped in the medicalization of the body and of corporeal difference as defective and, therefore, requiring correction by practitioners and/or accommodation by caregivers. A series of osteobiographies from historic US institutions (e.g., Erie County Poorhouse, Buffalo, New York) are presented with their contextually rich documentary and archaeological archives. These case studies critically evaluate the potential for socially perceived corporeal difference, its historical assignment as impairment, and the function of this social, and often political, evaluation. Rather than seeking to establish social accommodation, or a lack thereof, these analyses center the ingenuity, resilience, and social negotiations of the individuals whose skeletons present with corporeal difference (e.g., pathologies, trauma) as perceived through the bio/archaeologist's lens. They counter the notion of disability (a disadvantageous physical or mental condition that limits a person's activities), sometimes in spite of disablement (social prevention of individuals to full participation in society). The inclusion of a social disability framework in bio/archaeology avoids the exclusion of individual experience with perceived pathology and presents a more historical narrative of corporeal difference in the past.

Gendered Grave Goods: Relationships between Gender-Associated Artifacts and Biological Sex in the Precontact San Francisco Bay Area

Too often the identified biological sex of precontact human remains are assumed to represent the lived gender experience of the individual. At the same time, concepts of the gendered division of labor influence the association of classes of artifacts with genders. This paper reexamines data from excavations of burials in the San Francisco Bay Area conducted in consultation with members of the descendant communities designated as the Most Likely Descendant by the California Native American Heritage Commission. Using that existing data and framing it with ethnohistorical information, this paper investigates the relationship between osteologically estimated sex of individuals and artifacts traditionally associated with gender that were placed with burials as grave goods. These relationships are then used to examine how archaeologists interact with human remains and interpret the lives of past people. Specifically, portable mortars, pestles, bone awls, and projectile points and their occurrence with the burials of osteologically estimated male and female adults and children is analyzed and compared with ethnographic and ethnohistoric data. This research was undertaken without any direct analysis of human remains or artifacts, all of which were repatriated and reinterned. Members of descendant communities were consulted about appropriate use and approved access to the data.

Living with Floods: The Intersection of Past and Present Flood Management

Through the Levee Safety Program (Program), the United States Army Corps of Engineers partners with levee sponsors to manage more than 1,600 levees across the United States that help reduce flood risk to people, businesses, critical infrastructure and the environment. Implementation of projects under this Program must take into consideration several historic and precontact levees or mounds that are preserved within modern levees. This paper seeks to inform the community of practice of this phenomenon, and to better prepare CRM practitioners for the presence of precontact and historic deposits within and adjacent to public levee prisms.

Tumberg, Timothy**[297]***Rethinking “Hell’s Four Acres”: Consumerism at Whiskey Row*

The historic town-site of Agate Bay, on the north shore of Lake Superior in present-day Two Harbors, was developed in the 1880s in conjunction with and as a consequence of the opening of Minnesota’s first (Vermilion) Iron Range. Popular historic accounts claim that Agate Bay was a rough-and-tumble frontier settlement that became commonly known as “Hell’s Four Acres,” with an especially notorious section called Whiskey Row. Other research suggests that this wild reputation was a myth perpetuated by Minnesota Iron Company in order to leverage a buyout of prime waterfront real estate. Though occupied for only a short time, Agate Bay is a textbook example of archaeological potential because much of the platted town-site was capped by a wood platform shortly after its abandonment in the late 1880s, then by a large concrete coal storage slab from the late 1920s until October 2006, effectively sealing the site as a time capsule.

Archaeological investigations resulted in the recovery of more than 40,000 artifacts, which enabled focus on consumerism as a means of separating myth from reality and indicates a that reconsideration of the reputation of “Hell’s Four Acres” is in order.

Tumelaire, Jacob (IAC, LLC) and Audrey Waterman (IAC, LLC)**[224]***High above the River: Points, Pottery, and a Pithouse in Southern New Hampshire*

This paper presents the results of a targeted data recovery conducted at the Amoskeag West Bank site (27-HB-079) in Manchester, New Hampshire. First identified in 1933, a 2022 archaeological investigation established that the site encompasses a large but as-yet-undefined Native American cultural resource in the heart of New Hampshire’s largest city. IAC’s 2023 data recovery yielded valuable data about the site, confirming the presence of high-integrity cultural deposits from multiple eras of the precontact period, including evidence for a Paleoindian component. Archaeologists collected diagnostic lithic and ceramic artifacts and documented numerous cultural features, highlighted by a pithouse rare in the regional archaeological record. This presentation provides a summary of this significant Native American cultural resource and the major questions yet to be answered.

Tune, Jesse (University of Mississippi) and Sonya McGuire**[20]***Early Forager Responses to Ecological Changes in Southeastern North America*

The timing and process of initial human colonization of the Americas has been at the forefront of archaeological inquiry for more than a century. Today we have moved beyond simply asking “when?” and “from where?” did the first Americans arrive and are now able to investigate more nuanced questions about what life was like for those early foragers. The research presented here combines lithic analysis with large spatial datasets to investigate the settling in processes associated with some of the first foragers in southeastern North America. Southeastern foragers responded to ecological changes and possibly social pressures during the Pleistocene-Holocene transition by modifying their landscape-use strategies to map onto a restructured resource base. Landscape use patterns shifted from being centered around aggregation sites during the Late Pleistocene to being focused on site communities during the Early Holocene as foragers were settling into smaller territories.

Digital and Computational Methodologies for Masonry Typologies: A Quantitative Approach to Structure Classification in the Colca Valley, Peru

Archaeologists have long used architectural energetics to better understand the relationships between labor organization, political power, and materiality in premodern societies. The sixteenth-century Spanish invasion of the Andes caused unprecedented societal upheaval and, in the 1580s, the physical upheaval of people as the Toledan *reducción* system resettled communities into concentrated towns. It remains largely unclear how architectural production practices changed throughout this period despite scholastic attention to architecture features and building forms overall. Addressing production practices requires detailed regional masonry typologies such that labor-time estimates for sites and for individual structures can be calculated and compared. This study aims to systematize masonry typologies through the quantification of masonry features in the Colca Valley of southern Peru. It builds on existing descriptive research by utilizing photogrammetric and 3D models of various building types to extract wall feature data at 10 sites. Using metric features including stone sizes and counts per surface area, rectangularity, gap area, and angularity allows for more systematized identification of masonry types, especially in areas where unevenly coursed walls are common and complicate qualitative characterizations. Ultimately, a more robust typology will allow the authors to generate more nuanced energetics estimates across a variety of sites and structures.

Merchants, Mercenaries, and Migration in the Art of Cacaxtla (AD 600–900)

John Pohl's groundbreaking investigations of the tandem roles of merchant exchange, alliance building, and migration have caused us to reconceptualize the multiethnic sociopolitical landscapes of central Mexico and Oaxaca in the Epiclassic and Postclassic periods and the social actors that populated them. In the spirit of Pohl's work, this study reconsiders the nature of the central Mexican site of Cacaxtla, an Epiclassic fortified settlement with a mural tradition that makes overt stylistic, technical, and iconographic references to the art of the distant Maya lowlands. Though in particular Cacaxtla's so-called "Battle Mural" has generally been interpreted as a scene depicting the defeat of foreign Maya warriors at the hands of local central Mexicans, I argue that, contrarily, the mural vividly portrays the overthrow of local elites by a coalition of invading mercenaries wearing the trappings of Maya warfare. This foundational event laid the groundwork for the establishment of Cacaxtla as a foreign merchant colony that facilitated the movement of goods and people between central Mexico and the Maya Lowlands.

Turner, Bethany (Georgia State University)**[277]***A Sacred Frontier? Inka Settlement at Salapunqu*

During the fourteenth–sixth centuries, the Inka Empire transformed Peru's Urubamba Valley, located in the piedmont foothills of the eastern Andes, into an integrated landscape that was both economically productive and spiritually sacred. Extensive surveys have identified a shift whereby the Inka appear to have relocated settlements at higher elevations to the valley floor, coinciding with dramatic agricultural expansion and the construction of royal estates. The extent to which the Inka built their sites atop older sites is less well known in this region, especially since documented sites in the piedmont prior to 1000 CE are sparse. This study presents new $^{87}\text{Sr}/^{86}\text{Sr}$ data from individuals ($N = 39$) interred at the Inka site of Salapunqu, considered an administrative outpost and symbolic gateway to Machu Picchu. Tooth enamel $^{87}\text{Sr}/^{86}\text{Sr}$ varies widely, including values as high as 0.73032. These high values suggest some individuals spent their early lives in the Cambrian-Ordovician zone further north and east, approaching the Amazon region. Moreover, preliminary AMS dates for the study sample span two millennia, indicating the possibility that a known, much older site in the Urubamba Valley, with ties to the Amazonian foothills, was co-opted by the Inka when they built Salapunqu.

Turner, Michelle (Mystic Seaport Museum), Kellam Throgmorton (Northern Arizona University) and Jeffrey Ferguson (University of Missouri)**[335]***The Social Significance of Jemez Mountains Obsidian at Aztec Ruins National Monument*

Studying the sources of obsidian in the American Southwest has provided valuable insights into both resource procurement and the social and political processes that underlie it. We report on a large sourcing study from Aztec Ruins National Monument, a Chacoan community significant both for its political history and for its multiple great houses. Archaeological testing at the Aztec North great house, occupied for a short period between about 1070 CE and 1140 CE, revealed large quantities of obsidian debitage, with few formal tools, sourced entirely to two obsidian sources in the Jemez Mountains. At the Aztec West great house, occupied for nearly two centuries spanning the Chacoan and post-Chacoan periods, preliminary research also suggests the presence of large quantities of Jemez obsidian. In light of recent research on obsidian at Chaco Canyon and in the Rio Grande, we consider how obsidian use and exchange at Aztec compare to other regions. We also address the social significance of these patterns, including networks of relationships that brought obsidian to Aztec and the possible roles of color symbolism and ideological connections to distant sacred landscapes.

Recent pedestrian survey in the Oak Creek-Sedona region of Central Arizona executed as part of the Red Rocks Trail Restoration Project has identified a substantial number of Formative period sites belonging to the Southern Sinagua Tradition. Represented are habitation, agricultural, resource procurement, ritual/ceremonial, and special activity sites. Landscape archaeology emphasizes the intrinsic yet often overlooked connection between humans and their environment. Here we examine the interplay between the natural and anthropogenic and how the unique natural environment and terrain of the Oak Creek-Sedona region affected and was thus affected by human behavior.

Tutak, Danielle (University of Michigan), Kara Larson (University of Michigan) and Alicia Ventresca-Miller (University of Michigan)**[286]***Revisited Analysis of Early Bronze-Age Bone Tubes*

Comparative analyses have long helped archaeologists identify characteristics of artifacts including origins, social life, and use. However, this tool becomes problematic when broad conclusions are drawn without evidence beyond similar characteristics between types of artifacts. One example of this are Early Bronze Age bone tubes. Decorated bone tubes are found in many contemporaneous regions and cultures and archaeologists are generally able to compare tubes cross-regionally with each other, but this has led to overreaching assumptions about some artifacts' uses. Such is the case of Early Bronze Age Levantine bone tubes. Most Levantine bone tubes originate from a single workshop at Tell el-Hesi and these tubes are assumed to be pigment containers, as this is how similar bone tubes were used. Here, use-wear analysis and residue analysis of Levantine tubes along with an extensive literature review reconsiders established understanding of what these tubes were used to hold, and the workshop identified at Tell el-Hesi gives archaeologists an opportunity to compare a chronologically distinct set of Levantine bone tubes to those from other regions. Better understanding of these tubes' social lives allows better understanding of the cultures that used them.

Tydgadt, Lola (TraceoLab, University of Liège) and Veerle Rots (TraceoLab, University of Liège)**[58]***Getting a Handle on Form and Function: Functional Analysis of Aurignacian Formal Tools from Abri Pataud (Périgord, France)*

In Paleolithic Europe, the Aurignacian period marks the beginnings of the production of a multitude of formal tools, each with specific typologies that sometimes have been attributed to one or several functions and actions. Functional studies have shown that morphology does not suffice to infer use, and that one tool type can cover multiple functions. These studies enable us to perceive standardized tools differently by providing information about the materials with which they came into contact, the actions associated with their use, and the possible presence of hafting systems. Furthermore, they inform us about the life cycle of the tools and the investment they received, especially in terms of production, use intensity, and resharpening before

discard. Some morphotypes may also reveal traces unrelated to use that inform us about lithic production strategies. We address these various aspects by studying the microscopic traces present on a selection of nearly 300 formal tools (end scrapers, sidescrapers, burins, carinated pieces, Aurignacian blades) from Aurignacian layers 7, 8, and 11 of Abri Pataud (Périgord, France). This collection yielded hafting traces for some of the formal and functional categories and provides illustrations of rarely recorded production wear.

Long-Distance Obsidian Trade from Multiple Island Sources to Prehistoric Tuscany, Italy

Obsidian tools and flakes are regularly found at prehistoric sites in Tuscany, indicating long-distance trade and distribution during the Neolithic through Bronze Age periods (ca. 6000–1000 BC). Some 436 artifacts from six archaeological sites in Florence, Siena, and Grosseto, some 300 km from the nearest geological obsidian source, were tested with a nondestructive portable X-ray fluorescence spectrometer. Calibrated trace element results for Rb, Sr, Y, Zr, and Nb were used to assign specific geological sources, while geological samples for the sources on Lipari, Palmarola, Sardinia, and other Mediterranean islands were analyzed with the same instrument. In this study, Sardinia accounts for more than 50% of the artifacts tested, Lipari nearly 30%, and Palmarola almost 20%. Most of the Lipari and Palmarola obsidian artifacts are from the Middle Neolithic sites of Spazzavento and Chiarentana, and most of the Sardinia obsidian artifacts are from the Late Neolithic site of Neto-Via Verga and two survey areas of the Maremma Regional Park. These data are compared with previous studies of 937 obsidian artifacts from many sites in Tuscany, along with their specific location, archaeological contexts, and cultural periods. The obsidian distribution patterns are used to propose potential transportation routes and changes over time.

Introducing the Ancient Maya Kinship Project Consultation, Engagement, and Outreach Program

New archaeological aDNA approaches have the potential to dramatically change our understanding of the ancient Maya but it is important that living Maya people are aware of the research, provide their thoughts and input, and give their consent given the involvement of ancestral human remains. This poster presents the ongoing interview based consultation process which we developed as part of the Ancient Maya Kinship Project. To date we have interviewed 200 descendant Maya in Cayo District, Belize, to gauge their level of interest in archaeology, ancient genomic research, and any concerns they may have with such research. After conducting these interviews, we found that people are very interested in new scientific approaches to understanding what their ancestor's lives were like. Most people wanted to be included in archaeological research and learn more about the findings of the study and other archaeological studies. With these findings in mind we began supplementing preexisting Belize River Valley Archaeological Reconnaissance project outreach activities by hosting lectures, tours, food events, and excavation training.

Ugalde, Paula (Universidad Alberto Hurtado; Núcleo Milenio AFOREST)**[337]***Chair***Ugalde, Paula (Universidad Alberto Hurtado; Núcleo Milenio AFOREST), Rafael Labarca Encina (Pontificia Universidad Católica de Chile), Jay Quade (University of Arizona), Calogero Santoro (Universidad de Tarapacá) and Eugenia Gayó (Universidad de Chile)****[337]***Stable Isotopic Evidence for Camelid Mobility and Its Consequences for Early Hunter-Gatherer Settlement Patterns in the Hyperarid Core of the Atacama Desert, Chile*

We examine the stable isotopic signature of camelid and rodent remains from Paleoindigenous sites of the Pampa del Tamarugal (PdT), Atacama Desert (12,800–11,200 cal yrs BP; 800–1,200 m asl). $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ values suggest two groups of animals: (1) with higher $\delta^{15}\text{N}$ signal and increased C_4 diet and, (2) with lower $\delta^{15}\text{N}$ values and a C_3 -predominant diet. Through isotopic and taxonomic analyses, we hypothesize that the group with higher $\delta^{15}\text{N}$ was not local but source to the Puna (3,200–4,000 m asl) and could correspond to vicuñas. The second group, possibly guanacos and rodents, could correspond to animals from the PdT or from the Andean Steppe (4,000–4,500 m asl). However, most remains come from residential areas and represent young camelids, indicating that they were hunted locally. This demonstrates that the PdT supported life and that it was not a passageway from the Andes to the coast. Since there are two groups of animals, some of them represented by fleece, we propose that there could have been movement of humans and camelid remains from the Puna to the PdT. This movement could respond to seasonal migration or congregation of hunter-gatherer bands in the Atacama's lowlands.

Microblade Industries of Northeastern Asia during the Holocene: Case Study of the Ust'-Khaita Site in Eastern Siberia

Microblade industries emerge around 20,000 BP and spread rapidly throughout Northeast Asia and Beringia. However, at the turn of the Pleistocene-Holocene, microblade industries disappear in some areas while persisting in other regions until the late Holocene. The reasons behind the uneven disappearance of microblade industries are not clear, and to understand the reasons of the sociocultural dynamics it is necessary to study early Holocene microblade industries in detail. The Eastern Siberian site of Ust'-Khaita is highly representative of microblade industry development in the early Holocene. The cultural layers 7, 8, 9, and 9A (dated back to 7000–8500 BP) contain wedge-shaped, demi-conical microblade cores and osseous slotted tools. The stratigraphy of the site allows us to analyze these cultural layers relative to the boreal climatic optimum. The study of Ust'-Khaita indicates that the technology of microblade production developed dynamically. The characteristic of microblade industries provides the data for studies of other regions such as Japan, where microblade industries disappeared in the early Holocene, and British Columbia, where microblade technology was used until the late Holocene.

Uldall, Tamara, Caitlin Limberg (HDR Inc.), Trevor Payne (HDR Inc.) and Jennifer Ferris (HDR Inc.)**[43]***An Industry-Focused Approach to Piling Recordation along the Shorelines of Grays Harbor County*

Following non-native settlement in Grays Harbor County, Washington, on the Pacific coast, the harbor and adjacent rivers became integral to the growth and prosperity of the region's growing timber-focused economy during the early twentieth century. Native shorelines were transformed as piling-supported trestles, log booms, timber mills, and commercial wharves lined the harbor and riverbanks during the area's peak of economic prosperity. The economic downturn of the Great Depression, unchecked timber harvesting, and

implementation of modern environmental regulations led to a decline in the timber industry and the closure of most of the area's mills and related businesses throughout the latter half of the twentieth century. Our poster discusses HDR's recent survey of the remnants of the area's historic past and our approach to comprehensively document the hundreds of pilings and associated features that still stand along the shorelines today. Although most of the pilings and features are linked to the region's early twentieth-century timber economy, the individual piling cluster or feature has its own unique story that are linked to specific functions or enterprises. While examining these pilings within the larger industrial landscape, we explore their histories through our industry-focused approach to best tell their individual and collective stories.

Climate Change and Rural Livelihood in Calabria, Italy

Understanding how human activity, climate systems, ecosystems, and earth surface processes interact to change the capacity for different human livelihoods over time is crucial to finding livable strategies for coping with the looming climate crisis. Community-engaged historical archaeology provides a lens for doing so across decades of time in the recent past and illustrates the impact of these changes in local communities. In this poster, I draw on historical weather station data to compile a temporally contiguous dataset of daily climate records of the vicinity of Bova Superiore, Calabria, for the period of 1916–2022. I complement these weather records with a monthly spatial record of vegetation health for the period of 1981–2022 derived from AVHRR and MODIS satellite imagery and historical records and archaeological survey to create a timeline of climate, vegetation, and land-use change in the region over the past century. These data are used as input to landscape evolution simulation experiments to understand the impact of changing climate and vegetation on soil loss dynamics in the area over time in the context of local patterns of land-use, water management, and community infrastructure and to contemporaneous social and political changes happening in the greater region.

Illuminating Complex Mortuary Rituals in a Cemetery from Bronze Age Eastern Hungary

The Bronze Age Körös Off-Tell Archaeology Project (BAKOTA) has excavated 84 burials from a Bronze Age cemetery (Békés 103) located in the Lower Körös Basin in Eastern Hungary. Radiocarbon dates indicate that the cemetery was used for several hundred years, with the most active phase between 1600 and 1280 cal BC, a time that has been associated with the abandonment of tells in the region at the end of the Middle Bronze Age. Most of the burials were cremated and placed in ceramic urns. A systematic examination of MNI (minimum number of individuals), burned bone weight, and bone volume shows both consistency and variability across the cemetery. Urns contain evidence of one, two, or three individuals. Burials with multiple individuals typically consist of an adult and infant; however, some vessels contain only a single bone that is identifiable to another individual, or contain more than one individual, but significantly less total bone weight and volume than would be expected if all the bone had been included in the vessel. Altogether, this possibly points to a dynamic mortuary space where mourners and descendants actively engaged with the dead through practices such as repeated entry into the urns.

The Spatial Analysis of Housing Structures in Relation to Mortuary Features at Las Canopas (AZ T:12:137[ASM])
 Las Canopas (AZ T:12:137[ASM]) is a large prehistoric Hohokam village located on the south side of the Salt River with the site being occupied from the Estrella phase of the Pioneer period (AD 650–675) to the Civano phase of the Classic period (AD 1300–1450). During recent Phase II excavations at the site by Chronicle Heritage, a total of 285 mortuary features were encountered. The mortuary features were commonly located within housing structures floors and outside of houses often in discrete clusters. Statistical analysis conducted on the spatiality of mortuary features and housing structures suggests a shift in Hohokam society resulting in significant relationships created by the living relatives.

From Mayarí to “Protoagricola”: A Discussion on the Creation of Archaeological Cultures in Cuban and Dominican Archaeology

The diversity, complexity, and transformation of early settlers of the Caribbean are some of the main foci in current Caribbean archaeology. Since the 1960s, the presence of ceramics in some of these early contexts in Cuba and Hispaniola have generated new classifications and models where the ideas of diffusion, evolution, and transculturation dominate the explanations of this phenomenon. This has led to the creation of new cultures in both islands that impacted the traditional taxonomic and comprehension models of the early populations in the West Indies. This paper contextualizes and discusses the theoretical foci and how the archaeological evidence was managed in the creation of new cultures linked to this archaeological phenomenon in Cuba and Hispaniola. This paper also presents aspects of their current repercussion and questions that remain unanswered about the ceramic presence in the early archaeological contexts despite new advances and perspectives in studies of earlier populations in both islands and the Caribbean more generally.

Assessing the Viability of Limited Collection and In-Field Analysis Strategies for Ceramic Investigations at S'edav Va'aki, Arizona

One of the primary goals of the Arizona State University field school at S'edav Va'aki was to use minimally disturbing methods to accurately characterize the nature, spatial extent, and chronological placement of features within the project area. This goal was developed in the initial project treatment plan in consultation with the City of Phoenix Archaeology office, the Tribal Historic Preservation Offices of the Gila River Indian Community and the Salt River Pima-Maricopa Indian Community, and the Arizona State Museum in order to

limit unnecessary site disturbance. As a result, the project team focused on recording and photographing artifacts in the field to the extent possible and only collecting a small subsample of objects for additional analyses where necessary. In this poster we provide an overview of the ceramic analyses conducted for this project demonstrating how we were able to rapidly and efficiently obtain substantial information for stylistic analysis, chronological seriation, spatial analysis, and temper/technological analysis while only making limited collections. The tools and methods developed as part of this project provide resources for future projects in the Phoenix area focused on Ancestral O'odham sites and could be adapted to other settings as well.

Early Mesopotamian Urban Societies Were Not States

The “early states” of ancient Mesopotamia are factoids and straw men. Mesopotamia appears in textbooks as the prime example of the world’s earliest pristine states, and the flourishing of recent scholarship on the variability of other centralized large polities has often been via the juxtaposition of that variation against new datasets globally. Mesopotamian scholars have, however, been mostly slow to reassess our own centuries of scholarship through the lens of these other datasets. When one does, the Mesopotamian “state” appears as an anachronistic construct, throughout its first three millennia. This contribution begins by drilling down on the definition of “the state.” The definition used here draws on Max Weber and emphasizes patrimonialism and bureaucracy, a specific type of administrative structure, which did not exist in preclassical Mesopotamia. It was patrimonial at all levels, from farmer households to the household of the king; patrimonialism was not just a metaphorical extension of kinship but rather it was the durable indigenous form of kinship in Mesopotamia. Rather than kinship being replaced by the state, kinship evolved into a form capable of managing large societies in the way that scholars often assume is only possible via a state.

Terminal Classic Copper Production at El Coyote, Honduras

Archaeologists have long speculated that western Honduras was one source of the copper artifacts found in southern Mesoamerica from the tenth century onward. Until now, there has been little field evidence to back up this claim. Work conducted at the major political center of El Coyote in 2002, 2004, 2013, and 2018 has yielded clear signs of copper processing up to the point of casting, signs of the last activity being more equivocal. The dates for the copper workshop, though not straightforward, strongly suggest that artisans worked here beginning in the ninth century. We describe in this paper the stages of copper working for which we have direct evidence at El Coyote, review the lines of evidence used to date these practices, and consider how copper working figured within the political formations that took shape at the center during the Terminal Classic (CE 800–1000). We close by considering the implications of these findings for our understanding of the tumultuous political and economic changes that characterized much of southeast Mesoamerica during the ninth through tenth centuries.

Arqueología histórica del colonialismo en contextos insulares: Chiloé y su jurisdicción (siglos XVI-XVIII)

Los principales núcleos urbanos y fortificaciones en Chiloé coexistieron con un centenar de asentamientos, llamados pueblos de indios, desde la fundación de Santiago de Castro en 1567. Desde ese momento, la dinámica de relaciones interétnicas habría incidido en la conformación del sistema colonial basado en prácticas de co-residencia hispano-indígena, transformadas luego por lógicas socioeconómicas de dominio y la inserción de Chiloé en redes de intercambio continental. Abordamos el estudio arqueológico de las relaciones interculturales e impacto colonial en el confín austral de América. Para ello, se intenta refinar estudio del colonialismo y los mecanismos de colonización desde un enfoque que discuta la inserción en la historia universal de los habitantes de Chiloé como un mero antecedente o complemento del proceso de implantación europea y de descendencia de las sociedades criollas o mestizas posteriores. Para ello, se ejemplifican las relaciones de dominación, violencia y el surgimiento de nuevas formas de interacción, nuevos grupos, materialidades y modos de vida como resultado de procesos hibridación y criollización. Analizamos el fenómeno colonial y sus mecanismos mediante casos específicos dentro de este paisaje archipelágico, donde un reducido contingente colonizador emula, integra y hace parte de sus prácticas orientaciones económicas e identidades indígenas preexistentes y emergentes.

Maize in the Mix: Gas Chromatography Mass Spectrometry Analysis of a Fremont Ceramic Mug Recovered from the Snow Farm Site in Payson, Utah

The Snow Farm site, located on private farmland within the contemporary town of Payson, Utah, was inhabited by the Fremont people from approximately AD 700 to 1100 and is believed to have been a part of a larger village complex known as the Payson Mounds. The site is rich in Fremont artifacts and features, including three burials, some of which have been partially exposed by recent plowing. This study used gas chromatography mass spectrometry (GC-MS) to analyze soil from a small mug discovered in one of the burials that contained the remains of a middle-aged male. The analysis revealed traces of arachidic acid, commonly found in maize oil, extracted from maize kernels via mechanical or chemical means. Prior research suggests differential access to maize among the Fremont, with certain males consuming corn beer, implying elevated social status. These investigations indicate that these individuals, marked by maize-rich diets and elaborate burials, likely held higher societal positions. It is our suggestion that the mug found at the Snow Farm site likely contained a similar beverage, shedding light on the socioeconomic standing of the middle-aged male buried alongside this unassuming yet potentially significant ceramic vessel.

Revisita a Pisagua Viejo: Abordajes de arqueología histórica en la costa desértica de Tarapacá (Chile)

En el siglo XIX aparecen referencias escritas sobre Pisagua Viejo y la existencia de una aldea con iglesia cristiana en plena costa desértica entre Arica e Iquique, la que se describe como “Antiguo puerto donde se hizo el primer embarque de salitre en 1836”. Sin embargo, hacia 1880, el sitio constituía una ruina, donde se reconoce que “Era una población de los antiguos indios changos, que han existido en todas estas partes de la costa antes de la conquista”. Esta aldea fue construida sobre las últimas capas de basuras prehispánicas del conchal que ocupa la terraza marina donde se dispone, lo cual puede remontarse a los 4000 años AC, en tiempos arcaicos y extenderse hasta los períodos cerámicos tardíos, incluyendo una ocupación marítima del Inca no evidenciada previamente. Coherente con aquello, el asentamiento hispano estuvo vinculado al tránsito marítimo, así como a la factoría de pescado y la producción de vino asociada al valle de Camiña, una de las cabeceras coloniales e indígenas de Tarapacá (ca. 1581-1792). En este contexto, Pisagua Viejo representa un excelente conjunto arquitectónico prehispánico e hispano de la costa de norte de Chile, ofreciendo nuevas posibilidades para la aplicación interdisciplinaria de métodos de arqueología e historia.

Nominal Ruptures in Archaeological Heritage Governance? Heritage Ethics vs. Embedded Politics in the Participatory Paradigm of Peru's Qhapaq Ñan Project

This presentation discusses the permeability of the Qhapaq Ñan Project's participatory paradigm with historically rooted politics in archaeological heritage governance in Peru. In the early 2000s, the transnational nomination of the Qhapaq Ñan to the UNESCO World Heritage List harnessed a participatory approach for archaeological heritage management in the Andean region. Intergovernmental organizations advocating heritage conservation promoted this approach through recommendations, standards, and policies that emphasized community engagement, social inclusion, and sustainability. In the Peruvian context, specialists and managers of the Qhapaq Ñan's technical secretary (Lima) articulated strategies to build participatory practices out of a highly vertical and conservative heritage regime. Based on a qualitative methodology and archaeological ethnography, this study analyzes the processes, practices, and knowledge that underscore the Qhapaq Ñan's aim for a renewed heritage policy with a socially-sensitive ethos. It follows the concept of governmentality, to examine how the Peruvian state's technologies of power metabolized participatory and collaborative archaeology practices. The policymaking demonstrated tensions and resistances between emerging critical archaeological ethics and conventional forms of governing archaeological heritage. Therefore, it questions whether a state-led heritage participatory paradigm constitutes a nominal rupture that still favors the prevalence of the status quo.

Political Economy in Neighborhood Public Space at Angamuco, Michoacan

This paper looks at changes in the relationships between elites and commoners in neighborhood public spaces at the site of Angamuco, Michoacan, Mexico, drawing from a combination of Marxian political economy and collective action theory. The study uses a combination of viewshed analysis, agent-based modeling of accessibility, survey, and excavation to analyze how different groups interacted with neighborhood public spaces, centered around shrines or small temples in residential neighborhood plazas. It argues that earlier Classic and Epiclassic period occupations show more separation between elite spaces and commoner spaces, both geographically and in terms of spatial patterns. By contrast, Postclassic occupations constituting the bulk of the southern margin of the site show a mixing of these two patterns. It concludes that elites were actively colonizing commoner public spaces within urban neighborhoods, which likely created tensions around the role of secondary elites in the centuries leading up to the Late Postclassic imperial state. The later state likely sought to resolve these tensions through the creation of central bureaucratic institutions that undercut the authority of secondary elites.

Marxist Dendroarchaeology: Examining Labor's Effects on Landscapes and Living Conditions in Cebolla Canyon, New Mexico

The effects of unregulated (laissez-faire) capitalism on working class people and on landscapes are often only beneficial in the short term. The 1930s were especially difficult times for Americans as people became displaced during the Great Depression and the Dust Bowl. Many were forced to move into new areas in search of work and better living conditions for themselves and their families. This research examines labor's effects on landscapes and on the living conditions of Dust Bowl migrants using a multidisciplinary approach including dendroarchaeology, historical records, oral histories, and artifact analysis from early twentieth-century logging sites and homesteads in the Cebolla Canyon area of west-central New Mexico. The results help us to better understand labor conditions, including identifying periods of heavy logging in the area, examining how logging sites were structured and grew over time and assessing the living conditions of workers and their families. They also reveal long term landscape and ecological effects of logging under these labor conditions.

The History and Future of COSWA

The Committee on the Status of Women in Archaeology (COSWA) was formed to “understand the current status of women in the profession through the gathering of data and to improve the position of women in archaeology” (SAA.org). Influences from gender and feminist theory over the years have informed the work COSWA does to address barriers faced by women in the discipline. As the Society for American Archaeology strives to become more diverse and inclusive, COSWA is also working to expand our scope to identify and address barriers faced by people across the gender spectrum in archaeology. This paper will review the scholarly influences that inform our understanding of and approach to gendered issues in the discipline. We will also review current initiatives, future plans, and how to get involved with COSWA to participate in and/or contribute to our diversity, equity, and inclusion initiatives.

Osteogrammetry: The Efficacy of SfM Photogrammetry for Documenting Human Skeletal Remains

This research refines methods of digitally documenting human remains from archaeological contexts using structure-from-motion (SfM) photogrammetry and confirms the accuracy of employing this method for

metric and nonmetric data collection. SfM photogrammetry offers a low-cost and accessible way to create accurate 3D digital models of skeletal elements from 2D photographic data using little specialized equipment which could be accessible to most archaeological field projects. This research includes two pilot studies. The first will evaluate the metric accuracy of the skeletal models by comparing measurements taken from 20 femora by an experienced forensic anthropologist, a bioarchaeology student, and from digital models created and analyzed with Agisoft Metashape. T-tests will be used to determine the degree of interobserver error introduced by digital model creation and measurement processes. The second pilot study will examine the potential for non-metric, pathological analyses using digital models by analyzing skeletal remains recovered from three burials at a medieval site in San Donato, Lamon, Italy, modeled on-site during a single field season. The photographic quality of SfM models potentially acquired during the recovery process allows for close examination of surface texture unachievable by other methods of 3D documentation such as computed tomography and laser scanning.

Beekeeping, Ancestral Knowledge, and Interspecies Relationships: Exploring Place-Based Heritage in Yucatán
In her article “Saving the Other Bees,” Eve Bratman (2020) explores the successful reintroduction of beekeeping practices associated with the stingless species *Melipona beecheii* in the Yucatán Peninsula, which has resulted in the species thriving following near extinction. She attributes this success to grassroots initiatives undertaken to address biodiversity losses that emphasize cultivating intergenerational and interspecies relationships. This paper explores these topics through a multifaceted approach that focuses on ancestral knowledge of beekeeping practices encoded in the prehispanic (likely fifteenth century) Madrid Codex, and how communities today are engaging with these knowledge systems through intergenerational events that strengthen place-based heritage. We consider what the Madrid beekeeping almanacs—arguably created by scribes from the northern Yucatán Peninsula—reveal about stingless bee care and management, interspecies relationships, and cosmology; and how communities of eastern Yucatán, once a thriving region of honey production, identify with the beekeeping tradition documented in the codices and later postcontact sources, incorporating study of the Maya codices into secondary school education and displays at community museums. This connection to their ancestral past—and to the intangible heritage incorporated in the almanacs painted by the *ah tz'ib'* (scribes)—provides a source of pride and identity for communities in the region.

The Zooarchaeological Remains from San Miguel de Carnué (LA 12924)

I present an analysis of zooarchaeological remains recovered from the 2022 New Mexico State University Archaeological Field School directed by Dr. Kelly Jenks and a 1946 University of New Mexico Archaeological Field School directed by Dr. Paul Reiter at the ancestral frontier settlement of San Miguel de Carnué, occupied AD 1763–1771 in Tijeras Canyon, east of Albuquerque, New Mexico. This analysis is shaped by the understandings of the cultural, ecological, and economic changes caused by the introduction of domestic animals such as cattle, sheep, and goats as New Mexico’s communities were drawn into Spain’s transoceanic empire. I analyze human, animal, and environmental modifications; variations in anatomical part representations; taxonomic abundance; animal management styles; and how these animals contributed to the colonial economy. I compare my results to zooarchaeological assemblages recovered from Paa-ko, Tijeras Pueblo, and other neighboring sites in the Tijeras Canyon region.

Los cánidos en las ocupaciones post-teotihuacanas

Derivado del proyecto arqueológico “Estudio de túneles y Cuevas en Teotihuacan” es una colección de 455 cánidos que fueron estudiados para conocer su diversidad y la forma como interactuaron estos animales con los hombres en las diversas épocas (siglos VII-XX). En la colección fueron reconocidos perros comunes, xoloitzcuintles, híbridos de lobos y perros y coyotes. Las medidas obtenidas indican que los perros eran animales medianos y los híbridos de talla 20% mayor. Estos cánidos fueron principalmente animales que fueron utilizados por la gente, aunque también hay evidencia de ejemplares que vivieron en los túneles en épocas en las cuales hubo poca presencia humana en la zona. Los resultados mostraron que entre los siglos VII y IX el empleo de estos animales involucró lo funerario, el cuidado de espacios sagrados y ritos relacionados con el inframundo; entre los siglos IX a XII ritos relacionados con el agua; entre los siglos XII y XVI ritos ligados al agua y la guerra, así como actividades de manufactura y posteriormente protector y compañía de vivos bajo el esquema de pensamiento europeo.

Interpretative Approaches in Rock Art and Geoglyphs of the Atacama Desert: Between Theories and Methods

This study reviews the range of interpretative approaches that have delineated rock art research in the Atacama Desert, which has been mainly informed by ethnohistorical, ethnographic, and landscape archaeology perspectives. We focus on the role that prevailing Andean archaeological theories have played in the questions raised by archaeologists investigating rock art and geoglyphs and discuss how these theories are connected to the suite of methods employed to answer such questions. The main ideas, questions, and theoretical and methodological frames of reference that have been used are assessed, and we discuss the place of rock art and geoglyphs within the context of major problems of the discipline at a regional and global level.

Paleoenvironmental Reconstruction of Two Paleoindian Sites in North-Central New Mexico

Mapping environmental change through time can help archaeologists better understand patterns of human resource use. This poster presents the $\delta^{13}\text{C}$ and $\delta^{18}\text{O}$ values for bison teeth at two Paleoindian sites (Boca Negra Wash and Water Canyon) in north-central New Mexico. The $\delta^{13}\text{C}$ and $\delta^{18}\text{O}$ values are compared across the two sites to evaluate if there is a change in the habitat and climate occupied by the bison (and the humans that hunted them) during the Younger Dryas and Early Holocene. The results show that $\delta^{13}\text{C}$ values

remained consistent during the two periods, while the $\delta^{18}\text{O}$ values were more negative in the Younger Dryas than in the Early Holocene. Additionally, the $\delta^{13}\text{C}$ results demonstrate that the ratio of C_3 to C_4 grasses remained constant during the Younger Dryas and Early Holocene. My preliminary conclusion is that the $\delta^{18}\text{O}$ shift reflects distinctive hunting strategies during the two periods by the humans that preyed on the bison. However, further research is needed to demonstrate if the $\delta^{18}\text{O}$ values are due to climate or the herding patterns of the bison.

Incorporating Indigenous Feminist Theory into Rock Art Interpretation

The study of gender within the archaeological discipline has been a cornerstone of archaeological theory since the late 1980s. Though the study of gender has been foundational in changing our understanding of past peoples, there has been a severe lack of consideration of Indigenous women's knowledge as well as Indigenous feminist methodologies and theories within archaeological practice. This paper will examine not only how to incorporate Indigenous feminist thoughts but also how to identify Indigenous women's knowledge related to the archaeological record. Combining archaeological gender scholarship and Indigenous feminist philosophy, I synthesize the two theoretical frameworks to better understand Indigenous women-made rock art motifs from the Northwest Plains. I suggest that Indigenous women's specific ecological and cultural knowledge is essential to better interpreting and contextualizing this particular type of iconography. A sentiment that I wholly believe extends to aspects of the archaeological record created by other diverse and intersectional populations.

Architectural Investigations at a Multicomponent Site on the Shivwits Plateau

During the summer of 2019, members of the University of Nevada, Las Vegas, excavated two rooms within Pete's Pocket, a Virgin Branch Puebloan site located on the Shivwits Plateau, Arizona. The rooms, located about 300 m from the north rim of the Grand Canyon, were contiguous and circular, forming an almost Figure 8 shape. An unusually large amount of stone was associated with one of the rooms suggesting it likely was a tower. The second room had walls that suggest it was built using two types of construction technologies and it contained numerous handstones on its floor. We used Building Information Modeling, photogrammetry, and 3D modeling to analyze the architecture. The implications of these findings are discussed.

Isolation, Innovation, and Fraud: Assessing Failure in Historical Mining and Metallurgy

Mining and metallurgy are high-risk endeavors, and failure is common. In the first, the extent and nature of ore deposits are unknown, and the second is prone to mishaps due to inadequate temperature control, poor quality ore, and refractory malfunction, among other factors. Thus, failures in this industry—as measured by output—can be easily attributed to technical problems. However, placing them in broader context can lead to more nuanced and interesting answers that frequently implicate specific social processes in the failure to produce adequate amounts of metal. An examination of early colonial smelting in Porco, Bolivia, and nineteenth-century mining in Colorado illustrates how three such processes can result in failure: isolation from a community of practitioners, innovation, particularly by novices, and fraudulent behavior intended to deceive buyers and investors. Further investigation will undoubtedly reveal multiple reasons why technologies fail, suggesting that failure is an integral part of the human experience, rather than an isolated and exceptional event.

Van Dalen, Bastiaan (University of Exeter)**[245]***Bridging the Gap: Exploring Historical Human-Environment Dynamics within a Biodiversity Hotspot in the Gulf of Guinea*

To help protect the Earth's diverse species from disappearing at an alarming rate, research is needed in important biodiversity hotspots to understand how humans have interacted with their environment throughout history and how these insights can contribute to their future sustainability. Archaeology and paleoecology are ideally positioned for this. Unfortunately, however, Africa's islands have been largely overlooked. To bridge this gap, our research focuses on São Tomé and Príncipe, one of the most understudied biodiversity hotspots in the world, situated in West Africa's Gulf of Guinea. Being possibly the only country where no systematic archaeological fieldwork has yet taken place, Príncipe, in particular, offers an excellent research opportunity due to its exceptional biodiversity, high level of endemism, recent human presence, small size, low population, and limited urban development. With our research, we aim to shed light on the historical relationship, past and present, between humans and their environment in the archipelago. Following our earlier paleoecological fieldwork—the first of its kind on Príncipe—we will now conduct the first archaeological research on the island through an archaeological reconnaissance of the entire island using technologies like lidar, along with archaeological surveys and test excavations.

Van Den Bel, Martijn**[127]***Early Ceramics in the Coastal Guianas*

Ancient ceramics (beyond 2000 BC) have been found in the western part of the Guianas, notably in the coastal swamp areas of Guyana from the 1950s onward (Alaka). They are also known from the Courantyne River in Suriname (Kauri) and have only recently come to light in western French Guiana. The latter have been found at the terraces of the Lower Maroni River (Saint-Louis) between Suriname and French Guiana but also buried deeply in the White Sand Formations between the Sinnamary and Kourou Rivers in Central French Guiana (Eva 2), dubbed recently Balata for French Guiana. These ceramics are believed to be part of a larger early ceramic complex that emerges between Guyana and to the east of the mouth of the Amazon River (Mina) from ca. 3000 BC. In French Guiana they are also found in combination with rock-filled pits or earth ovens marking the introduction of earthenware and different modes of food preparation. The absence of griddles is notable for this complex and clearly differs from the (much) later ceramic complexes in the Guianas which appear by the end of the first millennium BC.

Recent research demonstrates that ancient Mesoamericans engaged in forest management long before they domesticated maize. Our research from El Gigante provides additional evidence for the antiquity of tree management practices in several different economically useful species. This presentation focuses on the avocado assemblage, represented by desiccated pits, pit fragments, and rind fragments, the latter numbering in the thousands. Using metric analysis of these materials, we demonstrate in situ domestication over an 8,000-year period, during which time pits got larger and rinds thicker as people selected for larger fruits. These findings establish southeastern Honduras as a new center of avocado domestication.

Van Dyke, Ruth (Binghamton University)**[28]***Exploring the Chacoan Landscape of the North American Southwest*

The UNESCO World Heritage Site of Chaco Canyon, in the North American Southwest, is well known for its monumental architecture and carefully choreographed landscape. Chaco Canyon lies at the heart of a 60,000-square-mile area that contains some 200 additional major great house communities, as well as features such as roads, agricultural fields, and rock art. Recent work across this landscape focuses on Native American descendant communities' deep and rich understandings of their ancestral places. Phenomenological and sensory explorations using GIS, lidar, and on-the-ground experiments provide dimensions that mesh well with Native perspectives. On the greater Chaco landscape, archaeologists and Indigenous cultural experts are working together to learn from one another and to protect the archaeology from destructive mining activities.

Van Keuren, Scott (University of Vermont), Marieka Brouwer Burg (University of Vermont), William Graves (Statistical Research Inc.) and Tate Norwood (University of Vermont)**[172]***Visions Around and Within: A GIS-Based Viewshed Analysis of Ancient Ballcourts in Northern Arizona*

By the eleventh and twelfth centuries AD, the region around modern-day Flagstaff was an emergent ceremonial landscape, evidenced by the proximity of sacred places, important topographic features, and large forms of ritual architecture. The latter included plazas, unroofed great kivas, platformed spaces, and ballcourts, which were engaged by people traversing a broader network of trails and shrines. In this poster, we consider how this landscape was experienced by examining the location and visibility of the region's 12 known ballcourts. These represent the northernmost examples of this quintessential Mesoamerican structure. Despite similarities in size and alignment, each seems to have unique visibilities in terms of viewership and sightlines to significant landforms. This poster uses GIS viewshed tools to explore two dimensions of ritual experience through visibility: how ballcourt activities were viewed from surrounding terrain and what vistas were observable from within the structures themselves.

Van Oss, Sarah (Tulane University)**[173]***Pulling it Together: Collecting, Collating, and Analyzing Quantitative Data from Written Reports using R*

Due to the nature of long-term archaeological investigations, data collection and curation methods change over time. This means that data can end up in several physical and digital locations, making the analysis of evidence challenging if it was collected years apart or by several investigators. In Lowland Maya archaeology, annual reports are required to be turned in to the government for the public record. Because they are regular publications and contain much of the information collected in the field, these reports, or informes, can be an easy and efficient way to gather site data when original collection documents are decentralized or not easily accessible. This poster describes how to employ R to collect and collate data into a database from these reports. This method allows for a deep and diachronic analysis of archaeological data that can be compared with current investigations and evidence, creating a more complete picture of the past. Collecting data from previously published reports also presents possibilities for the study of heritage data that has long been ignored or overlooked in archival collections. Overall, using R to collect data from reports can provide important context for current and future investigations.

VanPool, Christine**[333]***Chair***VanPool, Christine and Gavin Easley (University of Missouri)****[333]***Shaman-Magicians and Their Ecstatic Trances*

Altered states of consciousness (ASC) is a defining characteristic of shamanism. ASC, however, is not unique to shamans nor is it a single neurological/physiological phenomenon. Mystics and mediums also use ASC, and mediums are even “possessed” to greater or lesser degrees. In contrast, most shamans go on soul flights during “ecstatic” trances. (“Ecstatic” in this context means to be outside oneself as opposed to pleasurable.) During ecstatic trance, shamans interact with and manipulate unseen beings, energies, and/or deities. They hunt witches, petition deities, find objects, and divine the future. They might calm a sea goddess, so she releases the game animals she holds, or aid warriors as they attack their enemies. Shamans are consequently magicians, because magic is fundamentally about manipulating unseen beings and energies to effect changes in the physical world. As magicians they use magical items (e.g., drums, rattles, quartz crystals, fetishes) to better interact and engage with hidden forces and beings. Conceptualizing shamans as magicians shifts our focus to different aspects and roles of shamanism than are typically considered. Here we present cross-cultural regularities of “shamans as magicians” and their magical artifacts and tie them to the anthropology of magic.

VanPool, Todd (University of Missouri)**[333]***Chair***VanPool, Todd (University of Missouri), Christine VanPool (University of Missouri) and Brandon Massullo (Wooster Community Hospital)****[333]***Haunted Paquimé and the Creation of a Magical Community*

Human cognition both enables and limits the ways humans can interact with spirits and forces that are typically unseen or that otherwise transcend the physical world. Research in psychology, anthropology, and related fields indicates that social and physical contexts are central to activating the cognitive frameworks that facilitate spirit-human interaction, especially when paired with entheogens, physiological stress (e.g., sleeplessness, prolonged hunger, pain), and other factors that instigate altered states of consciousness. Here we explore how the built environment of Paquimé, the ceremonial heart of the Medio period (AD 1200–1450) Casas Grandes culture (northwestern Mexico), was intentionally formed to create environments that are cross-culturally associated with “haunted” locations that encouraged significant spirit-human encounters. This includes the use of light, the placement of burials and symbolically significant materials, and the form of the buildings themselves. These are linked to create inherently magical locations in that they have bundled objects and features that reinforce each other’s potency for representing and making accessible the spirit world. These locations consequently were distinctively primed to inspire spirit-human encounters. Examples we consider are the T-shaped ballcourt with its architectural and symbolic elaborations and other interior ceremonial spaces associated with human remains and darkness.

Digital Humanities and Religious and Social Archaeology of Medieval Central Eastern Europe: New Trends and Approaches

The present paper introduces the ERC project RELIC and its sister WEAVE project REPLICO, modeling how the general population was involved in significant historical processes such as Christianization and state formation by conducting a complex, comparative analysis and contextualization of archaeological and historical remains of the rural population living on the eastern fringes of the HRE during the Ottonian and Salian periods (tenth–twelfth centuries), exploring the influences of centers and networks of secular and ecclesiastical lords, of the natural environment, and of the economic infrastructure. Investigating this often-overlooked segment of the population, its hitherto unexplored or neglected role allows us to study how (top-level) changes in political and ecclesiastical organizations can be reflected in the evidence concerning the lower levels of society and of the local church network; how different strategies worked in different political settings, and what role local initiatives/agencies could have played in religious and political shifts.

Preliminary Survey and Excavations at Puerto Inka

Located 800 km from Cuzco, the Inka capital, Puerto Inka served as a crucial junction, linking the coastal Inka road with a transversal route to Cuzco. However, this region had remained underexplored in previous studies. By conducting excavations and surveys at Puerto Inka and its surrounding area, this research aimed to shed light on the Inka Empire's political economy, its methods of control, and the roles of local groups in this complex web of infrastructure. Additionally, it sought to compare Inka imperialism in the southern coast with other regions, ultimately contributing to a deeper understanding of the Inkas' unique mosaic of control and their place in history. Through satellite imagery, on-site visits, photogrammetry, digital mapping, ceramic analysis, and minor excavations, this comprehensive research endeavor provided insights into the Inkas' statecraft, their interactions with peripheral regions, and the significance of key sites like Puerto Inka in unraveling the mysteries of this ancient civilization.

The Puruwá Border: Archaeological Footprints and Ancestry in Tungurahua and Chimborazo, Ecuador

Who are the descendants of the ancient Puruwá? Archaeological settlements located in the central highlands of Ecuador, share certain features which researchers used to interpret as the materiality of ethnohistoric Puruwá. Human figures and heads manufactured in ceramics with profuse decorated faces and adorned in jewelry, copper ornaments, necklaces, beads made of shells, including *Spondylus*, and quartz appeared in individual tombstones. In addition, and recurrently, fine Cosanga-Píllaro vessels form part of the funerary pottery found in Puruwá sites. New evidence of such settlements in Puculpala, Colta, Patate Urcu, Píllaro, and Salasaka not only shows earlier occupation, but also continuous land use from the Formative to present times. Artifacts as well as environmental transformations are the footprints which lead to understanding the ancestry of Tungurahua and Chimborazo native descendants.

Vaughn, Evie, Kathryn Catlin (Jacksonville State University) and Douglas Bolender (University of Massachusetts, Boston)**[48]***Imagining Kotið: Artistic Visualization as Archaeological Practice*

This poster offers an artistic visualization of the Viking Age dwelling at Kotið, North Iceland. Based on geospatial data and photogrammetry collected in 2022 and 2023, the rendering demonstrates how this structure differs from previously excavated turf dwellings in Viking Age Iceland. Its small size, arrangement of interior space, and alterations to the walls and hearths suggest that it may make sense to interpret the dwelling as something other than a traditional longhouse. This poster demonstrates the utility of artistic renderings as an aid to archaeological interpretation, as we grapple with interpreting an unusual building form while disentangling the Viking Age dwelling from at least four other buildings later constructed on its footprint.

Vazquez, Mariana (University of Cincinnati)**[31]***Lidar-Based Aboveground Biomass Estimations for the Maya Archaeological Site of Yaxnohcah, Campeche, Mexico*

This study introduces a method for estimating aboveground biomass (AGB) in contemporary tropical forests near archaeological sites using lidar technology. Accurate AGB estimates are crucial for assessing wood resources available to the ancient Maya for city development. We propose a lidar processing model for the Yaxnohcah archaeological site's surrounding forest. Tropical forests exhibit diverse species distribution, necessitating consideration of this variation for precise AGB estimates. We identified four vegetation communities through Sentinel-2 satellite image classification and conducted field surveys within 73 500 m² transects. AGB estimates for transects required diameter, height, and wood-density measurements. Linear-derived models provided the relationship between each vegetation type's field data and lidar statistics. Predicted AGB values aligned with field measurements but varied between vegetation types: 83 Mg/ha for lowland forest, 178 for transition forest, and 215 for upland forest. These findings facilitated the creation of a wall-to-wall AGB map based on vegetation classes, enhancing archaeological research on past land use. The vegetation classification also revealed a spatial relationship between vegetation communities and the distribution of archaeological features in the ancient city of Yaxnohcah.

Vazquez Fiorani, Agustina (University of Notre Dame) and Mark Schurr (University of Notre Dame)**[202]***Experimental Archaeology of Traditional Andean Foods: A Contribution from Organic Residue Analysis of Replicated Formative Cooking Vessels from Northwest Argentina*

Organic residue and lipid analyses of ceramic artifacts provide important direct information on subsistence economies and foodways, pottery technology, and exchange and trade. Residue analysis needs to be enhanced by experimental data and reference libraries that provide solid frameworks to construct archaeological interpretations. Inspired by the extensive work on Old World experimental frameworks, this research focuses on South America species of economic and cultural interest within prehispanic societies by presenting the results of experimental and community-based work conducted in the Argentinian Andes with Indigenous communities (Tafí del Valle, Tucumán). We partnered with an Indigenous potter to replicate ancient cooking pots from the Formative period (ca. 200 BC–AD 800). Next, we cooked different traditional recipes using locally sourced, organic ingredients (maize, quinoa, squash, and llama meat) known to have been grown by villagers in the past. Culinary experiments were repeated several times to emulate daily use. Pots were buried for two months to simulate decay and then sampled for residue analysis by GC-MS and GC-C-IRMS. This poster contributes to understanding the agentive role of foodways in the adoption of farming lifeways by providing an interpretative frame for the identification of absorbed residues of traditional Andean villager foods and meals.

Vázquez López, Verónica (Escuela Nacional de Antropología e Historia; Univ. Pajonal is a Middle Preclassic site situated between La Venta and Aguada Fénix in Tabasco, Mexico. The site has a spatial layout similar to La Venta, formed by an elongated plaza with an E-Group at its center, several structures to the east and west edges, and a mound to the north. This pattern has been defined as the Gulf Middle Formative standardized complex, a subtype of the Chiapas Middle Formative pattern. Pajonal also has traits that resemble Aguada Fénix, i.e., 20 aligned structures on the east and west edges of the main plaza and a similar orientation. These traits make Pajonal a key site for understanding the interaction between the Middle Usumacinta region and La Venta. In 2022 we conducted excavations in the E-Group plaza. About two-thirds of the recovered obsidian was imported from San Martín Jilotepeque, Guatemala, and one-third was from highland Mexico, while the ceramics, highly eroded, include Middle Usumacinta region and Olmec types. These results indicate that the inhabitants of Pajonal interacted with both regions, although they were more actively involved with the obsidian exchange routes in the Maya area than with Highlands Mexico during the late Middle Preclassic period.

Velasco, Matthew (Cornell University)**[185]***Mummies and Mortuary Monuments Revisited: A Bioarchaeological Perspective on Ayllus and Open Sepulchers*

Open sepulchers (chullpas) are typically thought to have marked the social and territorial boundaries of Andean ayllus, corporate landholding groups based on descent. This proposed relationship between chullpas and ayllus follows from colonial-era accounts of Andean mortuary practices and finds empirical support in the archaeological record, in accordance with mortuary theories that link ancestral tombs to the demarcation of resource rights. Yet, ayllus are more than closed corporate groups. They are also integral wholes composed of multiple parts and different kinds of “persons.” Drawing on a decade of bioarchaeological research, this paper explores nested patterns of relatedness and difference at a large prehispanic chullpa cemetery in the Colca Valley, Peru. Tombs at the site were built one against the other in an agglutinated fashion, suggesting that chullpa practices were as much about building affinities as they were about staking differences.

Furthermore, cranial modification and isotopic data reveal that individuals buried together in open sepulchers embodied distinct identities and even relations to the land, a finding that does not undermine a relationship between tombs, ayllus, and resource rights so much as illuminate it. From a bioarchaeological standpoint, open sepulchers provide a window into ayllu practices in life as well as death.

La ofrenda del Edificio 5 de Ichkabal, Quintana Roo: Contexto arqueológico y observaciones epigráficas e iconográficas en torno a un cache del Preclásico Tardío

En abril de 2009 los arqueólogos Enrique Nalda Henández, Sandra Balanzario Granados y Karina González Hernández excavaron una ofrenda (*cache*) en el interior de una subestructura del Edificio 5 de Ichkabal, megalópolis maya del Preclásico ubicada en el sur de Quintana Roo. Dicha ofrenda contenía fragmentos de cerámica, copal, orejeras de jade y otros objetos, incluyendo un plato del grupo Sierra rojo en cuyo interior había seis conchas *Spondylus*. Las paredes del plato preservan un mismo cartucho jeroglífico pintado en sus cuatro lados (presumiblemente asociado con los rumbos cardinales o con las esquinas que alcanza el Sol en los solsticios), mientras que dos de las conchas tienen escenas y jeroglifos incisos, que parecen relacionarse con una narrativa mítica. En esta ponencia expondremos los detalles del contexto arqueológico, así como las distintas posibilidades interpretativas que conocemos para acercarnos al significado de las imágenes y los jeroglifos. Nos apoyaremos, además, en el informe técnico sobre las características fisiológicas y orgánicas de las conchas (Mainou Cervantes 2012), como también en el levantamiento digital 3D, fotogrametría (Balanzario Granados y Tokovinine 2020) y dibujos de las mismas.

Beyond the Stereotype: Working toward a Landscape-Based Model of Study and Cross-Cultural Exchange of Fluteplayer Rock Art Imagery in Chaco Canyon

The Fluteplayer is widely recognized within rock art, characterized by a figure holding and/or playing a flute. It has been misinterpreted as the Kachina Kokopelli. As a result it is now entangled with modern, predominantly Western, interpretations of the Kokopelli character, which are subsequently rooted in shamanistic interpretations of fertility. Although this association has been discredited, the ubiquitous interpretation of Fluteplayer imagery as Kokopelli detracts from the true cultural value of individual and unique imagery. This discussion will present current PhD research which aims to address this discourse within the study of Fluteplayer imagery using a landscape-based approach to establish a context and wider sociocultural placement of the image within Chacoan society, working toward a model of cross-cultural and respectful sharing of knowledge with Indigenous people. Research results are already showing diverse contextual placements for Fluteplayer imagery, alongside the comparative analysis of flute artifacts, illustrating the figure's wider sociocultural placement. With further planned research to conclusively understand the placement of the Fluteplayer within Chacoan society, it will move the image beyond the stereotype, offering a wider discussion about the image, alongside supporting the value of rock art and Indigenous knowledge to the wider academic community.

Venter, Marcie (Murray State University)**[163]***Discussant***Venter, Marcie (Murray State University), Lourdes Budar (Universidad Veracruzana) and Philip Arnold (Loyola University Chicago)****[216]***Expressions of Ballgame Ritual Participation at Matacanela in the Sierra de los Tuxtles*

In this presentation, we consider the accumulated evidence for ballgame ritual participation throughout the Classic period center, Matacanela, located in the south-central Tuxtla Mountains. We also account for related symbols from settlements in the immediate outskirts and incorporate them into the view of the broader cultural landscape. During fieldwork conducted over the past decade, several ritual deposits were encountered during stratigraphic excavations that suggest that the occupants of the area participated in varying ways in the larger ballgame phenomenon—the manifestations of that ritual engagement were both monumental and modest in scale. Ballcourts were constructed, sculpture was manufactured, and both were placed in arrangements that highlighted their changing importance during the site's growth, apogee, and decline. Moreover, portable symbols' personalized engagement in these collective rituals reveals ways that the ballgame and its participant observers linked the tradition to ebbing holds on authority during periods of cultural transformation.

Ventresca-Miller, Alicia (University of Michigan), Julia Clark (NOMAD Science), Jamsranjav Bayarsaikhan (Max Planck Institute for Geoanthropology), Peter Hommel (University of Liverpool) and Sosorbaram Khurelsukh (Mongolian Academy of Sciences)**[151]***Hearth Fatigue: Excavation of a Deeply Stratified Campsite from the Medieval Era in Northern Mongolia*

Until recently there were only a few examples of deeply stratified habitation sites in Mongolia. During survey, we located an erosional gully with several hearths, an ash lens, and cultural materials. Initial radiocarbon dates indicate that the site was occupied from 1000 to 1400 CE, spanning the pre-Mongol through Yuan dynasty eras. We returned to excavate Burgastain Am to understand the habitation history of the campsite. Test units reached a depth of 3 m, and we identified 11 hearths and a meter-thick ash layer. We also found evidence for discontinuous occupation of the site with pea gravel separating cultural layers. We are currently working through recovered materials including paleobotanicals, faunal remains, ceramics, sediments, and metals. The campsite is only a few kilometers from Erchuu Khot, a Mongol era palace or temple, and we are interested in understanding the relationship between these communities. The thick layer of ash at Burgastain Am might indicate that the site was intensively occupied for a short period or that it had a longer occupation. Future work will focus on understanding chronological variation in lifeways, subsistence practices, as well as ceramic technology and design.

Vepretskii, Sergei (Institute of Ethnology and Anthropology, RAS) and Christophe Helmke (University of Copenhagen)**[159]***The Tumultuous Times: The Shifting Alliances of Caracol Monarchs in the Sixth and Seventh Centuries*

The most extensive historical record of Caracol was produced under the reign of Tutum Yohl K'inich Tz'uumt' II (formerly known as K'an II / Ruler V), who reigned from AD 618 to 658. In addition to outlining his life and deeds, as well as those of his father Yajawte' K'inich Tz'uumt' II (a.k.a. Lord Water / Ruler III; reigning from AD 553–593+), these texts provide a unique vantage on the historical events of the sixth and seventh centuries, outlining alliances, reversals and crushing military defeats—including that of Tikal in AD

562. In unparalleled detail, the same sources also narrate relations with the Kaanu'l royal house, and the schism that occurred between AD 630 and 642, resulting in the fissioning of the dynasty and the establishment of the new capital at Calakmul. Rather than passive observers of these historical highlights, a careful reading of the texts reveals the capricious character of the agents, acting out on alliances, resulting in rapidly shifting allegiances and antagonisms. Here we will outline this tumultuous century (AD 553–658) and track the shifting alliances of Caracol's monarchs, focusing specifically on what the texts do record and also what the texts are resolutely silent about.

The Killing of Captives by the Moche of Northern Coastal Peru: Veneration or Violation?

Archaeological and bioarchaeological data and a rich iconographic tradition provide complementary perspectives on the taking and killing of captives by the Moche (ca. AD 200–900). While these practices clearly had important ritual aspects, there continues to be debate over the source of captives and their social identities (warfare or ritual combat; local elites or enemies) and the significance of such practices (ritual sacrifice or sanctioned killing; religious or political motivations) in Moche culture. While known best from excavations at major ceremonial centers such as the Pyramids of Moche, the killing of captives has been identified more recently at smaller centers in the Moche and other north coast valleys. Key elements for identifying sacrificed captives include their demographic profile (young adult males); ropes around the neck, wrists, or ankles; lethal perimortem injuries; and the context and manner of disposal of their remains. The latter includes denial of proper burial, commingling of bodies, dismemberment, mutilation, and other indications of disrespect for the victims. This presentation will focus on postmortem manipulation and disposal of bodies as a key element in interpreting these practices and distinguishing them from other forms of ritual sacrifice in ancient Peru.

Putting the Pieces Together: Paleogenomics and Bioarchaeology at Midnight Terror Cave

Since 2014, the Midnight Terror Cave (MTC) osteological assemblage has been subjected to archaeological, skeletal, isotopic, and paleogenomic analyses generating new insights regarding the use of the cave space as well as the individuals found within it. The thousands of human remains, animal bones, ceramics, and artifacts, have pushed us to consider Maya ritual and belief, in general, as well as its application within the cave itself. We have reexamined the role of women in ritual and sacrifice, age difference between sexes, and

postmortem mortuary practices. In this presentation, we synthesize the data to understand how the MTC population fits into the larger Maya landscape. Using genomic data obtained from 19 individuals from Midnight Terror Cave, Belize and Dos Pilas, Guatemala, we examine the population genomics of the human remains recovered from both caves as well as how they fit into the large landscape. Combining the results of this decade long interdisciplinary analysis, we now have a clearer picture for how MTC was used, how people moved through the space, and the implications for the study of human sacrifice.

Human Behavior and Environment: A Preliminary Zooarchaeological Investigation at the Alm Shelter Wyoming
The Alm Shelter in Wyoming lies in the foothills of the Bighorn Mountains, and its repeated use for 12,000 years provides a snapshot into human life throughout the Holocene. Moisture is a controlling factor in this (semi)arid environment. Mountains provided refuge and increased moisture access for humans, animals, and plants. This aridity also leads to poor bone preservation, adding import to this site through its addition to existing faunal and environmental data for the region. Faunal remains are used to investigate subsistence, mobility, and environmental reconstruction through stable isotope analyses, standard faunal analyses, and proteomics (zooarchaeology by mass spectrometry, ZooMS). $\delta^{13}\text{C}$ and $\delta^{15}\text{N}$ data allow for evaluation of faunal bone collagen preservation, while also providing data for vegetative landcover and aridity. The fauna will give insight into subsistence over time and whether hunting was done in the basin or on the mountain. Combined, the data can be used to explore relations between human behavior and the environment across the Holocene.

[323]

The Socioecological Determinants of Community Centers

Community centers often play a dual role in archaeological contexts, as a civic space where individuals can participate in shared rituals and exchange and as a residential space connecting a large number of unrelated households. Given that these two roles are not perfectly coincident with each other, it is interesting to consider why community centers get established where and when they do. Is it more about local resource needs or the distribution of the wider community? We propose to investigate this question using a spatial network framework applied to data derived from cyberSW, in three regions across the US Southwest: central Mesa Verde, the northern Rio Grande, and the Cibola area. In particular, we explore how community centers evolved in or near dispersed farming communities by describing a dense network for each region, with edge weights defined by commute times and node attributes defined by hindcasted climate variables relevant to maize farming. We then compare environmental conditions in and near the locations of those centers to two measures of network centrality (closeness and betweenness), with a focus on how those changed over time. Our results can help inform on broader discussions in urban science and economic geography.

Mothers on the Move? Sex- and Age-Related Differences in $^{87}\text{Sr}/^{86}\text{Sr}$ in Late Bronze–Early Iron Age Tilburg-Udenhoutseweg, the Netherlands

The urnfield cemetery of Tilburg-Udenhoutseweg was excavated in 2020 yielding a total of 230 cremation graves dating to the Late Bronze-Iron Age. The cremation graves were distributed over the entire cemetery as part of burial monuments, in clusters, or as individual graves. Osteological analyses of all the cremation deposits demonstrated the presence of 234 individuals, of which 69 nonadults, 107 adults, and 58 indeterminate. Of the adults that allowed sex estimation, 21 were female and 27 male. More than 90% (106/109) of the individuals had $^{87}\text{Sr}/^{86}\text{Sr}$ that matched the range in and around Tilburg (0.7091–0.7126). Only three individuals had higher $^{87}\text{Sr}/^{86}\text{Sr}$ (0.7127; 0.7128; 0.7146). Interestingly, the highest $^{87}\text{Sr}/^{86}\text{Sr}$ were observed in nonadults (including two of the outliers). In addition, the mean $^{87}\text{Sr}/^{86}\text{Sr}$ of females (0.7107) is statistically significantly higher than the male mean (0.7099), showing an age- and sex-related difference in diet. Apart from nonadult G300 that had $^{87}\text{Sr}/^{86}\text{Sr}$ of 0.7146 which does not seem to be present in the Netherlands, large-scale long distance mobility cannot be inferred. However, the age- and sex-related difference in $^{87}\text{Sr}/^{86}\text{Sr}$ could be indicative of more localized mobility. This paper demonstrates the importance of high-resolution $^{87}\text{Sr}/^{86}\text{Sr}$ to reveal sociocultural patterns within past societies.

Relatos de juncos y totoras en el Desierto de Atacama: Uso y significados en el Sitio Aragón I (3000 aC-1000 dC), región de Tarapacá, Norte de Chile

Desde el Perspectivismo amerindio se ha puesto énfasis en los mundos relacionales y las lógicas simétricas entre los humanos y no humanos. Sin embargo, desde este enfoque la arqueología ha dejado en un segundo plano la relación entre plantas y humanos. A partir del caso de estudio del sitio Aragón I (ca. 3000 aC-1000 dC), Desierto de Atacama, este trabajo tiene como objetivo estudiar y reflexionar sobre el uso, las injerencias y agencias de las plantas silvestres en contextos de cazadores recolectores del Arcaico tardío (ca. 5000-3000 aC) de la región de Tarapacá, norte de Chile. Los resultados indican un uso extensivo durante el periodo Arcaico de plantas de lechos de agua, tales como juncos y totoras. Particularmente, la especie *Schoenoplectus* sp., (juncos) fue recuperada extensamente en el registro, estando representada en todas sus partes (rizoma, tallos y flores) y con múltiples usos tales como rituales, alimenticios y artesanales, sugiriéndonos sus múltiples significados. En conclusión, se invita a reflexionar sobre las plantas y su presencia, no tan sólo como ecofactos inertes, sino como constructoras de las realidades cazadoras recolectoras desde sus usos y cualidades.

Persistence in Clay: A Thousand Years of Ceramic Traditions at Etlatongo in the Ñuu Savi Region

Archaeological research in the Nochixtlan Valley of the Ñuu Savi region has been stymied by the lack of useful ceramic chronologies when compared to other parts of Mesoamerica. Presently, only three phases cover the last 1,800 years of precontact occupation, which makes it difficult to make meaningful comparisons with neighboring regions. This has created the perception that development in the valley paralleled what transpired in other areas, or that there were long periods of social stability followed by moments of dramatic change. Recent excavations at Etlatongo have yielded significant ceramic collections that may help elucidate existent predicaments by making us to see ceramic traditions in a new light. Defined as learned and repeated practices that draw on embodied knowledge, traditions are actualized forms of making memory that transcend the inheritance of one's past. In this way, traditions articulate both continuity and change, through an array of different sociocultural practices. In this paper, I describe how ceramic traditions at Etlatongo contingently changed to interrogate whether our long chronological phases may correspond to persistent traditions.

Paleoproteomic Approach to Understanding Human Subsistence at the Late Upper Paleolithic Site of Ljubičeva Pecina (Istria, Croatia)

The region of Istria, today the largest Croatian peninsula, was a part of the Great Po region during the Late Pleistocene and therefore a big part of an intricate, now largely changed, ecosystem. The site of Ljubičeva pećina is one of many caves that played an important role for hunter-gatherer communities gravitating to this vast, and potentially fertile, plain. This rich site has a long stratigraphic sequence and, among other periods, bears evidence of human occupation at the very end of the Upper Paleolithic, approximately between 16 and 12 ka cal BP. Apart from traditional zooarchaeological analyses of the large faunal assemblage from trench B, a paleoproteomic approach to nondiagnostic osseous fragments is ongoing. Here we present the results of ZooMS analyses done so far in comparison to the available results of the morphological analyses. This gives us more data to get a better insight into behavioral patterns of these groups, such as planning, mobility and seasonality. Also, from a methodological point of view, we can assess how much and in what way the proteomic methods complement more traditional approach to faunal remains and, through estimation of collagen preservation, how they can be used in planning for further biomolecular analyses.

Building on Basso: Ndee Place-Making as Cultural Persistence and Survivance

Ndee place-based understandings of the past, present, and future are ageless and enduring. In his book *Wisdom Sits in Places* (1996) Keith Basso explains the moral and social underpinnings of Ndee ties to place through topography and storytelling. However, in reference to present and future intersections with Ndee worldview how do we build on Basso's seminal work contemporaneously? Are there ongoing forms of Ndee placemaking that are expressed through current cultural preservation and maintenance activities? How do persistent places speak to the contemporary wants and needs of Indigenous communities? How might past and present agricultural practices and exertions of food sovereignty evoke senses of place important to

concerns of climate change and overall Ndee identity? Heavily researched and extracted Ancestral Pueblo areas within the Ndee landscape provide ongoing intergenerational connections that speak to broad present-day tribal issues beyond archaeological research goals. This paper attempts to foreground place through the powerful lenses of Ndee place-based realities grounded in a multitude of “persistent relationalities” that speak to essence of Ndee life and what is needed to maintain such connections in perpetuity for overall Ndee well-being.

Internal Networks and the Materiality of Imported Gold in the Eastern Cordillera of Colombia (AD 600–1600)

The Muisca of the Eastern Cordillera of Colombia are known for making extensive use of imported gold to manufacture both votive metalwork and body ornamentation over a millennium. To better understand the materiality of this imported raw material, we present new computational models of the compositional datasets pertaining to Muisca metal assemblages and propose that the chemical signatures of the votive offerings reflect contributions of gold from people converging into specific locations for festivities. In turn, we argue that the symbolic value of gold among the Muisca was often based on processes and raw material movements at the intraregional scales, taking place after its introduction from foreign sources. We finally zoom into the contextual scale, presenting new data on votive assemblages from the archaeological site of Divino Niño, Sopó: here, elemental and technological analyses demonstrate the combination of multiple manufacturing hands and gold compositions in a single ritual context. While the dynamics of internal exchange networks are undoubtedly more difficult to reconstruct, our results highlight that the symbolic value of metals or other imported materials should not be assumed to be a priori or primarily placed on their value as foreign luxury goods, whether within the Isthmo-Colombian region or elsewhere.

Las redes de interacción interregional a larga distancia entre los Andes Centrales y Septentrionales durante el 3° y 2° milenio aC: Una perspectiva desde Shoymal (Amazonas-Perú)

Las excavaciones arqueológicas sistemáticas realizadas en Shoymal (Amazona-Perú) nos permitieron identificar un edificio volumétrico construido entre fines del 3° e inicios del 2° milenio aC (2300-1800)

aprox.), mediante el uso de grandes bloques líticos finamente tallados. Muchos de esos sillares contienen grabados en alto relieve con distintas representaciones, las cuales son similares a otras plasmadas sobre distintos soportes en sitios contemporáneos como La Galgada, Huaca Prieta, Santa Ana La Florida, Jaiva, Buenavista, Cerro Ventarrón, etc. Dichas similitudes evidencian la existencia de contactos interregionales, relacionados en gran parte a aspectos cosmológicos, en un área que abarcó parte de los Andes Centrales y Septentrionales, incluyendo a la Costa y la Amazonia. Durante dicho momento, este edificio correspondió a un centro ceremonial, asociado a un contexto funerario y ofrendas. Asimismo, en un periodo posterior que abarcó gran parte del 2° milenio aC (1800-1200 aprox.) se construyeron nuevos edificios y se caracterizó por el uso de vasijas cerámicas similares a las identificadas en sitios como Huacaloma, Montegrande, Pandanche y Manachaqui. Durante este periodo el edificio volumétrico fue cubierto paulatinamente con depósitos que contenían gran cantidad de cerámica, lo cual evidencia una pérdida del prestigio de este frente a nuevos edificios.

Historic and Ancient Terrace Use at the Hacienda Rincon de Guadalupe

This poster presents the findings for the first season of an archaeological dissertation project investigating changing land use at the Hacienda del Rincon de Guadalupe in Apaxco, Mexico. The hacienda is located within the Sierra Tezontlapan, bordering the states of Mexico and Hidalgo. It was constructed during the late eighteenth century, but there is evidence of significant early colonial, and even prehispanic, occupation of the area. Occupation of such an inclined and uneven area was facilitated by the use of terracing that served various residential, agricultural, and ecological functions. One of the goals of this project is to identify how terrace use and function changed in response to chronological and spatial positioning. Work conducted this summer included surface collections, mapping, and shovel testing for targeted areas in the terraced foothills surrounding the Hacienda center. We found that terraces further from the hacienda center were likely used at an earlier period in time and those at lower elevations are more likely to have been used for primarily agricultural purposes. Future work at this site will expand on these findings and will determine how construction methods were impacted by chronological and spatial factors.

Exploration and Evaluation of an Ash Pit at AZ T:12:137(ASM)/Las Canopas, Phoenix, Arizona

This poster will delve into the findings from an ambiguous ash pit discovered during Chronicle Heritage's recent excavations at AZ T:12:137(ASM)/Las Canopas, a prehistoric habitation site broadly occupied between AD 650 and 1450 in Phoenix, Arizona. The artifact assemblage, temporal and cultural affiliation, and discrepancies in determining use-history will be presented. The scientific goal is three-part: revisit resource procurement and specialized craft production theories, examine inconsistencies, and determine the feature's main function at the site. Artifact ornamentation and decorative styles attributed to the feature will be cross-referenced with contemporaneous habitation sites within the American Southwest to assess cultural identity and open discussion over established trade routes.

Just Add Water: ENSO-Driven Ephemeral Agricultural Systems in the Arid Chaupiyungas of Peru's North Coast

Abrupt climatic changes caused by El Niño Southern Oscillation (ENSO) bring profound ecological transformations to the Andean Pacific coast. Archaeological research has largely focused on the impacts (which have been shown to be largely negative) of ENSO-positive phases, or “El Niños,” on complex socioecological systems in coastal lowlands. This focus has recently broadened, exploring how ENSO impacts agroecological environments of the inland chaupiyunga zone, where El Niños cause significant amounts of precipitation in an arid environment. We document ephemeral irrigation-agricultural systems and ENSO-driven changes in productivity within the chaupiyunga. These systems draw surface water from channels that are not hydrologically connected to highland sources, but which derive moisture from El Niño-derived precipitation falling directly in the vicinity. We present information on labor requirements and productive potential of these systems. Associated archaeological finds suggest these systems were used as early as the Chimú and perhaps Moche periods and had intermittent use into recent times. These fields suggest ways in which some of the adverse impacts of El Niño events could be offset by strategies tailored to the hydroclimatic dynamics of ENSO. This findings are highly relevant, as anthropogenic climate change is predicted to increase the frequency and severity of ENSO dynamics.

Land Use and Change at the National Cemetery

Created in 1866, Vicksburg National Cemetery is perhaps most famous as being the final resting place for the 17,000 Union soldiers who participated in the Civil War. The importance of the cemetery, however, extends far beyond its designated period of historical significance. Archaeological evidence has revealed the presence of artifacts from a myriad of different time periods, from prehistoric to modern day, indicating that the use of Vicksburg National Cemetery extends far beyond being a place of commencement by those who have visited, occupied, and shaped the landscape that is now part of the National Park Service. This paper explores the various ways that the use of the land that makes up the National Cemetery has changed throughout time and how even after the cemetery was erected, the landscape was utilized for various other purposes other than mourning and revelry.

[69]

El Ombligo Burial Mound and Its Material Networks

Guasave, Sinaloa, has historically been identified as representing the northern Mesoamerican frontier based on the presence of Aztatlán culture tradition materials dating to circa AD 1150. To explain the purported Mesoamerican affiliation, researchers in the region have deployed hypotheses focusing on economic and ideological connections between the highlands of central Mexico and the US Southwest. El Ombligo burial mound funerary assemblages are the basis for all such discussions since the 1930s; however, we know very little about the social structure of local prehispanic populations. This poster presents a social networks analysis on the funerary assemblage of the El Ombligo site. The results of this research focus on parsing the number and heterogeneity of social roles in this community but also intersect with discussions of inequality, relations of power, and the emergence of new sodalities/identities in northern Sinaloa during the purported Mesoamericanization of northern Mexico.

[102]

Creative Clearance: Caring for an Important Place

S'edav Va'aki (formerly known as Pueblo Grande) is an ancestral O'odham (Hohokam) archaeological village site and Phoenix's only National Historic Landmark. Most of the site is preserved and maintained by S'edav Va'aki Museum (Museum) and includes a publicly accessible trail and non-public preserves. Hidden by trees and desert grasses and surrounded by fences, there remain areas of myriad surface artifacts and features, reflecting occupation from prehistoric to historical times. The Museum protects this land from illegal dumping, collecting, and other disturbances, a difficult task in the heart of an urban metropolis. Struggling for decades with managing these modern intrusions in a sensitive area called "Trashmound I," it was determined that non-excavation professional documentation was necessary. Through conversations with Arizona State University (ASU) School for Human Evolution and Social Change the team developed a mutually beneficial, nondestructive a field school in this location. The Museum and ASU collaborated with Tribes to develop a program in which students learned in-field artifact analyses, GIS mapping, archival research, and the importance of working in concert with descendant O'odham communities. The Museum benefited with sensitive areas clearly documented for protection and wealth of new information on an area that was not well understood.

Recent Research in an E-Group (Group AA) at Nixtun-Ch'ich', Guatemala

E-Groups in the Maya world are believed to have had ritual purposes, serving as meeting centers where political meetings or markets may have taken place. They are also believed to have celebrated solar cycles. At Nixtun-Ch'ich' three or four E-Groups are aligned on the site's east-west axis. Our excavation in one of the E-Groups (Group AA) found that it contained construction phases from the Middle and Late Preclassic periods. This group is in the central part of the site and was accessed by two avenues that we believe were site entrances. The exact uses of these building groups are debated, but the buildings' east-west axial alignment suggests that the structures could be used as astronomical observatories marking dates throughout the year as well as having astronomical references applied to its very architectural design, standing as a monumental representation of time. Water pools yearly on the eastern side of Group AA, suggesting that it was also tied to cycles of rain—the rainy season.

[227]

Buried Lives: An Archaeological Investigation of a Louisiana Plantation Midden

This paper delves into an in-depth archaeological investigation of the Evergreen Plantation Slave Quarters (16SJ B63) in southern Louisiana. Ground-penetrating radar (GPR) data analysis and subsequent excavation endeavors centered around units adjoining Cabin I uncover a vivid narrative. The exploration of Test Units 15, 18, 20, 21, and 25 reveals discrepancies between GPR indications and actual excavation depths, fostering a reevaluation of the site's historical timeline. The paper not only presents a meticulous analysis of the excavated artifacts but also situates these findings within the broader context of plantation archaeology in southern Louisiana. Moreover, this paper adopts a humanistic perspective, amplifying the voices of the

enslaved and their descendants who have been underrepresented in historical narratives. Through creative interpretation, the study provides a platform for the marginalized, offering a richer understanding of their experiences within the plantation setting. Ultimately, this paper seeks to reconstruct the buried lives of Evergreen's past inhabitants, contributing to a more authentic portrayal of plantation life and history. By illuminating the complexities of this historical site, this research strives to create a deeper connection between present and past, bridging gaps in understanding and fostering a more inclusive appreciation of the human experience.

Visualizing the Origins of Monumentality: The Case of Tiwanaku, Bolivia

Archaeologists examining early urban formations in the Andean Lake Titicaca basin have recently framed them as early “proto-urban” centers. In this paper, we reflect on our current understanding of the region’s proto-urbanism by deploying visualization methodologies to synthesize the evidence for Late Formative occupation at Tiwanaku (AD 200–600). While excavations and reconstructions conducted in the 1950s and 1960s concentrated on the later remains and froze the site as a timeless state capital, a number of under-analyzed archives are helping us to “unflatten” the emergent urban center into various periods of development. In addition, scholars have recently used increasingly precise radiocarbon dates to tease apart what made such social and political formations unique, from their seasonality, trade interactions, visibility of material culture, and extended kin networks. Our work at Tiwanaku and other sites in the region, such as Khonkho Wankane, is shifting our visions of the ancient altiplano, demanding new ways of seeing these early centers. We discuss some of the results from this ongoing effort.

To Be or Not to Be Attributed to Specific Plants? The Integration of Phytolith Analysis and Soil and Sediment Micromorphology

Despite extensive research during the last decades, phytolith botanical attribution remains a critical issue. Nevertheless, the development and expansion of reference collections confirm that some taxa produce very distinctive phytoliths at different taxonomic levels. Things become more complex when considering closely related taxa. Phytoliths found in domesticated taxa deriving from wild relatives provide one of the best illustrations of this phenomena. Indeed, such taxa, especially at the species level, typically produce phytoliths of similar shapes and types difficult to distinguish from each other. In such cases, morphometric analyses (measurements of size and shape) may allow us to discriminate taxonomically closely related species. However, the application of morphometric criteria is not straightforward, especially for archaeological contexts. Not only large samples of similar phytolith types are needed, but the phytoliths from an archaeological context should all originate from a single taxon and plant part. So far, only some primary archaeological contexts, such as ceramic jar contents, provide such conditions. By focusing on one cereal phytolith known as ELONGATE DENTATE/DENDRITIC, we are highlighting in this presentation how some of these issues can be overcome by the development of reference collections and the integration of phytolith analysis with soil and sediment micromorphology.

Let Them Rest in Peace: Cemetery Analysis of Unexcavated Graves at the First Baptist Church

Excavations at the First Baptist Church in Williamsburg, VA, revealed 62 burials on the west half of the lot behind the early nineteenth-century church. While three burials were chosen by the descendant community to be excavated, they also elected to leave the remaining 59 burials undisturbed, with the understanding that the Colonial Williamsburg Foundation would protect the area from development. While much information can be gained from excavating burials, this paper seeks to explore the wide extent of data that can be recovered from the unexcavated burials, including spatial analysis, artifact associations, and demographics. This analysis is further assisted by comparative examples of previously excavated Black and/or Christian cemeteries, which did not have the option of remaining undisturbed. ***Images of human remains may be shown in this presentation.

Resurrecting Kaskaskia: A GIS and Archival investigation of the Multiethnic Town of Kaskaskia, Illinois

Kaskaskia, Illinois, was established in 1702 as a Jesuit mission to the Kaskaskia. Through time it expanded into a large multiethnic fur trading and farming community that served as the gateway for the entrance of African slaves into Illinois. By the 1750s almost half of the town's population consisted of African peoples making it Illinois's largest African Diaspora site. Other residents included French, métis, creole, and Native American peoples. Heavily damaged by the Mississippi River in 1881, Kaskaskia declined over time until it today consists almost entirely of agricultural fields. The disappearance of the above ground structures has led to the widespread perception that Kaskaskia has been completely destroyed. However, by overlaying archival eighteenth- and nineteenth-century maps over the modern landscape we demonstrate that large sections of the town potentially still exist as archaeological sites. Among these are house sites identified on an 1830s map as the homes of African American and métis residents. We are now in the process of confirming the locations of these house sites through land owner, archaeological survey, and potentially remote sensing and test excavations as well as conducting research into records contained in the Jesuit Archives regarding their involvement with slavery in Kaskaskia.

From Mountain Worship to Guarding the Sacred Lakes: Surveys of Cerro Cañoncillo, Cerro Prieto Espinal, and Cerro Santonte

At the heart of the community, Cerro Cañoncillo and its lakes formed enduring sacred spaces across the landscape. In this paper, we explore in greater depth how the ceremonial centers of the region interrelated spatially and symbolically with neighboring mountains and lakes that were likely venerated as *wak'as*. Combining survey data and visibility analyses, we argue that Cañoncillo secured a unique and privileged place in the sacred landscape of the valley, but one that became increasingly secured and isolated away by the Late Intermediate period (1000–1470 CE) with the replacement of Huaca Colorada-Tecapa by Huaca Dos Cruces. Although Jequetepeque was predominately a landscape of fortified mountainsides during the Middle Horizon–Late Intermediate period (650–1472 CE), Cerro Cañoncillo lacked these features. Meanwhile, the heavily defended mountains of Cerro Prieto Espinal and Santonte guarded both this mountain and the lakeside oasis which lies between them. Cerro Prieto Espinal (~500–1500s CE) shows a pattern of mountainside worship that cleaved close to the mountain exclusively with north- and west-facing platforms and walls facing Talambo and Cajamarca. At Santonte, a south wall dating to the LIP highlighted an isolated south-north route from the now abandoned Huaca Colorada-Tecapa to the Cañoncillo lakes flanked by the three mountains.

The Afterlife of Pacatnamu: From Looting to Curanderismo

Site destruction from looting, climate change, agricultural activities, and urban development threatens the preservation of cultural heritage more than ever before, particularly due to a lack of site monitoring in some regions during the pandemic. This has long been the case in the North Coast region of Peru since the Spanish conquest. A significant amount of this ongoing destruction is brought about by looters, fueled by the global illicit antiquities trade, economic instability, political climate, and local curandero activity. The prehispanic city of Pacatnamu, dating to the Moche, Lambayeque, and Chimú periods (CE 600–1475), presents a significant example of the ongoing threats to this region. While it is a massive 3 km wide city of adobe mounds and plazas, its size and remote location have defied organized conservation. Some efforts have been made to help preserve Pacatnamu from erosional destruction. However, parts of the site have been destroyed by road construction and continue to be a target for intensive looting. Our research documents some key changes and alterations to the site from modern looting and ritual practices, including new clusters of pits with scatters of human remains, curandero dolls placed on huacas, and bags of coca leaves placed within pits.

Bone Tool Production and Use in Southern Coastal California: Examining a Process that Demanded the Use of Large Terrestrial Mammal Tool-Quality Raw Material

Fragmented bits of worked bone are relatively common in coastal California habitation refuse—or shell middens. I examine collections of worked bone from various mainland and Channel Island archaeological sites with a focus on understanding the role of functional, as opposed to decorative, bone artifacts from the region. I seek to understand what was necessary to the production and use of bone barbs and other osseous artifacts from the region with an emphasis on *chaîne opératoire* and the role of functional bone artifacts in California coastal subsistence economies.

Forging International Archaeological Research Collaborations and Mentorship Opportunities at Lower Dover, Belize

Our poster presents ongoing efforts at creating a collaborative research environment between international and Belizean early career scholars at the Classic Maya center of Lower Dover, Belize. Rather than incorporating Belizean collaborators in preexisting research projects, our current goal has been to collaborate with Belizean early career scholars to fashion their own research projects based on their interests and those of other local community members and stakeholders. This approach has long been advocated for among scholars engaged in community archaeology and truly has the power to create two-way

flow of knowledge and decolonize archaeology at its core. We present on several collaborative research projects including a comparative investigation of Late Classic elite households, survey and analysis of a historic period logging camp, and osteological study of commoner and elite well-being. The poster showcases our approach, outlines hurdles we have encountered, and concludes with our future plans.

Mapping Indigenous Laborers at the Pageant Tavern and Hotel on the Red Cliff Reservation on Lake Superior, Wisconsin, USA.

The Pageant Tavern and Hotel operated during the 1920s and 1930s on the Red Cliff Band of Lake Superior Chippewa Reservation in Northern Wisconsin. The Pageant Tavern was owned by non-Native and nonlocal businessmen, but the hotel staff and caretakers were Indigenous (Ojibwe) residents of Red Cliff. A recorded interview indicates the staff lived at or near the hotel, but little else has been documented about their experience. Targeted archaeological survey near the hotel in 2023 identified middens related to domestic activity in the area which were likely created or used by the Ojibwe staff. The paper describes the results of this survey, which offers new insights into the lived experiences of Ojibwe workers during the decline of the logging era and the emergence of tourism industry in Northern Wisconsin.

Orbiting the Oasis: Protein Residue Analysis Illuminates Past Interspecies Interactions in Jordan

Lithic tools excavated at Shishan Marsh (SM-1) dating to approximately 250,000 years have provided insight into human adaptability to the factors of climate change, water shortage, and ecological stress. Shishan Marsh was likely a refuge due to being a wetland in the middle of a desert, the paleommarsh setting episodically expanding into a lake. This attracted ancient humans, and wildlife no longer regionally extant, such as elephant, ostrich, rhinoceros, lion, and hippopotamus. Protein residue analysis, including the production of custom antisera, was instrumental in helping to investigate the interplay between humans, animals, plants, and water over time from the Pleistocene era into modernity. An overview of findings, methods, and potential for protein residue analysis to contribute to broad-based studies of this type will be discussed.

Pottery Traditions and Cultural Resilience: The Evidence from Yaxnohcah

A decade of research at Yaxnohcah informs our current understanding the Central Karstic Uplands and lays the groundwork for continuing research in the greater Bajo el Laberinto region. This paper summarizes the sometimes surprising results of ceramic analysis at the site, while acknowledging the limitations of single-site

strategies. Yaxnohcah was especially important during the Preclassic period, with early residents modifying the landscape and developing a local ceramic industry at about 900 BCE. By 600 BCE, Yaxnohcah potters had adopted the new waxy slips of a long-lived tradition that spanned the entire Maya region. Yaxnohcah thrived throughout the Preclassic but was overshadowed by Calakmul's rise during the Early Classic. Always resilient, Yaxnohcah housed a substantial Classic-era population and remained a home to some in the Terminal Classic and Postclassic periods. Pottery evidence for the waxing and waning of Yaxnohcah's neighborhoods across time provides a baseline for studying population dynamics in the greater Bajo el Laberinto region.

Quilts and Palimpsests: Intensive Agricultural Landscapes in the Llanos de Moxos

The Llanos de Moxos (Moxos) in the Bolivian Amazon is a useful case study for questions of settlement pattern, agricultural intensification, and social organization, particularly in light of its ambiguous status as both Amazonian and Andean, and neither Andean nor Amazonian. Moxos contains at least seven distinct examples of large landscape patterns of varying density, as measured by mapping forest islands, ring ditches, monumental mounds, causeways, zigzag features, fish weirs, raised fields, drained fields, mound fields, and domesticated wetlands. Comparisons within this set of related but distinct landscapes suggest that precolumbian communities organized their daily activities in a variety of ways, always in a context of marked seasonality. Recent research suggests that this variety of landscapes may have existed as early as 1700 BCE and persisted into the Jesuit period (ca. 1665–1767 CE).

Animate Pottery and Culture Phases

If pottery was animate in past cultures, does this not beg the question how would these powers, central to magical technologies, contribute to creation of archaeological phases? Archaeologists generally struggle to explain rise and fall in the popularity of artifacts. Indeed, the behavioral archaeologists developed artifact performance characteristic models in order to render such problems as comparisons of technologies underlying these assemblages. If we can incorporate artifact animacy into such behavioral archaeology models, then we can begin to address the role ritual technologies play in the formation of artifacts assemblages. In this paper I review how animacy contributes to ceramic technologies among Native peoples of the American Southwest and then translate these data into behavioral models of artifact performance. I then apply these models to a case study of Jornada Mogollon phases in southern New Mexico between AD 750 and 1450.

Bog Butter: Experimenting with the Preservative Nature of Peat Bogs

The anaerobic and highly acidic nature of peat bogs produces a perfect environment for preservation. Biological material that would usually decay, such as human tissue, is kept stagnant, unable to decompose thus

allowing for preserved individuals and items to be discovered. Peat bogs located in both modern-day Ireland and Scotland have produced an unusual type of artifact, Bog Butter. The butter, found in various types of containers, can be dated ranging from the early Bronze Age to the Early Modern period in Europe. To explore the meaning and purpose of Bog Butter deposits and peat preservation, a small peat bog was built to emulate the environment of northwestern Europe to closely study the production and preservation of Bog Butter. An exploration into the purpose of butter deposits in peat bogs could indicate the potential votive and religious, food storage, or flavor-enhancing purpose of this phenomenon. The intention of this experiment is to foster more understanding of the lifeways of the ancient Gaelic and Celtic peoples. By experimenting with the preservative qualities of a Peat Bog, the purpose, and cultural connotations of those who deposited the Bog Butter could become clearer, thus providing cultural context for people of the past.

Where Power, Policy, and Practice Intersect: Archaeology within Block Island's Great Salt Pond Archaeological District

The Block Island Wind Farm, the nation's first offshore wind project, was the first in a series of significant renewable energy projects proposed along the southern New England coast. At only five wind turbines, the project served as a unique pilot study that required balancing federal policy, tribal concerns, historic preservation, and archaeological research with the nation's desire to reduce its overall carbon emissions. This presentation will discuss the project, which with the assistance of the Narragansett and Wampanoag Indian Tribal Nations, led to the discovery of the significant Harbor Pond precontact Native American archaeological site and the partial archaeological study of a substantial Late Archaic (5000–3000 BP) archaeological component on Rhode Island's largest offshore island.

Commoner Agency, Hinterland Complexity, and Evidence for a Late Classic Commoner Marketplace in the Rio Bravo Basin, Northwestern Belize

This paper considers preliminary evidence for a Late Classic period marketplace at the site of Chawak But'o'ob, Belize. Group E, one of the largest settlement groups at this eighth-century agrarian site, is characterized by a well-bounded, spacious plaza that is larger and otherwise unlike any other public space at the site. This and other evidence for a marketplace will be discussed in the context of commoner complexity in the region.

Wooden Post Architecture and the Origins of Woodland Civic-Ceremonial Centers: New Evidence from the Spring Warrior Complex, Florida

Civic-ceremonial centers first emerged in the American Southeast near the Gulf of Mexico ca. AD 200–400 and served a dual purpose as home to resident villagers and as a place of ceremonial gatherings featuring

feasts, mortuary rituals, and mound construction. Over the past decade, archaeologists have learned that some of these sites began as “vacant” ceremonial centers that lacked residential populations and featured cemeteries and wooden structures at the future locations of mounds. This presentation will review features associated with wooden structures that preceded mound construction and village settlement at several sites in the Big Bend region of Florida and will highlight results of recent excavations at the Spring Warrior Complex (8TA154). Documentation of 13 posthole features near the platform mound at Spring Warrior revealed a portion of a large fourth-century CE structure that included several exceptionally deep posts and oyster shell chinking evidently used for structural support. By comparing these attributes to other Woodland buildings, we ascertain possible structure functions and consider their relevance to the origins of civic-ceremonial centers.

Spatial Analysis of Glass at Fort St. Joseph

Throughout the seventeenth and eighteenth centuries, alcohol was traded and consumed by both Europeans and their Native American neighbors. While historic documents relay the cultural and trade uses of alcohol, archaeological investigations have begun to compare the amount of glass found with the historical reports. The amount of olive green and dark blue bottle glass found at Fort St. Joseph, a French trade outpost in the Great Lakes region, is only a fraction of the material culture recovered. By using spatial analysis and careful examination I hope to gain further insights to the trade and consumption of alcohol at this eighteenth-century mission, garrison, and trade outpost.

New Insights from Archaeology into Life in Space: The Sampling Quadrangle Assemblages Research Experiment (SQuARE) on the International Space Station

From January to March 2022, astronauts aboard the International Space Station (ISS) carried out the first documentation of in situ material culture from a space habitat. Since then, we have identified and marked the locations of thousands of artifacts in the 358 photographs made by the crew in six sample locations across the ISS. At the 2023 SAA meeting, we presented our methodology and some preliminary, anecdotal observations from the SQuARE experiment. In this paper, we will present data, statistical analysis, and spatial analysis of the sample areas that allows for a re-assessment of ISS spaces and their functions based on their material culture. In this way, we demonstrate the validity of our methodology, while also generating actionable insights for designers and mission planners of future space habitats (who rarely have access to forensic analysis of previous ones).

Cultural Macroevolution in the Upper Pleistocene and Holocene of Eastern Siberia and Western North America
Geneticists have used phylogenetic analyses to model population movements associated with emergence and movements of distinct populations in northeast Siberia and the Americas. However, archaeologists have rarely taken advantage of this approach to examine the emergence and radiation of cultural traditions in these regions. In this paper, we draw on a cultural macroevolutionary perspective to model long-term evolutionary processes across Siberia and western North America during the Upper Pleistocene and Holocene. More specifically, we rely on multiple phylogenetic approaches to model cultural evolutionary processes related to lithic technological systems associated with hunter-gatherer-fisher groups over the long term in these regions. We test a number of long-standing hypotheses concerning evolution and spread of widely recognized technological traditions identified by archaeologists as: Dyuktai/Denali, Nenana/Berelekh, Western-Stemmed, Old Cordilleran, Nesikep, Clovis/Folsom/Northern Paleoindian, Plains/Northern/Shield Archaic, Arctic Small Tool, and Thule cultural complexes. We apply a Bayesian phylogenetics approach to a dataset representing thousands of years of cultural evolution and change, allowing us to examine the probability of different phylogenetic relationships while substantially avoiding issues of underdetermination. Thus, we offer insights into a range of discussions associated with peopling of the Americas and subsequent cultural evolutionary process.

Historias de pukaras: Trayectorias locales y diversidad en dos asentamientos de la precordillera del Desierto de Atacama durante el Período Intermedio Tardío y Tardío (900-1532 dC)

Abordamos el fenómeno de los pukara durante los períodos Intermedio Tardío y Tardío (900-1532 dC) en la región de Tarapacá del Norte Grande de Chile, a partir del registro arquitectónico y cerámico de dos pukara ubicados en una misma localidad en la precordillera del Desierto de Atacama. Estos asentamientos muestran usos y formas de habitar con intensidades y orientaciones diferenciadas. Con esto, se busca contribuir con un abordaje crítico, sustantivo y comprensivo de las sociedades prehispánicas tardías de las tierras altas, enmarcado en los debates arqueológicos sobre los órdenes sociales preincaico e incaico en los Andes Centro Sur. Por una parte, el pukara de Pariqollo presenta modestas dimensiones, pero con evidencias de haber sido intensamente habitado. En cambio, Kuico, pese a su mayor extensión y gran despliegue arquitectónico, no identificamos una densa ocupación. Ambos casos nos permiten proponer nuevas formas de concebir el fenómeno de pukara, no necesariamente como proyectos exitosos, sino que también como expresiones incompletas y opuestas, insertas en dinámicas sociales particulares que ensamblan a partir de historicidades diversas, con distintas intenciones, tensiones y acuerdos, alejados de lógicas lineales y progresistas.

Wandsnider, LuAnn (University of Nebraska)**[308]***Big Data Investigation of Persistence in Ethnically Homogenous and Heterogeneous Communities on the Late Nineteenth-Century Central Great Plains*

The archaeological record captures the material fallout of social processes operating at multiple temporal and spatial scales. Here I explore generational and supra-generational social processes of colonizers inhabiting a foreign and dynamic landscape under complex social conditions. Patent and census records allow for a big data approach to investigating the relative persistence of families who settled Custer County, Nebraska, from 1875 through 1900. Historical sociologists and anthropologists have documented the powerful role played by “tradition” or culture as families, hailing from different parts of (principally) western Europe, decided how to inhabit and subsist, and how children participated in their new life space. Some communities were ethnically heterogeneous, others less so; some were large, others quite small. The differential persistence of families living in these different social contexts and meeting the challenges presented to them is traced. I relate the Custer County case to other colonized landscapes.

Wang, Jiajing (Dartmouth College) and Xiaoli Qin (Fudan University)**[256]***Sacrificial Rituals and Dietary Complexity on the Eve of State Formation: New Insights from Dental Calculus Microbotanical Analysis at the Kangjia Site in China*

The Late Neolithic Longshan culture in China witnessed profound social and political transformations, characterized by the emergence of increasing social competition, long-distance trade, and inter-polity warfare. These developments eventually culminated in the formation of the first state-level societies in the Central Plains. Among the Longshan culture settlements, Kangjia provides some of the best preserved archaeological evidence for reconstructing both daily and ritual activities. The site provides evidence of house rituals involving competitive feasting, divination activities, and human sacrifice. This study examines the microbotanical remains from the dental calculus of human sacrificial victims at Kangjia to provide new insights into their dietary patterns and cultural activities. Preliminary findings suggest that the sacrificial victims had a relatively restricted plant-based diet compared to household animals and other Longshan people. This comparative analysis explores the dietary disparities, ritual activities, and political transformations that occurred right before the formation of the early Chinese states.

[86]*From Mesopotamia to Taiwan: Early Plant Ash Glass in the South China Sea*

Plant ash glass was common around the South China Sea from the eighth century CE onward. While this “late” plant ash glass was mostly found in the form of vessel fragments of Islamic origin, “early” plant ash glass appeared before the mid-first millennium CE, predominantly in the form of glass beads. Unfortunately, little is known about the provenance of this early plant ash glass. We present a recent analysis of glass ornaments made of plant ash glass from Daoye, Daoye South, and Wujianguo in Taiwan, dating between the first and eighth centuries CE. LA-ICP-MS and SEM-EDS analyses indicate these artifacts likely originated from Mesopotamia. A close comparison of Al_2O_3 , CaO , MgO , K_2O , and P_2O_5 concentrations reveals similarities to the Mesopotamia Type I sub-group from the Sassanian territories, and they contain less MnO than the later

Islamic period. The presence of magnesiochromite further supports their Mesopotamian origin. This research shows that the early plant ash glass in the mid-first millennium CE was likely produced in Mesopotamia and reached Taiwan through maritime routes passing the Sasanian territories, South Asia, and Southeast Asia. The findings shed light on the early circulation of plant ash glass in the South China Sea region.

[315]

Investigating the Pottery Use of Neolithic Ceramics from Guijiabao in Southwest China Using Organic Residue Analysis
 Guijiabao is an archaeological site in southwest China that dates from the Neolithic to the historical period. Its crucial location at the interaction of the Hengduan Mountains and the Sichuan Basin offers a unique opportunity to study the southward spread of new crops and species into this region. Although it is widely accepted that mixed farming of rice/millet was introduced into southwest China around 4700 BP, it is still unclear how much the new crops or animals were utilized throughout the Neolithic transition. To better understand the culinary practices associated with the early development of agriculture, we examined organic residues preserved in Guijiabao pottery using residue analysis approaches. Our results suggest that terrestrial animals, such as ruminants, predominated in the Neolithic samples, with one potsherd showing a C₃ plant source. The findings indicate that rather than widely adopting farming practices, the residents of Guijiabao might have relied mainly on wild animal hunting, supplemented by rice/millet farming. This might be a subsistence strategy used in the highlands of this area. Our future work will include a comparison with faunal remains and pottery samples across different types of pottery and temporal phases to have a clearer picture of the local subsistence.

“The World Is a Garden”: Human-Animal Relations and Sustainability Comparative Studies of Classic Maya and Early China

The interactions among organisms along with environmental factors in non-Western cultures, require to be reexamined since Western humanity-nature binary explanations fail to take into account indigenous ontologies. In the title, I prioritize environment among these three objects because I want to demonstrate that it is a prerequisite, helping shape the ways of human and nonhuman interaction. Ancestral Maya and early Chinese cosmologies share similar considerations of animals as fellow beings, each having roles in maintaining the world. In the presentation, I propose that ancestral Maya pursued a respectful, sustainable interaction with wildlife and the forest in the Classic period from 300 to 900 CE by archaeofaunal and paleoenvironmental evidence from diverse contexts, combined with ideology and ethnography records. I will first address the ontological shift from Western notions and introduce how indigenous worldview reframes Environment-Human-Animal relations. Next, I will discuss sustainability in natural resources. Through the case study from the ancestral Maya world, I prospect that this project may provide a reference for reexamining similar topics in early China.

Wang, Yuanyuan [19] see Dong, Yu

Wann, Kevin (Texas A&M University), Logan Kistler (Smithsonian National Museum of Natural History), Heather Thakar (Texas A&M University) and Courtney Hofman (University of Oklahoma)**[202]***Preliminary Archaeogenomic Insights on the Domestication of the Avocado Tree*

The avocado is one of the most popular fruits exported worldwide and was originally domesticated in three independent episodes that resulted in the three main horticultural varieties we see today. One region of origin spans from the highlands of southern Mexico to the highlands of Honduras. The El Gigante Rockshelter is a site in the Southern highlands with remarkable preservation conditions that promoted the conservation of desiccated avocado rinds dated between 11 and 1ka. I plan to analyze the genomes of these ancient avocados to understand how and why they fell under domestication. Through a suite of bioinformatic tools, I will assess the similarities between ancient and modern avocado cultivars to determine the loss of genetic diversity associated with domestication, the potential for long-distance fruit exchange, and the degree to which the ancient specimens are ancestral to the domesticates thought to have originated in the region of El Gigante. I predict that early (~4ka) ancient tissue will have a greater degree of ancestry to modern Honduran domesticates, while later (2.5-1ka) remains may have originated from an exotic region, which would signify the establishment of long-distance exchange networks following the emergence of the Formative and Classic state-level society.

Ward, Emily, Mara Stumpf (Texas State University) and Sara Juengst (University of North Carolina, Charlotte)**[70]***Health and Disease during the Ecuadorian Formative: A Case Study from Buen Suceso*

The Ecuadorian Formative period (3800–300 BC) is known for the creation of ceramics, a transition toward agriculture, and the development of sedentary settlements along the Pacific coast. These social and economic changes were often associated with declines in health, as people ate less varied agricultural diets and increasingly encountered pathogens transmitted in human and animal feces. However, not all people experienced these changes the same. Buen Suceso, occupied from 3800 to 1425 BC, reflects many of the social and economic patterns associated with the Formative period (circular village, ceramic technologies), but to date, skeletal remains have not shown a corresponding rate of lesions associated with malnutrition or infectious disease. This poster presents two cases of osteomyelitis, an indicator of infectious disease, from Buen Suceso, documented on two individuals excavated in July 2023. These two cases stand in contrast to the general lack of pathology from the site, prompting us to reconsider our ideas about health and disease at Buen Suceso.

Wardle, Joseph (University of Michigan)**[314]***2023 Excavations at Early Classic (AD 200–500) Jalieza, Oaxaca, Mexico*

Jalieza is an important archaeological site in the Valley of Oaxaca that was founded during the Early Classic (AD 200–500). It is an especially useful case study for understanding how and why the Zapotec state fragmented. Previous excavations at the earliest sector of Jalieza, a hilltop called Cerro Danilín, suggested that the site may have resisted incorporation into the Monte Albán state during this time. Recent excavations in two new areas of Jalieza offer preliminary evidence that (1) structures during this time were oriented similarly to Tilcajete, a site resisting incorporation into the Monte Albán-headed Zapotec state during its expansionist period; and (2) obsidian (whose access was regulated by Monte Albán) was relatively scarce at Jalieza. These results are a vital step toward understanding the role that Jalieza played in the gradual fragmentation of the Monte Albán state, which by AD 700 had broken into many smaller secondary states. The results of new excavations show that the collapse of complex societies can be gradual, as local communities gain their autonomy and resist re-incorporation.

Twenty Years of Interpretations from the Late Formative period Site of Jatanca (JE-1023), Jequetepeque Valley, Peru
 This paper will provide a retrospective of archaeological work that has been done at the Late Formative period site of Jatanca, located in the Pampa Mojucape of the Jequetepeque Valley, Peru. Since 2004, the architecture, ceramics, and surrounding landscape associated with Jatanca have undergone intensive analysis, which has provided an important foundation for subsequent work at chronologically later sites located within the immediate area such as Huaca Colorada and Tecapa. Finally, this paper will assess how our initial ideas associated with Jatanca have been subsequently modified in light of data collected from those nearby sites.

What 35 Students Tell Us: Reevaluating Traditional Field School Delivery Methods
 In 2019, the University of Idaho offered a field school in an alternative way—by having the field school incorporated into the regular academic year curriculum. With the cooperation of our registrar the class was folded into the regular fall semester class schedule. Four years later we did it again, resulting in 35 students enrolling in an eight-week urban field methods course. The field school was held on the grounds of our local high school and within walking distance both from the campus and from our town's business district. Working in a state (Idaho) that struggles with educating students, we have found that alternative delivery of field training addresses many issues. First, it enables students to gain field experience who otherwise cannot afford it under traditional field models. Second, it is a tangible way to demonstrate university engagement in the community that we are a part of. Finally, it is a counter narrative to the increasing skepticism about the relevance of higher education in rural communities. Ultimately, our project demonstrates how archaeology can meaningfully contribute to many of the pervasive challenges facing our discipline specifically and higher education in general.

Taphonomy and the Death Course: Materializing Value in an Anatomical Collection
 The Huntington Anatomical Collection, part of the Smithsonian Institution's National Museum of Natural History biological anthropology collections, is comprised of just over 3,000 individuals, about 50% of whom were foreign-born immigrants. They died in New York City public institutions between 1893 and 1921 and were dissected by Professor Huntington and his students. I consider the "death course" of Irish immigrants in the collection and trace how their movements—from public institutions to dissection tables and storage

rooms—materially altered the remains. Such taphonomy includes the addition of paper, ink, and metal, as well as the formation of silences and erasures, like the loss of names, the fragmentation of bone, and loss of elements. These death course taphonomies might be read in relation to value. Their bodies were variously (de)valued as indebted laborers in need of care and later as currency to repay so-called debts to society. As specimens, their research value was enmeshed in early twentieth-century concerns for race science, eugenics, and immigration policy, and in later methods-oriented research in forensic anthropology and osteology. These various notions of value left material marks on the remains and shape the ethical terrain of researchers' ongoing engagements with the collection.

Canoes, Canals, and Portages: Water Travel around the Northern Coast of the Gulf of Mexico, ca. AD 600–1800
Modern discoveries of Mississippian dugout canoes and a Middle Woodland canoe canal in coastal Alabama have prompted historical and archaeological research on water travel in the region. Applications of multispectral lidar and geophysical survey are proving useful in defining canal features, which have been partially obscured by changes in eustatic sea level since canal abandonment. Historical documentation of portages raises practical questions about how portaging the land links between navigable waterways was accomplished with dugout canoes.

The Salinar of the Middle Valley: An Overview of the Post-Initial Period Salinar Occupation at the Archaeological Site of Menocucho, North Coast of Peru

The Salinar phenomenon began after the collapse of the Chavín culture in part of the north coast of Peru around 500 BC. According to several studies, the Salinar period was a time of significant changes in the area. The inhabitants intensified agricultural production, connected with other regions, and apparently engaged in cycles of conflicts. The archaeological site of Menocucho, located in the middle section of the Moche Valley, was one of the first monumental sites inland after the Preceramic period (5000–1800 BC). It presents several occupations beginning in the Initial period (1800 BC). During two excavation seasons at the site, the authors identified a short but intense occupation corresponding to the Salinar period. Interesting changes occurred in both the architecture and the material culture. Additionally, this occupation was marked by intense pluvial events that left at least 20 cm of sedimentary layers created by recurrent flooding. In this presentation, the authors will provide evidence of the Salinar occupation at the site and engage in a discussion of what is understood as Salinar through the local and regional data and its implication for the future understanding of the archaeology of the north coast of Peru.

Waters, Michael (Texas A&M University)**[253]***Five Decades of Paleoindian Archaeology*

For over 50 years, David Anderson has investigated many aspects of the prehistory of North America, especially the American Southeast. At the start of his career, Clovis was considered the oldest evidence of a human presence in the Americas. Archaeological and genetic data now inform us that people were in the Americas from at least 15,000 to 16,000 years ago. This requires a reevaluation of everything we thought we knew about the First Americans—the route they took entering the Americas, how they dispersed across the landscape, the tools they made, how they interacted with the megafauna, and the meaning of Clovis. David Anderson has been at the forefront of Paleoindian research and has kept pace with these changes. He created the Paleoindian Database of the Americas (PIDBA), which presented the big picture—defining the distribution and density of Clovis and later fluted points across the landscape. His papers and books about the early prehistory of North America, especially the American Southeast, provide insight and ideas about the earliest people to inhabit this region. David Anderson has also been a mentor helping many early career scholars in their quest to dig into the prehistory of the American Southeast.

Watson, Caroline (College of William and Mary)**[325]***Temporalities of Disaster Taphonomy: A Contemporary Archaeological Case Study in Southern Puerto Rico*

Disaster landscapes dominate Puerto Rico's Anthropocene, past and present. Yet, since the devastating 2017 hurricane season, climate change and coloniality have materialized unprecedentedly as roofless homes, shifting coastlines, and abandoned lots. As recovery practices become a part of everyday life in Puerto Rico, a contemporary archaeological approach helps address the complexities of how and where disaster material exists at the intersection of ecological and social forces. In this paper, I outline the depositional layering of an archaeological disaster-scape in the southern coastal town of Playa Ponce. Several case studies address the nonlinear temporalities of taphonomy and the futurity of site formation, as archaeological sites are generated, transformed, and removed cyclically. I understand the current infrastructural landscape of Playa Ponce as the layered materializations of unfulfilled promises of repair, yet also as the accumulation of individual and community practices that emerge from living with dangerous infrastructure. Through embodied memories and stories of local residents, a material ethnography of disaster emerges from my archaeological observations. I use this to expand the temporal and causal framework of taphonomy, and to rethink mundane materials and infrastructures as possessing a sociality of disaster.

Witz Naab and Killer Bee Revisited: New Interpretations of Two Salt Mounds in Paynes Creek National Park, Belize
The Witz Naab and Killer Bee mounds are some of the few remaining onshore remnants of the Paynes Creek salt works. In this presentation, we will reexamine the interpretations of two salt mounds at the Paynes Creek Salt works. These excavations are part of a larger NSF funded project directed by Dr. Heather McKillop (Louisiana State University) excavating underwater sites associated with wooden buildings stunningly preserved by mangrove peat below the seafloor. Evidence of brine enrichment has been obfuscated at the underwater sites due to sea-level rise. This process is virtually universal in ethnographic and historic case studies elsewhere. This paper will discuss the initial findings and new interpretations concerning these mounds' possible function and potential relationship with the nearby submerged salt works.

Gone to Find Guinn: A Lost Farmstead at Wilson's Creek National Battlefield
Archaeologists with the Midwest Archeological Center (MWAC), local volunteers, and Wilson's Creek National Battlefield (WICR) staff conducted a systematic metal detector and magnetometry survey of the proposed location of the Guinn Farmstead. The site of an ambush during the Union Army's retreat in the August heat of 1861, Guinn Farm is important for a broader understanding of the first major battle of the US Civil War in the Trans-Mississippi. Results from the survey provided high-resolution data regarding subsurface artifact distributions that were ground-truthed during a metal detector inventory. The resulting data are presented in this poster and elaborate on the brief historical accounts from survivors. The project places Guinn Farm in the broader context of the brief and violent history of the "Bull Run of the West."

Wattenmaker, Patricia (University of Virginia)**[85]**

Toward a Multispecies Perspective on Human-Animal Networks in Early Urban Societies of Upper Mesopotamia
Decades before anthropologists advocated for multispecies anthropology and ethnography, Richard Redding was charting a new path for a multispecies approach to anthropological archaeology. His research reveals an implicit awareness of the complexity of human-animal relationships that is a hallmark of the multispecies concept. For example, his models of caprine herding and culling practices highlighted both the logistical challenges of raising multiple species in tandem as well as the needs not only of humans but also of the other animal species. Drawing inspiration from Redding's original and distinctive approach to the analysis of ancient human-animal dynamics, this paper examines zooarchaeological data from third millennium Upper Mesopotamia to consider how findings might be better understood through the lens of a multispecies approach. The analysis discusses and utilizes some of Redding's specific analytical techniques that provide a more holistic understanding of the web of interactions between humans and various animal species. For example, the use of density ratios makes it possible to track fluctuations in the abundance of each species through time. The paper aims to elucidate factors that underlie the multiple signature species distributions in urban and rural sites, ritual spaces, and houses of Upper Mesopotamia.

Watts, Christopher (University of Waterloo)**[331]***The Persistence of Presence in the Rock Art Traditions of the Great Lakes*

While recent scholarship has fruitfully considered the importance of Indigenous ontological commitments (e.g., to power and place) in the creation of rock art, notions of presence as a discrete component of an image's being remain underexplored. In this contribution, I seek to examine these notions as distinct from representational logics in their emergence within relational ecologies and qualities of action. Yet despite their ephemeral, distributed, and dynamic properties, notions of presence can also be understood as persistent in the way they continually provoke—whether by guiding the creation of panels in the past or in facilitating understandings of rock art in the contemporary present. In this way, investigating the persistence of presence is not about iconographically documenting veiled and static meanings across time and space but about recovering the interactive conditions through which presence was and can still be conceived. Rock art from the Great Lakes, particularly the petroglyphs of Kinooamaagewaabkong, near what is now Peterborough, Ontario, and Ezhibiigaadek asin in what is now the Sanilac Petroglyphs Historic State Park (Michigan), provide the case studies for exploring these ideas.

Watts, Corinne (University of Iowa)**[327]***Chair***Watts, Corinne (University of Iowa)****[327]***The Power of Reuse and Removal: A Case Study of the Indonesian Megaliths of Iowa City, Iowa*

The co-opting of cultural heritage is one of the ways that archaeological materials are “reused.” This process references and reinforces power structures related to cultural identity through the control of archaeological material, narratives, and meanings. In some situations, the process includes the physical movement of cultural material. In this vein, I consider the case study of 50 megaliths at Harvest Preserve, a private sculpture garden and nature preserve in Iowa City, Iowa. Around 3000 BCE, these megaliths were erected on the island of Flores, Indonesia, where they remained for several millennia. In the early 2000s, the owner of Harvest Preserve purchased these pieces through a Chicago-based art and antiquities broker and each of the megaliths was moved by boat and train from Flores to Iowa City. Through petrographic analysis of the stones, semi-structured interviews with the reserve's owner, and archival analysis, I examine the itineraries of these megaliths. Specifically, I discuss the ways that their removal, installation, and ongoing use demonstrate the ways that “reuse” of material changes with new spaces and actors, while still referencing earlier aspects of the object's itineraries.

Watts, Ian**[25]***An Ideology of Blood at the Root of Symbolic Culture*

At ~160 ka, roughly at the end of our African speciation, archaeologists identify a change from sporadic to habitual use of red ochre. This has been interpreted as primarily a pigment for decorating performers' bodies during communal rituals. What were these rituals, and why was red so central to the establishment and unfolding of the symbolic domain? Archaeologists and paleoanthropologists are cautious about turning to hunter-gatherer ethnography as a resource in evaluating competing explanatory hypotheses. Challenging convention, I present the first cross-cultural comparative review of African hunter-gatherer ritual use of red substances and associated beliefs. The most consistent symbolic theme encountered is a metaphoric relationship between women's reproduction and men's hunting. This accords with over a century of social anthropological speculative thought and a prediction made by the Female Cosmetic Coalitions hypothesis of the emergence of symbolic culture. This hypothesis also predicted—long before it could be tested—the establishment of habitual red ochre use by ~160–140 ka. The main competing hypothesis, positing intergroup competition between male coalitions, has yet to generate predictions testable in the light of symbolic

evidence. Ethnography cannot be transposed onto the deep past, but it can help constrain evolutionary interpretations of the early ochre record.

Tracing the Relationships between the Lower Ohio and Central Mississippi River Valleys through the Bradley Off-Site Remediation Project

The Bradley Off-Site Remediation Project remediates deep tilling that occurred during a Natural Resources Conservation Service project at the late precontact Bradley site (3CT7) in Crittendon County, Arkansas. The Bradley Project supports collections-based research important to the Quapaw Nation by exploring connections between the Mississippian Angel phase (1000–1450 CE) in southwestern Indiana and late precontact phases of northeastern and central Arkansas. Ties between these regions have been readily recognized through the presence of artifacts typical of the Central Mississippi River Valley—Nodena points, Parkin Punctate pottery, head pots, and human effigy bottles—at late precontact Caborn-Welborn phase (1400–1700 CE) sites at the confluence of the Wabash and Ohio Rivers. However, Nodena points, Parkin Punctate pottery, and human effigy bottles have also been recovered at the nearby Mississippian Angel Mounds center. Relationships between the Angel and Caborn-Welborn phases are unclear and there is a large degree of overlap in the geographic and temporal extents, material culture, and architecture of the two phases. This poster presents preliminary results of the Bradley Project that reevaluate connections between Angel and Caborn-Welborn phases to better understand farther flung relationships with the Central Mississippi River Valley.

The Carchi-Nariño’s Mollusks Shells Aerophones of the Royal Museums of Art and History of Brussels: Analysis by CT Scan

The archaeological collection of the Royal Museums of Art and History in Brussels gathers more than 377 precolumbian objects from Ecuador. Among these are 20 wind musical instruments (flutes and ocarinas) in ceramic from the Carchi-Nariño culture. These objects, which joined the collections in the 1990s, had remained dormant in the museum’s storage area, erroneously attributed and unstudied. These objects are exceptional on several levels. First of all, they belong to a little-known cultural group from Ecuador. Their uniqueness lies in the imitation of marine mollusk shells in ceramic, while at the same time being aerophones. Their iconography and decorative techniques are also very interesting. The purpose of this study was to highlight this set of objects. In addition to the formal, stylistic, and iconographic analyses, archaeometric analysis via CT scan were carried out to evaluate whether these ceramics imitate mollusk shells from the outside or, perhaps, also from the inside. These analyses also aimed to study the whistling system and the technological manufacturing processes. These objects are true technical prowess indeed. The shape of these mollusk shells, which roll up on themselves, involves material superimpositions and therefore complications for their shaping and firing.

Paleoanthropology in the Central Highlands of Kenya: A Knowledge Co-production Research Model

Human origins research in the East African region has largely focused on sites within the rift basin. The story of human origins is also credited to highly educated Western nation paleoanthropologists and a few local researchers. The work presented here demonstrates the importance of high-elevation tropical sites to human evolution using the Central Highlands of Kenya (CHK). The CHK covers the area encircled by the Aberdare, Mathews, and Kirisia ranges and Mt. Kenya. Based on newly discovered evidence from sites found here, these orographic features moderated local environments and hydrology, shaping evolutionary processes in the region. Using a knowledge co-production model in which locals at areas with prehistoric sites work together with scientists to carry out research, the work discussed here also demonstrates that local populations are an important resource in human origins studies. Since 2019, cooperation with residents at CHK has facilitated the rapid discovery of sites from the late Miocene to the Holocene by local people who know the landscape intimately. This also aids in wider participation by locals, increases the uptake of research products, and promotes pride in ancient heritage found at the CHK.

Botijas and the Black Pacific: Stylistic and pXRF Analysis of Amphorae produced by Enslaved Potters at Early Modern Nasca, Peru

Botijas were the universal packaging for dry and liquid goods transported throughout the global Iberian empires of the Early Modern world. Heirs to the potting traditions of Mediterranean amphorae, these vessels are the most ubiquitous ceramics at Spanish colonial sites in the Americas. We present new research combining stylistic analysis and portable X-ray fluorescence spectrometry (pXRF) to examine ceramic traditions among enslaved African-descendant potters tasked with producing botijas at vineyard estates on the southern Pacific coast of Peru. From the early seventeenth century through the mid-eighteenth century, these ceramicists produced botijas matching dominant Iberian forms, while motifs exhibit a range of innovative attributes. Botija setters resonate with Atlantic African decorative traditions. Preliminary pXRF analysis aids in our understanding of the development of these traditions and the organization of enslaved potters at the haciendas of the Nasca region.

Historic Human Remains Detection Methods and Results at Fort Scott (9DR8) US Army Cemetery, Lake Seminole, Georgia

Fort Scott (9DR8) was a US Army fort constructed in 1816 on the Georgia frontier on the north bank of the Flint River during the First Seminole War. Meant to be a temporary encampment, it was located to protect White frontiersmen pushing into Creek territory. Occupied until 1821, the fort's occupants participated in the destruction of Negro Fort on the Apalachicola River, the Fowltown Battles, and other skirmishes along the Florida-Georgia border. Ultimately, malaria won out and the fort was abandoned. Limited cultural resources investigations of the site began in the 1950s ahead of dam construction, but none identified the exact location of the fort's cemetery which was reported to contain 200–300 burials. Today, the fort's location is remote, overgrown, and beneath fallen trees from Hurricane Michael. There is no surface expression of the cemetery. Erosion and water encroachment from Lake Seminole threaten the site. As part of a Section 110 cultural resources investigation at the site in 2023, the Mobile District will use Historic Human Remains Detection (HHRD) dogs and ground-penetrating radar (GPR) to locate the nineteenth-century US Army cemetery at Fort Scott. This paper presents the results of this investigation.

A Community-Engaging Data Recovery of the Fennell Plantation: A Journey from Enslavement to Black Landownership in North Alabama

New South Associates (NSA) conducted a Phase III Archaeological Data Recovery of the Fennell Plantation (Site IMA840) on Redstone Arsenal (RSA) in Madison County, Alabama. The site occupation spans nearly 100 years (1843–1942) and records the transition from enslavement to Black landownership in North Alabama. Data recovery efforts involved a ground-penetrating radar (GPR) survey, unit and shovel test excavation, mechanical stripping, archival research, an archaeological literature review, artifact analysis, and specialized analyses of subsistence remains. These efforts provided valuable datasets for exploring the lifeways of both plantation owners and the Black enslaved population that helped to forge the thriving historic African American community of Mullins Flat. Throughout the data recovery process, NSA partnered with RSA Cultural Resource Manager Ben Hoksbergen to deliver a community-engaging approach that included an open house for media outlets, public talks for local archaeological societies, a social media presence, and volunteer opportunities for the public to participate in feature excavations. This approach facilitated positive outcomes, including engagement with descendent community members and public involvement in the recovery and interpretation of archaeological data.

Eating and Drinking at Chavín de Huántar: What the Microbotanical Evidence Can (and Can't) Tell Us

This paper presents the cumulative findings, to date, of ongoing microbotanical analyses carried with the aim of interpreting internal and external interactions from diverse contexts at Chavín de Huántar. Since microbotanical analysis offers us a view into the production and consumption of foods and beverages, we have a privileged, albeit limited, perspective on the nature of Formative period identities. Cuisine is a powerful marker of identity, not only in the consumption of foodstuffs, but also in its preparation and consumption. The preparation of food and drink is a laborious process that requires specific knowledge, context, and materials to complete, and both the act and circumstances of eating and drinking vary according to sociocultural norms. Further, the consumption of diverse foods in certain contexts points to different uses of space, as well as the different roles that people may have played in relation to the activities carried out within and beyond the monumental core of the site. Moreover, the presence of a large proportion of nonlocal ingredients helps us to better understand Chavín de Huántar's interactions with outside groups.

The Chronology of Basketmaker Perishable Craft Traditions in Southeastern Utah and Their Potential as Cross-Dating Proxies

The Cedar Mesa Perishables Project has documented almost 5,000 perishable artifacts from alcoves in southeastern Utah. As part of this research, the project has radiocarbon-dated more than 100 well-preserved textiles, sandals, baskets, wooden implements, and other perishable artifacts from Grand Gulch, Butler Wash, Allen Canyon, and Glen Canyon, creating the largest dataset of directly dated perishable artifacts from this region. With 80% of the sample represented by Basketmaker technologies, these data offer new insights into the chronological development of early Ancestral Pueblo perishable technologies and a more nuanced understanding of long-term technological and stylistic change during the 200 BC–AD

750 period. The potential use of Basketmaker sandals and other perishable artifacts as preceramic dating proxies is explored.

Discovering Camp Guernsey: An African American Civilian Conservation Corps Camp

The Midwest Archeological Center (MWAC) of the National Park Service has completed the initial stages of identifying the hitherto undocumented Camp Guernsey, a segregated, African American Civilian Conservation Corps camp in Senecaville, Ohio. Using lidar and minimal ground truthing, MWAC staff, in collaboration with staff from the North Country Trail, the Muskingum Watershed Conservancy District, and the Buckeye Trail Association have begun to discover the basic layout of this historic era archaeological site. The site holds high research potential for understanding the lifeways of the young Black men of Company 580 in the time between the two World Wars. Although the works of these men can still be seen at the nearby campground at Seneca Lake, primary historic sources are scant. Archaeology, aided by geospatial technologies, has the most potential for telling the story of this company.

Persistent Places, Affordances, and Temporalities on Chacoan Time Bridge Roads

Beginning in the 1980s, researchers noticed that some monumental avenues in the Chaco World (ca. AD 800–1200) of the Four Corners region of the US Southwest were “roads through time” linking non-contemporaneous sites. These so-called “time bridges” are often interpreted as monuments built by later generations to connect with the traces of ancestral dwellings, perhaps in service of political claims of continuity. In this paper, I draw on recent fieldwork to reexamine two Chacoan time bridge roads—the South Road and Asdzáán Tááh Íiyá (Taylor Springs) Road—and outline evidence suggesting that formalized roadways existed at these locations from their earliest periods of use. I explore the utility of conceptualizing Chacoan roads used across multiple centuries as persistent, affective places rather than as a form of memory work; in other words, places with qualities that attracted people and altered history across centuries. I consider some of the affordances of land and water—including springs, rain-making buttes, naturally occurring roadways, and fossils—that appear to have drawn Ancestral Four Corners people to construct roadways to such locales in the first place and trace elements of the changing relationships between roads, places, and people over the course of Chacoan history.

[52]

Hidden in Plain Sight: Documenting a Forgotten Chacoan Outlier in the Mesa Verde Region

While forgotten settlements are a common discovery in the jungles of Central America where dense canopies conceal all traces of prehistory, they are a much less common phenomenon in the American Southwest. However, recent research demonstrates that a poorly known Ancestral Pueblo site on private property in southwest Colorado is one of the most important sites in the region. First, it is a contender for the largest Pueblo I site in the Mesa Verde Region. Second, it is a Chacoan outlier. Third, its occupation spans the poorly studied period from the late AD 800s to early 900s when depopulation led to scarce settlements in the region. In addition, the site has produced approximately 10,000 chipped stone tools, over 1,000 ornaments, bifurcated basket effigies, and other noteworthy artifacts. For my master’s thesis, I mapped the site, documented its history, and analyzed thousands of its artifacts to better understand its occupation span, relationship to other sites, and potential contributions to our knowledge of the Ancestral Pueblo. The Crosspatch Site, as it is now called, has the potential to change our understanding of prehistoric occupation

in the Mesa Verde region, particularly during Pueblo I, the transition into Pueblo II, and early Chacoan influence.

Searching for the Submerged: Five Decades of Research Related to Drowned Prehistoric Sites in the Gulf of Mexico and Coastal Louisiana

Since 1975, personnel at Coastal Environments Inc. have applied a geophysical and geological approach in their search for drowned prehistoric sites on the outer continental shelf of the Gulf of Mexico and within marshlands of south Louisiana. Initial efforts culminated in the retrieval of numerous vibracore samples from the drowned Sabine River valley offshore Louisiana and Texas and the discovery of a ca. 8,000-year-old *Rangia cuneata* shell deposit about 17 m below modern sea level and 5 m beneath the Gulf bottom. Subsequent research in coastal marsh settings using similar techniques also successfully identified the presence of submerged prehistoric shell middens.

Buenos Aires Estuary Waterfront: The Zen City Wreck and Coastal Urban Archaeology

This contribution presents the status of research and institutionalization of the underwater and coastal cultural heritage of the city of Buenos Aires. For this purpose, the environmental information and characteristics of the archaeological landscapes surveyed between 1995 and 2019 in excavations carried out in lands “gained from the river” on different parts of the city are presented in a synthetic way. The text begins with a description of the environmental and historical characteristics of the city’s coastal sedimentary substrates, natural anchorages, and shelters. That is followed by the background and state of the question of archaeological investigations, in order to set the basis for the ontological and methodological framework of the work on a regional scale. We continue with the presentation of the materials and archaeological assemblages that were surveyed in order to analyze the variability of sites and the diversity of artifactual functions. The results of the analysis are presented and discussed on a regional scale and chronology, considering the archaeological visibility of coastal embankments, old docks and wharfs, anchorages, sectors with ballast or hides, shipwrecks, barracks, and shipyards.

Plenty of Fish for Fowl in the Watery Worlds of the Kerr Archive

Carved along the exterior of a cylinder vase (K6511), two waterfowl grip flailing fish with their beaks. These fishing fowl occur again on polychrome pots, effigy bowls, censer stands, and modeled stucco friezes.

Numerous examples of the “Waterbird Theme” came to light through the work of Justin Kerr, who initiated a discussion of the theme online and reinforced its merit for iconographic analysis. This paper uses Justin Kerr’s photographs to answer his call to examine the Waterbird Theme, which remains unclear despite its common occurrence in Maya Art. I specifically build on Justin Kerr’s observations that the Waterbird Theme overlaps with specific deities and corresponds to historic and modern Maya myths. Making sense of this theme offers one piece of the puzzle for a sequence of narratives found on vases in the Kerr Archive that relate to the death, journey, and afterlife of the Maya maize god.

[174]

Determining Datums and Considering Climate: The Relocation of Inundated Apalachee Bay Sites in the Modern Day Between 10,000 and 5,000 years ago, the sea level of the Apalachee Bay, Gulf of Mexico, was roughly 20 m lower than today, extending the paleoshoreline nearly 75 km further south and providing significantly more habitable land for prehistoric populations (Faught 2004). Although many submerged sites along the Paleo-Aucilla river channel have been surveyed, the reference datum used to identify their GPS coordinates was not recorded, making modern relocation efforts exceedingly difficult. By testing different reference datums for certain 1990s points and comparing these to coordinates of sites that have recently been relocated, this project seeks to determine what datum was likely used by former excavations and obtain accurate coordinates for other sites. An additional focus of this project is to develop an understanding of what time of year is best to engage in fieldwork by considering recent local weather data, given that the times formerly ideal for fieldwork now heavily feature dangerous conditions for boating due to the shifting climate worldwide. Both effective use of available time in the field and precision of coordinates are critical for relocating sites, leading to a more comprehensive understanding of Southeast prehistory and the establishment of better submerged site protections in the Apalachee Bay.

What Lovely Teeth You Have: An Examination of Canid Dental Anomalies and Their Use in Archaeology

A survey of over 200 published sources on archaeological domestic dogs in the Americas reveals that dental anomalies, particularly the absence of the first mandibular premolar, are mentioned in Native American domestic dogs with some frequency. They have even been promoted as a means of identifying domestic dogs in the Americas. However, this pattern has never been received a detailed examination. Traced through the literature, this idea appears to stem from Dr. Edward Cope’s analysis of a single dog mandible from what is today known as the Palmer-Taylor Mound in Orange County, Florida (published by Clarence B. Moore, 1893). When placed in context, it becomes apparent that congenital tooth loss occurs in modern wolves, coyotes, and foxes at rates approaching 10%. Though most veterinary sources focus on physically small purebred dogs where this condition is particularly common, dogs subjected to less selective pressure exhibit this characteristic at a rate of only 3%–7%. These data suggest that congenital tooth loss is not a reliable marker of domestication in dogs.

Tourist Trinket, Religious Object, Human Remains, or Something Else: Kapalas in the Online Market

Buddhist and Hindu Tantra practitioners have a well-known tradition of salvaging the skeletal remains of tantric monks from sky burials and converting elements for subsequent ceremonial use. These converted remains, broadly referred to as charnel ground ornaments, often include human skull calottes made into bowls (*kapalas*) and drums (*dumaru*) and certain long bones made into musical instruments (*rkang gling*). These items have appeared in ethnographic collections for centuries. With the advent of the online market, the sale of these items into the tourist and oddities market has exploded. Each year, hundreds of purported *kapalas* are listed for sale on eBay. The majority of these items are clearly real human bone. However, their provenience is dubious. It is clear that there are not enough sky burials to supply this robust trade. This presentation reviews four years' worth of eBay listings to understand the market and to contextualize them within the known religious tradition from which they purportedly derive. Combined with published accounts of active red markets in Asia, these auctions raise moral, ethical, and legal concerns. A proposed framework for management, documentation, and enforcement from an anthropological perspective is presented to continue the dialogue of protecting sacred objects.

Ten Years of DINAA: Lessons for Archaeological Methods, Practice, and Ethics from a Decade of Experience Compiling, Organizing, and Publishing Data with the Digital Index of North American Archaeology

On November 13, 2013, the Digital Index of North American Archaeology (DINAA) published its first set of completely free and open scientific and cultural data for about 86,000 archaeological sites. Ten years later, DINAA provides information for almost one million archaeological sites. This includes vast holdings of primary scientific and cultural data, bibliographic information and links to tens of thousands of research publications and reporting about particular archaeological sites, and links to scores of external sources of online or physical data and/or collections about particular archaeological sites. DINAA has become an important fixture in national and international scientific infrastructure, with hundreds of citations by researchers in Google Scholar, students in ProQuest Theses, and heritage experts in government reports, as well as massive amounts of press attention. The development and publication of DINAA as a public scientific resource has exemplified a wide range of the challenges and opportunities that digital methods encounter in the complex scientific, political, and ethical landscape of American archaeology. Issues to be discussed include (1) achievement of FAIR and CARE data principles, (2) developmental and long-term costs, (3) data-management preparedness of archaeological practitioners and educators, and (4) organization of stakeholder communities and offices for contribution and critique.

Wendt, LeeAnne (Muscogee [Creek] Nation)**[195]***Discussant***[WITHDRAWN]****Wengrow, David****[298]***Discussant***Wenzel, Jason (Gulf Coast State College)****[175]***Searching for Old St. Andrews: A Program for Community Archaeology in Panama City, Florida*

This poster exhibits current research by Gulf Coast State College in examining sites associated with the “lost” town of St. Andrews, which was initially established in 1827 on St. Andrews Bay in northwestern Florida. Believed to be abandoned in 1863 during the American Civil War, archaeological investigations at properties associated with the town’s early settlers have enhanced our knowledge of life in this frontier town. The recovery and examination of material culture associated with Indigenous peoples helps to further enlighten our understanding of the area’s deep cultural history.

Werens, Karolina (University of Oxford), John Pouncett (University of Oxford), Christophe Snoeck (Vrije Universiteit Brussel), Rick Schulting (University of Oxford) and Andrzej Weber (University of Alberta)**[171]***A New Bioavailable Strontium Baseline for the Baikal Region*

A new bioavailable strontium isotope ($^{87}\text{Sr}/^{86}\text{Sr}$) baseline was created for the Baikal region, covering ca. 1.5 million km². With an ongoing, extensive archaeological investigation of ca. 200 prehistoric cemetery sites in this vast area, there is a need for a reliable isotopic model of environmental strontium variation to contextualize human and faunal data. The new isoscape is based on 349 plant samples, including 174 new measurements. The strontium ratios in plants were highly variable and ranged from 0.70643 in the mafic rocks in Trans-Baikal to 0.75225 in Precambrian rocks of felsic origin on the west coast of Lake Baikal. The uniquely distinct geological variability and biodiversity in the Baikal region of Siberia provide favorable conditions for isotopic studies and method development. This paper compares and evaluates two approaches to modeling isoscapes: spatial aggregation and machine learning, each used to produce and compare effectiveness of geographic assignments based on strontium ratios measured in dental enamel. The new baseline and spatial assignments scripts can also be applied in other fields: forensics, environmental sciences or ecology, to support studies of provenance and mobility in both the past and present.

Werner, Helen (Beloit College)**[330]***In Support of a Holistic Approach to Bioarchaeology: The Distribution of Bacterial Genera by Presence of Material Culture in the Milwaukee County Poor Farm Cemetery*

Complicating the narrative of the traditional poor farm cemetery, the work of Patricia B. Richards has led to a more humanistic approach to interpreting archaeological data. This study presents oral microbiome data from 25 female individuals from the Milwaukee County Poor Farm Cemetery (MCPFC) population. After approval was given in spring 2022 by the Archaeological Research Laboratory at the University of Wisconsin, Milwaukee, bacterial DNA was extracted from dental calculus and the 16s rRNA gene was amplified. Four of the individuals showed the presence of a genera that has pathogenic species, suggesting a potentially high level of infectious diseases within the MCPFC residents. Statistical analyses showed an unequal distribution of pathogenic genera between the individuals who had little material culture present in their burials and those

who did not, potentially contributing to the reidentification of the MCPFC individuals, a central goal of the work being done with this population. Along with the presentation of these data will be a discussion of how the work of Dr. Richards has shaped our understanding of the complexity of life within a poor farm and how the integration of multiple lines of evidence can lead to a more holistic understanding of pauper cemeteries.

Drilling into the Past: Social Bead Making for Undergrad Learning

The first ostrich eggshell beads appeared across parts of Africa 50 ka and represent one of the earliest forms of ornamentation. Far from being uniform, research shows differences in bead diameter which cluster regionally and chronologically. These clusters are thought to represent distinct bead making traditions in eastern and southern Africa and are used as a proxy for tracking the migration of herders into southern Africa. Our experiment attempts to determine if there are other relevant but non-stylistic variables that influence bead diameter that could add complexity to these interpretations. During our research, we were assisted by numerous students, which led us to see the potential for bead making as a pedagogical tool. As a classroom activity, bead making requires little preparation, is safe, and features a shallower learning curve than similar alternatives such as flintknapping. Our experiment also generated a large volume of beads that could serve as a teaching collection. Not only do the beads give students the opportunity to handle replicated Stone Age technology, but they could serve as a dataset for students to manipulate, allowing them to learn the basics of data collection, management, and analysis.

Digital Palimpsest of Cultural Heritage: A Virtual Experience of the San Ignacio Church in Bogotá, Colombia

This interdisciplinary project uses photogrammetry and video game development software to capture and digitally re-create the interior of the San Ignacio church in Bogotá, Colombia. Established in 1610, this church served as the mother church for the Society of Jesus in Nueva Granada and continues to be one of the most spectacular examples of Baroque architecture in the Americas. This 3D immersive environment incorporates archaeological and bioarchaeological data to allow the user to experience both the present and the past virtually. Archaeological excavations from 2016 to 2017 uncovered information about the early architectural history and subsequent renovations, as well as funerary contexts for over 150 human skeletal remains with

well-preserved funerary textiles. We use 3D scans of one individual's cranium to create a digital facial reconstruction, which will be used to incorporate this individual into the environment as a character guide that shares information with the visitor. This project blends together cultural heritage preservation, public history, archaeological narratives, and interactive design to serve as an immersive teaching tool that is accessible for broad audiences.

Fixed if by Ice, Loose if by Sea? Harpoon Technology as Evidence of Hunting-Scapes in the Neoglacial Eastern Aleutian Islands

The effect of cooling climate during the Neoglacial period (3000–5000 BP) on societies in the Eastern Aleutian Islands is contested. Some archaeologists have argued that the appearance of toggling harpoon heads by 3000 BP indicate an adaptation to hunting marine mammals in an icy environment. This conclusion is problematic because toggling harpoons were frequently used in ice-free environments. Here, we examine whether the entire harpoon technological system—and particularly the foreshaft—are better indicators of past hunting-scapes, and we examine the implications this has for understanding hunting strategy in the Neoglacial Eastern Aleutians.

Ideas on an Interpretive Framework for Understanding Sites of Convict Leasing

Convict leasing was an exploitative, capitalist-driven system that successfully replaced race-based chattel slavery with class-based rented forced labor in the American South. The system sits at the intersections of race, masculinity, labor, economics, and modernity. It reveals the ways that widely condemned historical practices, such as enslavement, can be repackaged and made palatable for a modern society. In this paper, I explore the ways that materialities from sites of convict leasing, including artifacts, landscapes, and documents, can be used to understand the deeper ideological roles of convict leasing in reifying and upholding institutions of White supremacy, entrenched class systems, and unfree labor into the modern day. I bring together theories on Black feminist archaeology, Black geographies, materiality, abolitionism, critical race theory, and difficult heritage to illuminate the layered social meanings of convict leasing's material worlds. I apply these frameworks to the example of the Lone Rock Stockade, a late nineteenth-century convict labor stockade in Tennessee, in order to examine how explicit engagement with theoretical frameworks can transform our understandings of historical archaeological sites and cultural processes.

Yes, Virginia, There Is a Nineteenth Century in Maine

Northern New England has a rich and lengthy postcontact occupation history. New England archaeologists, historians, and SHPOs long focused on the “First” periods of settlement, such as seventeenth-century forts and eighteenth-century maritime sites, while nineteenth-century resources were dismissed. As Terry's first PhD student, I entered a rigorous immersion into the study of nineteenth-century ceramics, utilizing

minimum vessel counts as units of analysis. Our lessons were held on Sunday afternoons at Terry's home, where I had access to her extensive library and vast personal collection of ceramics. Her instruction led to my 1992 dissertation on nineteenth-century urban deposits at three sites, then later formed the foundation for decades of contract survey of nineteenth-century homesteads, farms, and mills in Maine, New Hampshire, Vermont, and Massachusetts. Terry's contribution to my success in bringing recognition of these resources cannot be overstated.

The Exploits of the JAE: Open-Access Publishing Meets Archaeology and Education

Education has become an important component of archaeology in all realms, from traditional teaching arenas in universities and K–12 schools to research to government and contract work. In 2017 the Robert S. Peabody Institute of Archaeology and the University of Maine, Orono, collaborated to found the *Journal of Archaeology and Education* (<https://digitalcommons.library.umaine.edu/jae/>), a peer-reviewed, open-access journal dedicated to disseminating research and sharing practices in archaeological education. The journal's founders recognize the significant role that archaeology can play in education at all levels and intend for JAE to provide a home for the growing community of practitioners and scholars interested in sharing their first-hand experiences and research. Since 2017, JAE has published 39 articles and two special issues with a total of 11,000 downloads. JAE's editorial board contend with issues around growing awareness and increasing submissions, as well as how to handle the ethics of human subjects research in environments where Institutional Research Boards are not always available and researchers are not consistently aware of the need to have their research vetted.

The Tiniest Burials: Fetal Burial and Personhood during the Late Roman Period in Egypt

Mortuary practices surrounding fetal-aged individuals are highly variable, providing opportunities for examining complex beliefs about personhood, social identity, and “wholeness” from cross-cultural and chronological perspectives. This paper examines the mortuary context of the unborn, or those individuals entering the mortuary landscape because of miscarriage, premature birth, or other factors within the Kellis 2 cemetery, in Dakhleh Oasis, Egypt. The unique hyper-arid environment has allowed for excellent preservation of human remains and evidence of bodily and funerary treatments. This cemetery represents early Romano-Christian mortuary practices where all individuals, regardless of age, were buried in a consistent mode of bodily treatment and placement in the landscape. Ten percent of the Kellis 2 juvenile population (46/463) are aged younger than 36 weeks of gestation, suggesting the death and treatment of these individuals had a meaningful impact on the lives of remaining family and within the cultural norms of the community. This context provides a distinctive and uncommon view into early Christian burial practices and how ideological beliefs about personhood extended across different levels of society. ***Images of human remains will be shown in this presentation.

Evaluating Long-Term Trends in Seasonality and Land-Use Changes in the Postcontact Llanos de Mojos

The Llanos de Mojos region in the Bolivian Amazon has a long history of human occupation that challenges

long-held ideas about the nature of precontact communities. It has a tropical savanna ecosystem with very strong seasonality, resulting in annual cycles of flooding and drought. Large, long-term sedentary populations appear to have adapted to this environment by constructing extensive anthropogenic landscapes, including raised agricultural fields, which were eventually abandoned after thousands of years of sustained use. The exact timing and reason for the abandonment of raised-field agriculture is unknown, though some argue the arrival of Jesuit missionaries, domesticated livestock, and new agricultural practices in Mojos in 1683 CE played a significant role. This project utilizes stable oxygen isotope analysis of sediment cores to determine if the abandonment of traditionally managed landscapes can be attributed to environmental factors in addition to the cultural factors associated with the arrival of Europeans in the region. If extreme changes in expected seasonal climate patterns occurred, then environmental factors may have contributed to the changing land-use practices evidenced by the abandonment of raised field agriculture, vegetation shifts, and increased reliance on European domesticates.

Could Large Mammal Faunal Remains Provide Indirect Evidence of Precontact Landscape Management?

It is widely acknowledged that fire was used throughout the western United States as a landscape management tool. Direct archaeological evidence is rare and successful studies that identify Native American burning rely on multidisciplinary approaches. One such study in California by Lightfoot, Cuthrell, and colleagues used changes in the relative abundance of small mammal species through time as part of a broader argument that precontact Native American burning was used to maintain open meadows in what is now a forested environment. In an unrelated series of studies, Broughton has identified a pattern of increased hunting of artiodactyls in the Late period. Using a detailed biological habitat suitability model for black-tailed deer I examine whether Late period increases in artiodactyl indices in central California may have been driven by regular Native American burning of chaparral habitats. If these patterns can be demonstrated it suggests that faunal data (old and new) could provide evidence of widescale landscape management.

Paleoenvironmental Signatures of a Persistent Place at Kharaneh IV, Jordan

Paleoclimatic and paleoenvironmental data are pertinent to understanding the processes that form persistent places. This paper presents new physical and chemical geoarchaeological data, including faunal C and O isotopes, sediment composition, and geological survey data, from Kharaneh IV, a large Early to Middle Epipaleolithic site in eastern Jordan, and aggregates existing information to define the site's unique environmental qualities and form a narrative of climatic change on the Kharaneh landscape. In addition to confirming dry periods before and after the site's occupation identified by previous research, we find that environmental conditions during the site's thousand-year history were relatively stable, with the exception of a temporary period of enhanced precipitation during the site's Middle Epipaleolithic occupation. While other water sources may have been available in the region, we find that the site's reliability over a thousand-year period encouraged continued reoccupations of the site and contributed to the formation of a persistent place.

Assessing Plant Use in the Early Upper Paleolithic: Macrobotanical Results from Mughr el-Hamamah, Jordan

The Mughr el-Hamamah (MHM) cave site, located on the Jordan Valley's eastern flanks, contains a prehistoric layer associated with Early Ahmarian artifacts. AMS ¹⁴C dates bracket the Early Upper Paleolithic (EUP) occupation between ca. 45 and 39 ka cal BP and are comparable in age to Ahmarian-associated layers in Kebara and Manot Caves. Excavations at MHM have revealed a rich assemblage of carbonized wood, nutshell, and seeds. A comprehensive macrobotanical sampling plan was carried out during the 2017 excavation season to collect carbonized plant material. After samples were floated in the field, they were sorted and analyzed at the Center for the Analysis of Archaeological Materials (CAAM) at the University of Pennsylvania.

Identification of the charred seeds and nutshell fragments from MHM provides detailed confirmation of the main botanical components of the EUP diet with an emphasis on edible legumes and pistachio nutlets, drawing an interesting comparison to the legume-rich assemblage from Neanderthal deposits at Kebara Cave, as well as other archaeological sites with preserved botanical material in the region.

The Implementation and Distribution of Thermoregulatory Technology in the Paleoindian Period

Thermoregulation was integral to the survival of the first and subsequent people who inhabited North America following the Last Glacial Maximum. Successive climate fluctuations necessitated the implementation of technologies that increased the probability of human survival. Previous research has examined the timing of thermoregulatory technologies in the archaeological record and the potential relationship between these technologies and erratic climate fluctuations during the Younger Dryas cooling event. Bone needles in the North American archaeological record primarily coincides with the Folsom cultural complex between 12,610 and 12,170 BP. The known distribution of this technology across Western North America over a moderately brief period of time suggests a necessity for implementing and sharing thermoregulation technologies across different regions and elevations. Twenty-four bone needle fragments recovered from Locality I of the Hell Gap site in Goshen County of Wyoming are all associated with the Folsom cultural component at the site. The density of bone needle fragments from this component at Hell Gap, and at other Paleoindian sites in North America, shows how the necessity for thermoregulatory technology was implemented to combat climate change during the Younger Dryas to facilitate human survival.

The Archaeology of Nataeł Na' and Its Implications for Landscape and Resource Use by Pleistocene Peoples in the Yukon-Alaska Borderlands

The multicomponent hunter-gatherer site Nataeł Na' represents the first evidence of Pleistocene-aged human occupation in the Copper River basin. One occupation dates to the Allerød interstadial and another to the late Younger Dryas climate reversal. To date, the Allerød occupation has been identified only by a small assemblage of lithic reduction debitage. The Younger Dryas occupation is represented by a more robust lithic assemblage recovered in association with a well-dated combustion feature. The limited nature of the excavation to date constrains the extent of interpretation that can be realistically applied to this assemblage, which has led us to employ a wide variety of analytical techniques during our investigation of the site. The location of Nataeł Na' makes the site a prime candidate for regional and interregional comparison of

the lithic technologies identified in the assemblage and the organization of those technologies. Viewing Nataef Na' from a landscape and even regional perspective has great potential to provide insight into the behavior and resource exploitation of the early inhabitants of the southern Yukon-Alaska borderlands. Our interpretations of the behaviors and technologies represented at Nataef Na' also raise interesting questions about the connection between this and adjacent regions during the Pleistocene.

From Trypillia to Tswana: A Global Perspective on Giant Low-Density Settlements

Early giant settlements such as Chaco Canyon, the Tswana “towns,” and the European *oppida* have long seemed anomalous to scholarship because they did not ally their vast extents with characteristics of conventional urbanism. These large, low-density settlements emerged periodically for more than 7,000 years across the globe. They occur far more frequently and in more diverse geographic areas than higher density settlements of similarly novel areal extents. Roland Fletcher (1995) identified that they functioned because by dropping to a low-density internal pattern they were not constrained in expansion by interaction stress or issues of communication. Without such constraint, they developed across a range of formal and operational characteristics, often with evidence of population mobility and within extensive regional interaction networks. But their expansions and persistence often appear somewhat random. Structurally, they were giant variants of common regional forms appearing within specific culture regions but ceasing to develop with region-scale systemic change. These settlements were both robust and vulnerable. More than 200 examples have been identified and there are many more. They constitute a human settlement behavior that we are only beginning to systematically explore.

[165]

Archaeology of the Apalachicola-Lower Chattahoochee Valley

Archaeological synthesis in this neglected region (in northwest Florida, southeast Alabama, and southwest Georgia) provides alternative models of cultural adaptations over the last ca. 14,000 years. Paleoindian evidence is densest in the tributary Chipola River but extends to the coast. As post-Pleistocene sea-level rise pushed the river eastward, Archaic peoples adapted to climate change, developed the earliest ceramics by about 4500 BP, and deposited estuarine shell middens. By Middle Woodland times (ca. AD 300–700) mound ceremonialism included a fascination with light, exotic forms, and fancy imports but not yet any apparent economic stratification. All this waned as people began growing maize inland, with Fort Walton period agricultural chiefdoms emerging by AD 1000. Old World invaders arrived nearby 500 years later, then colonists, leading to major depopulation, the disappearance of aboriginal material culture, and a confused protohistoric record. Creek groups moved south into Spanish Florida, becoming Seminoles. Settlements, including the largest Maroon community in the US, were destroyed by the emerging American nation. Recent historical archaeology research includes lost Civil War forts; the short-lived antebellum boomtown of old St. Joseph (1836–1844); industrial, agricultural, and military sites; and the destroyed landscape after Hurricane Michael in 2018.

I Didn't Get Here Because of My Trauma: I'm Here Because I'm Good at Archaeology

The monoraciality of archaeology perpetuates systems where many European American archaeologists assume archaeologists who are Black, Indigenous, and People of Color (BIPOC) have arrived because of affirmative action. Our presence is considered the result of traumatic lives that led to handouts; many think we were given scholarships, fellowships, and grants because of our BIPOC status and traumatic lives. While a range of BIPOC support resources are necessary and valuable, those of us who make it in archaeology did not become professionals because of the traumatic lives we've lived. This presentation discusses the pressure

BIPOC archaeologists feel to write about, research, and tell others about the traumas they've faced in their efforts to become a professional archaeologist. It extrapolates from Tina Yong's 2023 presentation on the "Trauma Essay" in college acceptance letters to examine how this is perpetuated in academia and professional archaeology. The talk ends with some suggestions for moving beyond this phenomenon.

Reviewing the Human Remains Detection Dog Workshop

The National Park Service's Center for Preservation Technology and Training (NCPTT) facilitated a workshop for archaeologists in May 2023 at the Poverty Point National Historic Landmark / World Heritage Site as part of an ongoing effort to research human remains detection (HRD) dogs for nondestructive archaeological investigations. HRD dogs supplement investigations by adding another layer of evidence to remote sensing surveys. NCPTT, the Friends of NCPTT, and Poverty Point hosted the workshop to expand the network between archaeologists and HRD dog handlers; review the theory and methods of canine search in different settings as the foundation for HRD; and conduct field exercises to demonstrate best practices to archaeologists. Additionally, data collected at Poverty Point historic cemeteries during field exercises, combined with past HRD dog and geophysical investigation results, provided insight on how results can vary with environmental conditions and different dog teams.

The Ontology of Landscape and Hunter-Gatherer Rock Writing

Landscapes are cultural constructs, shaped by cognition and actualized in behavior. Hunter-gatherer landscapes are traditionally viewed in two terms: settlement patterns and systems, and related adaptive/subsistence niches and patches. While useful, these approaches embody the epistemological imperialism of Western archaeology, and they leave unexplained ritual landscapes. How then do we explain the locations of the most visible expression of hunter-gatherer ritual, rock writing? And how do we explain unusual massive concentrations of these sites, with two or three orders of magnitude more motifs and ritual features than typical? Native Californian ontological beliefs about landscape based on the nature and distribution of supernatural power and how it manifests on earth explain the logic of two major rock writing concentrations: Coso Range Numic petroglyphs and Carrizo Plain Chumash pictographs. These examples illustrate the coherence and consistency of Native Californian religious beliefs, thereby providing an avenue for an emic understanding of the archaeological record.

Whitley, Tamara (Bureau of Land Management) and Kristina Doyle (Bureau of Land Management)**[44]***Life in a Land of Little Rain: Historical Agricultural Landscapes on the Carrizo Plain, California*

The Carrizo Plain National Monument (CPNM) contains a large number of structures and features associated with historical agriculture on the Carrizo Plain. This largely intact cultural landscape spans a period of significance from the Homestead Act through industrial scale dryland farming. Historical and archaeological contexts have been developed for the monument, and four farm/ranch headquarter structures have been formally evaluated and determined eligible for the National Register of Historic Places. Ongoing use and maintenance of the larger CPNM, however, has the potential to adversely impact isolated, but potentially contributing, features such as grain tanks, water tanks and troughs, corrals, and fencing. As important components of the agricultural working landscape, the identification of the associations and context of these features is critical to delineating and understanding this cultural landscape and preserving its ability to convey its values. This poster describes and discusses the process of documenting these resources and developing a NRHP district nomination and resource management plan for protecting this historical agricultural landscape.

Whitley, Thomas (Sonoma State University)**[10]***Discussant*

Whitney, John [310] see Allen, Mitchell

Whitridge, Peter (Memorial University of Newfoundland)**[331]***Graffiti Atmospheres and the Durability of Transient Places*

Although simple tags are liable to appear anywhere, contemporary graffiti thrives in places that are marginal to everyday traffic, such as alleyways, rooftops, overpasses and vacant or abandoned structures. Even in these places graffiti is usually impermanent; other writers will eventually go over it or the wall will be buffed by authorities to discourage its proliferation. Despite this characteristic marginality and transience, favored locations may be used year after year, often precisely because they are abandoned, remote, concealed, protected from the elements, or otherwise suited to writing. Persistent graffiti sites emerge where the atmosphere is conducive, but mushrooming graffiti also helps to produce a suitable atmosphere, giving rise to discursively dense panels of overlapping text, color, and graphical fragments that envelop crumbling concrete, brick, and steel. Like most modern cities, St. John's, Newfoundland and Labrador, has accumulated many such sites, ranging in scale from abandoned factories and military installations to narrow downtown alleys, and many of these are haunted by a postindustrial atmosphere of anarchy and decay that graffiti both seeks out and helps generate.

Whittaker, John (Grinnell College), Kathryn Kamp (Grinnell College), Chuck LaRue (Independent Researcher) and William Bryce (Logan Simpson)**[306]***Atlatl Dating and Violence in Rock Art in the American Southwest*

Atlatl-related motifs are prominent in a limited area of the prehistoric American Southwest. The motifs include atlatls and darts and images relating to hunting and violence, all socially and symbolically important. While recognizing difficulties in dating rock art, the atlatl-related images are closely associated with styles and motifs dated to the Formative, early horticultural Basketmaker II cultures of the Colorado Plateau before about AD 700. They do not co-occur with bow-and-arrow depictions, and the few apparently narrative scenes of violence suggest small-scale social conflicts, rather than larger group warfare. Later cultural systems changed as regional populations grew, became more dependent on agriculture, and adopted the bow and arrow.

Where Are the “Interesting” Skulls? The Practice and Taphonomy of Modern Interaction with Human Remains in Open Tombs

Modern interaction with ancient human remains is near-ubiquitous in aboveground open-air tombs, used in the Andes during the late prehispanic period (ca. 1000–1532 CE). These spaces are host to a range of activities, from looting and sale of artifacts by professional huaqueros to exploration by local history enthusiasts. While—or perhaps because—all of these practices disturb the primary archaeological context, I argue that modern rearrangement and removal of artifacts and human remains are forms of mortuary practice that should be studied by archaeologists. Specifically, this paper uses a case study from recent fieldwork to investigate the practice of rearranging isolated crania in *machay* (cave) tombs in southern Ayacucho, Peru. I hypothesize that, rather than a random sample of crania from the tomb, these represent a collection that “looters” have curated and arranged to be viewed by future visitors. As such, the crania displayed in prominent locations, such as the mouths of caves, will feature higher rates of cranial vault modification, fractures, and other features that are visually apparent and/or evocative to laypersons. This study carries implications for surveys and surface collections at open sepulchers and argues that certain forms of what is typically termed “looting” constitute thoughtful engagement with cultural heritage.

Neighborhoods on Cerro Amole, Oaxaca: Models for a Mixtec Cabecera

Intermediate levels of social organization—above the household, but below the entire settlement, city, or polity—are notoriously difficult to pinpoint in archaeological contexts, but they nevertheless represent a crucial frontier for building new archaeological theory to understand daily social life in the past. Ethnographic research demonstrates that informants recognize units such as the “neighborhood” and consider them important. In Mesoamerica, organizational units such as the Mixtec *siqui*, Aztec *calpulli*, and Maya *cuchcabal* were often formally recognized in social, military, and economic (especially tribute) systems. The mountaintop site of Iglesia Gentil on Cerro Amole, above the town of San Pedro Teozacoalco, was the *cabecera*, or administrative center, of Chiyo Cahnu, an important Postclassic Mixtec polity. Utilizing distributions of architecture and artifacts across the site based on data collected with GPS units from 2013 to 2017, three complimentary GIS-based models are evaluated for their ability to define neighborhoods.

Teaching and Learning Climate Change through Global Change Archaeology

Climate should be mainstream in education and be incorporated into all subjects because climate change is permeating. Many natural sciences are already centering climate literacy in coursework, but as the effects of climate change have become more visible and clearer, humanities, social sciences, and the arts are increasingly incorporating climate into their curriculums. Climate change education may take the form of both formal and informal learning and teaching and increasingly include immersive field projects and classroom activities using international case studies. Archaeology education already implements these approaches and is rich with insights relevant to environmental problem-solving due to its comparative nature, time depth, multidisciplinary perspectives, and interdisciplinary collaborations. Global-change archaeology

centers the archaeological record to the understanding of contemporary environmental problems. Incorporating global-change archaeology into all levels of curriculum can make clear human-environmental interrelationships and emphasize human adaptation and resilience from a long-term perspective. Engaging students with the climate crisis through global change archaeology can reveal the relevance of the archaeological record for addressing contemporary problems, such as the climate crisis. This poster will highlight examples that utilize scientific and cultural elements of the archaeological record as curriculum resources for teaching climate change within the framework of global-change archaeology.

Experimental Study of Hunter-Gatherer Base Camp Taphonomy in the Southern Appalachian Highlands

An experiment was undertaken to explore contextual and materials taphonomy initiated at the time of hunter-gatherer base camp abandonment in the southern Appalachian highlands. Acting out a fictional ethnography inspired by southeastern ethnohistorical accounts, 12 humans, accompanied by two dogs, made stone tools and processed subsistence items and deposited the remains in various contexts on an experimental site. Activities and deposits were mapped, and a motion-activated camera monitored scavenger activity for four weeks. Five years later the site was excavated. Smaller items had moved considerable distances, and most subsistence remains, especially bones of white-tailed deer, had been removed from the site by scavengers. This experiment reveals that precise reconstructions of human diets based on surface deposits are untenable.

From Survey to Surveillance in the US-Mexico Borderlands

Extractive industries such as gold, copper, and lead mining anchored settler colonial expansion in southern Arizona through the nineteenth and twentieth centuries, initiating survey-based cartographic practices as colonial method. These now-abandoned mining landscapes have since been incorporated into the contemporary border security landscape as US Customs and Border Protection (CBP) expands its surveillance infrastructure in the region. The rugged terrain of the Arizona highlands has become an experimental zone for “virtual wall” techno-security measures, including networks of sensors, cameras, and drones that map CBP’s vision onto the landscape. It is these sites where the surveillance system touches down, however, that the legacy of the historic frontier structures border security logics in unexpected ways: the mining landscape affords sites of capture, refuge, and countersurveillance, distorting the surveillance fantasy of disembodied vision. At a methodological level, this paper interrogates the parallels between archaeological survey and the techniques of state surveillance, asking how we might square the view from above with the view from the ground. This paper also uses archaeology to ground surveillance infrastructure not just in its historical precedents, but in its material traces and dependencies, making visible an object that is often seen as a nebulous network of dispersed power.

A Curious Presence: Examining Salado Polychrome Production and Provenance in the Phoenix Basin of Arizona through a Multi-method Approach

Between ca. 1300 and 1450 CE, Salado polychrome (Roosevelt red ware) pottery production and use spread rapidly, then persisted across the US Southwest, intersecting diverse cultural and regional traditions, and creating a material pattern termed the “Salado phenomenon.” In Arizona’s Phoenix basin during the Hohokam late Classic period, Salado polychromes appear curiously, with high ubiquity but low frequency, and unaccompanied by many of the material signatures that underpin explanatory models for their production developed in adjacent regions. To better understand the distinct material and social relations that structured how Phoenix basin residents obtained Salado ceramics, a study of Salado polychrome production and provenance was undertaken, examining museum ceramic collections from nine sites. A suite of complementary chemical and mineralogical characterization methods, including neutron activation analysis ($n = 278$), electron probe microanalysis ($n = 60$), and ceramic petrography allows the assessment of compositional and technological variability, the number and nature of compositional groups, their possible relationship to source locations, and the degree to which composition cross-cuts ware and type categories. Beyond elucidating the production and distribution of these ceramics, this research aids in understanding the social and practical meanings of engagement with Salado practices and materials in the Phoenix basin Hohokam context.

Boundaries: Where Iron Age Archaeology Meets Medieval Art History

While interdisciplinarity in archaeology increasingly has blurred the borders between humanities and sciences, an additional boundary in archaeology exists between what is considered Iron Age and what is medieval. The terms have been defined largely from the Continental point of view. In the North, the Viking Age, ca. 800–1050 CE, is considered the last subdivision of the Scandinavian Iron Age and is marked as the period of transition from a non-Christian to a Christian worldview. This conversion, which occurred earlier in the South, is studied by scholars from many disciplines including archaeology, history, visual arts, and religion, with diverse research traditions based on disciplinary and national boundaries. In this presentation, I will discuss the vagaries of studying the material culture of Viking Age Scandinavia both as an Iron Age archaeologist and as a medievalist art historian.

Clearing Away the Cobwebs: The AVCAR Orphaned Collections and Innovative Undergraduate Research

The Antelope Valley Archaeological Repository (AVCAR) houses over 300 archaeological sites from the western Mojave Desert. These collections constitute over 40 years of compliance-based and salvage archaeological excavations led by Antelope Valley College and the Antelope Valley Archaeological Society. While these documented sites vary in complexity, quantity, and size, they resemble some of the most extensive excavations within the region. AVCAR collections are largely unanalyzed and most of the associated field work remains unpublished; hence, they meet the typical definition of “orphaned” archaeological collections. Furthermore, various curation methodologies known to be research precursors provide organic and meaningful encounters that inspire undergraduate research. In this presentation, I will outline the various management strategies and research designs applied to the AVCAR orphaned collections, which have promoted student stewardship and research at the community college level. Additionally, by uncovering the research potential of the AVCAR orphaned collections, students have gained valuable insight into the process of collaborative efforts between local tribal governments throughout the region. By

employing “community-based” archaeological practices for the AVCAR orphaned collections, students can develop pragmatic skills that promote a more sustainable form of archaeology in the region.

Brown v. Board of Education National Historical Park: Archaeological Investigations and Geophysical Survey
Brown v. Board of Education National Historical Park commemorates the US Supreme Court’s 1954 decision to end legal racial segregation in public education and preserves significant resources like Monroe Elementary School in Topeka, Kansas. Before opening to the public on the ruling’s 50th anniversary, the Midwest Archeological Center completed several investigations of the former school and adjacent grounds. Among them were a geophysical survey in 1999, ground-truthing excavations in 2000, and eight archaeological monitoring projects between 2001 and 2003. A new series of ground-penetrating radar and resistance surveys were undertaken in 2021, the results of which were tested as part of a field school last year. Among the findings are the foundation of the first Monroe Elementary School, which served African American students from 1874 to 1927; remnants of contemporaneous homes that stood where the extant school building would later be constructed; and outbuildings, likely a series of privies associated with the first school. Combined with the Center’s earlier investigations, this research sheds light on a working-class African American neighborhood from the turn of the twentieth century that developed in association with the Civil Rights movement of Topeka.

Prepping for The End: How Changing Fears Impacted the Use-Lives of Fallout Shelters

People’s fears can have an impact on decision-making, how people interact with their surroundings, and how they design structures. This is something important to consider when analyzing the archaeological record. The current study contributes to understanding how people’s fears impact construction and maintenance of architecture by examining Cold War fallout shelters from New York in the Albany area. In reaction to fears of the end of the world resulting from nuclear war, both private and public shelters were constructed for protection and in hopes of survival. Historical documents and what remains of the shelters can help us understand the many fears people were dealing with when shelters were built, how people were meant to interact in these spaces, and how fears and the spaces themselves changed as the Cold War went on and after it abated. This study has broader implications about how fear can be reflected in building design and potentially the archaeological record, and how changes in cultural fears alter how spaces are utilized as the focus of those fears shift toward new perceived threats.

Wilcox, Shante (North Carolina State University)**[43]***Misuse and Abandonment of African American Cemeteries: How Social Inequalities Persist in Death in the Post-Civil War Southeast*

This study explores how African American cemeteries in the Southeast have faced environmental and human threats, which makes it difficult for descendant communities to piece together their backgrounds. American law offers some protections against the intentional desecration of cemeteries, yet the maintenance and landscaping of individual cemeteries is left to the responsibility of local officials, resulting in a lack of preservation that disproportionately affects historically African American burial spaces. The Geer Cemetery in Durham, North Carolina, and the Oberlin Cemetery in Raleigh, North Carolina, serve as case studies where volunteer organizations intervened and currently work to preserve the integrity of the grave markers, collaborate with descendants, and, in the case of Geer Cemetery, obtain a National Register nomination. Collaborative research with these organizations focuses on returning agency to the interred through GIS mapping of grave markers, genealogical research to aid in location of descendants, and comparative research of vital records with local, historically Whites-only cemeteries to illustrate differences in health. Finally, this research will be used to create a fictive, bio-historical narrative to engage the broader community and encourage continued preservation of these burial spaces.

Wiley, Trevor (Boston College)**[22]***Inter Duo Maria: Rethinking Early Medieval Settlement in the Forth-Clyde Zone through an Environmental Lens*

The twin estuaries of the Firths of Forth and Clyde in southern Scotland boast a wealth of evidence for studying early medieval settlement. The modern population density around Glasgow and Edinburgh has resulted in a relatively large amount of data from rescue excavations and surveys compared to other parts of northern Britain. However, the societal shifts and settlement changes which marked the transition from the Roman-dominated Iron Age to the Early Middle Ages remain poorly understood and are often placed in simple ethnic frameworks and conquest narratives. New excavations hold great promise for understanding settlement change and the development of new communities, especially in relation to local landscapes and the environment. My paper draws together several examples of such settlements, both older and recently excavated, to think about how they used their local ecological landscapes to build new communities and lifeways in the early medieval period. In turn, it then explores what these settled landscapes mean for our understanding of early medieval southern Scotland, and queries whether older models of conquest-driven cultural shifts are sustainable moving forward.

Wilk, Richard**[21]***Discussant***Wilke, Detlef, Aika Katharina Diesch (University of Bamberg) and Joachim Lorenz (Karlstein a.M.)****[255]***The Roman, Medieval, and Early Modern Potting Site of Dieburg South of Frankfurt/Main, Hesse, Germany, and Its Geochemical Pattern with a Stable Heavy Mineral Anomaly*

As part of an extended ceramic settlement analysis with 10 medieval find complexes in the lower Main depression, we studied Roman and late medieval to early modern pottery from Dieburg (district of Darmstadt), which is the only site with workshop wasters in the larger region. The Dieburg wares exhibit a characteristic anomaly of Ti, Nb, and Zr, which is also found in oil shale sediments (black-pelite/kerogenite)

of the Eocene maar lake of Messel, just 6 km to the west of Dieburg. The Messel Maar is one of several volcanoes in a small north-south stretched hill, which separates the lower Main depression from the Rhine rift valley. We used nondestructive XRF for pottery analysis and XRF and XRD for studying clay mineralogy. The late medieval potters were for sure not aware of the potential volcanic origin of their clay, but focused on this low iron, low cation containing raw material for the production of high-quality lead glazed stove tiles and loam slipped tableware, which was traded over a great distance.

The Skirmish of Jumonville Glenn 1754, Fort Necessity National Battlefield

Early on the morning May 28, 1754, Lt. Col. George Washington and Mingo allies exchanged fire with a party of French soldiers encamped in a glen, close to the English base camp at Great Meadow, in southwestern Pennsylvania. This skirmish, at what is now known as Jumonville Glen, was the first conflict between the British and French that led to the French and Indian War. Battlefield archaeological investigation was conducted in the Jumonville Glen at Fort Necessity National Battlefield in the spring of 2023. The investigation focused on locating the site where the skirmish took place and demonstrates that there is much to learn when using an integrated approach of technological field mapping and artifact analysis. This poster presents the methods used to overcome mapping challenges and dives into a high-resolution 3D spatial environment to analyze and interpret this brief, yet world-changing, exchange of fire.

Using Proteomics to Identify Ancient Pastoralism

Biomolecular analyses (proteins, stable isotopes, lipids, and DNA) have been integral in identifying the economic roles of domesticated animals in archaeological contexts. Materials such as human remains, dental calculus, ceramic matrices, and archaeological residues can provide valuable information on which animals were used for primary and secondary products, as well as determining which tissues were specifically used or consumed. While protein analysis has been more recently developed than the more well-established lipid and DNA analyses, the method offers newly possible insights. The combination of species and tissue specific information that amino acid sequences provide has been critical in clarifying which animals, and their products, were consumed by archaeological populations. Recovery and analysis of proteins from archaeological materials has been especially useful in contexts that suffer from either a lack of recovered faunal material or poor levels of preservation that makes zooarchaeological identifications challenging. Recently, this method has been used to illuminate the spread of milk use on the Bronze Age Eurasian steppe, to the Tibetan Plateau, and into Eastern and Southern Africa. Here, we will detail several projects that have increased our understanding of ancient dairy pastoralism across these regions as exposed by protein analysis.

Williams, Dane**[205]***The Chatelaine, Gender, and Diagnostic Artifact Use*

Chatelaines suspend multiple items to be employed for such purposes as grooming, tools, or keys and have been widely used from before the Roman occupation of England to well after the ninth century. Additionally, they have been used to determine gender identity within Anglo-Saxon burials. By examining the chatelaine's use as a diagnostic measure of gender within a culture and the resulting limiting interpretations, it will be shown that this artifact is not gendered in its overall usage and should cease being used to determine identity. Further, examining gender politics and the use of diagnostic artifacts, multiple long-held biases could be resolved, allowing for a greater understanding of gender identities, societal norms, and overall culture. The implications of this could affect both Anglo-Saxon studies and long-held cultural paradigms worldwide. Determining the use of diagnostic artifacts, such as the chatelaine, to arbitrarily assign gender identities is antiquated; the use of current research to create a more honest examination of identity when examining the material culture of burials is required. This research framework can have impacts on multiple levels ranging from feminist perspectives within history, heritage tourism, and the overall public education about the Anglo-Saxon culture.

Williams, Elizabeth (University of New Orleans)**[131]***Crucibles in the Antebellum Assemblage and Imagination: Unique Finds from a French Quarter Archaeological Investigation*

In 2017, the University of New Orleans located two privy shafts in a French Quarter house lot: one brick-lined privy shaft superimposed on the other unlined privy pit. The contents of the two fill episodes were temporarily distinct, one from the early nineteenth century and the other from the mid-nineteenth century. Mixture between the contents from the two privy shaft features limited in-depth interpretation of the features and their tangled assemblages, but identification of multiple crucibles from the younger deposit are interpreted as unique artifacts from this antebellum household. Without clear avenues of comparative artifact analysis, we reverted to asking basic research questions about why the crucibles could have been in the assemblage in general. By examining data from portable X-Ray fluorescence scans, anecdotes from historical newspapers, and historical primary source documents, this paper examines the role of the crucible in antebellum America—its uses, its potential, and its multiple connotations in a period marked by capital development and risk, Victorian obsession with morality and crime, and rapid technological advancement. Combined with the transition of commercial cottage industries to industrialized factories, these crucibles are part an integral transformation of the material culture of the antebellum period.

Williams, Joey (University of Oklahoma), Rui Mataloto (Câmara Municipal de Redondo) and Karilyn Sheldon (Western Iberia Archaeology)**[26]***Quis Custodiet Ipsos Custodes? Indigenous Responses to Roman Colonial Surveillance in Alentejo, Portugal*

If visibility is undertheorized in archaeology, then invisibility is doubly so. This paper investigates the avoidance of surveillance in a colonial context. The central Alentejo, Portugal, was, in the first century BCE, home to watchtowers established under the new Roman administration of the region. In this remote corner of Europe we can see the remains of a surveillance system and attempts at avoiding and countering it by indigenous Alentejans. In the decades following the Roman conquest of the peninsula, sites visible to Roman watchtowers were abandoned and new settlements established in areas invisible to them. The towers' surveillance system is reconstructed using viewshed analysis, and the use of that system in claiming territory is examined. Indigenous sites, such as Monte do Outeiro, Cabeça de Vaiamonte, and Rocha da Mina are considered for their ability to avoid observation by Roman authorities. Invisibility to the panoptic imperialism of the new Roman regime was just one element of nearly two centuries of resistance to imperialism in western Iberia. Yet the success of these towers resulted in the reorganization of the region into the province of Lusitania and the use of surveillance in other colonial frontiers and carceral spaces of the Roman Empire.

Archaeological Games Don't Have to Be Fair, and Breaking the Rules Is Okay

Many game players work under the assumption that all games need to be fair and balanced. Additionally, many assume that rules-based actions are at the center of gaming. This, however, is not the case when using games in the classroom. Having used games in the classroom for over 10 years, I've concluded that the best lessons are learned from unfair games. Often the social interactions that take place outside the rules can be more informative than moves made within the game. Here I outline several of my archaeological game-based activities and how I've changed them over the years. Additionally, I suggest how non-game mechanics can aid in student learning after the activity. Many of these insights come not from my archaeological training, but instead from my over 30 years of experience playing board games and roleplaying games.

The Potential for Using Long Bone Measurements to Determine Breed of Gallus gallus domesticus and Its Implications for the Archaeological Record

Poultry remains are often found in archaeological excavations and while the species can usually be identified, there has been little research on breed identification or purpose (egg production vs. meat production). This research aims to determine if differences exist between the long bone measurements of modern chicken breeds which can be useful for the archaeological record. We collected specimens of modern breeds (Silkie $n = 9$; Ameraucana $n = 8$; and OEG $n = 6$), skeletonized them, and took measurements of the femur, tibiotarsus, and tarsometatarsus according to published guidelines. Preliminary results show the femur greatest length (GL) could distinguish among breeds (ANOVA $F = 4.409$ $df = 2$ p -value = 0.0251). Tukey's pairwise comparison indicated that femur GL could distinguish between OEG and Ameraucana (p -value =

0.03) and between OEG and Silkie (p -value = 0.05). There is no difference between Ameraucana and Silkie. A principal component analysis on 12 linear measurements and seven ratios shows that the 1st PC (68% of the variance) separates between the Ameraucana and OEG/Silkie group, and the 2nd PCA (31% of the variance) separates between OEG and the Silkie/Ameraucana group. While results are tentative, they suggest the potential of using the long bone size and shape to differentiate between poultry breeds.

Establishing the Elemental Analysis Facility: Reflections on 20 Years of Research

With funding from the National Science Foundation, the Elemental Analysis Facility at the Field Museum has advanced research projects in archaeological chemistry to study research on trade and exchange, examine craft production, and assess the nature of archaeological materials. Established in 2004, the EAF is housed in one of the world's great natural history museums, and its labs promote research not only on museum collections but also on objects from collaborating institutions and researchers. Applications from techniques including laser ablation–inductively coupled plasma–mass spectrometry (LA-ICP-MS) and portable X-ray fluorescence (XRF) have been instrumental in this work. Collaborative projects have ranged from explorations of glass bead production and exchange to sourcing earthenware ceramics and developing portable laser ablation systems. Dozens of publications and large databases have been built, the latter of which provide for large-scale comparative analysis of exchange systems on continental scales. In this paper, we highlight the efforts to establish the EAF in 2004 and the funding models and structural framework that has led to its success.

Tanks of Vermont: Using 3D Imaging of Oversized Artifacts and Oral Histories to Build Community Engagement

The use of 3D imaging within archaeology is often focused on the modestly sized objects and artifacts that form the basis of most museum or research collections. With the appropriate instrument, however, even very large objects can be effectively imaged and used in both research and outreach contexts. In this poster, we present the results of a project designed to capture oversized artifacts of US military history, and accompanying stories. Veterans of Foreign War (VFW) halls throughout the state of Vermont often feature a tank outside, a testament to the technology and methods of warfare in the twentieth century. Using an Artec Leo 3D scanner, digital models of a variety of these tanks have been created and allow for detailed exploration of how size and design changed through time. Oral histories collected from veterans or their family members during the lengthy scanning process provide compelling personal counterpoints to the digital models and strengthen linkages between the university and surrounding community.

Tornadoes as an Impetus of Social Change in the Eastern United States

Mississippian and related sedentary settlements in the eastern United States often appear unstable in the archaeological record. The eastern United States is also in the most tornadically active area on earth. Tornadoes have been an impetus of settlement and social change in both the historic and modern era. Using 50 years of data collected by the National Weather Service, I demonstrate that it is probable that tornadoes effected many precolonial settlements in the American South. These effects could further expand on the unstable nature of Mississippian settlements, polities, and region as a whole.

Roads and Changing Mobility in Northwest Argentina (AD 1400–1800)

Mobility defines human behavior; roads make that mobility possible. We study human mobility along route networks in an area of the Middle Calchaquí Valley, Salta Province, Argentina, called La Hoyada Quebrada, a natural connection route to the puna. Archaeological research highlights the fundamental role of high ravines and valleys for communication between different environments, since at least the first millennium CE. Additionally, historical documents and secondary sources attest to the continued use and importance of this area as a transit zone until well into the twentieth century. As such, our case study focuses on analyzing the development of roads and networks in La Hoyada at two sequential periods in time: the Inka and the Colonial periods. La Hoyada incorporates an important Inka road segment that connects the Calchaqui Valley with the puna and then continues into the saltpans, linking this area with the Atacama Desert and northern Chile. The road segment included several ancillary structures, such as way-stations (*tampu*), that were then reused subsequently. With the introduction of the Spanish colonial system, this entire area became part of the Hacienda de Calchaquí, which had land dedicated to agriculture and pastures for the fattening of cattle that were then taken to Upper Peru.

Paul Gendrop's Río Bec, Chenes, and Puuc Architecture: New Insights after 40 Years

While certain Northern Maya Lowland architectural characteristics remain constant for these three peninsular stylistic “entities” defined by Paul Gendrop, such as few dynastic hieroglyphic monuments, ballcourts or E-Group complexes, the past 40 years have revealed many new, insular features: zoomorphic mask elements adorning massive monumental stairways, myriad deity characters other than “Chahk” enshrined in zoomorphic portals, and pan-regional construction elements that define massive temples and palace structures. This talk will highlight monumental temple and palace features in Río Bec’s Chicanná, Chenes urban centers Hochob and Santa Rosa Xtampak, and Puuc’s splendid Adivino and the Nunnery Quadrangle in Uxmal. While hieroglyphic programs give way to socio religious or ideological rather than individual dynastic display, each zoomorphic portal variant portrays distinct deity personalities from site to site and from region to region. Few ballcourt elements throughout the former Central Yucatán regional variants play a novel functional paradigm for this architectural assemblage. And finally, we will discuss whether those elements present distinct yet temporal and progressively complex “evolutionary” transitional Classic period manifestations from region to region, or if they are local variations of other key architectural social indicators that persist throughout time in the entire Maya Lowlands.

Change Detection Modeling at Eagle Nest Canyon

This paper investigates the use of drone-based 3D photogrammetry for mapping and monitoring landscape changes at Eagle Nest Canyon. Mapping before and after an extreme 2014 flood enables change detection modeling (CDM) using geographic information systems (GIS). By comparing elevation data from pre-flood and

post-flood DEMs, the study quantifies alterations caused by the flood. Results indicate significant changes in canyon bottom topography, with implications for site preservation and archaeological deposits. The research highlights the broader significance of using drone technology and GIS techniques for understanding landscape dynamics and potential impacts on archaeological sites, offering insights into recurring flood effects. The study also compares newly acquired drone-based lidar from the canyon with the older datasets.

Cordage as Ship Fastener: The Roman-Era Northwestern Adriatic Tradition of Sewn Boats

Across the globe and over the millennia, cordage has been used as a key element to fasten the hulls of wooden plank boats and ships. As such, cordage has been an integral element of naval technology. Furthermore, the communal nature of constructing sewn plank boats arguably puts cordage at the heart of community identity-building among the builders themselves. This paper will explore both the technological and social aspects of cordage as ship fastener through an examination of a distinct tradition of sewn boat building that persisted during the Roman period along the northwestern coast of the Adriatic Sea, which stands in contrast to the mortise-and-tenon joined boats and ships that dominated the contemporary Mediterranean world. In many ways, the cordage used to bind fast the hull planking of northwestern Adriatic sewn boats provides insight into ancient lifeways. It has helped refine chronologies for the manufacture and repair of the vessels. It serves as a remnant of the decision-making strategies of the community of builders. And the raw material from which it was spun, often an import from the western Mediterranean, ties the builders into the colonial machinations of the Roman Empire.

Securing the Future for PKKP through the Remediation of Juukan Gorge and Beyond

Following the destruction of Juukan Gorge, the PKKP Aboriginal Corporation led the Juukan Gorge Remediation Project, which saw the rehabilitation of the broader Juukan Gorge area within line of site from the Juukan-2 rockshelter. This paper is an exploration of those rehabilitation efforts, which includes the re-excavation of Juukan-2, and the negotiation of a co-management agreement over mining operations. Beyond the physical rehabilitation, the PKKP Aboriginal Corporation had to act fast to build a working relationship

with Rio Tinto that would last, and that would ensure another event like this destruction would never happen again. Through a co-management approach, the PKKP Aboriginal Corporation has been able to agree to a new working arrangement that gives Traditional Owners an equal say over what happens on their Country, particularly where heritage approvals and impacts are concerned.

The Cross in the North: Pictish Christianization in Light of the Northern European Experience

Christianization in Northern Europe's first millennium CE has been intensively studied by numerous disciplines and is often viewed as a cause or outcome of social, political, and economic changes. Christianity arrived at different times through differing processes, far better understood in some areas—e.g., Scandinavia—compared to Scotland, where it arrived during Pictish ascendancy in the region. As elsewhere, hagiographies shed some dim light from the proselytizing perspective, but their reception by the indigenous Picts and the impacts on their society remain opaque; the Christianized Picts were displaced by later groups, and thus there is no continuous protohistoric to early historic tradition preserved. Given the archaeological evidence of local and long-distance interactions between the Picts and their contemporaries in Ireland, England, Scandinavia, and the Continent, we examine several Christianized Pictish sites to ask how religious change in neighboring areas might inform research questions and hypotheses about possible developments in Pictland.

Approximate Bayesian Computation Evaluation of the Interactive Effects of Climate Change and Subsistence Economic Intensification on Precontact Population Dynamics in Western North America

Past population change is connected to significant shifts in human behavior and experience, including landscape manipulation, subsistence change, sedentism, technological change, material inequality, and more. However, population change appears to result from a complex interplay of human-environment interactions that feedback on each other, influencing and simultaneously impacted by processes such as subsistence intensification and climate change. Here we explore complex system dynamics of population change using theoretical and Approximate Bayesian Computational modeling combined with the archaeological record of the past 4,000 years in the Colorado Plateau and Great Basin regions of western North America as case studies to identify causal relationships and the different manners in which climate change may have interplayed with subsistence economic intensification and population dynamics. Using standard distance metric evaluation on the performance of 1,000,000 simulations compared with reconstructed past population sizes in each region reveals how climate change impacting landscape productivity can influence carrying capacity and structure population growth such that, when populations reach carrying capacity (Malthusian ceilings), intensification in their subsistence economy can send feedbacks into the socioecological system spurring rapid, differential, population growth. Comparisons of the two regions highlights how varied socioecological circumstances can produce alternative pathways to, and limitations on, population expansions.

Obsidian across the Formative–Classic Period Transition at Teotepac, Veracruz, Mexico

This paper focuses on obsidian at the site of Teotepac, Veracruz, Mexico. Specifically, we discuss importation and consumption patterns during the Formative–Classic period transition (Late Formative to Early/Middle Classic period). Overall, the consumption of obsidian (a raw material not available locally) at Teotepac tends to reflect larger regional and Gulf Coast-wide trends. However, the persistence of obsidian from the Guadalupe Victoria, Puebla source as a prominent part of the Teotepac lithic assemblage well into the Classic period stands out as rather anomalous. We discuss this situation and provide a few possible explanations for the continued importance of Guadalupe Victoria obsidian at Teotepac.

Understanding Reindeer Riding in the Archaeological Record of Northeast Asia through Ethnoarchaeology

Although the innovation of reindeer transport transformed societies across Northeast Asia, tracing the prehistory of reindeer domestication and riding has proven particularly challenging. Recent cross-species archaeozoological research has built an expanded paleopathological toolkit, but to date there are few mechanisms to understand the role of mounted reindeer riding in the deep past. Here, we present osteological insights from domestic reindeer in northern Mongolia, where mounted riding remains an important mode of transport in pastoral lifeways of the Tsaatan community. Our study of modern skeletal material suggests that reindeer riding produces recognizable alterations to the skeleton, including left-biased asymmetry, pathological changes and deformation to the thoracic and cervical vertebrae, and exostoses of the lower limbs. Comparison of reindeer tack and skeletal pathology with those from domestic horses shows key differences that may reflect the unique modality and equipment used in of reindeer riding and help trace the origins of this important innovation in archaeological contexts across prehistory.

The Diné Kin Ya'a Community

Kin Ya'a (towering house) is a prominent Chacoan great house that was the center of large community in the eleventh and twelfth centuries. This area has been utilized by the Navajo (Diné) over the course of two or more centuries. Nevertheless, there has been a shortage of research done on the Diné occupation of this particular region. According to oral histories within the Diné community, Kin Ya'a is the ancestral origin of one of the four original Diné clans. Kin Ya'a is an important archaeological site that features prominently in numerous oral histories recounted by the Diné, particularly in relation to ceremonies such as the "Excess way" and "Blessingway" (Fransted 1979). This research aims to examine the archaeological remains of Diné homesteads, agricultural sites, and shrines within the designated region. In my research, I employ

ethnohistorical methodologies, engage in conversations with local communities, and conduct pedestrian surveys. I intend to examine the changing significance of the Kin Ya'a region. What are the historical changes in Diné land use within this region? How have Diné perceptions of Kin Ya'a shifted throughout time—or remained the same?

Vessels and Bones: Ritual Offerings from the Grupo Kuche Palace Throne Room

During the PARB project's 2023 excavations of the Terminal Classic (AD 800–1000) Grupo Kuche palace throne room (N1050E0815) at Kiuic, we unearthed two major and distinct ritual offerings. The first was thought to be a lip-to-lip cache located on the northwest corner near the top of the structure beneath a collapsed audience chamber. It was later revealed to be a secondary burial containing several more intricate vessels, including those with incision work, cloisonné decoration with maya blue pigment, and a carved fine-orange piece from the Gulf Coast. The second was a series of dedicatory vessels and artifacts found in excavations below the plaza floor directly in front of the structure's eastern staircase. Here, we identified at least 12 but upward of 20 vessels given the amount and variance of vessel fragments recovered. The associated artifacts were numerous pieces of shell, obsidian, chert, speleothem, carbon, quartz, and organic materials, including worked shell earrings, chert and obsidian tools, and residual food stuff. In this paper, we discuss the reasons, meanings, and importance of such ritualized behavior in better understanding the inner workings of both the throne room and palace at Kiuic. ***This paper and presentation will contain images of human remains.

Not Biting Off More Than We Can Chew: Experimental Archaeology in an Online Classroom

Experimental archaeology is a valuable tool for investigating the past and can be used to develop hands-on, high-impact learning opportunities for undergraduate students, helping to demystify the scientific process. Assigning such activities can also address some of the assessment challenges posed by the use of generative AI in student work. In the fall of 2023, community college students enrolled in an online world prehistory course engaged in experimental projects related to food processing and technology. This paper explores the scaffolded approach taken to guide these early-career students as they selected, conducted, reflected on, and showcased their experiments through online portfolios. Successes and challenges of this approach in the online classroom are discussed, along with recommendations for adapting it to other settings. Taken in small bites, hands-on experimental projects offer a digestible way for students to connect with the past in creative and rewarding ways.

Witcher, Robert (Antiquity)**[63]***Discussant***Witelson, David (Rock Art Research Institute, University of the Witwatersrand)****[156]***Best Foot Forward: The Social Significance of Cattle Forelegs in South African San Rock Art*

Rock paintings of cattle raids are common in South Africa's southeastern mountains. Traditionally, such scenes are thought to illustrate some degree of conflict between two groups. The postures of the cattle depicted in the same scenes have been interpreted as showing movement such as walking or being driven from one place to another. Such art-historical interpretations overlook not only the robust tradition of ethnographically informed rock art research in South Africa but also the embodied symbolism of cattle themselves. In African farmer and agropastoral societies, it is the chief who receives particular "cuts" or pieces of a slaughtered or hunted animal. This raises two questions. First, why is the right foreleg in rock paintings of cattle sometimes shown extended in a manner unlikely to be a stylistic exaggeration of bovine movement? Second, why do African farmer beliefs appear to have been depicted in a distinctly hunter-gatherer rock art tradition? This contribution seeks to answer these questions by considering who the audience was for such performances of image-making. It challenges the conclusions of Western art-historical approaches by revisiting the rich painted details in cattle-raiding scenes and drawing on the ethnographies of southern African hunter-gatherers and agropastoralists.

Life before Death: A Bioarchaeological Study of the Biosocial Histories of Human Sacrifices at Pampa la Cruz (Montículo 2), Moche Valley, Peru

Human sacrifice is a form of ritual theater staged by emerging empires to articulate new power asymmetries and legitimize imperial enterprises. The culmination of the event is the death of the victim because ritual homicide transforms the body into an efficacious offering while generating vivid images of coercion and the immutable authority of the state. Although lethal wounds provide physical evidence of this pivotal moment, a lifetime of biosocial experiences on sacrificed bodies may be examined to infer the experiences of individuals in the context of social change. Over a decade of collaborative research conducted by the Huanchaco Archaeological Program indicates that the Chimú Empire (AD 1000/1100–1450/1470) sanctioned periodic ritual events of human sacrifice at multiple locations near the capital city Chan Chan in the Moche Valley. This research presents the results of a bioarchaeological analysis of human skeletal remains from a newly excavated sector of Pampa la Cruz (Montículo 2). This work supports previous studies suggesting that human sacrifice served the various facets of Chimú statecraft. Using a social bioarchaeological perspective this research also contributes to ongoing efforts to contextualize the biosocial histories of human sacrifices against the mosaic of imperial developments in ancient societies.

Producing a Digital Interpretive Environment: The Role of Digital Documentation and Game Engines in Reaching New Audiences with Critical Stories of the Past

Two goals of the North Brentwood Digital Heritage and Archaeology Project are educational outreach and restorative justice. Digital documentation and gaming are an increasingly important part of those efforts. Multiple classes of students have taken an active role in engaging with the community to provide digital heritage services, including the development of a tour app, GIS, 3D documentation of at-risk sites, and the development of a digital interpretive environment using Unreal Engine. These grant-supported efforts have relied on the commitment of community members, students, and graduates in and out of the classroom. The digital Windom Road Barrier environment preserves a 70-year-old guardrail that separates the historically Black community of North Brentwood from the historically White community of Brentwood. The imminent success of a years-long effort to remove and memorialize the barrier's history brings mixed emotions to some of the community members whose lives were shaped by this seemingly mundane artifact of daily life. One hundred years of gains made the removal of the barrier possible, but its erasure from the cultural landscape brings challenges to sharing this dark history with the youth. This project is the beginning of a new approach to cross-generational storytelling to preserve North Brentwood community heritage.

[256]

Toward a Synthesis of California Archaeobotany

I take a pan-regional frame of reference to address the impressive variability in more than 7,500 analyzed plant macroremains samples from the desert, coastal, and interior lowland and upland reaches of California. I focus on the effects of variation in habitat, including animal resources, especially fish and shellfish, as well as plants. I also consider topography and climate, as well as settlement and land use histories, that influence the markedly different longitudinal macrofloral sequences from more than 25 regions of California.

Rain Born of the Mountains: Hydrology, Vistas, and Political Control

Mesoamerican archaeological sites often take advantage of the surrounding natural landscape to enhance both the political machinations of the ruling elite and the sacred ideals of the community at large. In Guatemala, Belize, Mexico, and other highland or steep regions, archaeologists have repeatedly demonstrated the dynamic relationship between the natural environment, specifically mountainous or sloped topography, and associated rain/run-off, and architecture. The predominantly Classic period (250–900 CE) site of Copan in western Honduras is likewise exemplary, embracing this hilltop and rain-dependent ethos at several satellite settlements within the Copan Valley. An additional theme explored is the intertwined aspects of utility and viewshed in the placement of these architectural groups. The higher elevations of many settlements are conveniently close to available rainwater and are highlighted by panoramic views of the land below. These are also physical features of political control in the form of distribution, access, and visual monitoring, while simultaneously bolstering the spiritual and symbolic power of the buildings, their inhabitants, and local authority.

The Architecture of Fear: Archaeological Evidence of Fear's Influence on Built Environments

The influence of fear on our interactions with each other and the world around us is ubiquitous. Despite this, it can be challenging to recognize its effects in the archaeological and historical record. However, built environments create enduring physical evidence and their elements reflect the cultural fears of their makers. This evidence is multiscalar, occurring in various forms from domestic vernacular architecture to large municipal constructions. The intensity of the fear integrated into architecture can also vary, ranging from simple protection from the elements to existential fears at a societal scale. This paper will focus on examples of cultural-scale fears that past societies were addressing in their architecture and connect it to more recent and contemporary cases. It will discuss some of the ways archaeologists can identify and study the role of cultural fears through analyses of built environments in the archaeological record and provide case examples of how fear can influence and be reflected in the architecture of diverse cultures in the past and present.

Picking Up the Pieces: The Continued Influence and Impact of Redding's "Breaking the Mold" on Animal Domestication

Richard Redding's work on "breaking the mold" on how we explain the development of food production is emblematic of the major contributions he made to zooarchaeological thinking: his creativity, curiosity, and willingness to question dearly held beliefs. In this paper, we overview some of Redding's many insights about expanding our field's approach to variation in human-animal interactions, particularly his skepticism of

unilineal trends, his exhortation to imagine more variable ways for people and animals to interact in the past, and his insistence to meld multiple lines of evidence together without giving any one data source undue primacy. We then discuss how his work influenced our own research into the dynamics of changing human-animal interactions during the early Holocene with cattle in central Anatolia and pigs across northern Mesopotamia. We particularly highlight how Redding's insights continue to help resolve puzzling patterns and drive inquiry forward.

Taphonomic Analysis with Multisite Big Data in the Central Mesa Verde Region

Understanding taphonomic patterns across large spatial scales can greatly enhance archaeological interpretation. However, standardized data curation across many sites is a significant challenge. Thus, opportunities for taphonomic analyses that employ big multisite datasets are rare. Data curation practices in archaeology are often different from those in other data rich sciences—such as software engineering and bioinformatics—where documentation with open-source software and the programmatic integration of basic tasks are commonplace. In addition, archaeology may have restrictions in data sharing related to culturally sensitive information. With improved curation, data analytics approaches enable archaeologists to tackle large challenges, such as multisite taphonomic analyses in rapid, efficient, and powerful ways. Crow Canyon Archaeological Center has systematically curated data from projects in a universal database for decades. In the 1990s, this information was incorporated into a relational database, which is currently managed using PostgreSQL and networked for real time analyses with R. Faunal analysis protocols were also explicitly designed with data quality standards during database construction. Faunal and taphonomic data from approximately 130,000 specimens across 50 archaeological sites are curated. We showcase how these data aid the interpretation of region-wide taphonomic patterns bolstered by data science practices.

Pottery Production and Use at the Shang Dynasty Village of Guandimiao

The Shang Dynasty is widely regarded as China's first historical dynasty and has been a focal point for archaeological research for nearly 100 years. While extensive excavations at the late Shang capital at Anyang, as well as other large Shang sites, have provided a window into many aspects of urban society, relatively little is known about groups living under Shang control outside of major political centers. Excavations at the late Shang site of Guandimiao revealed a nearly complete village with the most striking attribute being the high number of pottery kilns, which outnumber houses. However, the economic role of this community within the wider Shang economy, as well as the organization of ceramic production at the site, remains unknown. Here I present the results of the first large-scale study of use-alteration and forming marks on nearly 200 whole vessels from the site, which provides insight into vessel construction, learning, production organization, use, and overall economic organization at Guandimiao.

Is This Democracy? Consensus Decision-Making and Collective Self-Governance in Mesoamerica

The term "democracy," with its roots in the Greek word *demokratia*, originally referred to the capacity of "the people" to make collective decisions regarding wider society and to effect change in the public sphere.

As republicanism emerged in Europe and North America in the eighteenth and nineteenth centuries, “democracy” was co-opted and came to be conflated with a form of the state in which citizens vote for representatives to exercise political power on their behalf. This narrow understanding of “democracy” has led to the perception that democracy is historically rare, a uniquely “Western” invention that traces its roots to classical antiquity. This paper considers historical and contemporary examples from Mesoamerica, societies structured around relatively decentralized, egalitarian processes of decision-making, which rely on consensus-building and collective deliberation. How does the concept of “democracy,” as commonly conceived, limit our understandings of these societies and communities, and how do these examples, in turn, have the power to transform our own understanding of the term? Furthermore, how does the reconceptualization of “democracy” posed by these examples from Mesoamerica challenge narratives of “Western modernity,” and how do they affect political discourses today?

How Dugouts (and Digging) Transformed the South Carolina Lowcountry, 1670–1720

Long before colonization, coastal inhabitants in Carolina’s Lowcountry used dugout canoes for trading, fishing, and gathering oysters. When the English intruded into this watery environment in 1670, many settlers migrated from Barbados, bringing captive Africans and hopes for establishing a profitable system of slave-based, staple-crop agriculture. After experimentation, rice became their export of choice, but success depended on moving this bulky product from dispersed plantations to a central shipping point. Swamps made overland travel difficult, so separate tidal rivers provided the best pathways for transporting people and goods. Indigenous neighbors, despite dwindling numbers, provided useful boats and paddlers, but ferrying backcountry furs and casks of rice through the open ocean to reach the port of Charlestown proved dangerous and inefficient. Solving this dilemma would make some in Carolina’s White minority extremely rich. The game-changing but little-known solution came in three parts. Native Americans shared knowledge of useful small streams and “haulovers” that joined adjacent rivers, offering shorter and safer routes to Charlestown harbor. Enslaved Africans provided the forced manpower to dig connecting canals and widen them to accommodate rowing oars. And European craftsmen modified dugouts, using several logs to create wider boats (called pettiaugers) that could transport heavier loads.

Visualizing Salt Production below, above, and on the Ground in Ixtapa, Chiapas, Mexico: Insights from Ethnography, Aerial Photogrammetry, and Geochemistry

The Ixtapa saltworks in highland Chiapas have the distinction of being one of the last Precolumbian saltworks in the interior Maya world that is still in use, and members of Proyecto Arqueológico Sak B’alam y Salinas del Interior de Chiapas and Winthrop University’s Environmental Studies Program have been conducting

investigations there for the past five years. While earlier work focused on geochemical analysis and ethnography to understand the techniques used in salt production and the elemental and nutritional properties of the salt itself, during the 2023 field season, project members began a formal investigation of the neighboring archaeological site, La Tortuga. The results of preliminary excavations, materials analysis, and UAV photogrammetry will be discussed in relation to the insights gleaned from longer-term analyses in the present paper, with a particular focus on reconstructing the history of salt production, changing patterns of social organization, and interregional ties.

A Foreign Ingredient in a Local Tradition: Chaco Canyon Pottery and the Chaco–Chuska Connection

In the mid-twentieth century, Anna Shepard discovered that much of the pottery found in Chaco Canyon, New Mexico, was apparently produced in the Chuska mountain and slope area some 70 km to the west. Since then, Southwest archaeologists have studied the dynamics of Chaco–Chuska interaction and the intensity and complexity of Southwest exchange patterns. As part of a larger study of late (ca. and post-AD 1100) Chaco Canyon ceramic assemblages from sites including Pueblo Bonito, I examined a sample of Chaco Black-on-white (ca. AD 1075–1150) and Chaco-McElmo Black-on-white (ca. AD 1100–1200) sherds. These two ceramic types, while never the most abundant in an assemblage, were likely locally made in Chaco Canyon and are emblematic of Chaco's late occupation. Under magnification, a small number of sherds with the typical macroscopic properties of Chaco and Chaco-McElmo Black-on-white contained abundant Chuska trachyte, a dark igneous rock nonlocal to Chaco Canyon but characteristic of Chuska pottery. This mix of local ceramic tradition and foreign ceramic ingredient frustrates archaeological typologies but serves as a reminder of the movements of past potters, the raw materials they used, and the pots they made.

Building Community in the Northeast

The Northeast NAGPRA Community of Practice was founded in 2023 in an effort to build community and strategize on issues and opportunities related to NAGPRA implementation that are unique to the region. Our goal is to improve trust, develop communications and increase cooperation. Discussion topics include split collections, collectors and collecting practices across the northeast, working with non-federally recognized tribes, and identification of ancestral lands without relying on colonial or US treaties. Thematic concepts address building trust between tribal communities, institutions, and agencies; legacies of acquisition; density of regional institutions; and academic and archaeological overreach. Group membership consists of tribal communities from the northeast, public and private institutions, state agencies located in the region, and nonlocal institutions with collections from the northeast.

Two Balades in the Same Landscape: Perspectives of Oral History and Archaeological Survey on the Cultural Landscapes of the Dog Island Region, Nunatsiavut

As part of an ongoing fieldwork program in the Nain region of Nunatsiavut (Newfoundland and Labrador), the authors worked together in 2022 on a survey of Inuit archaeological sites on Dog Island and Sculpin Island. Already-known archaeological sites were revisited and a number of new sites were documented (sod houses, tent rings, hunting blinds, caches, and lithic scatters). Three remarkable locations documented in the course of this survey will be discussed in this presentation. All three are, in many regards, typical of sites of their type and age; nevertheless, all three were challenges to find and to interpret given their particular compositions and settings in the landscape. A lively discussion regarding these sites' forms and functions developed between the authors; one with a formal archaeology training and the other with extensive personal archaeological experience with archaeology and living on the land in the region, applying his own knowledge and his family's oral histories. This presentation will describe these sites and contrast how the two authors viewed and interpreted them. The paths of these two archaeologies show important points of divergence and convergence that are informative for landscape archaeology and for the practice of community archaeology.

Wooten, Kimberly (California Department of Transportation, Cultural Studies Office)

[71]

Recording Baselines: Getting Climate Change and Plastic Pollution Data into the Archaeological Record

Archaeological site records are a tool for recording not only a site's cultural constituents—landscapes, features, artifacts, built environment components, etc.—but also a format for documenting any adverse impacts that have occurred to those resources. What if those site record forms were structured not only to record the standard project development impacts but allowed an option for capturing baseline information specifically on climate change impacts to cultural resources? In California, and across the United States, impacts from sea-level rise, wildfire, erosion, extreme rain events, and even plastic pollution are all becoming increasingly recognized as adverse effects to cultural heritage. Information captured on site records would help focus professional attention on issues surrounding climate impacts on cultural heritage and form an important baseline from which future archaeologists, heritage preservation specialists, climate scientists, environmentalists, and other researchers could build. This poster is intended to be interactive, and input will be sought from working professionals on ways to capture data on climate change impacts to cultural resources within the context of site recordation.

Not Just Jed and Jethro: Erasing Diversity from Public Memory in the Ozarks

The dominant historical narrative of the Ozarks characterizes the region as rural, White, and agrarian, with racial diversity and industrialization limited to modern urban contexts and nearby cities like St. Louis. Building on the work of descendant-activists and avocational historians, our research in northwest Greene County, Missouri shows that while this part of the Ozarks is now predominantly rural and White, it was more industrial, urban, and racially diverse in the late nineteenth and early twentieth centuries. Using archaeological, documentary, and oral history data, we investigate the growth of Black and White communities supported by local limestone industries, daily life in Black and White households in these

communities, and the eventual relocation of most Black households from northwest Greene County by the mid-twentieth century. An application of critical theory to the results illuminates the processes that created today's rural, White communities and the concomitant erasure of economic and racial complexities from public memory, in both Greene County and the Ozarks generally. The findings demonstrate the value of archaeology in producing more accurate, multivocal narratives relevant to past and ongoing inequities.

Application of Plant Wax n-alkane and GDGT-based Paleoenvironmental Proxies Derived from Archaeological Cave Sediments: A Case Study from the Middle Stone Age site of Bizmoune, Morocco

Lipid biomarkers derived from plant waxes (n-alkanes) and the cell membranes of bacteria and archaea (GDGTs) are potentially powerful paleoenvironmental proxies in the field of archaeology given their durability and ubiquity in terrestrial sediments. We use the distributions of glycerol dialkyl glycerol tetraether (GDGT) and plant wax n-alkane structural forms in conjunction with compound-specific stable isotope analysis of plant wax n-alkanes ($\delta^{13}\text{C}$, δD) to investigate vegetation history, environmental moisture, and temperature through time during Marine Isotope Stage (MIS) 5/6 at the Middle Stone Age cave site of Bizmoune, located in southwestern Morocco. The use of lipid biomarkers for paleoenvironmental reconstruction is relatively new in its application to near-entrance cave sediments, particularly for GDGT-based paleotemperature proxies. Here we discuss the successes and challenges faced when applying these methods to cave mouth contexts.

Triangulating Piipaash History along the Lower Gila River, Southwestern Arizona

Contemporary Piipaash of the Gila River and Salt River Pima-Maricopa Indian Communities, in the greater Phoenix area of south-central Arizona, have histories tying them to the lower Gila and lower Colorado Rivers. These "down river" landscapes were their exclusive territories until they moved upriver for safety and solace among their Akimel O'odham allies in the middle Gila River valley. Piipaash ancestors completed this profound demographic transformation less than a generation before the region's annexation by an expanding US Empire in 1848/1852. While an outline can be pieced together through ethnohistoric and oral historical records, archaeologists have all but ignored this social process and its material signatures. This paper synthesizes recent collaborative research that is weaving together a Piipaash cultural landscape along the lower Gila River. Known for its immense galleries of rock imagery and fields of ground figures, the lower Gila also hosts ancestral Piipaash settlements that offer authorship for the images. Attention to the substance and structure to these settlements provides a better understanding of the history and demography of the Piipaash and other riverine Yuman Tribes, and Patayan archaeology more broadly.

Spaces of Survivance: Recovering Nineteenth-Century Choctaw Homesteads Misrecorded in Archaeological Literature
 Historic Indigenous sites are often mislabeled in archaeological literature. As some scholars have explained, a common reason for this stems from the conventional practice of labeling cultural affiliation based on traditional artifact classifications. More recently, others have discussed how past preservation ethics within the cultural resource management industry have prevented sites associated with historically marginalized communities from being recorded. In this paper, we review a century's worth of federally funded surveys conducted within the geographic boundaries of the Choctaw Nation in Oklahoma. While our results convey a historic exclusion of Indigenous sites from the archaeological literature, we offer a few viable practices to prevent this practice from continuing.

Willamette Valley Project Overview: Using Subbottom Profiling, Coring, Augering, Geomorphic Mapping, and Regional Archaeological Data to Inform Sensitivity Modeling and Archaeological Research Design in the Willamette Basin, Oregon

The US Army Corps of Engineers (USACE) manages the Willamette Valley Project, a system of 13 dams and associated reservoirs in the Willamette River Basin, Oregon. Environmental settings of these 13 project areas vary by elevation, substrate, vegetation, and other characteristics, but all are located along major rivers draining into the Willamette River. During this multiyear project, an interdisciplinary team used geomorphic mapping and subbottom profiling of reservoir beds to select targets for coring and augering during annual reservoir drawdowns. During low water, field checks of subbottom profiling data, particularly in areas with associated water column noise (WCN), provided the opportunity for the team to physically verify interpretations—a step not easily attained offshore where this method is often applied. The radiocarbon ages of materials from cores and augered samples span the Late Pleistocene through Holocene and helped identify which landforms are more likely to contain buried cultural materials and how deeply they might be buried. This geomorphic information was used in concert with cultural data from throughout the Willamette River Basin to inform our archaeological sensitivity model, research design, and management recommendations.

Only Murders in the Cavespace? Considering Archaeological Assumptions about Human Interments

As if by default, deposits of human remains in caves and cenotes in the southern Maya Lowlands dating to the Late and Terminal Classic periods have been interpreted by many archaeologists as sacrificial victims. The position seems predicated on an assumption of both the accuracy and universality—across time, space, and variations in cultural fabric—of colonial period descriptions of ceremonies associated with rain propitiation centering on cenotes in the Yucatán Peninsula of the northern Lowlands. Focusing primarily on caves in Belize, we briefly review the basis for archaeological claims of ceremonial homicide and some well-attested examples thereof. Using this as our baseline, we then explore a case example from a large, commingled deposit of skeletal remains in Actun Kabul. We propose that rather than the product of sacrifice, the age distributions of individuals included there and in other caves of the region, along with features of the broader context of interment (including culture-historical), best reflect the complex funerary ritual of high-status and elite Maya families of the Classic period.

Searching for Pueblos among the Dunefields: Remote Sensing Investigations at Four Pueblo Settlements on the Fort Bliss Military Reservation

In the fall of 2017, the Fort Bliss Cultural Resources Team funded a unique project to assess the potential for using remote sensing technologies to analyze the subsurface characteristics of buried cultural sites to support National Register of Historic Places nominations. Geophysical remote sensing and aerial multispectral imaging methods were utilized over a two-year period at four sites to locate and define buried pueblo rooms and room blocks that were not visible on the site surface. Other features, such as water reservoirs, canals, and pithouses, were also identified. The effectiveness of various geophysical methods for identifying buried features was compared. Ground-truthing excavations confirmed the presence of prehistoric architectural features in seven of the nine test units placed over anomalies. In addition to the study of prehistoric settlements, the historic agricultural landscape of the Plowed Field site was revealed through archival research combined with geophysical methods.

Ballplayers, Captives, Kings, and Queens: Examining the Identity of Key Players in Veracruz Ballgame Rituals

In south-central Veracruz, representations of ballplayers, captives, kings, and queens defy clear categorizations, made more complex by costume and gender designations, hierarchical proportion, natural sexual dimorphism, and symbolic roles versus historic portraiture; distinctions that may be intentionally blurred. On stone stelae, mural paintings, and narrative ceramics, rulers wear ballgame regalia, captive ballplayers can sometimes be seen towering above their captors, and elite women take part in the “dressing,” binding, and ritual beheading of defeated ballplayers or subjugated rulers. In this presentation, I examine Epi-Olmec and Classic period art in conjunction with archaeological context, to move beyond the “why” and “what” of Veracruz ballgame rituals, in a quest to identify the “who” of key individuals and supporting cast.

The Importance of Archipelagoes

The role of islands in the western Indian Ocean has been well explored by archaeologists and historians, who point to a combination of natural and social advantages created by these bounded worlds. What has been less commented on is the role of archipelagoes as crucial units of exploration. In this paper, I review the archaeology and history of archipelagoes along the eastern African coast, suggesting that they were central to social development and connectivity in the region between the seventh and fifteenth centuries CE. The Kilwa archipelago of southern Tanzania is then the focus of a discussion of archipelagoes as urban clusters, drawing on recent research from the region. The paper suggests that archipelagoes not only offer important settings for social growth, but that the natural advantages of the setting also contained the seeds of disaster for the inhabitants during the period of European colonialism from the sixteenth century onward.

Health Status of the Inhabitants of the Medieval Village and Town in Greater Poland

Studying living conditions of any population in the past using indirect indicators such as skeletal lesions is challenging, as their occurrence can be connected and influenced by different factors such as individuals' immune systems. However, porous skeletal lesions (porotic hyperostosis, cribra orbitalia), and linear enamel hypoplasias (LEH), have extensively been used as nonspecific indicators of health conditions in past populations. Such indicators of stress are often associated with nutritional deficiencies, anemias, parasite infections, or chronic disorders. The aim of the study is to describe the health status of the inhabitants of medieval villages and towns from similar periods and environments (medieval settlements from Greater Poland). This study examines human remains from the town Dzwonowo (fourteenth–eighteenth centuries), and the village Gać (fourteenth–sixteenth centuries), both vanished settlements discovered within the Zielonka Forest in Poland. Individuals included in the study were examined macroscopically for the occurrence of the aforementioned porous skeletal lesions and LEH. Additionally, the severity of cribra orbitalia in particular was evaluated. Paleopathological data were then compared between sexes, age-at-death categories, and between the two sites. Our results contribute to the narrative of population-level and individual-level health and nutrition during the Late Medieval and post-Medieval periods in Greater Poland.

Xie, Liye (University of Toronto)**[19]***Rammed-Earth Construction as a Catalyst for Social Transformation*

This paper explores a series of inquiries regarding the role of rammed-earth construction during the late Neolithic and early Bronze Age in China, specifically focusing on how the organization of human resources propelled social transformation. The study encompasses the following dimensions: First, community dynamics. How did the collaborative nature of rammed-earth construction projects potentially foster community relations? Second, hierarchical structures. What could be the implications of the social dynamics within construction for the broader societal hierarchy? Third, cultural influence. To what degree did the rituals and shared experiences associated with construction likely contribute to cultural unity and influence the acceptance or rejection of new social norms? Fourth, sustainability of change. How might the necessity for repeated reconstruction and repair have sustained community involvement and shaped lasting social impact? Through an exploration of these questions, this paper aims to provide insights into the intricate relationship between rammed-earth construction, labor organization, and its potential as a catalyst for social transformation with historical and cultural contexts.

Yaeger, Jason (University of Texas, San Antonio), Bernadette Cap (San Antonio College), M. Kathryn Brown (University of Texas, San Antonio) and Rachel Horowitz (Washington State University)**[251]***The Contributions of Belize Archaeology to Our Understanding of Ancient Maya Economies*

Archaeologists working in Belize have made signal contributions to our knowledge of Maya economies and their relationships to political processes and dynamics. In this paper, we examine the ways that archaeological research at Maya sites in Belize has advanced our understanding of these topics; (1) centralized marketplaces as key nodes for exchange and distribution of goods and their roles in Classic Maya society; (2) the organization of specialized production of key goods (including salt, chert tools, obsidian tools, shell beads, and granite manos and metates) and the ways those goods were exchanged more widely; (3) agricultural

intensification; and (4) the heterogeneity of ancient Maya economies on a regional scale. We also discuss the contributions of Belizean archaeology to broader debates about the relationships between economy, society, and polity, including (1) the household as a key locus of economic production and consumption; (2) the role of small communities in self-organizing processes of regional economic integration; and (3) the relationship between consumption and social constructs of identity, desire, and status. In all of these areas, archaeologists working in Belize have led the way. We close by discussing how current research in Belize continues to set the agenda for understanding Maya economies.

Navigating the Field: New Perspectives from Women of Color in Archaeology

Archaeology as a discipline emerged as an extension of colonialism, and although recent efforts over the last several decades have worked to “decolonize” the field, nonlocal perspectives continue to be prioritized by Western institutions. This paper seeks to address perpetual inequality within the field of archaeology by highlighting normalized practices by researchers within the “culture of archaeology.” It is our contention that, as a symptom of the persistent coloniality present within archaeology, many archaeologists are trained to view the world as a sort of cultural buffet, in which they are invited to actively participate in the construction of a history they do not belong to. This positionality reinforces nonlocal worldviews onto non-Western contexts. The goal of this paper is to discover viable solutions for creating equity within the field; to discuss, highlight, and validate successful cases despite challenges that minority researchers face. In this way, we seek to humanize our field by reclaiming the joy and responsibility we have as cultural heritage specialists. We discuss our projects and community work across Southeast Asia and Northeast Africa that relate to community engagement, working with marginalized communities, utilizing indigenous perspectives, and combating the colonial nature of archaeological work.

Integrating Isotopic Data across Ancient Anatolia for Paleoenvironmental Reconstruction

The increased availability of stable isotope data has made it possible to carry out comparative studies across space and time. In this paper, we review published and unpublished stable oxygen, carbon, and nitrogen isotope data derived from zooarchaeological, archaeobotanical, and bioarchaeological remains across Anatolia from the Neolithic through to the modern period. We evaluate trends in spatial distribution of values as well as temporal variation. The Faunal Isotopes Database in Neotoma provides a repository for multiproxy data types, and allows for an integrated approach to reconstructing paleoenvironment. In particular, we emphasize the importance of regional comparisons for interpretation of archaeological data. This analysis provides an additional baseline for considering the environmental context of important cultural and social transitions through time.

Locality on the Frontier

In recent years, several archaeological investigations have been conducted in northern Peru and southern Ecuador, which are considered “northern frontiers” in the Andean archaeology. While it has been pointed out that these areas are important for understanding interregional interactions in the ancient Andes, solid empirical data have not been presented to evaluate this issue. In addition, our previous studies in these areas

have focused only on interregional interactions and overlooked the locality of each region. Therefore, in this presentation, we discuss the locality of each region based on frontier perspectives using our new data from the Jaén region in northern Peru, especially the sites of Inyatambo and Turuco, the Cañar region in southern Ecuador, and the sites of Cerro Narrío and Loma de Pinzhul.

Body Modifications within the Southwest through Rock Art and Ceramics.

In the Jornada Mogollon cultural area, anthropomorphic representation in rock art and ceramics provides evidence for prehistoric body modification, specifically tattooing. This presentation will focus on the history of the Jumanos, Tompiro, and Mansos. When the Spanish arrived in El Paso in the fourteenth century, they encountered the Manso, Jumanos, and Tompiro peoples with tattooed faces. Hypothetically, these people all descended from the Jornada Mogollon. To begin exploring this hypothesis, I examine evidence of facial or body modification during the El Paso phase. I consider rock art imagery from Cottonwood, Hueco Tanks, and Three Rivers. Additionally, I'll document imagery on ceramic vessels including Villa Ahumada Polychrome, Ramos Polychrome, and Chupadero Black on White.

Human Strategy and Paleoclimate in the Andean: Variation in Intensity Occupation in the Laguna del Diamante (ca. 2000–500 years BP)

Laguna del Diamante (34°S) is a high-altitude wetland (3,000 m asl) with resources that have been attractive to human societies for the last 2,000 years. This article evaluates the variable intensity of its occupation in five temporal segments between 2030 and 440 cal BP, according to a chronology modeled from 14 radiocarbon

dates excavated in stone enclosures at three sites. The variation in the density of proximal flakes is used as a proxy of human occupation intensity. We assess the correlation of more intense human occupation and environmental changes in temperature and humidity, as recorded at three high-altitude lakes: Aculeo, Chepical, and Maule (33°–35°S). These archives include proxies for vegetation cover, ice cover extent, and changes in precipitation derived from the Westerlies and the El Niño Southern Oscillation. There is a correlation between favorable conditions and more intense occupations at multiple times in the sequence. We discuss two periods of greater intensity: 1200–1280 cal BP (calibrated medians), when summer temperature and precipitation was higher, and 450–500 cal BP, when temperatures were lower and the Inca were in the area.

The Paleoindian Database of the Americas: On Such a Full Sea Are We Now Afloat

The Paleoindian Database of the Americas (PIDBA) freely shares primary and detailed attribute data on tens of thousands of ancient lithic tools spanning the Paleoindian and Early Archaic time periods. In its first iteration in 1990, David G. Anderson compiled descriptive datasets into a tool for investigating the distributions of certain technologies and how they can apply to questions at scale. PIDBA has become now a 30-something-year-old cottage industry of sorts with numerous researchers volunteering time and effort to sustain PIDBA and advance research. PIDBA from its inception has been inclusive and open for any interested researchers to join in, or for researchers to access separately and make use of the provided lithic survey data, maps, attribute data, and spatial information. This presentation will outline the future state of PIDBA and how it will connect with other digital infrastructures. Additionally, this is a lesson on community building fostered by PIDBA and other Anderson projects like DINAA: projects where young and less young scholars work together hand-in-hand, where ideas and innovation are welcomed and encouraged, thus rising a tide of collaboration, and we must take the current when it serves.

Distance and Power in Early Medieval Coinage in Spain

Compared to most other archaeological artifacts, coins contain a large amount of information relating directly to political administration. Spatial patterns in this information should provide a way to see how processes of political power operated in practice. Using information on early medieval coin finds in the

Iberian Peninsula, it can be seen that widely varied spatial patterns can be found under different political and economic circumstances, even when the technology of travel, transport, and administration remained largely the same. During a period when ordinary monetary circulation might have a range of a few hundred kilometers, extraordinary political circumstances could cause significant numbers of coins from Persia or the Transcaucasus to end up in Spain, thousands of kilometers away. Both the long-term norm and the unusual events are important to understanding the structure and capabilities of political actors in this period.

Transcending the Niche of a Wild Progenitor: An Ecological Niche Perspective on the Spread of Archaeological Soybeans in China

This study investigates the influence of climate change on the distribution and adaptation of wild soybeans and how it impacted ancient gathering/farming practices related to soybeans. Through quantitative pollen-based reconstruction and ecological niche modeling, it traces the effects of climate change on soybean domestication and post-domestication developments. During the early Holocene (9000–7000 cal BP), the presence of soybeans started to shift from highly suitable to less suitable areas due to climatic fluctuations. This underscores the significant role of climatic factors in shaping soybean distribution during this period. Starting around 5,000 years ago, farmers, in response to climate challenges, began employing varietal diversification strategies in soybean cultivation. The 4.2 ka BP climatic event, characterized by deteriorating precipitation and temperature conditions, accelerated the development of soybean landraces. These varietal diversification strategies likely facilitated the spread of soybeans into different regions, including their movement southward into Fujian and Yunnan and westward into Gansu.

Bringing Artifacts Home: The Opportunities and Challenges of Collaborative Interpretation

Place and context give meaning to the artifacts that archaeologists uncover. Yet, artifacts are usually curated in museums and archaeological repositories far from the sites where they were unearthed. This spatial disconnect is often a source of tension for descendant communities. Using the Homolovi State Park in northeastern Arizona as a case study, I examine how exhibit development involving collaboration between archaeologists and members of the Hopi Tribe provided a context to reconnect artifacts with their place of origin. Interpretative projects, such as this one, can also enhance the goals of collaborative archaeology projects beyond field seasons and research projects while also contributing to tribal heritage initiatives. These types of initiatives also face challenges (e.g., funding, sustainability, and secure exhibit spaces) that require project partners to think “outside the box,” both literally and figuratively. Collaborative interpretative projects can also contribute to decolonizing museum practice and tribal initiatives to foster respect for the footprints of their ancestors.

No Smoking Gun: The Potential and Limitations of Isotopic Sourcing of Archaeological Cinnabar in the Central Andean Region

Identifying spatial patterns and diachronic changes in the intensity and range of the circulation of goods can provide crucial insights into shifting economic, social, and political organization of ancient societies. As such, archaeologists interested in identifying evidence of long-distance interaction in the past have increasingly turned to geochemical methods to trace the movement of nonlocal resources. In the archaeological record of the Central Andean region, cinnabar pigment is one of a few notable nonperishable resources with a limited number of geological sources. Drawing from a wide range of specimens from both museum collections and scientifically excavated archaeological materials, we explore a novel, multi-method approach for sourcing cinnabar ore, comparing isotopic ratios detected with MC-ICP-MS for mercury (Hg) and IR-MS for sulfur (S). Our results offer a cautionary tale for the use of sulfur isotopes in geochemical sourcing. Although we highlight the challenges and limitations of MC-ICP-MS analyses of mercury isotopes, we confirm that this method offers some promise for sourcing studies in the Andes and beyond.

Wild and Cultivated Plant Usage of a Late Precontact Site (11SI754) in the American Bottom

The Stemler Site (11SI754), a small Mississippian settlement in the American Bottom, was occupied during the Late Stirling and Early Moorehead Phases (ca. AD 1150–1275), as the population at Cahokia and the broader region was decreasing. It has been theorized that an overreliance on maize (*Zea mays*) led to the dispersal of people from and collapse at Cahokia. This study aims to provide nuance to these regional dynamics with a study of plant resource utilization at Stemler. Through an analysis of wild and cultivated seeds crops and a comparison of their rates of usage to maize, this study will shed light on the period during which Cahokia's role as a regional powerhouse was changing and provide insight into the lives of small-scale settlements.

Island Horticultural Technology Wooden and Woven: An Ethnoarchaeological Case from Taiwan

Horticultural knowledge played an evolutionary role in the successful colonization and occupation of islands. Compared to more durable fishing and hunting tools, gardening tools are made of perishable wooden and woven materials that rarely preserve in the archaeological record. Because women perform a large proportion of gardening tasks, their technologies are often overrepresented in plant materials and underrepresented in archaeological contexts. Ethnoarchaeology can provide valuable reference information about gardening technological systems. This paper presents an introduction to gardening tools and systems of Taiwan's Amis culture from the 1920s and 1930s, curated in the National Museum of Ethnology in Osaka. This is the first time these tools have been presented in the United States.

Bridging the Distance: Creating Virtual Cultural Heritage Resources for Educators

The Arkansas Archeological Survey and Shiloh Museum of Ozark History share a mission to preserve and present information about the cultural heritage of Arkansas. During the COVID pandemic, our usual route to sharing (in person presentations/workshops) was cut off. The Arkansas Archeological Survey put together a virtual program called Native American Days to bring together stakeholders to present short lessons to middle grade students about the history of Arkansas and how the Native Nations whose people once called Arkansas home live today. Each year since 2020, we have brought together archaeologists, State Park Interpreters, Tribal Historic Preservation Officers, and Native Artists to speak to students about Arkansas's history and the multitude of ways by which we understand that history. We ask speakers to align their presentations with fifth–eighth grade Social Studies standards and advertise the program to schools throughout Arkansas, eastern Oklahoma, and southwestern Missouri. There have been hiccups along the way, but the program has allowed us to reach thousands of students as well as work with members of Tribal Nations who are also interested in outreach about cultural heritage. This poster will present details of the program and advertising as well as problems that we have overcome.

“Milwaukee’s Forest Home Cemetery Is a Place for the Living Too”: The Reemergence of Deathscape Recreation at Forest Home Cemetery

The original design and use of the Garden Cemetery deathscape encouraged recreation and social interaction among the living and the dead. Forest Home Cemetery, a historic (1850–present) Garden Cemetery in Milwaukee, Wisconsin, hosts more than a dozen events in the cemetery each year, including tours, reenactments, a 5K run/walk, Door’s Open, a Day of the Dead celebration week, and “Shakespeare in the Cemetery.” This paper explores a renaissance of Victorian Garden Cemetery recreation at Forest Home, identifying recurring themes (financial considerations, advertisement, and landscape use) and highlighting distinctive new engagements facilitated by the “changing face of death.” In recognition of Patricia B. Richards’s research emphasis on human actors, ethnographic field notes and archives, including social media platforms, were utilized to provide data on landscape use at Forest Home. I argue that we are witnessing a transformation of the deathscape at Forest Home, with implications for increased community engagement and a reimagined necrolandscape.

Zaneri, Taylor (International Institute for Social History)**[22]***Changing Rural Production Strategies during Urbanization in Medieval Lucca*

The later Middle Ages saw significant changes in the ways that humans exploited their natural environments, fueled by rising populations in cities and the development of commercial industries. This has been studied historically, often through the lens of urban elites, but it is less clear how these changes occurred from the perspective of the countryside. This paper will use the hinterland of the medieval city of Lucca, Tuscany, as a case study from 1000 to 1300, to investigate changes in the focus and intensity of agricultural production and the exploitation of animals. Conducting a regional analysis, this work will combine GIS land-use modeling with zooarchaeological data to provide an integrated picture of how the agricultural economy shifted over these 300 years. It will also stress the importance of the decisions of rural producers, who over this period, shifted their productive activities to participate in wider commercial interactions. As such, production became increasingly specialized by environmental zone. I will argue that such shifts were not only driven by elite and urban demands but were, in part, the result of the decisions of producers themselves, who altered their productive activities to take advantage of new economic opportunities and possibilities.

Zavala, Georgia**[41]***Analysis of Burned Hematite from Boxed Springs Site (41UR30)*

Boxed Springs (41UR30) is an Early Caddo archaeological site, known for its earthen mounds and looted cemetery. Gradiometer results from 2020 revealed multiple circular features throughout the southern area of the site, likely indicative of domestic structures. In addition to presumed structures, gradiometer results indicated several anomalies, which were hypothesized to be a storage pit, midden areas, or hearths. The present study provides an analysis of a burned hematite feature identified from the gradiometry survey that was uncovered in the summer 2023 season. This feature provides insight on hematite processing, which is an important raw material for pigments. The hematite feature has the possibility of providing further interpretive hypotheses regarding Early Caddo lifeways.

Trailblazer, dirt archaeologist, influencer, historian, disrupter, curator, socialite, ethnographer, polyglot. Most of us are familiar with Zelia Nuttall mostly through her brilliant research on the Mixtec codex that, until recently, carried her name on the catalogue of the British Museum where it is currently kept. Only the tip of

the iceberg in her diverse career, Nuttall has recently been recognized as one of the most prolific Mesoamericanists and anthropologists at the turn of the twentieth century. This was no small feat, especially for a female scholar with Mexican heritage, and a single mother, who constantly had to fight restrictive paradigms, academic chauvinism, and personal hurdles. In this presentation we will revisit three aspects of Nuttall's research legacy: codices, purpura, and pirates. Drawing from our recent fieldwork along the Oaxacan Pacific coast and previously unpublished sources, we will demonstrate how these seemingly disparate lines of interests are closely interconnected from a transhistorical and global perspective. Through her interdisciplinary vision and acute attention to detail, Zelia Nuttall not only laid the foundations for contemporary reconstructions of these transcontinental maritime and terrestrial networks, but also for a methodological framework that is best suited for collaborative research today.

Sexual Division of Labor and Technological Change at the Pleistocene to Holocene Transition in the Great Basin

A recent reinterpretation of global ethnography challenges the “men hunt, women gather” stereotype, finding cross-cultural evidence that women regularly hunted in foraging societies. Another study finds bioarchaeological evidence of women's role in hunting large game during the Pleistocene-Holocene Transition in the Americas. Although provocative, these findings provide no theoretical context for understanding variability in sexual division of labor or for anticipating consequent effects on the archaeological record. They do resonate with earlier studies of contemporary foragers based on Human Behavioral Ecology. While reliable higher energy resource availability aligns men's and women's prey choice, unreliability causes their foraging objectives to diverge. Shifts in the reliability of resource procurement prompt gender-based labor shifts that further influence technological investment. When large game is secure, both genders invest in technology that reduces the costs of hunting and processing larger prey. Conversely, divergent subsistence strategies lead women to invest more in technology that reduces the handling costs of low yield but reliably acquired resources. These dynamics shed light on pivotal technological shifts in ground stone, bone, and basketry technology during the Early Holocene in the Great Basin.

[333]

World Visions: Plains Vision Questing as Epistemology

We combine archaeology, oral history, and ethnography to argue for the epistemological power of visions and their complementary role—along with ontology and ordering schemes—in the fabric of Native American philosophies and practices. Waking visions and dreams are central to the long-term cultural history of Plains people. Among the Blackfoot, for example, they are closely related to coming of age, spiritual vows, and acquiring enough knowledge to become “elders” in society. Archaeology and cultural practice indicate a close connection between vision questing and specific landforms as well as connections with stunning viewsheds. We provide illustrations from recently recorded, high-elevation vision quest sites in the northern Rocky Mountain Front.

Mothers, Mentors, and Belonging in the Academy: The Unintentional Legacy of Patricia Richards

Mothers in academia occupy the intersection of two demanding worlds: the rigors of scholarly pursuits and the responsibilities of childrearing. They face systemic barriers, including gender bias, limited access to resources, and inflexible tenure-track structures. Balancing research, teaching, and motherhood can be a precarious juggling act and women are often told to choose a career or a family. Pat Richards's unintended legacy demonstrates that women can do both. Pat successfully raised her children on archaeological projects. She embodied the resilience and innovation of academic mothers, and she inspired other women to do the same. This presentation provides an overview of mothers in the academy, specifically anthropology and archaeology. It will highlight the ingenuity and tenacity of mothering during field projects and how women have succeeded through the use of mentorship networks, advocating for family-friendly policies, and challenging traditional notions of academic success. Finally, it will argue that by acknowledging the unique struggles of academic mothers and celebrating their accomplishments, we can work toward a more inclusive and equitable academic landscape. Mothers in academia not only advance knowledge but serve as inspirations, paving the way for future generations of scholars and female scientists.

Contributions of the Kerr Corpus to Maya Paleography: Aspects of Sign Development, Regional Variation, and Idiosyncratic Style in Maya Writing

Paleography (from Greek παλαιό- 'old' and γράφει 'writing') was long understood as the study of the origins and development of signs (e.g., *De Montfaucon, Paleaeografica Graeca*, 1708), but since the welcome focus on ductus (i.e., shape, stance, and stroke-order in sign-formation) pioneered by Mallon in *Paléographie romaine* (1952), paleography has instead come to be understood as the unconscious habit of scribes in revealing when and where their texts were composed on formal considerations alone. This study intends the term in both senses and seeks to cast light on the significant contributions that Justin and Barbara Kerr have made to present understandings of the origins and development of Maya writing through their assiduous compilation

and remarkably unrestricted dissemination of a considerable corpus of Maya vessels. Close study of over 1,000 high-resolution images of hieroglyph-bearing ceramics in their corpus has provided considerable information on the iconic origins, formal developments, and regional variation of Maya writing across several centuries of use (ca. 250–900 CE). As will be seen, these precious records also make possible considerable nuance in the paleographic dating of undated inscriptions, and the identification of repainting and outright forgeries that might otherwise serve to mislead scholarship.

Analyzing Images from the Jebel Qara Environment: Preserving Painted Rock Art in the Cave Shelters of Southern Arabia

Protected in cave shelters, Dhofar's painted rock art in Oman are well-preserved and give an unprecedented glimpse into Arabia's pre-Islamic history. The pictographs and accompanying South Arabian inscriptions, which extend from the coastal plain to the Rub' Al Khali desert and to the Jebel Qara mountains at the beginning of the incense trail, where the history of frankincense began globally in the first millennium BC. The rock art of the mountains, painted in red and black ink, depict images from the natural environment that are classified as flora and fauna indigenous to the local landscape, including also hunting-battle scenes, ritually dressed figures, dhows and other types of ships, pastoral-life scenes, wadi-maps, alphabetic letters, and hand prints that possibly invoke protection. This paper presents an analysis of scenes and features, including high-resolution photographs curated and photographed as a cultural heritage preservation and conservation project for the Sultanate of Oman. The exhibition under the auspices of the Diwan of the Royal Court has traveled since 2017 in the USA. As a community-based, digital humanities preservation project, it consists of 31 high-resolution photographs, digitized charts, and 3D images from seven archaeological field sites, along with ethnographic and epigraphic research in Dhofar.

SIMuR Simulation: The Interdisciplinary Creation of a Virtual Reality Environment Archaeological Pedagogy, Research and Outreach

In 2019, a three-year NSF IRES grant (#1854153) was awarded to Bridgewater State University, Ilia State University, and the Cyberarchaeology Lab at UC San Diego to engage US undergraduate students in

interdisciplinary research of historical and ongoing human-environmental interactions in the Shiraki Plateau in the southeastern part of the country of Georgia. Part of this multidisciplinary project was to develop components of an interactive virtual collection of archaeological artifacts from cultural sites and hydrological data from the Shiraki Plateau, as well as a virtual reality (VR) environment for education and outreach. This resulted in the creation of two distinct virtual environments—the Virtual Museum of Archaeology of South Caucasus (VMASC), an interactive virtual collection of artifacts from the archaeological sites at Shiraki; and a virtual reconstructed environment of a general Late Bronze Age site on the Shiraki Plateau—through the work of US undergraduate students from BSU and graduate students from ISU. This presentation is designed to show the work of these students and scholars, particularly Giorgi Datunashvili of ISU, and to demonstrate future applications of this and other VR environments for archaeology in California, Massachusetts, and in Georgia.

Tracing Cannabis in the Historic Past: New Insights from Chemical Residue Analysis

Today, marijuana consumption is becoming decriminalized across the Western world. This legal change is often followed by increased research activity, specifically regarding crop “improvement” and the concentration of the plant’s psychoactive compounds. This situation resembles the process characterizing the commodification of tobacco during the colonial era. Nonetheless, while archaeologists, historians, and others have accumulated an important body of evidence around the distribution, repurposing, and impact of tobacco in new consumer populations, the same cannot be said for psychoactive cannabis. Empirical data about its initial move from southern Asia to eastern Africa, its journey across the continent, and its eventual spread to the Americas remains scarce. This appears to be partially due to the low preservation potential of major cannabinoids such as THC and CBD. Here, we will present the ORA results of ethnographic and historic African pipes. Our discussion will focus on the potential of minor cannabinoids to serve as biomarkers in the analysis of residues that have undergone pyrolysis. We hope that more accurate protocols for the study of archaeological artifacts can help in reconstructing the history of cannabis. More importantly, a clearer picture of past shifts in consumer dynamics could contribute to inform present-day policy debates.

Living with an Etruscan Past: Medieval Use of Earlier Architecture and Artifacts at San Giuliano (Lazio Province, Italy)

Excavation and analysis of material culture is one way that scholars in the present endeavor to understand the people of the past. At the same time, we must consider that these people had encounters with their own archaeological history, made manifest in material objects, tombs, and architectural ruins of previous societies. In this paper, I explore how the medieval inhabitants of San Giuliano, a fortified castle site in Lazio province (Italy) dating to the tenth–thirteenth centuries, made use of the remnants of earlier cultures. I explore how

San Giuliano's medieval inhabitants reutilized numerous components of the earlier Etruscan occupation of the San Giuliano Plateau, dating to the sixth–third centuries BC and representing the last time that the plateau had seen extensive residential, civic-ceremonial, and mortuary activity prior to the medieval occupation. I focus primarily on the reutilization of constructed spaces both above and below ground, ranging from the medieval clearance and reuse of an Etruscan *cuniculo* (a subterranean water management tunnel) to the transformation of a crumbling Etruscan temple into a Christian chapel and associated cemetery. This research contributes to a burgeoning conversation regarding how people in the past understood, reused, and reshaped the material remains of their predecessors.

Creating Diasporic Scandinavian Identities in Viking Age Iceland

The Viking Age migrations that settled the North Atlantic resulted in a diaspora, creating a series of colonies that looked back to Scandinavia for their shared historical identity. This paper focuses on the diasporic experience in Iceland and the formation of a new Icelandic ethnic identity. The origin and ethnicity of the settlers of Iceland can be approached through written sources, archaeological remains, isotopic analyses, and genetic studies. Written sources—sagas, chronicles, law books—agree that the population consisted of mostly (though not exclusively) Norse settlers from Norway and the Scandinavian colonies in the British Isles. Recent genetic studies support a multiethnic origin of the Icelandic settlers. However, the texts and the genetics diverge in the proportions of the settlers vis-à-vis their places of origin. A somewhat more homogeneous picture is provided by the archaeological record, which has yielded the material correlates of a relatively uniform identity that is culturally Norse and religiously Norse pagan. This paper reviews the diverse datasets available for Viking Age Iceland to unravel the complex picture of the origins of the early Icelanders and the processes involved in the subsequent genesis of a new Icelandic identity.

Water and Land: A Case Study of Panlongcheng in the Middle of Yangtze River

In the past few decades, research on the Panlongcheng site has achieved important results and progress in many aspects, but few scholars have discussed the site's geomorphological environment, especially the water environment. Researchers have long believed that the environment and landscape of Panlongcheng we see today are no different from the early Shang period. However, recent archaeological discoveries indicate that there may still be some cultural remains underwater. Therefore, we used a combination of underwater surveys, drilling, and digital mapping to expand our knowledge of the landscape of Panlongcheng during the early Shang period. This included mapping the lake basin through single-beam echo sounders and drilling to preliminarily observe the stratum and collect samples underwater. We also conducted radiocarbon dating on the samples collected at the bottom of the lake. The result indicates that the lake was formed not earlier than 1100 BC, which means that there was no lake during the early Shang period. Therefore, the landscape and environment of Panlongcheng and other related issues should be reexamined. In addition, we hope that the methods we used in this research may also provide some help and inspiration for related archaeological work in shallow water areas in inland China.

Precolumbian Water Management in the Andean Puna and Neotropical Forests of NW Argentina: Strategies for Sustainability in Contrasting Environments

Agropastoral landscapes in South America boast complex and diverse geographies and histories. Numerous investigations have revealed that the contrasting environments in the Andes, far from remaining pristine,

underwent extensive transformations by past human societies, which have had lasting repercussions on their biodiversity and soil morphology. In this study, our objective is to assess and compare the water management techniques employed by precolumbian communities in the high Andean plateaus and the eastern Neotropical forests of NW Argentina, using an interdisciplinary approach that incorporates soil analysis (microremains and biomarkers), spatial analysis, and ethnographic research. The examined occupations in the arid Andean region of Cusi Cusi (Jujuy, Argentina) span from AD 1200 throughout the Inka and colonial periods. Meanwhile, our case study in the eastern forests of Catamarca province covers a period between AD 500 and 1000, marked by extreme climatic fluctuations. This research aims to shed light on both the positive and negative outcomes of the techniques employed in these highly contrasting environments, with a primary focus on their sustainability.

Gaining Insight into Lithic Technology in East-Central Pennsylvania through the Study of an Amateur Collection

The farm fields of east-central Pennsylvania contain an abundance of artifacts that span much of regional prehistory. Not surprisingly, many of these artifacts have been collected by local amateurs. Here, we analyze an assemblage of projectile points collected from the Kramer Farm in Kutztown, Pennsylvania. We explore how morphometric attributes (e.g., size, shape), indices of retouch, and raw material vary in relation to projectile point type. Our analysis provides insight into projectile point design and evolution, lithic resource preferences, technological organization, and land use. Despite the imperfections that often characterize amateur collections and the controversy that surrounds their study, our study demonstrates that collaboration between archaeologists and collectors can be beneficial, as archaeologists gain access to artifact assemblages that expand our understanding of the past.

Creating Frames of Reference for Seaweed Consumption in the Americas: A Cross-Cultural Approach

Though seaweed consumption has only been exceptionally documented in most archaeological contexts, ethnographic data accounts for the extensive and intensive use of seaweeds and seagrasses. This study uses ethnographic data to propose new hypotheses that can inform future archaeological research by showing recurrent and non-case-specific choices. In this paper, we present a preliminary study aimed at investigating

the different types of seaweed consumption across Indigenous societies from North, Central, and South America. We use the eHRAF (Human Relation Area Files) ethnographic databases corresponding primarily to the nineteenth and twentieth centuries in order to retrieve data on how these societies use a number of seaweed species for different purposes. The study shows the uses of seaweed for food, salt, seasonings, and as a commercial resource. Seaweeds were also integrated into recreational and social activities, as well as into the symbolic dimension. Such results will allow us to assess the relative importance of seaweed consumption in hunter-gatherer, horticulturalist, pastoralist, and agriculturalist societies.

The Urban Grid: Connecting Water Management and City Organization in Nixtun-Ch'ich'

Nixtun-Ch'ich', a Middle Preclassic settlement along Lake Petén Itzá is known for its city organization. Nixtun-Ch'ich' has been surveyed in a variety of ways including a theodolite with an electronic distance measurement (EDM), total station, lidar, and photogrammetry. These various maps of Nixtun-Ch'ich' show how the central axis, urban grid, and fossa—i.e., the water management and city planning—work with the natural topography to protect it from the elements and to encourage social interaction. As a result, these public goods further demonstrate how Nixtun-Ch'ich' was a “collectively organized city center,” with less of a focus on leadership and more of a focus on tying citizens/occupants to the city.
