The ANNUAL MEETING of the Society for American Archaeology provides a forum for the dissemination of knowledge and discussion. The views expressed at the sessions are solely those of the speakers and the Society does not endorse, approve, or censor them. Descriptions of events and titles are those of the organizers, not the Society.

SYMPOSIUM ABSTRACTS

Global climate is affecting archaeological sites and heritage at a scale and rate unprecedented in the experience of archaeologists over the last 150 years. Coping with sea-level rise, increasingly frequent wildfires, severe storms, and other climate change impacts requires approaches beyond those typical of heritage management over the last 40 years. One innovative approach is engaging local communities to protect threatened properties and to do in-depth documentation of those that will be lost. Some initiatives have given extraordinary levels of training and empowerment to local communities. This forum showcases successful approaches in a variety of global settings.

[2] Symposium · WHEN DISASTER STRIKES: ENVIRONMENTAL IMPACTS ON COLLECTIONS PRESERVATION
Cultural heritage collections are threatened resources. Climate change exacerbates physical risk posed by insufficient facilities and infrastructure. Many museums, repositories, and collections facilities worldwide are ill-equipped to handle increased frequency of natural disasters exemplified by recent flooding in Louisiana, wildfires in California and Arizona, Super Storm Sandy, and Hurricane Katrina. New collections of fragile, perishable, and organic materials rescued from sites facing imminent destruction encounter poor refuge in overburdened, vulnerable facilities. While collections may be “saved” via excavation, future research, education, and public outreach remain imperiled if the facilities to house these new collections are substandard. Most repositories are inadequately prepared for and therefore susceptible to the gamut of natural disasters. Confronting these challenges offers the opportunity to develop collaborative solutions that will not only benefit heritage preservation across the world, but also enrich research relevant to that changing world. This symposium brings together international experience and expertise focused on more effective planning for response to climate threats and the preservation challenges they pose.

[3] General Session · OLMEC ARCHAEOLOGY

[4] Electronic Symposium · DEVELOPING APPROACHES IN THE STUDY OF PREHISTORIC COPPER IN NORTH AMERICAN ARCHAEOLOGY
From studies at the turn of the twentieth century using assay techniques demonstrating that copper was of New World origins rather than Old, to typological studies and metallurgical studies in the mid to late twentieth century, to the sophisticated elemental analyses of the early twenty-first, analysis of prehistoric copper materials has been an active area of research throughout the development of American archaeology. Unlike the rich theoretical and methodological approaches used in other material analyses involving lithics and ceramics, copper analysis trends toward the idiosyncratic, the under problematized, and the under theorized. Yet research involving prehistoric copper has recently experienced a notable growth, and from this growth there have emerged new approaches, questions, and social issues that may be addressed using copper. Among these remain the traditional provenance studies, but research has expanded or is expanding into social processes, dynamic interactions between communities, studies of ritual economies, issues of copper technological organization and production, and others. This session highlights this growing body of research and methodologies and begins to explore the range of methods, problems, and theory that may support the future development of copper studies in North American archaeology.

[5] Electronic Symposium · THE SOCIAL USES OF FOOD IN ANCIENT MAYA CULTURE
From feasting as a mechanism for the evolution of complexity to the competitive trade in cacao beans among elites, food and cuisine were deployed in a myriad of ways to cement social relations and reinforce specific identities in the ancient Maya world. The study of foodways encompasses not only diet but all the cultural behaviors and beliefs surrounding consumption—ritual offerings and restrictions, medicinal preparations, competitive consumption, and the role of nostalgia or memory around food. This session presents a series of case studies of Classic Maya foodways from Preclassic to Postclassic contexts. From this rich foundation we will move beyond specific examples to a more comprehensive understanding of the mechanisms by which food was instrumental to the development of ancient Maya culture. How was diet codified as a marker of Maya identity? Which foods emerged as key components of state ritual and how was their production manipulated? In what ways did cuisine become a specialized knowledge base that reinforced hierarchy? Papers will address the ideological as well as nutritional aspects of Maya cuisine, the economic or political significance of shared foodways, and the role of foodstuffs in the dynamic processes of identity formation.

[6] Forum · ADVANCEMENTS AND PROSPECTS IN GEOARCHAEOLOGY TODAY: THE SAA GIG AT 20, PART 1
In celebration of 20 years of the Geoarchaeology Interest Group (GIG) in the Society for American Archaeology, we seek to clarify the present and future contributions of geoarchaeology, in terms of practical techniques, analytic and interpretive methods, and theoretical approaches. Whether as its own field or hybridized multidisciplinary endeavor, geoarchaeology has grown over the last decades to encompass a multitude of research themes and operational procedures, but what unifies this diversity under the name of geoarchaeology? Furthermore, what are the current and emerging new challenges for practicing geoarchaeologists as relevant for today’s concerns of sustainable development, values of landscapes as heritage resources, and the place of human societies within a changing environment?
[7] Poster Session · CURRENT RESEARCH IN MESOAMERICA I

[8] Poster Session · BIOARCHAEOLOGY IN MESOAMERICA

[9] Poster Session · CURRENT RESEARCH IN MESOAMERICA II

[10] Poster Session · PROCESOS POLÍTICO-ECONÓMICOS DE LA COSTA DEL GOLFO MESOAMERICANA
Este simposio pretende integrar visualmente algunos de los trabajos arqueológicos relacionados con los procesos económicos y políticos que se llevaron a cabo en el área de la Costa del Golfo de Mesoamérica, abarcando diferentes etapas y regiones.

Since being defined more than two decades ago, the Three Rivers Region of the southern Maya Lowlands has been intensively studied by a number of researchers. The area includes the Department of Petén, Guatemala, and the adjoining northwestern portion of Belize, and is within the Rio Azul, Rio Bravo, and Booth’s Rivers that converge to form the Rio Hondo. The Three Rivers Region includes the well-known sites of La Milpa, Blue Creek, and Rio Azul. This poster symposium will present recent work from the region.

[12] Poster Session · NEW RESEARCH IN WEST MEXICO: STATE OF MICHOACÁN
The western Mexican state of Michoacán extends from the Pacific coast, includes parts of the Sierra Madre Occidental, and stretches north to the Lerma River. This region has a long cultural occupation and, by the end of the Postclassic, it fell within the Tarascan Señorío, a powerful rival of the Aztec empire. Tarascans are known to have an isolate language, being prolific traders, excellent coppersmiths, and, in comparison to their neighbors, had a very distinct culture. In 2014, Dr. Jose Luis Punzo-Díaz launched Proyecto Arqueología y Paisaje del Area Centro Sur de Michoacán, which includes sites located near Lake Zirahuen and north of the Balsas River basin. Since then he and his team have intensively investigated a number of archaeological sites, which have added to the body of knowledge of this unique culture. This poster session attempts to bring together a cross-section of the most recent work.

[13] Symposium · ALTICA: THE MILLENNIUM BEFORE TEOTIHUACAN
One of the big questions for archaeology is the origins of complex societies. Although one of the largest and most influential cities and states, Teotihuacan, developed in the northeastern Basin of Mexico, there has been little research in recent decades about the Formative period before the rise of Teotihuacan. The Altica Project that began in 2014 is an important step in addressing the limited problem-oriented research at Formative sites in the Basin of Mexico for over two decades. Altica is the earliest-known settled village in the Teotihuacan Valley and one of the only first-farming village sites in the Basin of Mexico that has not been engulfed by the urban sprawl of Mexico City. Despite its small size and remote location, Altica was an important piece in Early and Middle Formative exchange networks as it played a role in the early trade of Otumba obsidian and imported other goods from distant places in Mesoamerica. Papers in this session present findings from excavations and surveys at the site and studies of its artifacts and features. Contributors discuss topics ranging from diet, exchange/procurement networks focused on obsidian and ceramics, tool technologies, and the cultural and biological identities of its inhabitants.

[14] Symposium · FORENSIC ARCHAEOLOGY
This session aims to highlight recent projects from those active in forensic research and case work. As forensic archaeology continues to grow as a discipline and is utilized with increasing frequency by law enforcement officials, case studies are of great use to those engaged in forensic field work. In addition, research is essential to strengthening the theoretical foundations of forensic archaeology. This session also features research projects that will be of benefit to future forensic work and criminal justice. Those involved in research have the opportunity to address areas untouched by current practitioners. By bringing together researchers and practitioners, this symposium aims to create meaningful dialog and spur collaboration.

[15] Symposium · THE VIKING PHENOMENON
In December 2015, the Swedish Research Council made an unprecedented investment in archaeology with a ten-year, multimillion dollar grant to establish a center of excellence in Viking Studies at Uppsala University. Much of the recent research into the Vikings and their time (c. 750–1050 CE) has focused on the complex processes of state formation and Christian conversion that eventually gave rise to the modern Scandinavian nations. Far less attention has been devoted to the very beginnings of this trajectory: who really were the Viking raiders in a specific sense, why did they do what they do, what kind of societies produced them, and why did they start to expand so violently at precisely this time? The answers to these questions concern the very origins of the Viking phenomenon, and our focus is thus on the critical period 750–850 CE and the decades either side. This session presents a range of ongoing archaeological work within the project: issues central to our understanding of how Scandinavia came to be what it is today, and the sometimes problematic ways in which this knowledge of the Viking-Age past is received in contemporary society.

[16] Symposium · PERSON, PLACE, OR THING: ONGOING QUESTIONS AND EVIDENCE FOR NEW ENGLAND SETTLEMENT AND MATERIAL CULTURE
The various investigations at New England archaeological sites presented in this session have yielded new information to help address old questions. Settlement patterns and artifact typologies have long been the basic contextual foundation for interpreting cultural change. These investigations provide new insights that expand on New England’s cultural history.
[17] General Session · INDIGENOUS ARCHAEOLOGIES

[18] Symposium · METHODS AND MODELS FOR TEACHING DIGITAL ARCHAEOLOGY AND HERITAGE
As the role that digital methods play in heritage and archaeology has increased in importance, so has the challenge of teaching those digital methods. Who should be taught digital methods? Should undergraduate and grad students be taught digital methods alongside non-digital methods? Should instruction in digital methods be curricular or extracurricular? Should instruction in digital methods take place in the classroom, the lab, or in the field? How should existing scholars or professionals be taught digital methods? What concepts, platforms, or technologies should be taught? What underlying values about the application of digital methods in archaeology and heritage should be expressed in teaching programs? All are relevant questions whose answer requires measured design, careful planning, and thoughtful implementation. The purpose of this session is to explore these critical issues by highlighting a series of case studies, each of which approaches the challenge of teaching digital methods within archaeology and heritage differently. Beyond the case studies themselves, the session hopes to highlight generalizable models that might be adapted and adopted in a wide variety of institutional, professional, or scholarly settings.

[19] Symposium · CONSTRUCTING ARCHAEOLOGY: MOVING SEX/GENDER AND SEXUALITY RESEARCH FROM THE PERIPHERY TO THE CENTER
The majority of archaeological projects neglect sex/gender and sexuality research due to a social construction within our community that relegates these topics to the periphery of archaeological discourse. This session aims to move sex/gender and sexuality studies from the periphery to the center by examining the implementation of such research in a variety of archaeological projects with differing regional fouls and research goals. The papers in this session impress upon the archaeological community that such lines of inquiry should be routine in classroom instruction, field work, and lab analysis. The research presented addresses new theoretical engagements, methodological approaches, and interdisciplinary work that allow for a practical approach to the investigation of sex/gender and sexuality constructs in past communities. The diverse approaches illustrate that sex/gender and sexuality is still, and will remain, an important topic that anyone studying the past should, at the very least, consider.

[20] Symposium · CITIES, LARGE VILLAGES, OR NEITHER? THE CONUNDRUM OF “MEGASITES” IN PREHISTORY
“Giant” settlements, or “megacities” were a periodic feature of human settlement history from around 4000 BCE right up to the nineteenth century CE. Such sites are usually characterized as “urban,” “pre-urban,” or “proto-urban,” but urbanism has become an exceedingly plastic categorization with a rather nebulous definition. Furthermore, these sites appear to share behavior which is quite different to that of classic urban sites, challenging our assumptions about how such settlements should classified. A session at the SAA conference in 2013 explored the characteristics of some prominent examples of these settlements, including the European Iron Age Oppida, Cahokia and Great Zimbabwe. This session is designed to revisit and deepen that discussion by considering new research in those regions and bring together new ideas and data that have emerged in the past four years. A consideration of these settlements in this context has the potential to provide significant new insight into the structure and organization of human settlement behavior in prehistory.

[21] Symposium · SOME LIKE IT HOT: ANALYTIC DIVERSITY AND COMPLEMENTARITY IN THE EXPLORATION OF PAST COOKING AND CUISINE
Diet and subsistence are established avenues of archaeological inquiry. The last decade, however, has witnessed greater attention afforded to the cooking techniques employed by past societies. Cooking, a crucial component of cuisine, lies at the intersection of adaptive and social behaviors, allowing for insight into both decisions about nutritional enhancement of foods and the constraints placed on cooking practices by cultural factors, such as identity and ideology. Globally, a diversity of methods is being employed by archaeologists to explore various aspects of past cooking habits, each yielding unique but often complementary data. This symposium explores the types of information yielded by different analytic methods and thereby initiates a dialogue among researchers about how these methods might be used in tandem to create richer and more complete interpretations about past cooking behaviors.

[22] Symposium · FOUNDATIONS FOR INNOVATION: THE LEGACIES AND INFLUENCES OF ARCHAEOLOGICAL SCIENCE AT MCMASTER
McMaster University has a long history in archaeological science, including major advances in stable isotope analysis, provenience studies, and long-term human-environmental interactions. Interdisciplinary research programs have included the pioneering work of Henry Schwarcz in using stable isotope geochemistry for paleo-climate and paleo-diet research, and the materials characterization research of Ron Hancock at the McMaster Nuclear Reactor. Ongoing research and student training now take place within a wide range of specialized archaeological laboratories, established with the support of the Canada Foundation for Innovation. Students are trained at labs focusing on stable isotopes, XRF, ceramic petrography, fisheries, ancient DNA, paleoethnobotany, sediment cores, and in a larger research repository for Ontario archaeological materials. These laboratories have catalyzed research programs across Canada and globally, and are examples of the rapidly evolving state of archaeological science at McMaster as well as ongoing collaborations between institutions. In this session, current researchers and alumni will draw on a wide range of case studies to explore the history of archaeological science at McMaster, the innovative archaeometric and bioarchaeological studies emerging from McMaster laboratories, the application of these studies to diverse social questions, and the state of ongoing collaborative research across the broader landscape of archaeological science.

[23] Symposium · A TASTE FOR GREEN: AN AMERICAN/EUROPEAN PERSPECTIVE ON ANCIENT JADE, TURQUOISE, AND VARISCITE EXCHANGE
Often along vast expanses, ancient societies traded certain commodities that were considered valuable either for functional or symbolic reasons, or rather, a combination of both factors. We shall address the state of the art with regard to the acquisition of jade, turquoise, or variscite, all of which share a characteristic greenish color and engaging appearance. We wish to explore how, in
addition to constituting economic transactions, the transfers of these materials were also statements of social liaisons, personal capacities, or relationships to places or unseen forces. We are centering on two study areas, Western Europe and Mexico/Southwest United States, which are far apart not just in geographical terms but also regarding their chronology and socioeconomic features. While some North and Mesoamerican groups range from relatively complex farming societies to state-like organizations during the first and second millennia AD, their European counterparts are comparatively simpler polities spanning the fifth–third millennia BC. By contrasting the archaeological evidence from diverse areas we may gain insight into the role that production and movement of green stones played in their respective political and ritual economies. Also, we think it useful to compare scientific approaches applied to different parts of the globe.

[24] Symposium · ISLAND ARCHAEOLOGY IN EAST ASIAN PERSPECTIVES
Islands have intrigued archaeologists in their distinctive cultural trajectories and human-environmental dynamics that have still impact on modern times. Islands can provide unique insights into several anthropological questions, including peopling, island adaptations, landscape modifications, isolations and connections over the oceans, and more. Research on islands’ past in East Asia has tuned into a regional focus, rather than a broad comparative perspective that can resonate globally. A main goal of our symposium is to create a synergy through discourse on differences and similarities in sociocultural, environmental trajectories in several islands during the Anthropocene. Research areas in focus include islands spotted in the Yellow Sea, East China Sea, and East Sea (Sea of Japan).

[25] Symposium · MEDIEVAL CITIES IN THE EURASIAN STEPPE
The Eurasian steppe is the iconic territory of mobile populations. However, through much of recorded history the region has also seen the development of a long-term tradition of immobile urban inhabitation that has been an integral part of its mobile societies. Broadly, this session will address historical archaeology in Asia, the malleability of ecological and economic frontiers, hybridity and adaptation, urban settlement, and political landscapes. Specifically, we will offer detailed, data-rich challenges to the long-held dichotomy between mobile and immobile populations and the asymmetric and hidebound models of relations between them. Presenters will discuss topics including urban forms and styles of the Eurasian steppes, networks of interaction and exchange, and communities linking immobile cities to mobile agents, the biographies of individuals living in and managing polities and economies, and the dynamics of political landscapes within and around urban centers. This symposium will be not only valuable to specialists, but also present challenges and novel approaches—methodological and theoretical—to the archaeology of borderlands and unsung urban settings worldwide.

[26] Symposium · CULTURAL CONTACTS ALONG THE SILK ROAD DURING THE EARLY BRONZE AGE
It is likely that the Silk Road has played a significant role even before Han Dynasty. The cultural contacts between China and Central Asia can be traced back to the early Bronze Age. The early interaction and integration of Eastern and Western cultures may also occur in this time period. The migration and exchanges of different groups and different cultures were affected the formation of Chinese civilization with diversity characteristics. The geographic areas discussed in the session mainly cover the Northwest Zone, especially Xinjiang, Gansu, Ningxia, Qinghai, Western Shaanxi and Western Inner Mongolia, central Asia. The highlights of the discussed time period include the late Neolithic to Bronze Age.

[27] Symposium · 2017 FRYXELL AWARD SYMPOSIUM: PAPERS IN HONOR OF NAOMI F. MILLER
(SPONSORED BY FRYXELL AWARD COMMITTEE)
Naomi F. Miller is the 2017 recipient of the Fryxell Award for Interdisciplinary Research in archaeology. The Fryxell Award is presented in recognition for interdisciplinary excellence of a scientist who need not be an archaeologist, but whose research has contributed significantly to American archaeology. The award is made possible through the generosity of the family of the late Roald Fryxell, a geologist whose career exemplified the crucial role of multidisciplinary cooperation in archaeology. The 2017 Fryxell Award recognizes the area of plant sciences. Miller specializes in the study of human and landscape relationships through the analysis of macrobotanical remains from archaeological sites. Her career as a preeminent archaeobotanist and prolific researcher has led to over 100 publications and she has continually pushed the boundaries of archaeobotany through interdisciplinary collaborations and innovative work on archaeological site preservation. To reflect the diversity of Miller’s contributions to the field, this symposium brings together scholars working with plants, across methods, times, and regions, to present original research addressing the research themes with which Miller has engaged in her career.

[28] Symposium · ROCK ART, EMBODIMENT, AND IDENTITY
We challenge contributors to explore concepts of embodiment and “process” within non-Western ontologies and ethnographies as a lens onto meaning, motivation, and identity. In archaeological contexts, embodiment is usually taken to mean an analysis of the body as lived experience. Turner (1996) for instance suggested that every society is concerned with the “regulation” of populations in time and space, and with the representation or manifestation of the “exterior” body in social space. Researchers can therefore treat images as direct metaphoric comments on social processes, at the same time accepting that artists and viewers experienced the images (in a somatic sense) and did not simply intellectualize them. Process, on the other hand, is akin to the notion of chaîne opéraatoire, and refers to the process of making rock art, from the conception of images through to the “fixing”—and, sometimes, subsequent manipulation, reconfiguration, and “consumption”—of images. By focusing on these broad concepts, and using specific case studies from several countries, this session aims to contribute further insights into how rock art was, and is, viewed and used by the original artists and subsequent viewers to shape, maintain, and challenge ideologies and identities.
[29] Symposium · HIGH-TECH STORYTELLING IN ARCHAEOLOGY
(.SPONSORED BY NATIONAL GEOGRAPHIC SOCIETY and ESRI)
Recent advances in technology have dramatically transformed how archaeologists study and interpret the past. Techniques such as lidar, drone photography, and ground-penetrating radar are readily becoming standard components of an archaeologist’s tool kit alongside trowels, brushes, and picks. GIS software has become more powerful and easier to use, allowing archaeologists new ways of collecting, analyzing, managing, and communicating their data. Although these methodologies provide extraordinary potential, they also require a critical examination of their limitations. Furthermore, as archaeologists adopt more high-tech methodologies, they must negotiate challenges with data storage and visualization as well as the attention-grabbing headlines that often accompany the use of cutting-edge tools. This symposium highlights attempts to use twenty-first-century technology to explore ancient societies across the globe. Participants not only will demonstrate how various technologies have advanced our understanding of the past, but also they will reveal how they have (or have not) overcome difficulties using those technologies. In addition, participants will engage in a discussion of how to use high-tech storytelling in order to bring to life the stories of ancient peoples and cultures for a generation bred on tweets and viral videos.

[30] Symposium · BREASTFEEDING AND WEANING PRACTICES IN ANCIENT POPULATIONS: A CROSS-CULTURAL VIEW
Breastfeeding in humans is both a biological process and a culturally determined activity that is shaped by complex interactions of beliefs about health and nutrition, construction of childhood and parental identities, religious values, and lifestyles. Infant feeding practices have important implications for population dynamics, as they affect fertility, morbidity, and mortality patterns. Shortening the duration of breastfeeding has a significant effect on the cognitive and emotional development of children; however, it has potential benefits for the survival of the group by shortening inter-birth intervals. Since the discovery that the nitrogen stable isotope ratio (15N/14N) in body tissues can be used to reconstruct breastfeeding and weaning practices (BWPs), there have been numerous studies aimed at developing more precise models to reconstruct BWPs in archaeological populations. These studies have improved our understanding of the social and biological determinants of ancient populations, such as health status, child development, social systems, and reproductive strategies. During this symposium, discussions will explore the new methodologies, models, and sustained uncertainties involved with BWPs reconstruction in archaeology. The exchange of results regarding the BWPs of ancient populations in different world regions will further enrich our knowledge of the temporal and cross-cultural variations of BWPs in ancient human groups.

[31] Symposium · BODIES AS NARRATIVES: REVISITING OSTEObIOGRAPHY AS A CONCEPTUAL TOOL
Bodies are stories. They combine a lifetime of biological change and culturally negotiated activities with corresponding bodily responses. The traces of the life course are embodied in the skeleton itself. The term “osteobiography,” introduced by Saul and Saul (1989), refers to the life history recorded in the human skeleton. Reading skeletal data interpretively within cultural and behavioral contexts to trace unique life paths can help to bring human remains out of the ghetto of specialist appendices and into humanistic and multidisciplinary analysis. However, the concept of osteobiography has rarely been systematically explored, remaining simply the detailed description of the skeletal remains of a single individual. This session provides a focused discussion of the concept. Among the topics to explore are
- The normative biography as a cultural narrative weaving together time, history, and individual experience
- The experience of activity, health, and illness
- How bodies become gendered, aged, and individuated
- Habitual activity molding the body and its identity
- The role of narrative, contingency, and risk in human lives
- Methodologies for constructing osteobiographies, lacking between individual and social scales of analysis and combining archaeological, textual, and/or iconographic evidence
- Biographical narratives as bridges for outreach, education, and communication

[32] Symposium · THE ISLAND ANTHROPOCENE
The colonization of islands has generated significant research interest in archaeology. Islands have long been thought of as laboratories for biological evolution and as important case studies for the development of social and political processes. Though the colonization of islands is often viewed in regional and even macro-regional frameworks, this session takes stock of the state of archaeological knowledge on the impetus, timing and nature of island colonizations at the global scale. This session explores whether island colonization is inherently different from the colonization of mainlands due to the fact that islands are circumscribed, often small and have vulnerable environments. This session further considers variations in colonization processes occurring on a diverse array of islands, including large and small islands, oceanic and continental islands, and islands that experienced multiple waves of colonization. Papers that explore the unique nature of the colonization of islands in a biogeographic, spatiotemporal, or social sense are welcome. Important themes for discussion are anthropogenic changes in the landscapes and biotic communities of islands, islands as nodes within networks of trade and interaction, and the impact of climate on ancient island communities and archaeological sites.

[33] General Session · ARCHAEOLOGY IN CHINA

[34] Symposium · PUEBLO MOVEMENT AND THE ARCHAEOLOGY OF BECOMING
The concept of movement—pertaining to people but also including weather, moisture, spirits, blessing, and animals—is an essential part of Pueblo identity and history. Movement is also the driving force of every Pueblo’s cosmogony from emergence into this world to finding the “middle place.” The process of becoming Pueblo is not only shaped by histories of people coming together and moving apart, but also by creating unique philosophies tied to social and natural landscapes. Conversely, these philosophies mold the actions of Pueblo people throughout their dynamic histories. This session explores how diverse modern Pueblo identities, cosmologies, and societies are inherently connected to histories of movement and draws deeply from archaeological, ethnographic, and historic sources. While Southwestern archaeologists have embraced population movement, and in particular migration, in
Recent years, we seek to also examine how additional types and scales of movement including coalescence, fissioning, feasting, short-term mobility, exchange of goods and ideas, and the effects of Spanish colonization shaped, and were shaped by, Pueblo identities and societies. Case studies are presented from across the American Southwest with an explicit de-emphasis of the distinction between the prehistoric and the historic to facilitate a holistic discussion of Pueblo history.

[35] Symposium · REIMAGINING HUMAN-ANIMAL RELATIONS IN THE CIRCUMPOLAR NORTH

Although relations among northern peoples and animals have conventionally been approached ecologically and economically, the emergence of human-animal studies suggests a reframing of these relations as equally social, experiential and meaningful. Nonhuman animals, in turn, are recognized as having complex social and cognitive lives and interspecies interactions of their own. An extraordinary northern zooarchaeological record speaks not only to the processing and consumption of animals but to the labor and violence to which domesticates were subjected, and to the biological unfolding of all animals' lives as registered in their tissues. There is also a thick record of technologies related to the harvesting, harnessing and utilization of animals, and depictions of animals and human-animal relations in figurative art. The ethnographic, ethnohistoric, oral historic and ethnoarchaeological records further provide access to ethnozoological discourses and practices related to animal use and animality. This session draws together archaeologists working in various parts of the circumpolar north to think through the record of human-animal relations in novel ways. How did variously positioned actors in different times and places conceptualize and relate socially to nonhuman animals, and how did nonhuman animals relate to their world, including humans and other animals, in an archaeologically visible manner?

[36] Symposium · THE ARCHAEOLOGY OF GLOBAL HISTORY

Archaeological research is local almost by definition. But facing topics such as the emergent processes linked to global history we need to relate to a wider picture since material culture may stem from any part of the world. This session aims to bring together papers that explore the linkage between the local and the global, highlighting methodological issues that challenge our work and showing how the articulation of global trends with local dynamics took place. Thus, we introduce papers dealing with the circulation, distribution and introduction of people, artifacts, technologies, and plants and animals as well as those showing how a global framework helps us understand a single site.

[37] Symposium · ARCHAEOLOGICAL EPISTEMOLOGY IN THE DIGITAL AGE

Digital technologies are becoming integral to archaeological practice, from research to pedagogy and public outreach. In the past decade, many archaeologists have reflected on how these technologies impact their work in the field and in the classroom, but they largely focus on how they developed, implemented, or improved digital tools or techniques designed to organize, analyze, and disseminate data. Yet as digital technologies become increasingly essential to how archaeologists investigate the past, we must also consider how they create new ways of engaging with, interpreting, and classifying materials, things, sites, and regions. For example, how do—or could—digital databases alter our understanding of relationships between and inextricable assemblages of humans, organisms, things, soils, and environments? Must the digital data we create themselves become artifacts of an archaeological record imagined as a collection of static entities? Or can the digital data add a new dimension to our understanding of the archaeological record as a dynamic process made up of sequences of entrained elements? How do digital tools change the way we “assemble” constellations of artifacts and practices, and consequently, reconstruct the past? This session addresses these questions of archaeological epistemology in the digital age.

[38] Symposium · MODELING PEOPLE, PLACES, AND THINGS: REVISITING ARCHAEOLOGY AS MODEL-BASED SCIENCE

Ten years ago, Kohler and van der Leeuw proposed “rethinking archaeology as a model-based science,” which makes conscientious use of simplified representations of socio-natural systems in order to both build and apply archaeological theory. Since that time, use of computational modeling in archaeology has grown, topics being modeled have diversified, and methods for model-building have become more flexible and accessible. There has also been increasing interest in applying archaeological models to contemporary social and environmental issues, incentivizing integration with real-world datasets from within and outside archaeology. This emphasis on application brings new opportunities and challenges, and invites revisitation of questions concerning model generality and equifinality. In this symposium, we focus on the topic of application in model-based archaeology, looking at how archaeologists have applied models, as well as how they would like them applied. The symposium is guided by three broad questions: First, how do we model people in the past, as individuals or aggregates, and who gets modeled? Second, what are the roles of space and place in a model, and when/how do they matter? And finally, how do we connect computational models to the things that compose the archaeological record and to other “real world” phenomena?

[39] Symposium · COPAN I: THE LATE CLASSIC PERIOD

This session explores data pertaining to the first half of the Late Classic period at Copan in Honduras. This period is marked by the reign of three long-lived rulers: Ruler 11, K’ahk’ U’ul’ Chan; Ruler 12, K’ahk’ U’ul’ Wittz’ K’awil; and Ruler 13, Waxaklajuun Ubaah K’awil. Under K’ahk’ U’ul’ Chan the population of the valley rose significantly. Under K’ahk’ U’ul’ Wittz’ K’awil the Copan polity is believed to have first expanded into a state. Ruler 12’s reign saw the dedication of stelae both in the center of the city, as well as in areas outside of the Copan Pocket, including in Santa Rita. He erected at least one altar at Rio Amarillo, gifted ceremonial ceramic vessels as far away as Tazumal, El Salvador, and performed a scattering ritual at the site of Quirigua, Guatemala. Waxaklajuun Ubaah K’awil stepped into the shoes of his illustrious predecessor and for 42 years ruled over a community whose art style burgeoned. He proclaimed Copan one of the corners of the Maya world along with Calakmul, Tikal, and Palenque, and presented himself in the guise of various gods on stelae in the Great Plaza, and yet ended his reign beheaded by the ruler of Quirigua.

[40] Symposium · CONTROLLED EXPERIMENTS IN LITHIC TECHNOLOGY AND FUNCTION

Investigating how stone tools were produced and used by hominins is one of the key research areas in the study of the evolution of human behavior. Over the last decades, paleoanthropological research has focused on diverse aspects of stone tool–related behaviors of past humans, such as the procuring of raw materials, manufacturing techniques, the manipulation of physical
proprieties (e.g., heat treatment), and actual tool use. Experiments have long been used to address these different aspects, aiming to replicate the manipulation of different types of rocks in laboratory-like, forensic settings. Controlled experiments try to improve archaeological interpretations by isolating different physical or chemical factors for a better understanding of which and how different variables affect final results. Further, controlled experiments are designed to improve the identification, measurement, and analysis of all the involved variables and. This session focuses on state-of-the-art research using controlled experiments in both lithic technological (production-related) and functional (use-related) studies. The session’s primary aim is to explore different methodological protocols and standards as well as to address research questions aimed at interpreting the archaeological record. A secondary aim is to create awareness of controlled experiments as a valid and important tool in archaeological methodology.

[41] Symposium · BATTLEFIELD ARCHAEOLOGY: PAST, PRESENT, AND FUTURE
Battle represents the climax of political conflict culminating in a loss of life, often on a large scale. Archaeologically, battle is manifest in the rapid deposition of an assemblage of materials and features as well as buried and unburied remains of victims. The social and political consequences of battle often extend far beyond the episode of fighting. Battle can dramatically reshape political boundaries as well political, social, demographic, and economic organization. This symposium focuses on the changing methods, practices, and motivations for the study of battlefields. New technologies, political agendas, historical repercussions, and moral responsibilities to those who died and their surviving families all shape the nature of battlefield studies. Our goal here is to present the latest work within the framing archaeological theory of how we study battlefields, why we do it, and the ramifications of what is learned from battlefield sites. This symposium is limited neither by spatial or temporal parameters. The papers, however, do more than present archaeological contexts; they contextualize the study of battlefields within the science of archaeology and the changing mores of humanity.

[42] General Session · GLOBAL DEVELOPMENTS IN LITHIC ANALYSIS I

[43] General Session · PUBLIC ARCHAEOLOGY I

[45] General Session · ARCHAEOLOGY IN SOUTH AMERICA I

[46] Poster Session · NORTH AMERICA: PACIFIC NORTHWEST II

[47] Poster Session · TECHNOLOGY, SUBSISTENCE, AND SETTLEMENT ON THE PACIFIC NORTHWEST COAST

[48] Poster Session · ARCHAEOLOGY OF STRANDED, INTERTIDAL, AND SUBMERGED SHORELINES ON THE NORTHWEST COAST OF NORTH AMERICA II

[49] Poster Session · ARCHAEOLOGY OF STRANDED, INTERTIDAL, AND SUBMERGED SHORELINES ON THE NORTHWEST COAST OF NORTH AMERICA (SPONSORED BY HAKAI INSTITUTE)
Coastal Archaeology in Northwestern North America is offering an expanding range of insights into the late Pleistocene peopling of postglacial environments and the purposeful transformation of the intertidal zone during the late Holocene to enhance and manage shellfish and fish populations. Attentiveness to relative sea level change and employing interdisciplinary tools and methods is a key driver enabling both of these research trajectories. This poster session invites emerging research contributions on this theme from along the Northwest Coast, including the Central Coast and the Discovery Islands in British Columbia where the Hakai Institute has launched a long-term archaeological research program. This poster session aims to provide an enjoyable forum for this convergent research on the coastal margin.

[50] Poster Session · COMPLEX FISHER-FORAGERS OF THE INTERIOR PACIFIC NORTHWEST: THE HOUSEPIT 54 PROJECT AT BRIDGE RIVER, BRITISH COLUMBIA
The Bridge River site is a complex fisher-forager village most intensively occupied between 1,000 and 2,000 years ago. Previous research suggests that it grew to maximum size of at least 30 co-occupied housepits with a population estimated to be 800–1,000 persons by ca. 1250–1300 cal. BP. After this time the village declined in size and was eventually abandoned for several hundred years. During the centuries immediately prior to abandonment, the village was reorganized spatially and developed evidence for inter-household inequality. The Housepit 54 project at Bridge River was developed to gain an understanding of household history during the period of rapid village growth and decline. The final season of excavations in 2016 confirmed a stratigraphic sequence of 17 anthropogenic floors and approximately six periods of house expansion. Interdisciplinary research is focused on examining social and economic factors associated with household history along with a host of tangential interests including breeding and consumption of domesticated dogs. Posters in this symposium explore housepit stratigraphy, dating, cultural inheritance, lithic technological organization, subsistence (zoarchaeology, paleoethnobotany, and isotope studies), canid phylogeny using ancient DNA, geochemical signals in floors and lithic raw materials, spatial distributions, and public interpretation of indigenous cultural heritage.
[51] Poster Session · PALEOARCHAIC SETTLEMENT OF THE SOUTH SALISH SEA DURING THE LATE PLEISTOCENE-HOLOCENE TRANSITION: A VIEW FROM BEAR CREEK (45KI839)

The Bear Creek site (45KI839) in Washington State’s central Puget lowland is among the earliest lithic artifact-bearing, professionally excavated archaeological sites on the Pacific coast between Haida Gwaii and the Santa Barbara Channel. Data recovery excavation in 2013 provided an unprecedented view of Native American settlement in a rapidly changing coastal lowland setting during the Late Pleistocene-Holocene (LPH) transition. The site is an epitome of difficulties inherent in finding deeply buried, intact early components in dynamic depositional environments. Our site formation model is therefore foundational, drawing on geoarchaeological data at the basin- and micro-scales, on paleoenvironmental evidence, and on a comprehensive dating regime. The lithic assemblage includes stemmed and unfluted concave-base projectile points and a variety of bifacial and expedient flake tools sharing affinities most closely with Western Stemmed Tradition assemblages throughout the greater interior Pacific Northwest and Great Basin, and is similar to a string of LPH sites along the coast from Haida Gwaii to South America. The contributions to this site explore individual analytic facets of the investigations at the Bear Creek site, while drawing broader conclusions about this site as a coastal variant of the Western Stemmed Tradition.

[57] Symposium · EARTH OBSERVATION FOR ARCHAEOLOGY IN ARID LANDS

Nowadays, the use of geospatial technologies in archaeology is widespread among archaeologists. Arid lands, characterized by patchy and scarce vegetation, low urbanization, and excellent visibility of archaeological remains, are an ideal scenario for the application of nondestructive, noninvasive, and cost-effective investigations based on remotely sensed data. In this session, we wish to bring together researchers working on world’s arid lands, to share results, issues, and perspectives on Earth Observation for archaeology in hot and cold deserts and semi-deserts. We aim at fostering the debate around remote techniques to the archaeology of arid landscapes, gathering papers addressing multi-proxy approaches for the reconstruction of past human-environment interactions by means of geospatial technologies. No limit is set on the geographic or chronological contexts.

[58] Symposium · CASTING EMPIRE: METAL PRODUCTION IN THE EARLY IMPERIAL CHINA

It is widely recognized in the literature that the production of metal objects, including ritual vessels, weapons, coins, and a wide range of daily use tools, played an essential role in the state financial system of ancient China. Nonetheless, many underlying but essential questions related to metal production still have not been fully explored, such as the management of techniques and labor, forms and organization of workers, ways to control the procurement and movement of raw materials, and transportation of final products or resources. This symposium provides a platform for scholars to introduce their latest research addressing issues mentioned above. We expect the communication fostered by the symposium can not only enhance the understanding about the contribution of metal production to the historical formation of Early Chinese Empires but also facilitate the identification of new methodology and theoretical frameworks for studying debitage or remains in archaeological contexts.

[59] General Session · ARCHAEOLOGY IN THE AMERICAN SOUTHWEST II

[60] Symposium · PRECOLUMBIAN TEXTILE TOOLS AND TECHNOLOGIES: CASE STUDIES FROM NORTH AMERICA AND MESOAMERICA

While the importance of textiles and the techniques of pre columbian textile production have been well documented in the Andes, far less research has been conducted on textile tools and technologies in North America and Mesoamerica. With only a few specific exceptions, the climates of these regions are not conducive to preservation, and textiles themselves are therefore only rarely preserved. Several other sources of relatively untapped evidence on textile production exist, however, in other archaeologically recovered material culture such as implements used for creating textiles, including spindle whorls, net gauges, needles, and weaving awls; objects used with or associated with textiles, such as fishing net weights and floats; and even raw materials such as cultivated or collected fibers and pigments. This session explores how analysis of these artifacts carries great potential for insights into textile techniques and technologies, as well as into the practical and symbolic use of textiles in these societies.

[61] Symposium · MAKING FAUNA MATTER IN ARCHAIC PERIOD RESEARCH: EXPLORING ADAPTATION, POPULATION GROWTH, AND CULTURAL PRACTICE THROUGH THE DIGITAL INTEGRATION OF EASTERN ARCHAIC FAUNAL DATASETS

Although recovery and identification of animal remains from Eastern Archaic sites has been standard procedure for decades, zoarchaeologists usually have not been at the forefront of archaeological debate about Archaic period variability and change. Even though they are commonly examined at the site and local level, faunal data have been critically evaluated in macro-assessments of what happened during the Archaic in only a few instances. Fortunately the development of digital repositories such as the Digital
Archaeological Record (IDAR) means that it is now possible to incorporate faunal evidence into archaeological research more directly. Preservation and integration of more than 50 significant faunal databases in IDAR by the Eastern Archaic Faunal Working Group (EAFWG) has facilitated the exploration of possible causes for variability and change in the use of aquatic resources by Archaic peoples within and across the subregions of the interior North American Eastern Woodlands. The methodological approaches of the EAFWG and the integrative tools available in IDAR have made it possible to closely examine faunal data at multiple scales. Ultimately the work of the EAFWG is leading to new perspectives on the roles of ecological, demographic, and cultural factors in the choices of Archaic period populations.

[62] General Session · ARCHAEOLOGY IN SOUTH AMERICA II

[63] Forum · REPATRIATION 101
The 2016 SAA Survey on Repatriation revealed that the level of experience that someone has with repatriation affects their opinion of its impact on archaeology. Many respondents who have actively worked in repatriation view the process as successful, or as having benefits for the profession. This forum will share examples of repatriation work and allow SAA members to hear firsthand accounts of repatriations and learn about the process and procedures. It is hoped that this will clarify the issues involved for those archaeologists who have previously only viewed this work from afar. The participants have conducted repatriations and work in museums, universities, and for tribes. Topics to be discussed will include the documentation of human remains, the challenges of multiple tribe repatriations, the involvement of non-federally recognized tribes, and processes that are distinct to universities and to museums. Audience questions about the details of repatriation will be greatly welcomed.

[64] Forum · AFRO-LATIN AMERICAN ARCHAEOLOGY
This forum will present and debate a rapidly growing focus of study in archaeology: the roles, material lives, and lived experiences of peoples of African descent in Latin America and the Caribbean. During the long history of the African slave trade, over 90 percent of the Africans forcibly imported into the Americas went to Latin America and the Caribbean. Archaeology of African and African American contexts in the United States is now a well-established realm of inquiry that has given us an unparalleled view into the unwritten history of enslaved and free daily lives; the impacts of African presence in Latin America were just as profound and started even earlier. In fact, the events and processes related to and produced by Afro-Latin Americans-cultural forms, community practices, and pivotal agents—were crucial to the making of Latin America and continue to be a vital element informing Latin American life today. A focus on Afro-Latin American archaeology opens up dialogues about colonialism, gender, race, labor, and systems of power and inequality and offers the possibility to transcend boundaries in archaeological practice and knowledge inhibited by colonial jurisdictions and contemporary nation-states.

[65] Forum · PERTURBING THE PEACE: A TRIBUTE TO JOAN GERO
Joan Gero (1944–2016) was an independent thinker, a purveyor of creative ideas, and a pioneer in engendering archaeology. Over the course of several decades, her thoughtful and provocative contributions opened new vistas onto the way archaeological knowledge is constructed, the workings of gender within the field, and the Andean Formative period. In her final work, entitled Yutopian: Archaeology, Ambiguity, and the Production of Knowledge in Northwest Argentina, she argued strongly for the importance of situating knowledge production, honoring the ambiguity of the archaeological record, and resisting the tendency to erase “disobedient data.” This symposium brings together friends, colleagues, and intellectual heirs to celebrate her contributions to the discipline as well as her legacy in terms of moving beyond binary thinking and “unflattening” the past.

[66] Forum · METADATA AND DIGITAL MANAGEMENT IN ARCHAEOLOGY TODAY
The increased availability of digital technologies has revolutionized the way we record archaeological information. We can take thousands of photos of a site or artifact, have each photo linked to a specific location, and record a multitude of other variables quickly and easily. However, this exponential increase in the creation of digital information about archaeological sites, from new data collection and the digitization of legacy materials, has not resulted in a corresponding increase in the discussion of data preservation and management. Digital asset management and metadata have yet to be priorities for many archaeological projects. This often causes archaeologists to spend hours outside of the field dealing with information management issues because adequate planning and guidelines have yet to be employed consistently. While these issues are not new, the increasing call for open science and accessibility pushes archaeologists to organize their digital information into accessible formats with appropriate metadata to describe that information. These needs point to the importance of integrating digital information management and metadata into archaeological project planning as early as possible. This forum is interested in discussing metadata and digital management in archaeology today by exploring current practices and encouraging standards across the different sectors of archaeology.

[67] Lightning Rounds · THE QUESTION OF C-SHAPED STRUCTURES ACROSS THE MAYA LOWLANDS
This session will focus on the topic of “C-shaped structures” and related architectural forms across the Maya lowlands, including “open-fronted structures” and “bench-type buildings.” Many more C-shaped structures have been identified since their establishment as important horizon markers for the Terminal Classic period more than twenty years ago. C-shaped structures and related architectural forms from northern Maya lowland sites will be considered alongside those from the southern Petén and Petén Lakes regions, as well as western and northern Belize. By bringing together scholars who have investigated these structures over the last few decades, we will more thoroughly compare and contrast these architectural forms that appear at the end of the Classic period and their associated archaeological contexts. Through these discussions we hope to achieve a clearer understanding of formal variation, potential functions, and what these types of structures represent within the larger setting of the Classic to Postclassic transition.
Moving beyond established archaeological narratives of the human uses of caves, we will explore some of the diverse political tensions surrounding social engagements with these spaces, particularly from an historical perspective, drawing on case studies from around the world and from a variety of disciplines. Examples of issues we seek to discuss include: power relations inherent in religious rituals/secular activities performed in and around caves; cave deities/forces sometimes regarded as threatening the order of the outside world, and therefore often actively appeased, controlled, destroyed or evicted; different religious/political groups fighting over control of sacred caves; tensions over the maintenance of secrecy about the locations of special caves; conflicts between local people and outsiders over the occupation and use of important natural and cultural heritage caves; competition between cave owners or environmental groups over their commercial exploitation; tensions between the development of tourist show caves and the protection of caves and karst areas from environmental pollution and other damage; tensions between looters and archaeologists over archaeological deposits in caves; tensions over legislation enacted to protect caves; tensions over whether or not certain caves should be designated as national monuments; and tensions between different artistic and scientific conventions in representing caves.

Funding for archaeological research from governmental and philanthropic sources is becoming scarcer. Philanthropy is becoming results driven, moving away from basic research and increasingly into short-term projects. At the same time, costs for archaeological research are increasing, reflecting upward shifts in living costs at emerging economies and costs of analytical research. This session will address three questions through papers from established funders and innovators pursuing alternative funding models. First, what are the drivers of this new environment and how will impact-oriented philanthropy affect funding for archaeology? Second, how are established funders responding to these trends and how do they see the future of funding for research? Finally, does the experience so far with alternative funding approaches suggest that they are able to replace sources in decline?

In this session, scholars present new data on the Copan Valley, and other closely-linked sites, in the latter half of the Late Classic period, and during the Postclassic period. The most important ruler of this era was Ruler 16, Yax Pasaj Chan Yopaat, who governed for 47 years. Following his death, only one unfinished monument was dedicated, Altar L, which features Ukit Took’, the 17th Ruler. Debates exist as to the potential causes of the cessation of the construction of monumental architecture at Copan and the large demographic drop that occurs in the ninth century CE. Scholars have questioned whether Copan was completely abandoned and if so, when as well as investigated to what degree the hinterlands were or weren’t abandoned. New work on ceramics, lithics, the environment, and recent excavations will add to the ongoing conversation concerning Copan’s ancient and more recent past. Rather than review previous hypotheses, researchers will present new data concerning Copan. The Postclassic history of the valley, in particular, has benefited in the last decade from the excavation of post-collapse occupations such as at the site of Rastrojon and around the center of Rio Amarrillo.

Academic interest in the Chinese Bronze Age has tended to focus on larger scale social processes, such as state formation, urbanization, and technological change. This symposium seeks to broaden the understanding of the period by exploring the smaller scale processes that people engaged with in the daily lives. By covering Bronze Age lifeways, we hope to highlight the significance of bottom-up processes and their recursive relationship with the larger social transformations occurring at this time. This symposium will introduce recent archaeological discoveries relating to daily lived experience in Bronze Age China, covering topics such as houses and household activity, craft production, daily ritual practice, cooking, and other aspects of quotidian life.

Excavations at the Neolithic Anatolian tell of Çatalhöyük have spanned more than two decades and comprised multinational teams of researchers, students, staff, and volunteers. The overarching aims of the project include a commitment to reflexive archaeological practice and to situate the site within its environmental, economic, and social context. These aims have remained largely unchanged, though many research questions, interpretations, practices, and technologies have transformed. This third and final phase of the Çatalhöyük Research Project (ÇRP) has focused on the multi-scalar synthesis of data collected from various specialist labs, as well as the archiving of the vast corpus of collected data. With the long-standing excavations coming to a close, we consider the current state of research and methodologies conducted at the site within the context of the changes and continuities that have occurred throughout the project’s life span. In particular, we highlight the unique set of challenges and opportunities that arise from working with large amounts of legacy data. Topics that may be explored include: challenges and opportunities inherent in working with large datasets, legacy data, and the nature of and potential for collaborative work.

The notion of intersectionality—conceiving identity categories such as race, age, class, and gender as covalent and entangled—is neither new nor new to archaeology. Archaeologists have long been paying simultaneous attention to multiple vectors of identity. Yet intersectionality’s agenda seems radical, even as it becomes mainstreamed within scholarly and popular contemplations of power. Within archaeology, intersectionality joins a host of postmodern approaches to categorical plurality that treat structural identity categories as fluid and multivalent. More established approaches, such as hybridity, postcoloniality, feminism, and critical theory, are compelling but have their own limitations. Does intersectionality offer something different? Can archaeology offer anything to the study of intersectionality? Is any archaeology of violence, privilege, and embodied identity intersectional, regardless
of context or intent? Or does intersectionality demand a politically disruptive agenda? Is it even appropriate to apply this framework outside of the black/feminist/capitalist contexts in which it originated? With these questions in mind, session papers will take a critical, experimental approach to intersectionality within a variety of archaeological contexts.

[75] Symposium · ARCHAEOLOGICAL MICROHISTORY AT A PLANNED COLONIAL TOWN IN HIGHLAND PERU
A generation after the Spanish invasion of the Inka Empire, the indigenous communities of the Viceroyalty of Peru were subjected to one of the largest mass resettlement programs by a colonial power: the Reducción General de Indios (General Resettlement of Indians). Over a million native people were resettled to reducción towns to facilitate religious indoctrination and tribute collection, and more broadly, to colonize the deepest recesses of everyday practice to produce newly “civilized” communities. How such colonialist global schemes actually manifested in disparate contexts in the Andean landscape, however, is only beginning to be explored archaeologically. This session presents the largest scale excavations in a highland reducción to date. Situated in the exceptionally well-preserved reducción of Santa Cruz de Tuti (a.k.a. Espinar de Tuti) in the Colca Valley, the Proyecto Arqueológico Tuti Antiguo (PATA) excavated in varied domestic and ritual spaces in 2016, including elite indigenous domestic compounds, the sacristy and rectory of the main parish, and a chapel. Our results compare the contexts of domestic and liturgical practices of indigenous households and the clergy, and trace out threads of continuity and change through the colonial and early republican eras.

[76] Symposium · WHAT TO DO WITH “MEGASITES” IN PREHISTORY? FURTHER EXPLORING THE “MEGASITE” CONUNDRUM
Periodically in the prehistory of human settlement, very large sites have appeared that challenge our assumptions about settlement categories. Such sites, including Chaco Canyon, the Trypillia megasites, Bigo, Taosi, and Co Loa, are often characterized as urban, proto-urban, pre-urban, or not urban. However, even when making allowances for regional variation in urban form, these sites are anomalous. Roland Fletcher has argued that they might usefully be considered as examples of a unique trajectory of growth toward extensive dispersed settlement forms, complementary to but different from the trajectory of low-density agrarian urbanism and the recent trajectory toward dispersed industrial urbanism. A session at the SAA conference in 2013 explored the characteristics of some salient examples of these settlements, including the European Iron Age Oppida, Cahokia, and Great Zimbabwe. This session will include additional regions and time periods, particularly in Africa, South America, the southwest USA, and Asia and extend the discussion of how to theorize them. A consideration of these sites as comparable phenomena has the potential to transform our models of settlement growth, give new significance to regional culture histories, and perhaps have implications for our urban future.

[77] Symposium · HISTORICAL ECOLOGY FOR APPLIED ARCHAEOLOGY: CLIMATE CHANGE, RESOURCE MANAGEMENT, AND GOVERNANCE
Historical ecology is a research program concerned with the interactions of people and environment through time and the consequences of those relationships on the formation of contemporary and ancient landscapes, habitats, and culture. Archaeology has developed theoretical and methodological tools for contributing to historical ecological research and constitutes a major part of this multidisciplinary effort. Through its applied lens, historical ecology continues to grow as a major field of inquiry dealing with questions around climate change, environmental conservation, Indigenous governance and autonomy, and resource management systems. This session explores how archaeologists are using the historical ecology research program to guide their research design, praxis, and even ontologies. Such research will highlight current and on-going archaeological contributions to climate change research, and ecological/heritage management and conservation that is socially just.

[78] Symposium · ADVANCES IN ARCHAEOLOGICAL OF PREHISTORIC AND EARLY CHINA
The last decade has witnessed a dramatic progress in development of research on archaeological sciences in China. Recent achievement in this area has resulted in some interpretations on new materials of prehistoric and early historic China that would be of interest to international communities. Papers in this symposium will present ongoing projects that address new methods, results, and perspectives. Papers have striven to integrate analyses into broader interpretations of meaning of the origin and evolution of human and technology, transition of culture, origins of agriculture, rise of early state, and paleo-environmental reconstruction and so forth from approaches of archaeological sciences (e.g., archaeobotany, zooarchaeology, stable isotope analysis, use-wear and residue analysis, material analysis), ethnoarchaeology, and anthropology.

[79] Symposium · TOOLSTONE PAPERS IN HONOR OF THE CAREERS OF CHARLOTTE BECK AND GEORGE T. JONES
This session honors the careers of Charlotte Beck and George T. Jones and the important contributions they have made to lithic studies. The session combines papers by former students and colleagues and a discussion of their careers to address Beck and Jones’s impact on lithic analysis, particularly the study of lithic procurement, mobility patterns, geochemistry, reduction sequences, and technological organizational and evolutionary approaches to archaeology. While Beck and Jones’s work predominately focused on the Great Basin, their influence has reached beyond this geographic area, due to the transferable nature and broad applicability of their approaches to archaeology. They have had broad methodological and theoretical impacts on the field of archaeology, which session participants will address through discussions of research in a variety of geographic regions, temporal contexts, and to address a wide variety of thematic issues. These papers highlight the important contributions Beck and Jones have made to archaeology throughout their careers.

[80] Symposium · NIGHT AND DARKNESS IN PRECOLUMBIAN MEXICO AND CENTRAL AMERICA
As night rose in Mexico and Central America, another realm emerged to replace the world of daylight and warmth. Temperatures dropped as the sun set, crepuscular animals appeared, selenotropic plants delighted in the moonlight, and humans engaged in a variety of nocturnal activities that differed significantly from those conducted during daylight hours. Darkness is one aspect of the night that is not exclusive to it and lends itself to analysis as well. Using similar theories for studying the day, practice theory, nighttime household archaeology, phenomenology, and adaptationist approaches all set the stage for enlivening the nightscape and
darkness. Variables such as age, gender, class, ethnicity, and occupation, among others, are interwoven and constitute integral aspects of reconstructing the night and illuminating darkness since individuals within society experience culture from their own unique viewpoints. The four-field approach presents an advantage for exploring the depths of darkness, whether at night or otherwise, as ethnography, linguistics, and biological anthropology contribute to a well-rounded archaeology of the night. By approaching the study of ancient cultures from a dark perspective, we can learn a great deal more about how ancient humans flourished and coped, for they lived in light as well as darkness.

**[81] Symposium · MOMENTS IN TIME: RE-CREATING HISTORY WITH THE BAYESIAN APPROACH**

This session brings together papers that discuss how archaeologists can use the Bayesian approach to create histories approximating lived experiences on multiple scales. Over the past five years there have been many studies that used Bayesian modeling to revise aspects of ancient European history. These projects have generally produced chronologies of higher accuracy, transparency, and reproducibility than those created from informal interpretation. This work has been referred to as the third radiocarbon revolution, partially because it has required European archaeologists to completely rethink long-standing culture-historic chronologies and devise new narratives for interpreting the past. A theme of the session is how chronological reexaminations with Bayesian modeling interface with archaeological theory. In many cases the Bayesian approach has involved the quantification of previously unrealized temporal phenomena and this session will address how our theoretical approaches in archaeology might change due to powerful temporal analyses. Papers in this session will: 1) review how Bayesian chronological modeling has begun to challenge understandings of important topics, 2) discuss specifically how Bayesian modeling has revised historical narratives, and/or 3) problematize long-standing chronologies and discuss plans for their revision.

**[82] Symposium · IN THE LAND OF THE SKY: RECENT INTERDISCIPLINARY ARCHAEOLOGICAL RESEARCH IN THE LOWER RIO VERDE VALLEY, OAXACA**

This session presents results of the last decade of interdisciplinary archaeological research in the lower Rio Verde Valley on the Pacific coast of Oaxaca, Mexico. Archaeological research during this period has focused on the Formative period, although ongoing settlement pattern studies, paleoecological research, and human dietary studies have implications for the entire prehispanic sequence. Major research problems that are discussed include the origins of agriculture and sedentism during the initial Early Formative period; the relationship between religion and politics at the end of the Formative; urbanization and political centralization; the aftermath of political collapse; and the impact of Formative period environmental change on settlement, land use, and diet. Data presented in the session are the result of large-scale excavations at the Early Formative period site of La Consentida, the Terminal Formative urban center of Rio Viejo, the Terminal Formative outlying sites of Cerro de la Virgen and Loma Don Genaro, and the Early Classic period site of Charco Redondo. Papers also present paleoecological research based on sediment cores extracted from ponds and estuaries, isotopic studies of human and animal bone, geoarchaeological research on soil fertility, regional full-coverage survey, archaeozoology, and studies of artifacts from the region.

**[83] Symposium · POLITIES, HINTERLAND COMMUNITIES, AND EVERYTHING IN BETWEEN: TWENTY-FIVE YEARS OF ARCHAEOLOGICAL RESEARCH IN NORTHWEST BELIZE**

This session synthesizes 25 years of archaeological investigations taking place in the Rio Bravo Conservation and Management Area (RBCMA) of northwest Belize, a region that was deeply transformed by the life practices of the Maya over a period of nearly 2,000 years. From small beginnings in 1992, the Programme for Belize Archaeological Project (PfBAP) has since grown to encompass various research efforts, fostering cooperation among archaeologists, geographers, and environmental scientists. As a result, an extensive body of data concerning the character of many of the region’s recorded sites has been produced, shedding light onto the lives of the ancient Maya that inhabited this corner of Mesoamerica from the Preclassic (1000 BCE–250 CE) to the Terminal Classic (850–950 CE) periods. This session builds on the regional focus to explore the interrelationships between the varying communities from various theoretical positions as supported by empirical data. Sites discussed in this session include the large Maya sites of La Milpa, Dos Hombres, and Maax Na. Mid-level sites of Say Ka and Wari Camp are also discussed, forming a bridge to the numerous smaller settlements that extend across the landscape such as Medicinal Trail, Hun Tun, and La Milpa North.

**[84] Symposium · REGIONAL TO INTERNATIONAL COLLABORATIONS IN AMERICAN ARCHAEOLOGY: THE LEGACY OF SUZANNE FISH AND PAUL FISH**

During the course of five decades, Paul Fish and Suzanne Fish have instigated and nurtured a series of innovative archaeological research and educational partnerships with their numerous colleagues and students in the Americas. These collaborations have established highly productive linkages among groups and individuals from a diverse range of institutions including universities, national and international government agencies, nonprofit research foundations, and other stakeholders. Consistent and crosscutting themes of their research collaborations include (but are not limited to) traditional agriculture and water management, social organization and craft economies, and coastal foraging adaptations. Mentoring students and engaging in community outreach are also central to the initiatives that Suzanne Fish and Paul Fish have developed and supported during their professional careers. These activities include numerous archaeological field schools as well as laboratory training programs at the Arizona State Museum and the School of Anthropology at the University of Arizona. Their former students are now practicing archaeology throughout the Americas and beyond. This session features presentations by a small sample of their many colleagues in the Greater Southwest, Mesoamerica, and South America.

**[85] Symposium · RETHINKING METHODS OF FAUNAL ANALYSIS**

Much progress has been made in recent years with respect to the analysis of faunal remains. Advances include improved protocols for the study of seasonality, the production of new control data on carnivore feeding behavior, as well as efforts focused on a better understanding of the process of identification and quantification of faunal specimens. However, many questions remain open or require additional research. For instance, how robust are our faunal identifications? Are NISP and MNE replicable and accurate measures of abundance? How can we explain variation in counts of cutmarks or in the identification of taphonomic agents? Do
archaeozoologists produce accurate interpretations of seasonality patterns? This symposium will address these and other methodological problems that are central to the analysis of faunal remains.

[86] Poster Session · ADVANCES IN BIOARCHEOLOGY AND ARCHAEOLOGICAL SCIENCE

[87] Poster Session · NEW GEOARCHEOLOGICAL AND GEOPHYSICAL RESEARCH

[88] Poster Session · OBSIDIAN SOURCING, ANALYSIS, AND IMAGING

[89] Poster Session · INTERPRETING LITHIC ASSEMBLAGES

[90] Poster Session · ARCHAEOLOGY IN EUROPE I

[91] Poster Session · ANALYTICAL METHODS FOR LITHIC TECHNOLOGY

[92] General Session · BIOARCHEOLOGY AND GENETICS

[93] Forum · A HISTORY OF THE CARIBBEAN IN 100 OBJECTS
This forum stars objects from the Caribbean with a story to tell. Fifteen minutes of interview-style discussion between presenters, session moderators, and the audience will focus on a single object from the Caribbean that crosses past and present, its appearance, meaning, production, contexts, overarching historical connections, and relevance for contemporary society. From the humdrum and overlooked, to the extraordinary and exhibited, these objects of conversation are tied to stories about a place, community, practice, or moment that reveal the rich history of the cultures and societies of the Caribbean from particular and personal perspectives. This forum will be recorded and later launched/broadcast as one or more episodes of the podcast series A History of the Caribbean in 100 Objects as told through objects from the earliest period to modern times. For more information see http://www.shoresoftime.com/podcast/.

[94] Symposium · ORIGIN AND DEVELOPMENT OF THE PRECOLUMBIAN CITY OF TAMTOC, IN THE HUASTECA POTOSINA, MEXICO: RECENT INVESTIGATIONS
Tamtoc is one of the most important settlements in northeastern Mexico, wherefore it is essential to address the phenomenon of the urban society with an interdisciplinary approach. The aim of this symposium is to characterize the constituents proper of the historical and cultural development of this urban society that managed to develop one of the most distinctive settlements in the so-called Huasteca region during prehispanic times. The contributors are going to present the results of a variety of recent investigations intended to promote the dialogue and increase the awareness of the issues discussed here.

[95] Symposium · EXPLORING PREHISTORIC PERCEPTIONS OF “NATURE”: CAN WE GO BEYOND ECONOMIC HUMAN-ENVIRONMENT INTERACTIONS?
Archaeology has witnessed a theoretical fluorescence of “ecological” approaches (i.e., HBE, Niche Construction, Historical Ecology) resulting in human-environment interactions as a common research theme. Western culture traditionally makes a clear distinction between nature and culture, but this is not typical of worldviews among preindustrial societies. Past perceptions of human relationships with nature are essential for understanding the impact prehistoric societies had on their environments. Here we aim to push theoretical boundaries, to ask how we can understand prehistoric perceptions of “nature.” Using varied regions and datasets, can we move beyond the more common essential economic discussions and probe our evidence to gain meaningful insights regarding how people in the past understood their place in “nature.” While prehistoric art is often employed toward this question, ecological datasets are usually not. But, could the materials which made the dwellings, the resources that formed the basis of foodways, and the ecological “footprint” of past societies also provide similar insights? It is with this perspective in mind that we wish to explore human perceptions of nature through interdisciplinary studies. This collaboration could be key to interpreting our ecological and archaeological datasets toward a greater understanding of human behavior.

[96] Symposium · PROTEINS IN PLAY: THE APPLICATION OF ANCIENT PROTEINS TO THE STUDY OF DIET, DISEASE, CULTURE, AND EVOLUTION
The last few years have seen a growing interest in the application of protein analysis to archaeological materials, analogous to the application of DNA sequencing. This session will highlight the various contributions the study of ancient proteins can make to our understanding of the archaeological past. Despite the relative infancy of the field, we are currently witnessing a diversification in the types of tissues analyzed, time periods sampled, and questions asked. Drawing on this diverse array of possibilities, this session aims to provide a platform to discuss methodological developments and trends, novel applications, and future directions.

[97] Symposium · ASSESSMENT IN ARCHAEOLOGY EDUCATION: PROJECT ARCHAEOLOGY RESEARCH
Project Archaeology is well-known around the country for its inquiry-based archaeology curricula. We reach an estimated 300,000 students annually with our curricular materials. While these numbers are great, it is also important to know if students are understanding the materials and learning the lessons we teach. If students have been taught the curriculum, but do not understand
the importance of stewardship or how to interpret evidence to build content, our materials will be useless; if the materials do not meet the needs of educators, they will soon be outdated. Including descendant communities in curriculum development, assessing the needs of teachers, and monitoring results of consultation to maintain long-term relationships are also important areas of research for archaeology educators. To this end, Project Archaeology national staff, state program coordinators, and master teachers have participated in several research projects to assess student learning and the efficacy of professional development for educators.

[98] Symposium · LOST NARRATIVES: CURRENT HISTORICAL ARCHAEOLOGY IN SOUTHERN CALIFORNIA
One of the most powerful roles of historical archaeology in the modern era is the telling of histories that have been overlooked. These “lost narratives” represent society as a far more complex entity than that encoded in national/regional ideology. This is particularly true in southern California where mainstream perspectives on history are distinctively simplistic. Until relatively recently, historical archaeology in the region was also comparatively traditional, focused on colonial-era missions or narrow slices of historic contexts exposed by modern construction. Recent projects, however, delve more deeply into the complexity of southern California, emphasizing questions of memory, consumption, identity, conflict, political economy, and the sheer intricacy of the communities that have coexisted in the region over time. Papers in this session represent time periods from the late eighteenth century through the 1940s. Documentary analysis combines with diverse archaeological methodology to maximize new interpretive opportunities and creative applications of theory. Engagement with descendant communities and the use of legacy collections enrich these projects and highlight fruitful directions for future scholarship.

[99] Symposium · FROM FORAGERS TO FRONTIERS: RECENT RESEARCH ON THE ARCHAEOLOGY OF THE ORDOS REGION, CHINA
A recent increase in archaeological fieldwork in the Ordos Region, China combined with new methodological and theoretical frameworks has led to new understandings of previous assumptions about the development of life in this understudied region. Occupying a vast territory covering the areas of southwestern Inner Mongolia, Ningxia, and Shaanxi Province, the Ordos Region plays a very important role in forming a better understanding of Chinese prehistory. This session includes papers that span from the Upper Paleolithic period to the Han Dynasty. The goals of the present session are to synthesize and advance research on understanding environmental change and human response, movement of domesticated plants and animals in prehistory, cultural interaction and entanglement with Central Asia, developments in metallurgy and jade, and the position of this region as a frontier in prehistory.

[106] General Session · USING ETHNOGRAPHIC AND ETHNOHISTORIC SOURCES IN ARCHAEOLOGY

[107] General Session · THE ARCHAEOLOGY OF CONFLICT IN THE HISTORIC ERA NORTH AMERICA

[108] Forum · CARING FOR HOMELANDS, PART 1: TRIBAL HISTORIC PRESERVATION IN THE UNITED STATES
(SPONSORED BY INDIGENOUS POPULATIONS INTEREST GROUP; COMMITTEE ON NATIVE AMERICAN RELATIONS)
Tribal Historic Preservation Offices are charged with the responsibility of preserving, maintaining, and revitalizing tribal cultural resources for future generations. In addition to these programs, numerous other federal, state, and non-recognized tribal communities operate similarly oriented cultural resources departments. This forum brings together Tribal Historic Preservation and Cultural Resource Managers from across the United States to discuss the current state and future trajectory of tribal resource management. This forum is part of an ongoing attempt to highlight the unique issues that tribal communities encounter when attempting to care for cultural resources that extend well beyond the tangible remains associated with the archaeological record. Panelists will address how their offices and communities define tribal historic preservation; discuss how they developed their plan for managing tribal cultural resources; and share the strategies they use on the ground to implement these plans. Of particular focus is examining how each program balances the requirements of state and federal heritage preservation regulations with the specific needs and cultural values of the communities whose interests they protect.
In response to recent studies showing a sexual harassment and assault problem in the field sciences, the Women in Archaeology Interest Group sponsored the Forum Addressing Sexual Harassment and Assault in Archaeology at last year’s meeting in Orlando. This provided space for archaeologists from across the discipline to come together and brainstorm ways to create safety in our field. This year’s forum will focus on efforts of the SAA and the SAA community at large to implement action proposed at the forum. Work-in-progress includes a clear statement on sexual harassment and assault from the SAA, as well as the development of education and support programs at all levels of the discipline.

In celebration of 20 years of the Geoarchaeology Interest Group (GIG) in the Society for American Archaeology, we seek to clarify the present and future contributions of geoarchaeology, in terms of practical techniques, analytic and interpretive methods, and theoretical approaches. Whether as its own field or hybridized multidisciplinary endeavor, geoarchaeology has grown over the last decades to encompass a multitude of research themes and operational procedures, but what unifies this diversity under the name of geoarchaeology? Furthermore, what are the current and emerging new challenges for practicing geoarchaeologists as relevant for today’s concerns of sustainable development, values of landscapes as heritage resources, and the place of human societies within a changing environment?

Archaeological science is becoming increasingly complex, and progress in this area is slowed by critical limitation of journal articles lacking the space to communicate new methods in enough detail to allow others to reproduce and reuse new research. One solution to this is to use a programming language such as R to analyze archaeological data, with authors sharing their R code with their publications to communicate our methods. This practice is becoming widespread in many other disciplines, but few archaeologists currently know how to use R or have an opportunity to learn during their training. In this forum we tackle this problem by discussing ubiquitous research methods of immediate relevance to most archaeologists, by using interactive, live-coded demonstrations of R code by archaeologists who program with R. Topics include getting data into R, working with C14 dates, spatial analysis and map-making, conducting simulations, and exploratory data visualizations. Forum participants will be able to participate by following along with the live-coding on their own laptops (current versions of R and RStudio must be installed in advance; both are free), and discussing applications of the methods presented with the discussants.

Archaeological science is becoming increasingly complex, and progress in this area is slowed by critical limitation of journal articles. Join hosts of the archaeology podcast network in a discussion about podcasting as a tool for public outreach. How can podcasts help archaeologists convey information to other professionals and the public in a way that respects the cultures represented but that is also informative and educational? Are podcasts here to stay? Are they an effective tool for public outreach in archaeology?

Osteoarchaeological research in China has traditionally focused on questions of population affinity to investigate the relationships among ancient groups. While such studies have produced valuable information on past populations, one result has been to stress the biological over the bio-cultural interpretation of the human past. The aim of this session is to provide more nuanced explorations of health, disease, and behavior through contextualized bioarchaeological analyses of human skeletal remains from a diverse array of environmental and cultural settings in ancient China. Contributions of this session will address questions within the bio-cultural framework that integrates biological data from human remains with their cultural and ecological contexts. Our goal is to offer new perspectives in the study of human adaptation and life-ways in ancient China.

Faunal remains have become important materials unearthed from archaeological excavations in China. Zooarchaeological data could provide much information of human-animal interactions in the past, such as animal trading and exploitation, utilization, and domestication. New studies on those recovered faunal remains have used a variety of analytical methods such as morphological measurements, pathological examination, age structure profiling, sex ratio reconstruction, isotopic analysis, and DNA research to target many different questions. This session provides a platform to showcase some of these new studies from China and to demonstrate the power of using new methods to examine old bones for the study of human-animal interactive history of the past in China.
[117] Poster Session · HUMAN LIFESTYLE AND ADAPTATION IN PREHISTORIC CHINA
In recent years, human lifestyle and adaptation in prehistory, and the potential role of environmental changes in those processes, have been intensively studied in China. This session aims to present new findings, ideas, and theories in how and why human adaptation shifted in prehistoric China. This panel will clarify the relations between human adaptation and environmental changes across China and provide suggestions on what research is needed in the future. Researches from bioarchaeology, zooarchaeology, archaeobotany, paleoenvironment, and other related perspectives are warmly welcomed.

[118] Symposium · ARCHAEOLOGICAL SURVEYS IN LIGHT OF NEW TECHNOLOGIES
The focus of the session is to reflect on the nature of information that is/can be captured through archaeological survey, and to explore the interpretative challenges and opportunities that survey information offer beyond simply “identifying sites.” We will address these questions in light of the ever increasing adoption of information and computing technology, both in the field and in the lab. Does the adoption of new technology open up new research venues? Are we applying these technologies to resolve old questions perhaps in a more efficient and expeditious manner? Can we identify common trends, and more importantly, gaps in our patterns of use? At which stage of the survey process is technology being used most (e.g., planning, conducting, processing)? How well suited is current technology for the rigors of the field? What aspects of technology (e.g., battery power, processing, connectivity, user interface) are most critical and in what way? To what extent do these, and similar questions, open new interpretative opportunities?

[119] Symposium · ANCIENT MEXICO AND THE LEGACY OF HENRY B. NICHOLSON
Henry B. Nicholson dominated the field of Aztec studies for over four decades leaving behind a vast amount of scholarship. In the decade since his passing, that corpus continues to stand the test of time with many of his works being among the most cited resources in the field. His contributions to ethnohistory, archaeology, and iconography are vast and provide the point of departure for many specialists. It is certainly a legacy worthy of contemplation. This session will unite both junior and senior academics through a series of papers aimed at contemplating just how his legacy continues to impact current research. While this impact has been great on Central Mexican studies in particular, it has also influenced important cultural areas outside the Basin of Mexico including the Gulf Coast and Chichen Itza.

[120] Symposium · THE TULA REGION INTERACTION AND MIGRATION PROJECT (TRIMP): YEAR 1
The tumultuous Epiclassic period in central Mexico has long provided fertile ground for evaluating anthropological, archaeological questions since its original definition over 75 years ago. Recent work in the region has produced new data that are beginning to flesh out and test previously conceived hunches and, in some cases, upending established models of local and regional economic, social, and political relationships and networks. One such project is the Tula Region Interaction and Migration Project (TRIMP), which began its first field season during the summer of 2016. The project combines archaeometric analyses of existing ceramic, lithic, and osteological collections with new excavation at Cerro Magoni, one of the principal political centers of the local Tula region during the centuries preceding the foundation of the Toltec state. Our session reports the results of the TRIMP to date and contextualizes its preliminary inferences within the continuing evolution of ideas concerning central Mexico during the Epiclassic. The papers presented demonstrate the untapped opportunities available in the Tula region in particular, and Epiclassic central Mexico generally, to inform and influence broader anthropological understandings of cross-cultural patterns on multiple scales.

[121] Symposium · MIDDLE PLEISTOCENE SUBSISTENCE IN THE AZRAQ OASIS, JORDAN: PROTEIN RESIDUE AND OTHER PROXIES
Excavations at Shishan Marsh, a former desert oasis in Azraq, northeast Jordan, reveal a unique ecosystem and provide direct family-specific protein residue evidence of hominin adaptations in an increasingly arid environment approximately 250,000 years ago. In this session, we detail the lithic, faunal, paleoenvironmental, and residue data that suggest that Middle Pleistocene hominins were able to subsist in extreme arid environments through a reliance on surprisingly humanlike adaptations.

[122] General Session · TEACHING ARCHAEOLOGY

[123] Symposium · ORIGINS AND TRANSFORMATIONS: THE WESTERN ISLANDS OF THE PACIFIC OCEAN
Research programs focused on the islands of the Western Pacific Ocean are increasingly dedicated to the analysis of postcolonization processes. Models describing the ecological transformation of islands, demographic changes, and the technological innovations developed by settled populations to maintain social connections over vast distances articulate with ever more discrete spatially and temporally sensitive archaeological analyses to provide a framework to interpret these processes. These studies contribute to better resolution of the development of evolutionary trajectories creating favorable conditions for more complex social organization. This symposium highlights recent studies in a number of archipelagos, including the Marianas, Fiji, Tonga, and Samoa.

[124] General Session · PRESERVING HERITAGE SITES

[125] Symposium · CERAMICS AND SOCIETY AMONG THE CLASSIC MAYA CITIES OF THE WESTERN PETÉN
This symposium focuses on the ceramic traditions of the Classic Maya cities of the Western Petén. These cities, virtually unknown a decade ago, possess a common, interconnected history. The sites between Central Lakes region and the Mexican frontier, dwelt in apparent harmony, lacking the militarism of other regions of the Classic Maya world, and sharing many artistic and epigraphic traditions. Most apparent is that they shared many aspects of their disparate ceramic traditions, suggesting a significant level of...
interaction and exchange. Gift exchange, commerce, and artisan interaction developed throughout the Classic period, creating a
shared ceramic tradition. This symposium focuses on these traditions, their differences and their similarities, and the physical
vessels themselves that moved through this region. The evidence suggests a unique set of social and political relations between the
Maya peoples of the region, one geared for mutual cooperation, rather than the military competition of the Maya world around them.
This session will discuss the ceramic record and the social and political implications of this evidence for the cities of El Perú-Waka',
La Corona, Motul de San José, La Florida-Namaan, La Joyanca, and other centers inside and outside this region.

[126] Symposium · INVESTIGATING A TEN-MILLENNIA RECORD OF HUNTER-GATHERER LIFeways IN THE
NORTHEASTERN CHIHUAHUAN DESERT
The Lower Pecos Canyonlands of southwest Texas contains one of the longest and best-preserved records of hunter-gatherer
lifeways in North America. Since 2009, the Ancient Southwest Texas Project (Texas State University) and Shumla Archaeological
Research and Education Center have been conducting intensive multidisciplinary research into understanding aboriginal hunter-
gatherers in this unique area on the northeastern fringe of the Chihuahuan Desert. Focusing on sites and assemblages ranging from
earth ovens and rockshelters to rock art and bedrock features, presentations will highlight research strategies used to investigate
the diverse hunter-gatherer record spanning from Paleoindian to protohistoric times in the rugged canyon lands of the Rio Grande
borderlands. Investigative approaches include rock art, geoaarchaeology, 3D data acquisition, methodology, chronology,
paleoethnobotany, and zooarchaeology.

[127] Symposium · BEYOND DOMESTICATION: INVESTIGATIONS INTO THE HUMAN-CANINE CONNECTION
The interpersonal relationships humans have with domesticated dogs have a great influence on the way in which these animals are
conceptualized in terms of both their value and social standing within a human group. Once domesticated, dogs filled many different
roles within human societies, from beast of burden to food resources to companions. These relationships were likely multifaceted
and may not always be easily discernible in the archaeological record. However, new research questions and investigative

[128] Symposium · MARKETS AND CAPITALISMS IN INDIGENOUS SOCIETIES IN THE COLONIAL AMERICAS
Archaeological studies of colonial encounters in the Americas have increasingly focused on the role of capitalism within European
imperial projects. However, this growing attention on capitalism is vulnerable to endless debates over definitions and transitions,
potentially resulting in interpretations that tell us more about Eurocentric notions of capitalism than the complexities of colonial
economic arrangements. This session asks participants to move beyond trait-based definitions of capitalism in an effort to
understand the actual economic practices that emerged from the friction of local colonial encounters. Specifically, we seek to
unpack the tangled web of economic relationships that characterized colonial societies, refocusing our analysis on the ways in which
indigenous groups perceived, managed, and ultimately captured colonial markets for their own political and economic goals. We
examine the diversity of colonial encounters in the Americas (Spanish, English, Russian, French, etc.) as well as studies of
continuities and disruptions across prehistoric/historic boundaries. By centering indigenous societies, the case studies in this
session move beyond considerations of capitalism as an ideal type, and instead explore the laborers, traders, and consumers
directly responsible for the creation of colonial political economies.

[129] Symposium · PREHISTORIC ECONOMIES IN MIDDLE-RANGE SOCIETIES: PAPERS IN HONOR OF KATHERINE
SPIELMANN
This symposium honors the scholarly contributions of Katherine Spielmann to the field of archaeology. Mirroring Dr. Spielmann’s
research interests, this symposium focuses on prehistoric economies in smaller-scale and middle-range societies, primarily in North
America. Former students examine a variety of topics on this subject, including the processes underlying economic intensification,
the role of feasting and ritual in small-scale economies, and the variety of conditions under which small-scale and middle-range
societies with relatively noncomplex political systems develop complex, specialized economies and systems of exchange. Reflecting
Dr. Spielmann’s interest in human-ecosystem interaction, papers also investigate the long-term ecological changes that resulted
from settlement by relatively sedentary farmers in particular environments. The overarching goal is to highlight both the
interconnectedness of these themes and the positive impact of Dr. Spielmann’s ideas and research on her students and the
discipline as a whole.

[130] Symposium · RECENT ANALYTICAL CONTRIBUTIONS TO CHACOAN ARCHAEOLOGY
This session highlights recent studies about Chaco Canyon archaeology which emphasize new research approaches to long-
standing questions about the social, economic, and organizational features that characterized the period of emergent complexity
associated with the construction of “great houses” between ca. AD 800 and 1200. Contributions especially explore the role of
scientific methods, quantitative analysis, and geospatial techniques in addressing a range of critical explanatory issues.

[131] Symposium · LIDAR IN THE MAYA HEARTLAND: RESULTS OF THE 2016 LIDAR SURVEY IN GUATEMALA’S MAYA
BIOSPHERE RESERVE
During the summer of 2016, the National Center for Airborne Laser Mapping conducted the first phase of an ambitious lidar survey
of over 1,400 km2 of forested areas within the Maya Biosphere Reserve (MBR) of the northern Petén district of Guatemala. The
project, sponsored by Fundación PACUNAM (a Guatemalan nonprofit organization focused on the research and conservation in the
MBR), included areas currently under investigation, including Tikal, El Zotz, Holmul, La Corona, Xultun, San Bartolo, Waka’,
Naachtun, and Uaxactun. These are some of the most important lowland Maya centers that flourished throughout both the Preclassic and Classic periods, many of which have been mapped to various degrees of completeness with traditional field methods. The project also targeted areas where only cursory archaeological research has been conducted, such as between the sites of Xmakabantun and Holmul in the northeast and swaths of the Parque Laguna del Tigre in the west. The participants will present results relevant to not only the detection and interpretation of archaeological and environmental features in each coverage area, but also the methodological issues raised during the various stages of lidar data analysis that might prove useful to future applications of this technology in similar environmental conditions.

[132] General Session · ARCHAEOLOGY OF THE MEDITERRANEAN REGION

[133] Symposium · IDENTITY AND CHANGE: ARCHAEOLOGICAL INTERACTION ACROSS ARCHIPELAGOS, INLAND SEAS, AND OCEANS
This symposium examines the emergence, dynamics and change of island societies, linked together in wider coastal and island worlds. Papers address the archaeological evidence for interactions between different communities over time and explore the nature and significance of interactions that emerge as distinct island identities. The symposium seeks to address the changes that take place in islands over long timescales notably between prehistoric and globalized historical societies, taking examples from the central Mediterranean and regions bordering the Atlantic. In many cases, striking new data from recent fieldwork are brought to bear, including isotopes, trade characterization and environmental data. The symposium has deliberately taken examples from seas with different degrees of closure, and where contrasts between early and later maritime technologies can be compared. A key theme of the symposium is the broader political context of island societies and how island communities respond to changing conditions as measured in environmental impact and local development.

La movilidad humana es un aspecto fundamental que ha caracterizado a las poblaciones de los Andes Centro-Sur a través del tiempo. A pesar de que durante los casi últimos 40 años diferentes modelos han intentado explicar la movilidad y contacto en el área, ciertas preguntas subsisten con respecto a cómo ocurrió, quiénes se movían, de dónde provenían y por qué viajaban. La mayoría de los modelos propuestos han dado énfasis a la economía y rol de las poblaciones tanto de tierras altas como altiplánicas en el control de la movilidad y pisos ecológicos, principalmente a través de caravanas de llamas en periodos tardíos, actuando de forma homogénea en la región andina. Sin embargo, recientes perspectivas plantean patrones de movilidad particulares asociados a los diferentes grupos e historias/memorias locales que habitaron en la costa, valles, pre-cordillera y puna. El objetivo de este simposio es evaluar desde una mirada crítica y constructiva la movilidad en los Andes Centro-Sur considerando y complementando distintas líneas de evidencia que hasta la fecha han arrojado nuevas luces en torno a ésta temática. De esta manera, se plantea re-pensar los patrones de movilidad desde una perspectiva interdisciplinaria y más allá de la racionalidad económica.

[135] Symposium · ANCIENT METALLURGY IN MESOAMERICA: LOCAL EXPRESSION AND INTERREGIONAL CONNECTIONS
Throughout ancient Mesoamerica, numerous metallurgical and metalworking traditions developed during different time periods, and among different cultural groups. These traditions emerged through a range of cultural influences, particularly from the Andean and Central American metalworking regions, and eventually incorporating Spanish metallurgical technologies. These external cultural connections strongly influenced the development of local metalworking, through the introduction of new technologies, and shifting the focus of local traditions toward new goods and raw materials. Local traditions, however, also developed unique trajectories. This was, as a result of local demand for particular goods and styles, probably also due to their position within interregional exchange networks with relation to raw material sources, or large populations of wealthy consumers capable of supporting specialized artisans. The present symposium will focus on the latest decade of research into local metalworking traditions within Mesoamerica, including the use of copper and copper alloys, gold, and silver. Authors will particularly consider local expressions of artisanal styles and technologies, while also examining shared influences between the various traditions. They will also consider these technologies with respect to the relationships between mining and processing sites, with secondary production sites, and distribution networks.

[136] Symposium · RITUAL DURING PERIODS OF DECLINE, COLLAPSE, AND REGENERATION IN ARCHAIC STATES
The notion of state "collapse" has come under scrutiny recently for both modern and archaic states. A range of specific topics about this issue have been debated including what defines collapse? What predicates collapse? Are some types of states more prone to collapse than others? How do decline and collapse manifest in the political, economic, religious, and social realms? Political and economic factors in the collapse of states, both modern and ancient, have often been the focus of discussion, but religion and ritual are prominent in many of the modern examples of societies declining, collapsing, and regenerating. The frequent prominence of religion and ritual in contemporary situations stimulates questions about the ritual expressions of and responses to decline, collapse, and regeneration in earlier states. By examining the role of ritual in a variety of archaic states, this session will explore how the decline in a state’s ability to continue in its current form affected the practices of ritual and in turn how ritual as a culture-forming dynamic affected decline, collapse, and regeneration of the state.

[137] Symposium · MOUNTAIN TOWNS AND CROSSROADS: ARCHAEOLOGY OF THE SIERRA SUR OF OAXACA, MEXICO
The goal of this session is to bring together and share information coming from archaeological research in the Sierra Sur of Oaxaca, Mexico. For over half a century, archaeologists have focused research on the Valley of Oaxaca and the coastal lowlands when reconstructing the complex prehispanic history of Southern Mexico. Often left out of the dominant narrative of ancient Oaxaca, the story of the Sierra Sur is important to consider as it provides a broader context for theories of social complexity, conquest and colonialism, migration, and economics. Emerging narratives developing out of data generated from fieldwork in the Sierra Sur of Oaxaca suggest that we should continue to reevaluate our current narratives, which are based on research primarily from the Valley
of Oaxaca and coastal regions. By bringing together researchers working in the Sierra Sur region, this session will bring attention to this region and enrich our understanding of Southern Mexico as a whole.

[139] Symposium · RECONSTRUCTING INDIGENOUS PRACTICES IN MUSEUM SETTINGS: PERSPECTIVES AND APPROACHES

Museum collections present rich resources for the recovery and reconstruction of indigenous technologies and practices that may have been partially or completely lost in recent centuries. Archaeologists in particular have frequently engaged with museum artifacts in attempts to reconstruct the lifeways, technologies, and histories of indigenous populations. Additionally, anthropologists, curators, conservators, historians, artisans, and craftspeople, all of whom may be members or nonmembers of indigenous communities, have engaged and will continue to engage with the material legacy of indigenous populations in museums. Dialogue among members of these groups is essential to the enrichment and ethical practice of museum research within and beyond the field of archaeology, and we propose this session as an opportunity for the presentation and discussion of methods and techniques of analysis in museum settings; the production, display, and dissemination of knowledge related to past and present indigenous practices in museum settings; the ethical and epistemological concerns that arise with native and non-native engagement with museum collections. The session draws on contributions from specialists in diverse fields and of diverse cultural backgrounds with the aim of furthering common goals in the area of indigenous material-culture studies as well as archaeological engagement with professional and public stakeholders.

[139] Symposium · MANIPULATED BODIES: INVESTIGATING POSTMORTEM INTERACTIONS WITH HUMAN REMAINS

Following death the human body becomes the focus of a diverse range of activities that include, but are not limited to, burial in the earth. The unburied dead include those who receive non-burial forms of funerary treatment and individuals whose remains are intentionally exhumed or unintentional disturbed. Examining the archaeological traces the unburied dead can illuminate the diverse interactions with, and perceptions of, dead bodies and body parts in the past. This session seeks to draw together new research that examines postmortem interactions with the dead including both non-burial modes of treatment and manipulation of human remains. This might involve analysis of human remains from non-burial contexts; studies of funerary treatments of the body that do not culminate with insertion into the ground; or investigation of post-burial activities that result in the exhumation, manipulation, and/or display of human remains aboveground, whether this occurs soon after death or much later. This session aims to highlight potential comparative perspectives across social, cultural and temporal contexts, thereby examining the reasons why, contexts within, and means by which the material body is manipulated after death.

[140] General Session · RECENT PALEOINDIAN STUDIES I

[141] Symposium · A GLOBAL DIALOGUE ON COLLABORATIVE ARCHAEOLOGY

Active collaboration with a wide variety of stakeholders forces practitioners to rethink how and why we do archaeology, indeed even to question what archaeology is and can be. This seminar explores the tenor, breadth, and practicalities emerging from a decade of collaborative practice. Drawing from a wide range of practitioners with different temporal and regional foci, this session takes an international view of collaboration in archaeology. The moderated session presents global collaborative archaeology, both as a challenge to current practice and an impetus for the future. Presenters were asked to grapple with big questions such as:

- How does archaeology change with a focal shift from product to process?
- What ontological and epistemological challenges and promises arise in this work?
- How does collaboration destabilize and invigorate method and theory?
- What are the best ways to train a new generation of practitioners in collaboration?
- What changes to institutional structures will be required for collaborative archaeology to reach its full potential?

[142] General Session · THE ARCHAEOLOGY OF FOODWAYS

[143] Symposium · EVOLUTIONARY ADAPTATIONS AND POPULATION HISTORY OF THE ATACAMA DESERT

The Atacama Desert, despite its extreme aridity, scarce water sources, and hostile climate, has been inhabited by humans since the terminal Pleistocene. Encompassing a range of ecological zones from southern Peru and northern Chile, and extending into the altiplano region of Chile, Bolivia, and Argentina, human and cultural remains from the Atacama Desert provide critical data that enrich our understanding of the initial peopling of South America and events that occurred thereafter. Because of Atacama’s unique ecology, humans who occupied this region faced challenges that differ from other areas of South America. Thus, this symposium encompasses archaeological and biological research focused on evolutionary adaptations and population movement over 10,000 years of human prehistory in the Atacama Desert and the areas surrounding it. The papers in this symposium present new methodological approaches and theoretical interpretations, including analyses of ancient DNA, dental calculus, isotopes, and 3D morphometrics. Our symposium features a team of international and interdisciplinary researchers whose collaborative goal is directed toward new interpretations on biocultural evolution, foodways, health/disease, and social complexity among prehistoric human lifeways in the Atacama Desert and adjacent regions of South America.

[144] Symposium · ARCTIC AND SUBARCTIC COASTS: CURRENT RESEARCH AND MODERN CHALLENGES

The coasts of the Arctic and Subarctic are dynamic ecosystems, posing challenges to the people who have occupied them, live there today, and the archaeologists who conduct research there. Throughout much of the Holocene they were occupied by diverse peoples who had complex relationships with their environment, as do the people who live in these regions today. This session examines current research focusing on those relationships, from processes of colonization and adaptation to the mitigation of modern impacts on heritage resources resulting from a changing global climate. Archaeologists who focus on the Circumpolar North incorporate a wide array of theoretical and methodological approaches; however, all of them realize the broader importance of the
study of northern peoples and the ecosystems of which they are a part. The papers presented in this session are a sampling of the innovative and challenging projects that focus on northern coasts. They represent the current state of Arctic and Subarctic archaeological coastal research and examine its future.

[145] Symposium · RECIENTES APORTACIONES SOBRE EL ESTUDIO DE LA CULTURA MATERIAL DE SANTA CRUZ ATIZAPÁN, UN CENTRO REGIONAL DEL CLÁSICO TARDÍO–EPICLÁSICO EN LA CUENCA DEL ALTO LERMA

El presente simposio, se enfoca en la valoración de la nueva información generada a partir del análisis de materiales arqueológicos recuperados en exploraciones sistemáticas efectuadas en el sitio de Santa Cruz Atizapán, Estado de México. Los trabajos propuestos en el simposio permiten una aproximación al conocimiento de las materias primas locales empleadas para la manufactura de vasijas cerámicas, así como a la identificación del papel que jugó la cerámica Engobe Naranja Grueso en el sitio. Por otra parte, el estudio de las colecciones óseas sirven para entender algunos aspectos de la vida cotidiana de los habitantes del Alto Lerma durante el Clásico tardío y Epiclásico (450–900 d.C.). Se analizan diversos indicadores arqueológicos a partir de metodologías innovadoras que representan una valiosa aportación para las investigaciones arqueológicas.

[146] General Session · AFRICAN ARCHAEOLOGY I

[147] Forum · GRAPPLING WITH COMPLEXITY: A FORUM IN HONOR OF KATHARINA SCHREIBER

This forum in honor of Katharina Schreiber will address several issues regarding the development and expansion of ancient complex societies. The discussants will address three major topics: 1) the origins and development of complexity on the south coast of Peru, 2) Wari imperialism and the mosaic of control throughout the Andean region, and 3) the cross-cultural impact of Schreiber’s work on the study of complex societies in other areas of the globe. The goal is for participants to present certain aspects of their research, reflect on how Schreiber has influenced their scholarship, and generate discussion that will stimulate future research ideas.

[148] Forum · ARCHAEOLOGICAL VOLCANOLOGY

This forum seeks to define the short- and long-term, near- and far-ranging effects of volcanic eruptions on human society throughout history worldwide. Archaeological techniques of data recovery will be considered together with geoscience analyses and sociologically oriented research methodologies. Forum participants circulate papers prior to the SAA meetings; the seminal points in those papers will be presented as discussion points for the forum. The outcome in the first instance is envisioned as a position paper distinguishing this line of research from other disaster archaeologies, noting where analytical techniques differ (e.g., tephrochronology and the use of isochrons) and where shared theories and methodologies are useful. Participants work in various areas of the world where volcanoes have visited extensive damage on populations, but particular attention is also given to far-field consequences. Localized cultural reactions will be examined for “best practice” and avenues will be sought to reach out to both disaster risk reduction research as well as volcanology, and not least to disseminate these insights to policy makers.

[149] Forum · BEYOND DATA MANAGEMENT: A CONVERSATION ABOUT “DIGITAL DATA REALITIES”

In a recent “Introspective Digital Archaeology” blog post, Jeremy Huggett asked frank questions about the feasibility of reusing data that archaeologists archive in digital repositories (see https://introspectivedigitalarchaeology.wordpress.com/2016/06/29/digital-data-realities/). Despite years of investment in high-profile digital archive programs, data still sees little reuse. Huggett asks whether data are still too siloed, with too little linking for effective discovery and reuse. If so, what measures can we take to better capitalize on research data management so that data reuse becomes more commonplace? Forum discussants will consider digital archaeology beyond the current status quo of “data management” to better situate the sharing and reuse of data in archaeological practice. Within this theme, the panel will discuss data stewardship and preservation, new pathways for interpretation and science, the place of “big data” in archaeology, public engagement, transparency, public policy, compliance, and improving digital literacy. How do we envision the future of digital archaeological data and what ethical implications should we consider? Given the realities of funding and the structure of academic institutions, are these visions realistic? If so, what do we need to do to get there? If not, how can we adjust our visions to fit with these digital data realities?

[150] Forum · PROFESSIONALS, AVOCATIONALS, COLLECTORS: RECALIBRATING THE RELATIONSHIP

SAA established the Professional Archaeologists, Avocational Archaeologists, and Responsible Artifact Collectors Relationships Task Force in 2016 to define appropriate relationships among professionals, avocational archaeologists, and responsible artifact collectors in light of SAA’s Principles of Archaeological Ethics and relevant laws. Chaired by Bonnie Pitblado, the task force solicited a wide range of diverse comments and issued a statement in September 2016 along with proposed action items. Despite decades of mutual distrust, much engendered by misconceptions by all parties and amid the predictable criticism, a surprising range of agreement was found in solicited comments and among task force members. Major themes identified inspired action items that emphasize the need for mutual education and outreach, and that suggest an ethical imperative not to shun but to collaborate with responsible collectors. The forum will discuss themes, ranges of views expressed, and action items proposed.

[151] Poster Session · ARCHAEOLOGY IN WESTERN ASIA

[152] Poster Session · AFRICAN ZOOARCHAEOLOGY

[153] Poster Session · EARLY AND MIDDLE STONE AGE ARCHAEOLOGY IN AFRICA
[154] Poster Session · METHODOLOGICAL ADVANCES IN AFRICAN ARCHAEOLOGY

[156] Poster Session · CENTRAL AMERICA AND CARIBBEAN

[157] Symposium · RETHINKING ARCHAEOLOGIES OF PILGRIMAGE

At its core, pilgrimage is a relational phenomenon. Firsthand accounts of these sacred journeys reveal that humans, otherworldly beings, landscapes, objects, memories, and more move and assemble in various ways that often have profound historical effects. Certainly ancient pilgrimages and the convergences they instigated were equally efficacious. Most archaeologists, however, focus on identifying material traces of pilgrimage activities, and attempts to understand the role of pilgrimage in economics, politics, religion, and social life typically result in functional or structural explanations. Simply put, pilgrimage is conceived as a way to maintain social equilibrium or as part of an underlying social blueprint, and its relational underpinnings are unexplored. The primary idea of this symposium is that the relationships a pilgrimage instigates are the source of the journey’s effectual power. Thus, the goal is to focus on how these connections occur and alter the social world. Participants are encouraged to engage with recent theories of phenomenology, animism, relationality, movement, and affect and use multiple lines of evidence to tackle these issues. Overall, the intent is to reinvigorate archaeological studies of pilgrimage using newer social theories.

[158] Symposium · THE LIMITS OF “LANDSCAPE”: ALTERNATIVE ARCHAEOLOGIES OF SPACE

The classical notion of landscape is strongly tied to western thought—and more particularly to northwestern Europe, where it developed during the Middle Ages within a specific context of people’s relationship to the land. It is furthermore closely related to the history of visual representation (including the invention of perspective and cartography), enlightenment science, and Western convictions about human-nature relationships. In this setting, the landscape came to refer to a sense of territoriality, visual perception, and domination over nature (and others). However, we can safely assume that these values did not characterize human living space in the same way or to the same degree in deep history and/or other regions of the world. In accordance with recent trends in archaeological research and interpretation, we are exploring critical reformulations of the landscape concept (e.g., “taskscape,” “maritime landscape,” “soundscape” etc.), as well as alternative notions (such as connectivity, heterotopia, liminality, etc.) that may better fit the spatial and cultural realities of distant societies, both in time and space. The classical landscape concept has its limits from a historical, cultural, and intellectual point of view, and it is an explicit aim of this session to explore these limits and cross boundaries.

[159] Symposium · BEYOND (BETWEEN, WITHIN, THROUGH) THE GRID: THE CONTOURS OF MAPPING AND GIS IN HISTORICAL ARCHAEOLOGY

Geographic Information Systems (GIS) are powerful tools available to archaeologists. This session explores the myriad ways in which GIS not only represents findings, but also generates new data and research questions to answer methodological and theoretical problems in archaeology. As Robb and Pauketat (2013:9) argue, archaeologists have “yet to break the scale barrier,” and the challenge to keep in view both macroscale and the microscale phenomena remains. As part of our discussion of GIS, this session therefore aims to explore how archaeologists consider scale, place, and space in their use of GIS. Further, we are also interested in how archaeologists incorporate time, which has often presented a challenge for archaeologists using GIS, into their analyses. This session is broadly focused on the use of GIS to generate new questions and data. Within this general theme, topics may include novel uses of GIS; postcolonial geography; problems of scale; movement and migration; representations of time and space; embodied mapping; indigenous mapping; and the politics of representation that reemerge with visualization tools.

[160] Symposium · THE PISGAH CULTURE AND MISSISSIPPIAN ADAPTATION ON THE APPALACHIAN PERIPHERY

As recent Mississippian studies have recognized, the processes of integration and adaptation that characterized the expanding Mississippian frontier from A.D. 900 to 1500 was distinctly heterogeneous. The Pisgah culture of the Appalachian Summit in western North Carolina offers a unique opportunity to consider the range of factors that influenced variation in the process of Mississippianization. Pisgah’s unusual mountain environment makes it an unlikely candidate for the maize-based surplus economy so often associated with Mississippian societies, and the relatively late adoption of Mississippian practices within some Pisgah communities begs the question: why did local communities in the Appalachian Summit undergo Mississippianization? This session invites participants to present evidence on various archaeological aspects of Pisgah culture. Specifically, by considering how Pisgah compares to its neighbors in the South Appalachian Mississippian tradition, we aim to understand how cultural interactions and the limitations of the natural environment both shaped the prehistoric landscape and paved the way for subsequent colonial encounters.

[161] Symposium · COMPLEXITY IN SUB-SAHARAN AFRICA: ARCHAEOLOGICAL AND ETHNOARCHAEOLOGICAL APPROACHES TO LANDSCAPE, CRAFT, AND TRADE IN THE PAST 3,000 YEARS

(SPONSORED BY SOCIETY OF AFRICANIST ARCHAEOLOGISTS)

This session explores archaeological and ethnoarchaeological approaches to the study of the foundations and unfolding of social complexity in sub-Saharan Africa through the interconnections of landscape, craft, and trade in the past 3,000 years. In this period, iron technology was established across the continent, agriculture spread, complex polities rose and fell, and African participation in global trading networks intensified. Landscape is used here broadly to contextualize these developments. Papers address the coevolution of early farming landscapes in the early Iron Age; how social identities were produced in village, community, and regional spaces over time; and monumental construction. Local, regional, and global trading networks moved and connected people and products across vast distances. Global trade extended into Africa’s interior impacting local economies and the structure, nature, and scale of authority and power. Social inequities based in the production and consumption of prestigious and mundane craft
products emerged and many contemporary artisans continue to work within social structures of inequity while contending with market globalization.

[162] Symposium · INTERDISCIPLINARY APPROACHES TO STUDYING HUMAN SOCIAL DYNAMICS: A CASE STUDY FROM SOUTHERN BELIZE
From 2008–2011 the NSF-HSD funded project (Development and Resilience of Complex Socioeconomic Systems: A Theoretical Model and Case Study from the Maya Lowlands) employed interdisciplinary approaches to explore the intersections human and ecological dynamics in the development and disintegration of a complex polity during the Maya Classic Period. The goal of this project was to model human behavior in the context of climatic and environmental change over a 2,000-year period, drawing on archaeological, paleoclimate, and paleoenvironmental proxies as well as longitudinal ethnographic studies of human decision making in a small agrarian community. Our data suggest multiple scales of interaction between socioeconomic complexity, population growth, and development of anthropogenic landscapes. Papers in this session will present data on land use, settlement patterns, climate and landscape histories, and polity development and decline, as well as strategies for engaging in cultural and environmental heritage educational programs in descendant communities.

[163] Symposium · INVESTIGATING INTERACTION FROM TUNACUNNHEE TO TALAJE: PAPERS IN HONOR OF RICHARD W. JEFFERIES
Spanning the Middle Archaic to the Mission periods, the wide-ranging work and research of Richard W. Jefferies is united by a common theme of interaction. From the study of bone pins among hunter-gatherer groups throughout eastern North America to his work on the Spanish missions of San Jose de Sapala and Santo Domingo de Asao/Talaje, a core theme of Jefferies’s work has been the examination of how individuals and groups engaged with one another through material culture and what that meant for larger cultural processes. In particular Jefferies’s study of carved bone pins was foundational in that it took a neglected artifact category and used it as a proxy to examine regional questions of interaction at multiple scales. Papers in this session take as their inspiration the work of Richard W. Jefferies and engage with the theme of interaction across the Eastern Woodlands.

[164] Symposium · ARCHAEOMETALLURGY OF THE NEW WORLD: CURRENT RESEARCH, APPROACHES, AND METHODS
Metallurgy and metalworking first emerged in the Andean region of South America, and appear to have progressively spread northward along the continent, as far as Mesoamerica, developing into local technological traditions. Copper, silver, and gold as well as different alloys comprised of these and other metals, were fashioned as ornaments used in religious ceremonies and for the enhancement of elite cultural status as well as more mundane items. In the last few decades, important aspects of the production, distribution, and use of such goods in different regions of the Americas has been inferred by scholars, often from combinations of ethnohistorical, archaeological, and archaeometric data. This symposium attempts to explore research developments comparatively in archaeometallurgy of the New World, departing from studies of diverse nature, including ore sources, mining technology, mineral processing, and extractive metallurgy as well as the social and technological choices that governed metallurgical production in different regions in the Andes, the Intermediate Area of Colombia and Lower Central America, and Mesoamerica.

[165] Symposium · UPPER PALEOLITHIC TRANSITIONAL “MOMENTS” ON THE IBERIAN PENINSULA
Anthropologists have a long-standing interest in understanding cultural continuity and change. Modern research in Upper Paleolithic archaeology has a legacy in cultural-historical research, which focused on defining cultural periods based on unique artistic styles or tool types. These periods form the basic lexicon that archaeologists use to characterize Upper Paleolithic adaptations. Recently, Upper Paleolithic researchers have shifted focus to transitional “moments” in prehistory, where they have incorporated precise radiocarbon chronologies, environmental reconstructions, and robust analytic modeling techniques in order to document cultural changes (i.e., from Gravettian to Solutrean). This session will focus on one European Upper Paleolithic region—the Iberian Peninsula—as a case study for how archaeologists can address long-term cultural continuity and change. The session’s contributors will discuss how Upper Paleolithic behavioral transitions were influenced by several interrelated factors: (1) global climatic and local environmental change, (2) regional and subregional cultural adaptations, (3) demography, and (4) inter-regional interactions with groups who resided within Iberia and in adjacent regions (e.g., the French Pyrenees). Overall, this session will distinguish Iberian cultural adaptations and transitions in relation those in other European Upper Paleolithic settlement areas.

[166] Symposium · CONNECTIVITIES IN PREHISTORIC AND CLASSICAL WEST/CENTRAL MEDITERRANEAN
The prehistoric and classical Mediterranean world were alive with small-scale interconnections, but archaeology still focuses on the macro themes of large-scale societies (Greek, Phoenician, or Roman) who divided up the Mediterranean between them. These are of course important, but often neglected are the micro connections that took place within and between the different local prehistoric and protohistoric communities which can provide a more nuanced flavor of the myriad of complex interactions that took place in the network of ancient activities. Moreover, connectivity is often used only to describe maritime contact between islands and landmasses, and while, for the Mediterranean, it is important to understand contact by sea, the mountainous landscape of many of the Mediterranean areas, cut by rivers or broken by plains, also provide possibilities for connections and are fruitful geographies for investigation. In this session, focusing on the lesser-studied western Mediterranean we want to encourage comparative, localized perspectives and—at the same time—break down the prehistoric-historic divide that often hampers research in this area.

[167] Symposium · ARCHAEOLOGY OF INDIA
Postcolonial Indian archaeology has typically conformed to a north-centric narrative of Indian history, as is reflected in the intensity of archaeological study of the Indus Valley Civilization in northern India and in Pakistan. While fruitful, this narrative has obscured wider examination of archaeological phenomena across India. This session aims to shed light on the lesser-known archaeology of India. Since the 1970s, Indian archaeologists have increasingly thought of archaeology as a means of generating information on Indian history and have thus sought to further the documentation and collection of archaeological data across India. These interests
coincided with the acceleration of natural resource extraction initiatives and the increasing frequency of road, power plant, and dam construction. Large-scale building projects often resulted in the displacement of local communities and the destruction of archaeological and historical sites. To that end, this session invites papers that collectively reflect the full scope and diversity of current research on archaeological phenomena from throughout the whole of Indian history, broadly defined, and across the entire Indian Republic. Papers that employ spatial methodologies are especially welcome.

[168] Symposium · GLOBAL PERSPECTIVES ON THE ARCHAEOLOGY OF RITually MOUNDED LANDSCAPES

Mounds constructed of all sorts of materials (stone, earth, shell) in myriad forms have attracted archaeologists from the very foundations of the discipline. From some of archaeology’s most famous sites to humble features barely noted on the landscape, mounds offer opportunities to examine past behavior from a variety of perspectives. One consensus that appears to emerge in the archaeology of mounded landscapes is that these features are often constructed in relation to “ritual” of some sort. Yet ritual remains a remarkably slippery concept in archaeology. The meanings, symbolism, and contexts of these mounds often necessitate a detailed reading of the landscape and associated settlements and ecologies. This session pulls together recent archaeological research on mounded landscapes from around the world to examine some of the theoretical and methodological approaches currently being used to explore concepts of ritual in past societies. Specifically, case studies will explore the ritual activities in the past that resulted in the construction of the mounded landscapes that now form part of the archaeological record.

[169] Symposium · CONNECTING MIDDLE PALEOLITHIC DATASETS: THE INTERPLAY OF ZOOARCHAEOLOGICAL AND LITHIC DATA FOR UNRAVELING NEANDERTHAL BEHAVIOR

Stone tools and butchered animal bones are the two main categories of archaeological remains from Middle Paleolithic sites. Both provide distinctive insights into Neanderthal behavior. The aim of this session is to explore the interplay of these datasets; how can they inform on each other and in what ways can they be integrated? Firstly, we invite presentations with a strong methodological focus, assessing how faunal remains can directly inform on lithic technology and vice versa (e.g., cutmark morphology, damage signatures, use wear). Secondly, we would like to discuss new and existing taphonomic and behavioral models that have been based on the integration of faunal and lithic data, including theoretical constructs, archaeological applications, and site-based and regional studies. Suggested topics include, but are not limited to:

- Taphonomy (e.g., spatial distributions, fragmentation, weathering, artifact condition)
- Site use, occupation duration, and exploitation intensity
- Linking lithic and faunal diversity, mortality, and seasonality (incl. prey choice, hunting technology, carcass processing)
- Mobility patterns (e.g., isotopes, raw material sourcing)
- Identifying region-, time-, or environment-specific behavior

We want to provide a forum to discuss ideas, approaches, and models that can then be further developed to be published in a special journal volume.

[170] Symposium · AD 600 CULTURAL AND ENVIRONMENTAL TRANSFORMATION IN ANCIENT PERU

In Peruvian archaeology AD 600 has been recognized as a period of important social and environmental transformations, which chronologically has served to mark the end of the Early Intermediate Period and the start of the Middle Horizon, characterized by the demise of archaeological cultures such as Moche and Nasca and the appearance of Wari material culture in the coast. Recent research centered on this time period has confirmed that important climatic oscillations, such as the presence of an El Niño event of considerable proportions, characterized this moment. Likewise, this research is showing a longer presence of Early Intermediate Period societies in different parts of the Peruvian coast. This session proposes to reevaluate this period from different regions, focusing on the varied political, cultural, religious, and environmental responses triggered by this context. Among these responses are the exploitation of water resources for the construction of new settlements and the enlargement of irrigation systems, as well as the aggrandizement of local elites in different parts of the Peruvian coast. Likewise, this session proposes to reexamine the validity of current chronologies, particularly in relation with the end of the Early Intermediate Period and the beginning of the Middle Horizon.

[171] Symposium · AN HISTORICAL ECOLOGICAL APPROACH TO THE INVESTIGATION OF EARLY SOCIAL COMPLEXITY IN THE HORN OF AFRICA: FIRST STEPS

(Sponsored by Eastern Tigrai Archaeological Project)

Papers will present preliminary results of a new investigation initiated by the Eastern Tigrai Archaeological Project (ETAP). We have formed a transdisciplinary research partnership between Simon Fraser University, Addis Ababa University, and the University of Kansas, which will integrate the work of archaeologists, paleoenvironmentalists, and ethnoarchaeologists. We aim to blend scientific and traditional knowledge to understand human-environmental interactions taking place at two critical points in the later prehistory of the Horn of Africa: the origins of social complexity during the Pre-Aksumite period (c.1600–800 BCE) and the Pre-Aksumite to Aksumite transition (c. 400 BCE–CE100). Papers will focus on integrating: archaeological studies on ceramics, lithics, grindingstones, zooarchaeology, and archaeobotany; paleoenvironmental investigations of stable isotopes, soil micromorphology and soil charcoals; and studies of traditional farmer adaptations to environmental stress, completed within a framework of historical ecology.

[172] Symposium · ARCHAEOLOGIES OF HEART: EXPLORING THE ROLE OF EMOTION AND SPIRIT IN ARCHAEOLOGICAL RESEARCH AND PRACTICE

Feminist and indigenous models of research and wellbeing invite us to fully utilize our emotional, social, intuitive, and spiritual selves, as well as our best intellectual and rational selves, in our research pursuits. In this session, we propose to explore “Archaeologies of Heart,” in research practices, pedagogies, and outcomes. What propelled this session was our asking, If we all love archaeology so much, why don’t we talk more explicitly about our feelings? Why don’t we get our hearts involved in our work and research in more than an implicit manner? Our collective goal is to find and speak our unique and authentic voices about issues
in our discipline that matter to us and to develop means by which we can begin to transform archaeology to incorporate our whole selves, from the individual to the community, classroom, and institutional levels. Drawing on the growing literatures on heart-centered practice, indigenous ontologies, and feminist perspectives, we invite our panelists to consider and reflect on questions and concerns: What are heart-centered practices? What do they look like, and how would they translate into archaeology? What would be the outcomes of a heart-centered archaeology? How might it change the interpretations we make about the past?

[173] Symposium · THE SCIENCE OF ORGANIC RESIDUE ANALYSIS AND THE ART OF CULTURAL INTERPRETATION I (SPONSORED BY SOCIETY FOR ARCHAEOLOGICAL SCIENCE and PALEORESEARCH INSTITUTE)

For those interested in the analysis of archaeological organic residues (biomolecular, micro-, and macroremains), our primary interest is in the development of public and professional presentations to bridge the gap between the science and the significance behind the data. Because many chemical and morphological methods are complex and unfamiliar to scientists and laypersons alike, explaining the rigor and the validity of the methodology often dominates the presentations. The cultural implications of the findings are oversimplified. We challenge researchers to create presentations that are suitable for the general audience, where the method and the interpretation are given equal weight. We encourage the use of creative, well-constructed, and easily understood visuals. We also welcome presentations that target specific age groups, such as high school and secondary education forums. The cultural interpretation should extend beyond the past and reach into the present—how well can a general audience understand the method and the meaning of the research? We hope that the papers produced for this session will be subsequently presented in academic and public forums. Our goal for this symposium is that it becomes an exercise in communication that increases the relevance of archaeological work and its accessibility to the public.

[174] Symposium · THE USE OF PLANTS IN ANCIENT RITUALS: NEW PERSPECTIVES FROM PALEOETHNOBOTANY

It is only recently that systematic paleoethnobotanical studies have begun to be adopted as key components in the study of ancient ritual practices. This approach represents an important innovation for highlighting the role of the “natural world” in ceremonies of the past, as well as providing an additional perspective for understanding the ancient worldviews that were embodied in such practices. Paleoethnobotanical approaches also constitute a key tool for reconstructing the chaîne opératoire of the deposits that result from ritual practices, particularly when compared with other associated artifacts and ecfacts. Fine-scale analysis of archaeobotanical remains from ritual contexts has already proved essential for reconstructing the behaviors and often meticulous actions involved in the construction of ritual sequences. This analytic approach thus represents an essential stage for achieving a broader understanding of the sociocultural, political, and ecological aspects of ritual practices. Our symposium aims to present and discuss new theoretical and methodological approaches in the study of ancient ritual practices in the Americas that are symbolically or materially related to the vegetal world.

[175] Symposium · METHODOLOGY AND INTERPRETATION IN THE ARCHAEOLOGY OF ROCK ART (SPONSORED BY ROCK ART INTEREST GROUP)

In the pursuit of innovative instrumental technique, enhanced interpretive insight, and successful approaches to preservation, this Rock Art Interest Group sponsored symposium is intended to provide a context within which recent archaeologically informed rock art research can be shared.

[176] Symposium · TSIMSHIAN ARCHAEOLOGY: 50 YEARS OF RESEARCH AND 10,000 YEARS OF HISTORY

Modern archaeological research began in the Prince Rupert Harbour area of Tsimshian Territory in 1966 with research from the National Museum of Canada (now the Canadian Museum of History) and supported by Tsimshian people and their governments. This work framed archaeological research across Tsimshian territory including the lands of the Nine Tribes (Metlakatla and Lax Kw’alaams), Kitsumkalum, Kitselas, Gitxala,a, Gitksan, and Gitga’at and developed the careers of many of the luminaries of archaeology and related fields. Their research and that of the generations of scholars they mentored have been at the forefront of interpretive and methodological developments and have advanced the understanding of Tsimshian archaeology and history. This session brings together case studies of leading edge genomic analysis, household archaeology, oral history analyses, paleoenvironmental reconstructions, ethnographic comparisons, Indigenous critique, spatial analysis, and radiocarbon modeling, showcasing the legacy of a half century of partnership between different disciplines and communities in one of the world’s most well-known research programs.

[177] Symposium · SEEDS OF THE PAST, SEEDS OF THE FUTURE: PAPERS IN HONOR OF STEVEN A. WEBER

Archaeology has the potential to inform us about how humans have found sustainable solutions to challenges such as climate change, overpopulation, and environmental degradation. Through the study of long-term adaptations in human subsistence, ethnobiology is uniquely poised to understand how humans met (and can continue to meet) challenges in their food supply. Dr. Weber founded the Society for Ethnobiology and has worked extensively throughout South and Southeast Asia: areas where his work enhanced our understanding of early subsistence systems but also provided key examples of how modern food systems can benefit from an understanding of the deeper past. Papers presented in this session take a worldwide approach to honoring Dr. Weber’s contributions to making our understanding of past human subsistence relevant to the future.

[178] Symposium · UNRAVELING SOCIAL DYNAMICS THROUGH ARCHAEOLOGICAL SCIENCE

Social archaeology and archaeological sciences are expanding and innovative fields of archaeological research that do not collaborate as often as they could or should. Their potential for intellectual cross-fertilization is significant, but still underexploited. The aim of this session is to illustrate how the methods of the archaeological sciences (a.k.a. archaeometry) can be used to address issues beyond subsistence and technology, in order to explore the social dynamics of past populations. Concepts such as agency, body, identity, gender, household, memory, symbols, power, and materiality often serve as the bonding element between the material and social dimensions of landscapes, sites, and artifacts. This session will bring together archaeologists who dissect the
social dimensions of past societies using these concepts and methodologies, regardless of the time period, geographic area, or theoretical framework they navigate in. Our intent is to create an open and inspiring discussion on scientific ways to unravel ancient social dynamics.

[179] Symposium · QUINTESSENTIAL PLACES: ANALYZING THE CHARACTER OF PRECOLUMBIAN SITES
Settlements of all sizes are quintessential, or have distinctive traits that help to characterize and distinguish them. Papers will analyze the quintessence of places from Native North America through the Andes and query what makes a site distinctive. Previous archaeological and art historical analyses of place may have incorporated these aspects, but perhaps not under the rubric of “quintessential.” Distinctive traits may be attributable to topography, plan, geological features, visual culture, inhabitants, and practices such as rituals and social interaction. Such traits may be tangible or intangible, isolated, or intersecting. Above all, quintessential places are sites of dwelling and experience that are shifting rather than static. Quintessential places are not unlike the Roman genius loci (“spirit of the place”), with orientation, identity, and experience substituting for spiritual aspects of Roman spaces. Orientation may be directional or spatial, and overlap with identity. Identity also may be embodied in land use, architectural and artistic styles, and imagery. Experience can include movement, rituals, climatic and astronomical phenomena, and social and filial interaction. In addition, scale, authenticity, narrativity, interiority, and place as an ecosystem encompass the character of a place.

[180] Symposium · SAILING AT THE EDGE OF TIME: GLOBAL PERSPECTIVES ON ISLAND COLONIZATION
(.SPONSORED BY JOURNAL OF ISLAND AND COASTAL ARCHAEOLOGY)
The timing and drivers of colonization into previously uninhabited areas is a central theme in archaeological research. Questions of when, who, and from where remain important research topics in many regions as these form a baseline from which we construct explanations of the past. Islands provide a particularly rich setting to study colonization as reaching them often involved unique adaptations, including specialized watercraft, translocated domesticates, and long-distance interaction networks. However, the intricacies of colonization are often contentiously debated, as archaeological, linguistic, paleoenvironmental, and biological perspectives can present substantially different and sometimes conflicting information, particularly regarding the timing of initial island settlements. This symposium brings together archaeologists from island regions across the globe to discuss current theoretical, substantive, and methodological issues in island colonization research.

[181] General Session · RECIENT ZOOARCHAEOLOGICAL RESEARCH I

[182] Symposium · MAYA HIGHLAND AND PACIFIC COAST ARCHAEOLOGY: NEW DATA, DEBATES, AND DIRECTIONS
PART 1
Recent archaeological investigations in the Highlands and Pacific coast of Guatemala and Chiapas, combined with major chronological revisions, are challenging traditional characterizations of this complex region of Mesoamerica and fueling new debates and correlations with neighboring regions. In this symposium, case studies picked from a broad range of subregions will serve to highlight this complexity, while also focusing attention on a number of key themes, including stability and change, inter- and intra-regional interaction, and community and ethnic identity. Researchers will discuss the theoretical, methodological, and technical approaches they are using to address these topics and present new data derived from recent analyses of material culture, sculpture, architecture, and settlement patterns. The symposium will serve to update scholars from neighboring areas of Mesoamerica on recent research, and will also stimulate increased communication, collaboration, and data-sharing among current regional and subregional specialists.

[183] Symposium · EL HOMBRE, SU ESPACIO, TIEMPO, INTERACCIONES Y ASPECTOS BIOARQUEOLÓGICOS
En esta mesa se expondrán una serie de trabajos recientes en diversas áreas de Mesoamérica, buscando con ello aportaciones importantes en el área del conocimiento de las culturas que trabaja cada investigador, todas ellos con un enfoque bioarqueológico el cual emplea diferentes técnicas de otras disciplinas lo cual permite un conocimiento más integral de los grupos humanos que se estudian; tal como señala Talavera y colab, en su libro Modificaciones culturales en los restos óseos de Cantona, Puebla. Un análisis Bioarqueológico publicado en 2001/1, el análisis bioarqueológico es “una propuesta analítica que incluye técnicas y métodos de la arqueología, antropología física, historia, geología, bioquímica, entre otras, para la interpretación de los restos humanos de las poblaciones pretérritas”. Con lo anterior se da la oportunidad a los participantes de ver lo que ocurre y como se trabaja en otras áreas, ya que la mayoría de los investigadores solo nos enfocamos a participar en foros locales o relacionados al área de interés, lo que provoca un desconocimiento de lo que suceden en el resto de las áreas geográficas.

[184] General Session · RECIENT PALEOINDIAN STUDIES II

[185] Symposium · BLOOD IN THE WATERS: VIOLENCE IN THE MISSISSIPPIAN AND LATE PREHISTORIC EASTERN WOODLANDS
The Late Prehistoric and Mississippian populations of the Eastern Woodlands were deeply interconnected, engaging in long-distance trade and cultural transmission across great swaths of North America. Groups traded for exotic goods and nonlocal pottery, sharing the iconography that adorned them. They also traded blows; groups like the Oneota, Mississipians, and Fort Ancient engaged in repeated instances of conflict. Archaeological evidence of conflict is represented by the many palisaded villages throughout the region and iconography depicting warrior figures. Bioarchaeological evidence of conflict tells a more nuanced story. Skeletal evidence of trophy taking, injury recidivism, lethal and nonlethal trauma, and patterned victimization reveal that conflict in the Eastern Woodlands was not just an ongoing series of indiscriminate raids designed to kill and capture helpless victims. Instead, some individuals were off-limits and victims fought off attackers. Aggressors performed a multitude of different acts, lethal and nonlethal, on their targets, attempting to injure and kill some, while killing and maiming others. Papers will focus on the nuanced
details of conflict in the Mississippian and Late Prehistoric periods of the Eastern Woodlands, and cover a range of topics including victim identity, types of trauma, and conflict practices as seen through the bioarchaeological record.

[186] Symposium · TEACHING THROUGH THE PAST: ADVANCES IN TECHNOLOGICAL ANALYSIS OF THE ARCHAEOLOGICAL RECORD
Over the last half century, archaeology has continuously adopted new technologies to more effectively study the past, and has grown as a technologically savvy and innovative field. Twenty-first-century archaeologists must not only be skilled in traditional methods of analysis and interpretation of the archaeological record but learn to incorporate a myriad of ever-changing platforms of technology into their skill set. From computer modeling to geophysical survey methods, from high-resolution satellite imagery to chemical analysis of lithics, advances in technology have helped piece together the story of human history and prehistory in ways previously not possible. With greater accessibility and ease of use, technology has become a constant companion to archaeologists both in the field and the lab. It has allowed for the collection, analysis, and comparison of big datasets and encouraged new interpretations of old knowledge. This session will explore a few of the recent advances in technological tools as well as new applications for existing technologies to the field of archaeology.

[187] General Session · STRUCTURE AND SPACE AT MAYA SITES II

[188] General Session · THE ARCHAEOLOGY OF IMMIGRATION AND DIASPORA IN THE HISTORIC UNITED STATES

[189] General Session · DIGITIZING THE ARCHAEOLOGICAL RECORD

[190] General Session · ARCHAEOLOGY IN THE ARCTIC

[191] Poster Session · ADVANCES IN ARCHAEOLOGICAL METHOD AND THEORY I

[192] Poster Session · ARCHAEOLOGICAL APPROACHES TO SYMBOL, RITUAL, AND MEANING IN THE AMERICAN SOUTHWEST

[193] Poster Session · ADVANCES IN ARCHAEOLOGICAL METHOD AND THEORY II

[194] Poster Session · NORTH AMERICA: PACIFIC NORTHWEST I

[195] Poster Session · A LINK TO THE PAST: TEXT MINING AND ENTITY RECONCILIATION WITH THE DIGITAL INDEX OF NORTH AMERICAN ARCHAEOLOGY (DINAA)
The Digital Index of North American Archaeology (DINAA) provides a continuously expanding open-source gazetteer of archaeological data from governmental site file inventories across North America. While visualizing spatial distributions of commonly recorded archaeological attributes across modern municipal boundaries alone can provide unique insights into the past, the expansive utility of an open and linked infrastructure is realized when data are coupled to other web-enabled information systems. Text mining, entity reconciliation, and unique identifiers allow DINAA to interface with publications, archives, museums, scientific journals, and web-enabled genetic datasets. This poster symposium focuses on using DINAA to create and visualize these links to the past with specific examples, including text mining of American Antiquity through JSTOR, and linking archaeological records to published information on ancient DNA datasets through the National Center for Biotechnology Information. The current state of DINAA will be reported with maps and metrics detailing up-to-date North American coverage.

[196] Poster Session · LEARNING ABOUT THE PAST WITH FRAGMENTS FROM THE FIRE: STUDENT RESEARCH ON AN NSF-REU FIELD SCHOOL
Significant population increases, the intensification of craft production, and new forms of agricultural output characterize a major transition between the eighteenth and seventeenth centuries BC on the Great Hungarian Plain. Many archaeologists consider these changes hallmarks of an emerging social class. Yet research from different parts of Eastern Europe suggests that societies were organized in a variety of ways during this regional florescence. This session describes recent investigations into a Bronze Age community buried at the cemetery of Békés Jégvermi-kert (Békés 103) in Eastern Hungary. The project includes an international team of undergraduate students funded by the National Science Foundation Research Experience for Undergraduates Program and the Central European Institute at Quinnipiac University. During the 2016 summer lab season, a team of 11 students conducted independent research projects on a range of datasets from the cemetery and surrounding area, focused on understanding patterns in trade, identity, and cremation burial practice. In this session the students present their findings related to the site, the funerary customs, and how the cemetery population fit into the trade, population movement, and new identities emerging in Bronze Age Europe during the mid-second millennium.

[197] General Session · DISCERNING SOCIAL COMPLEXITY IN THE NORTH AMERICAN ARCHAEOLOGICAL RECORD
La Sierra Norte de Oaxaca o Sierra Juárez, ha sido una de las áreas menos exploradas en este estado del sur de México. De raíces zapotecas, esta importante región ha sido foco de atención de investigadores en los últimos años, este simposio mostrará las principales investigaciones que se encuentran desarrollándose en diversos puntos de este territorio montañoso. También es importante presentar cómo los trabajos arqueológicos han ido a la par de un intenso diálogo con las poblaciones que se encuentran allí asentadas, requiriendo de interacción entre diversas instituciones tanto públicas como privadas, logrando avances significativos que nos acercan a una comprensión cada vez más completa del área, de su pasado y de su presente.

In the collective imaginary of prehispanic communities of Northwest Mexico, the American Southwest, and Central Mexico, caves hold a very important place. Not only were they used as spaces for shelter or home, they were also used as locations where ancestors rest, where vision quests were performed, and where the walls retain the wisdom and messages of the community in the rock art. This symposium presents recent research on caves as places where human communities interacted, lived, and shared experiences among themselves and with their landscapes.

A long-ignored region between the research hotspots of the Moquegua Valley (Peru) and the Lluta and Azapa Valleys (Chile), the Tacna area is witnessing an explosion of archaeological investigation. With some of the most fertile coastal valleys in the region, the area's long-term connections with the altiplano have long fascinated scholars interested in mobility and the emergence of long-distance connectivity through trade, colonization, and state projects. The participants in the session show how current work is shedding new light on key questions in Andean archaeology concerning mobility, verticality, and identity formation. Beginning with Lavalée’s key project at Quebrada de los Burros, the region is emerging as an important location to better understand several classic archaeological phenomena—including the Chinchorro culture, Tiwanaku colonies, and LIP ethnogenesis—as well as develop new methodological and thematic directions in Andean archaeology. The emerging research also pushes up against national divisions in scholarship, providing a case study in the possibilities of finding new ways to understand the past beyond the confines of the modern nation-state.

The archaeological record is a nonrenewable resource. Professional ethics dictate effective preservation and require long-term access to data recovered in archaeological investigations. The goal, of course, is to enable us to build on past efforts though comparative and synthetic research and by new and replicative research using such digital collections. This forum features academic, agency, and CRM managers and scholars who have made digital collections with notable potential for reuse available through tDAR, the Digital Archaeological Record. The participants will describe these digital data collections, discuss how they are organized in tDAR to foster effective reuse, and will highlight suggestions for new research in which they could be reused productively. The forum will be of interest both to those seeking to preserve their data and make them available into the future and to professionals and students interested in reusing the data that are now accessible. The SAA Student Affairs Committee supports this forum topic and is cosponsoring the forum.
[207] Symposium · LIVING AT THE MARGINS: ARCHAEOLOGICAL AND ETHNOGRAPHIC RESEARCH ON POST-EIGHTEENTH-CENTURY IRISH AND SCOTTISH RURAL LIFE
Margins, both socially and ideologically, are materially defined by local economic practices and national policies. This session focuses on post-eighteenth-century material life on the margins of Ireland and Scotland, defined in differing ways by researchers, governments, and those living along coastal and upland areas. Archaeologists in this session explore the conception of margins and marginality from a multifaceted framework to interrogate the underlying assumptions about material culture, landscape, place, and economy in “marginal” locations and communities. The study of such porous spaces has revelatory potential to help us understand altered social dynamics. Through case studies, presenters considering the nature of life along the edge, how it is ascribed from different perspectives, and the linkages between the core and periphery.

[208] Symposium · ARCHAEOLOGY OF CULTURAL FLUIDITY IN TAIWAN
From maritime-based foragers to Neolithic farmers and Austronesian pioneers, the prehistoric societies of Taiwan exemplify cultural fluidity—defined as resiliency leading to transformative evolutionary change—as an adaptive strategy. This session offers fascinating case studies that examine cultural fluidity from an evolutionary perspective. Geospatial, archaeological, and artifactual data will be featured as well as updates about emerging discoveries on this unique island and the related Pacific sphere.

[209] Symposium · THREADS ACROSS TIME AND SPACE
These papers take a comparative approach to the study of woven cloth viewed from the perspective of textile materials, tools, and texts available in archaeological contexts. Spatially and chronologically, the papers comprise evidence for cloth production from the New and Old Worlds in both the prehistoric and protohistoric periods. Our approach draws on an anthropological tradition in which cloth has been viewed throughout history for its value as a medium of exchange and gift giving, as a signifier of interaction among societies and cultures, as a means of reinforcing kinship and religious relations and enhancing the authority and power of political elites, or distinguishing between urban vs. rural producers. The papers demonstrate the ways in which these social aspects of cloth are embodied in the making and crafting of textiles, through spinning, weaving, and cross-craft collaboration among allied technologies, such as agriculture and fiber processing and the social and environmental contexts in which their technical aspects of production have developed.

[210] Symposium · NOT JUST GOOD TO SEE: GLOBAL PERSPECTIVES ON SCENES IN ROCK ART
There is considerable temporal and geographic variation in the conventions involved in the choice, rendering, and layout of subjects in rock art. Just as the emergence of naturalism through the application of perspective is said to have created new ways of representing and seeing the world in the European Renaissance so too changes in the ways images of animals were represented with regard to other animals, humans, and non-figurative signs likely testify to changes in the ways prehistoric people experienced the world around them. The purpose of this session is to invite scholars with an interest in the variation of fauna in rock art to explore how we can use comparative studies of rock art to identify key differences in the ways in which people engaged with their natural and cultural landscapes.

[211] Symposium · FEASTS AND RITUAL STRUCTURES: ETHNOARCHAEOLOGICAL AND ARCHAEOLOGICAL PERSPECTIVES
Feasts and rituals are key elements in understanding human cultures worldwide, as foods and material cultures served for feasts and rituals are representing a core of the any cultures. This session combines ethnoarchaeological and archaeological studies to aid in understanding the role of feasting and ritual in the evolution of human societies, particularly focused on transegalitarian societies. The first half of this session presents the results of ethnoarchaeological studies of traditional feasting and ritual in Papua New Guinea and Japan. These studies discuss how feasting and ritual are related to evolution of transegalitarian societies and how they can be identified archaeologically. The latter half of the session explores evolution of feasting and ritual among Jomon societies as case studies.

[212] Symposium · ARCHAEOLOGY AND NEW OR ALTERNATIVE RELIGIOUS MOVEMENTS
New and alternative religious movements make copious use of ancient symbols, beliefs, and practices. From the use of the Egyptian ankh in the Western occult tradition to the creation of Neo-Pagan Druidic orders and identities, these symbols, beliefs, and practices hold potent meanings to those who employ them today—meanings that are grounded in a perceived authenticity derived from their antiquity. The act of reuse, however, resituates and thereby alters the meanings and significance of these things. For many archaeologists, this shift in meaning creates a tension with the representations of ancient cultures as produced by the academy. Our session will explore this tension through analyses of newly creative or appropriative religious and spiritual behaviors involving archaeological materials, as well as the ramifications of these acts for public archaeology.

[213] Symposium · BEYOND TYPOLOGY: CURRENT TRENDS IN CERAMIC ANALYSIS IN CHINA
For many years, the main approach to ceramics from archaeological sites in China consisted of creating ceramic typologies aimed at establishing cultural chronology. While these typologies still provide an important foundation for our understanding of past societies, recent years have seen the rise of new approaches and methodologies in ceramic analysis in China. For example, chemical and petrographic analyses of ceramic pastes are providing insight into production provenances and techniques; residue and use-wear analyses are revealing changing dietary preferences; noninvasive methods such as pXRF are generating new data from objects too delicate or unique to be traditionally sampled. In addition to new methodologies, new theoretical approaches are also shaping the ways in which both recent results and past studies are being interpreted, questioning established typologies and throwing new light on processes of ceramic production and usage as well as changes in and interconnection between different ceramic traditions. The aim of this session is to bring together scholars working in multiple time periods across China to present and discuss their research, thus allowing for a better understanding of emerging trends and techniques in this field.
[214] Symposium · AN INTRODUCTION TO THE SOCIO-ECOLOGICAL ENTANGLEMENT IN TROPICAL SOCIETIES (SETS) PROJECT
The ultimate goal of the Socio-ecological Entanglement in Tropical Societies project (SETS) is to promote the cross-cultural, transdisciplinary examination of the tropical experience, past and present, as a means to explore resilience and vulnerability to changing socio-ecological circumstances. This session presents the results of the initial phase of the research program, which focused on the comparative assessment of data quality and quantity across five principal foci (water management, agriculture, settlement, epicentral capitals, and integrative mechanisms), spanning eight geopolitical “divisions” (Belize, South India, Sri Lanka, Myanmar, Thailand, Cambodia, Java, and both north and south Vietnam). Our detailed literature reviews and comprehensive site visits—which have so far concentrated on the Classical, or “Charter States” of the various subregions of interest—have also allowed us to generate some preliminary insights into the adaptive capacity of tropical, agrarian-based, dispersed urbanism, with particular reference to key land-use, climatic, economic, and geopolitical transitions.

[215] Symposium · CRAFTING AND CONSUMPTION IN PREHISPANIC MESOAMERICA: A DIACHRONIC PERSPECTIVE/LA PRODUCCIÓN Y EL CONSUMO DE ARTESANÍAS EN MÉSOMÉRICA DURANTE LA ÉPOCA PREHISPÁNICA: UNA PERSPECTIVA DIACRÓNICA
Recent research has begun to conceptualize prehispanic handicrafts within a theory of goods. This approach focuses on the social encoding of goods (handicrafts) as gifts or commodities. From a theoretical perspective, the encoding of handicrafts (especially exotic or special items) as gifts has direct implications with respect to social embedding and restricted consumption. Conversely, the encoding of handicrafts as commodities (e.g., regional goods or bulk luxury goods) implies a very different political-economic strategy that privileges much freer production and wider access to products. Thus, understanding the social encoding of goods allows scholars to better apprehend how crafting and consumption figured into or impeded the development of exclusionary political-economic strategies that seek to control handicrafts through social embedding and restricted markets, or more collective political-economic strategies in which political architects seek to develop economic institutions that encourage broad social participation in commercial transactions (e.g., open markets). Accordingly, this symposium seeks to investigate the changing roles of goods in prehispanic Mesoamerica from the Early-Middle Formative through the Late Postclassic and how these roles affected production and consumption in terms of social embedding, commercialization, and collectivity.

[216] Symposium · TRADITIONAL KNOWLEDGE AND LITHIC RESOURCES
(SPONSORED BY PREHISTORIC QUARRY AND EARLY MINES INTEREST GROUP)
Many archaeologists who carry out research on the geological sources of raw materials used for stone tools, pigments, construction materials, or adornments have remarked on the repeated coincidence between these locations and local traditional knowledge. Oral traditions, ethnographic documents, and toponymy, for example, regularly contain references to locations where raw materials could be found that would have been useful to people in the past. In addition, there is often a relationship between the sacred or cultural landscape and these extraction locations. This relationship can imbue the raw materials with meaning and power that becomes inherent to the materiality of the objects made from these materials. This session will bring together researchers from around the world that work on several different time periods in order to compare and contrast the traditional knowledge base and the archaeological data on raw material extraction sites.

[217] Symposium · SEATS OF POWER: FUNCTIONAL SECTORS IN MESOAMERICAN PALACES
Power in ancient societies may be displayed in different scales and settings. In some cases economic power involves the concentration of staples, the managing of craft production, or the control of trade routes. Social control may involve the concentration and management of labor for state purposes. Political power is evident in territorial control and state expansion. Symbolic power is often called upon when sanctioning the acts of rulers. Palace structures as seats of power are clear in archaeological data on raw material extraction sites. This symposium will explore how archaeologists detect functional sectors within a palatial complex or building in Mesoamerican archaeology.

[218] Symposium · MAYA HIGHLAND AND PACIFIC COAST ARCHAEOLOGY: NEW DATA, DEBATES, AND DIRECTIONS, PART 2
Recent archaeological investigations in the Highlands and Pacific coast of Guatemala, combined with major chronological revisions, are challenging traditional characterizations of this complex region of Mesoamerica and fueling new debates. In this symposium, case studies picked from a broad range of subregions will serve to highlight this complexity, while also focusing attention on a number of key themes, including stability and change, inter- and intra-regional interaction, and community and ethnic identity. Researchers will discuss the theoretical, methodological, and technical approaches they are using to address these topics and present new data derived from recent analyses of material culture, sculpture, architecture, and settlement patterns. The symposium will serve to update scholars from neighboring areas of Mesoamerica on recent research, and will also stimulate increased communication, collaboration, and data-sharing among current regional and subregional specialists.

[219] Symposium · LIFE AND DEATH IN ANCIENT NUBIA: ARCHAEOLOGICAL AND BIOARCHAEOLOGICAL PERSPECTIVES
While often considered and presented in isolation, the archaeological study of mortuary contexts and the bioarchaeological study of human remains should be considered in tandem for broader interpretations of past lifeways. Mortuary contexts and human remains are often the only remaining and strongest evidence of past populations, particularly when ancient settlement sites are inaccessible or absent. This is particularly true for many regions and time periods of ancient Nubia, where without many written sources, the interpretation of Nubia’s past relies on archaeology and bioarchaeology. Mortuary landscapes (even those within settlement sites) and human remains of ancient Nubia reflect many cultural and biological aspects of this dynamic civilization, particularly in light of its
ever-changing and complex relationship with ancient Egypt, including population identity, social and political complexity, population mobility and change, the transmission of ideas and material goods, subsistence practices, and disease. The aim of this symposium is to present mortuary evidence from both archaeological and bioarchaeological perspectives to give a broader understanding of culture and identity in ancient Nubia. The contributed papers will focus on the diversity of funerary practices and biological and cultural identity as related to all time periods of Nubian history.

[220] Symposium · NORTHERN SOUTH AMERICA II: MOBILITY, LANDSCAPES, AND SOCIALSCAPES
Archaeological research in Ecuador, Colombia, and Venezuela is often overlooked compared to other areas of South America that have disproportionately captured the public eye, such as the Central Andes and the Amazon Basin. Local groups have demonstrated an impressive interregional mobility throughout time, as well as there being common archaeological evidence of long-distance exchange of materials between the Pacific coast, northern Andes, northwestern Amazon, and the Caribbean Coast, thus indicating highly varied yet intimately connected landscapes and socialscapes. The purpose of this session is to highlight the exceptional archaeological contributions of this diverse geographic region at the northernmost extent of the continent.

[221] Symposium · ONGOING RESEARCH IN EURASIAN ARCHAEOLOGY: ASSESSING THE IMPLICATIONS OF NEW EVIDENCE
This session explores the results of recent archaeological research in Russia, Central Asia, the Caucasus, and the adjacent areas. Nearly three decades of post-Soviet international scholarly engagement have greatly advanced our understanding of Eurasian prehistory and made this knowledge available to English readers. While theoretical perspectives and field methods are constantly being refined, some of the same themes continue to guide regional research. They include pastoralist subsistence and mobility strategies, the global spread of domesticated crops, the origins of the Indo-European languages, technological innovations in metallurgy, and draft animal transport, broad-scale interactions over vast distances, developmental pathways of Eurasia’s complex societies. This session brings together graduate and postgraduate scholars working across time periods and research questions to discuss current archaeological projects in the region. The aim of the session is to facilitate the exchange of theoretical perspectives, expertise, and ideas among those involved in shaping the future of Eurasia’s past.

[222] General Session · ANDEAN ARCHAEOLOGY

[223] Symposium · INSIGHTS FROM INCREMENTS: ADVANCES IN GEOCHEMICAL AND MICROSCOPIC ANALYSES OF HARD TISSUES
Recent advances in the microscopic and geochemical study of biological hard tissues have broadened archaeological understandings of past human-environmental dynamics, especially in island and coastal settings. Hard tissues that contain macro- and micro-incremental growth structures, such as fish otoliths, corals, coralline algae, teeth, and shells serve as ideal proxies as they record local environmental conditions in their structures as they grow. In addition to past environmental information, the analysis of hard tissues reveals insights into changes to animal populations from climatic stress, as well as resource depletion. When combined with ancillary archaeological evidence, these data can provide new insights into seasonality, sea surface temperature, and paleosalinity, in addition to understanding both long- and short-term patterns of landscape and resource use. This session highlights the interdisciplinary nature of this research, connecting archaeologists, biologists, geochemists, and sclerochronologists to share their latest research and methods in hopes of propelling and strengthening future archaeological investigations of hard tissues.

[224] Symposium · BURNING LIBRARIES: ENVIRONMENTAL IMPACTS ON HERITAGE AND SCIENCE
(SPONSORED BY CLIMATE CHANGE STRATEGIES AND THE ARCHAEOLOGICAL RECORD COMMITTEE)
The past decade has seen increasing concern expressed worldwide about the multiple challenges posed by global environmental change to human heritage and the archaeological record. Rising sea levels, increasing storms, increasing wildfire, and warming soil temperatures in the circumpolar north and at high elevations are all impacting the archaeological record in ways never seen before. This generation will see the destruction of thousands of sites—some already famous and of recognized heritage value and others that are exposed by one storm only to be destroyed by the next. At the same time, archaeology is increasingly recognized as a global change science that is making significant contributions to resource management, environmental conservation, and more effective scenario building for a genuinely sustainable future. Just as our resources are becoming recognized as a “distributed observing network of the past”—as multiple libraries of Alexandria rich with data for many disciplines—we are realizing the extent and urgency of the threat. Our libraries are on fire right now.

[225] Symposium · ANIMALS AND THE SACRED PRECINCT OF TENOCHTITLÁN: BIOLOGY, ARCHAEOLOGY, HISTORY, AND CONSERVATION
After eight field seasons (1978–2016) working at the sacred precinct of Tenochtitlan, the Proyecto Templo Mayor (INAH, Mexico) has recovered an amazing diversity of animal species. As a result, more than 300 species have been identified. The resulting information has been on display to the public in a gallery devoted to fauna in the Templo Mayor Museum and has also been published in numerous studies on biological, ecological, and taphonomic aspects of the animals deposited in offerings. Among our principal conclusions regarding the faunal remains from the Templo Mayor, we can mention a) the presence of species corresponding to six different phyla (Porifera, Coelenterata, Echinodermata, Artropoda, Mollusca, and Chordata); b) the predominance of species endemic to regions quite far away from the Basin of Mexico; c) the scarcity of edible species and the clear interest on the part of Mexico priests in those animals that were attributed with profound religious or cosmological significance; d) evidence of captivity; e) traces of cultural processes for modifying the animal cadavers, some of which may be qualified as “taxidermic” interventions; and f) the use of fauna in offerings to re-create vertical tiers of the universe and with this to configure veritable cosmograms.
[226] Symposium · ALTERNATIVE PERSPECTIVES ON THE PEOPLING OF THE NEW WORLD: A SYMPOSIUM IN HONOR OF RUTH GRUHN, THE “FIRST LADY” OF FIRST AMERICANS STUDIES
(SPONSORED BY CENTER FOR THE STUDY OF THE FIRST AMERICANS, TEXAS A&M UNIVERSITY)
Dr. Ruth Gruhn has long served as a proponent for alternative records and non-Clovis-centric models of the Pleistocene peopling of the Americas. Over her long career she conducted field-based Paleoindian research in the Intermountain West of North America, Baja California, Guatemala, and northern South America, and she became well-known and respected in nearly every country of the Western Hemisphere. The papers in this session commemorate Dr. Gruhn’s contributions to non-Clovis Pleistocene archaeologies across the Western Hemisphere, Paleoindian studies in Latin America, and the concept of a Pacific coastal migration. We also celebrate her enduring, selfless role as Paleoindian archaeology’s “intercontinental” ambassador.

[227] Symposium · FRISON INSTITUTE SYMPOSIUM: THE FUTURE OF “BIG DATA” IN ARCHAEOLOGY
Archaeology is currently experiencing a new “revolution” toward the use of “big data.” Various research teams worldwide have started to integrate the enormous masses of archaeological data generated since the 1960s into online databases that are openly accessible to the entire profession and public. This enhancement of data accessibility promises to transform multiple facets of the discipline, from the leveraging of CRM gray-literature, to the kinds of scientific questions researchers are able to ask, to the greater involvement of archaeology in interdisciplinary research and public engagement. The nascent turn toward big data approaches means that many of the theoretical and methodological problems/prospects involved with this kind of research must still be critically assessed at project-comparative, international scales. This symposium brings together different big data projects worldwide in order to address many of the outstanding theoretical and methodological problems/prospects and provide a framework for the future.

[228] Symposium · STUDY OF HUMAN ECODYNAMICS AT TSE-WHIT-ZEN, A 2,800-YEAR-OLD LOWER ELWAHA KLALLAM COASTAL VILLAGE IN WASHINGTON STATE, USA
(SPONSORED BY ISLAND AND COASTAL ARCHAEOLOGY INTEREST GROUP)
Extensive 2004 excavation of the Tse-whit-zen village, traditional home of the Lower Elwha Klallam Tribe, documented multiple houses spanning the last 2,800 years with exceptionally fine geo-stratigraphic control; faunal samples from 10 L buckets, screened to ¼" mesh, allow for detailed reconstruction of animal use. Occupation spans several large-magnitude earthquakes, periods of climate change, and a gradual increase in sheltered intertidal habitat. Our geo-zooarchaeological project provides an important case study that adds to developing scholarship in human ecodynamics, which uses archaeological and other multidisciplinary knowledge to study the complex and dynamic interactions between humans and their environment in deep history. The link between social structure and social response to environmental stress has been highlighted in several case studies, but differential intracommunity resilience in the face of disaster has been little studied. Our project addresses this need by examining faunas—foundational resources for any community—to evaluate the resilience of distinct social units in a marine forager community. We model and test the effects of environmental change on animal resources and examine both diachronic and synchronic variation in resource use by social units. Tribal members add their own perspectives on the importance of Tse-whit-zen and the recent archaeological project.

[229] Symposium · THE SCIENCE OF ORGANIC RESIDUE ANALYSIS AND THE ART OF CULTURAL INTERPRETATION II
(SPONSORED BY SOCIETY FOR ARCHAEOLOGICAL SCIENCE and PALEORESEARCH INSTITUTE)
For those interested in the analysis of archaeological organic residues (biomolecular, micro-, and macroremains), our primary interest is in the development of public and professional presentations to bridge the gap between the science and the significance behind the data. Because many chemical and morphological methods are complex and unfamiliar to scientists and laypersons alike, explaining the rigor and the validity of the methodology often dominates the presentations. The cultural implications of the findings are oversimplified. We challenge researchers to create presentations that are suitable for the general audience, where the method and the interpretation are given equal weight. We encourage the use of creative, well-constructed, and easily understood visuals. We also welcome presentations that target specific age groups, such as high school and secondary education forums. The cultural interpretation should extend beyond the past and reach into the present—how well can a general audience understand the method and the meaning of the research? We hope that the papers produced for this session will be subsequently presented in academic and public forums. Our goal for this symposium is that it becomes an exercise in communication that increases the relevance of archaeological work and its accessibility to the public.

[230] Poster Session · ANDEAN ARCHAEOLOGY

[231] Poster Session · SOUTH AMERICA I

[232] Poster Session · SOUTH AMERICA II

[233] Poster Session · SOUTH AMERICA III

[234] Poster Session · EUROPE III

[235] Poster Session · BIOARCHAEOLOGICAL RESEARCH IN EUROPE

[236] General Session · CURRENT RESEARCH IN MESOAMERICAN ARCHAEOLOGY
Symposium Abstracts of the SAA 82nd Annual Meeting

[237] Symposium · CASAS GRANDES: ADDRESSING KEY ISSUES OF CHRONOLOGY, CULTURE CHANGE, SOCIAL ORGANIZATION, AND EXCHANGE
Casas Grandes, also known as Paquimé, was one of the largest and most complex sites in northwest Mexico. The culture is characterized by a unique blend of Southwest and Mesoamerican traits, yet it has received far less scholarly attention when compared to its neighbors to the north and south. As such, there are a number of critical issues that require further investigation, including site and regional chronology, settlement and exchange patterns, relationships with outside groups, and the nature of the site itself. The papers in this symposium address these key areas of deficiency through a variety of methodological techniques, including radiocarbon dating, ceramic and lithic analyses, XRF, biodistance, and stable isotope analyses. In so doing, this symposium provides new insight into the prehistory of Casas Grandes, as well as its relationship to surrounding regions.

[238] Symposium · ECOLOGICAL ADAPTATIONS AND NEW FORMS OF PASTORALISM? NEW INSIGHTS INTO HERDING PRACTICES IN THE ANDES DURING PREHISPANIC TIMES
The Andean pastoralism and the establishment of trades between different ecological levels (concept of Andean verticality) are the basis for the emergence of complex societies in the Central Andes. Llamas and alpacas are the only large domestic mammals in the Americas. With the intensification of their breeding, camelids occupied a fundamental economic, social, and religious role in Andean life. Today, camelid livestock are confined above 3,500 masl to the ecozone of the puna or altiplano, while their presence during prehispanic times in other areas (such as the Pacific coast, for example) is attested by archaeological skeletal remains, textiles, and iconographic representation. However, modalities subtending the camelids’ adaptation to these different environments, as well as herd and territory management, remain unknown. The objective of this symposium is to document these modalities and the different herding practices by gaining new insights into diet, mobility, location of breeding, and health status of archaeological camelids. These data will allow us to understand how prehispanic societies adapted their practices to the difficult of the environment, and show that herding practices were varied and not restricted to breeding at higher altitudes.

[239] Forum · ARCHIVING US: COLLECTING ORAL HISTORIES FOR TOMORROW’S HISTORY OF AMERICAN ARCHAEOLOGY
(SPONSORED BY HISTORY OF ARCHAEOLOGY INTEREST GROUP)
When studying early American archaeology, researchers can rely on a rich trove of physical correspondence that grace many archives to understand theoretical and methodological developments in our discipline—and the people and personalities that guided these developments. However, the documentary record is becoming more intangible and ephemeral as archaeologists increasingly rely on electronic communication and social media. As SAA members age and retire, we risk losing those personal insights that are key to contextualizing American archaeology—and writing future histories of the discipline. In response to these critical challenges, this forum focuses on a new oral history project spearheaded by the History of Archaeology Interest Group (HAIG) that is aimed at collecting personal insights and recollections from SAA members at or near retirement, or already retired, and nonmembers who are acknowledged as key to the development of American archaeology. Here discussants will outline this new initiative, share insights on interviewing and recording techniques, and invite SAA members to join in these efforts both at upcoming SAA meetings and regional venues.

[240] Symposium · WHEEL OF FORTUNE: CERAMIC ANALYSIS AND THE STUDY OF TECHNOLOGY, EXCHANGE, AND SOCIOPOLITICAL CHANGE IN THE MEDITERRANEAN AND GREATER NEAR EAST
The ubiquity of ceramics in excavation renders them one of the most productive types of data for the study of social, economic, and political processes in ancient societies. Advances in digital and scientific techniques have supplemented traditional methods of analysis, opening new avenues for exploring larger anthropological questions through ceramic study. The aim of this session is to survey the diverse methods available for the use of ceramics data in research examining economic and political changes and sociocultural phenomena. Topics addressed will include the adoption of new dining customs, the transference of technological knowledge between master potter and apprentice, change and disintegration of political economies, imperial integration of consolidated regions, and the nature of trade systems and their governing political structures. A variety of analytical approaches will be employed within session papers, ranging from chemical and petrographic studies of clay sourcing and production technique, functional use and contextual analyses, and distributional and network approaches to object mobility. This session will incorporate datasets from broad regions of the Mediterranean and Greater Near East from prehistory to the Roman period.

[241] General Session · EASTERN WOODLANDS ARCHAEOLOGY

[242] Symposium · MAKING A “-CENE”: ARCHAEOLOGY, POLITICS, AND THE ANTHROPOCENE
The concept of the Anthropocene relies on ideas about the human past, the relationship between humans and nonhumans, and the material politics of the contemporary world. Many of the central engagements of archaeology have become objects of concern for other disciplines and new publics. Viewed from archaeology’s ongoing engagement with these ideas, the political implications of the turn to (and the contents of) the discussion of the Anthropocene are uncertain. Often these discussions recruit or rely on narratives about the human past and what it can tell us about human nature and our potential futures. This session interrogates how discussions of the Anthropocene in the contemporary moment rely on particular narratives about the past, and how these relate to archaeologists’ understandings of the politics of the past and our accounts of politics in the societies we study. Politics, here, is not limited to questions of the polity or political subjectivity, but includes questions of inequalities in access to materials and power, as well as humans’ relationship to nonhumans. As such, it draws together a number of strands of recent theoretical interest in archaeology, including symmetrical archaeology, new materialisms, human-animal relationships, and a renewed interest in the archaeology of the political.

[243] General Session · MAPPING THE MAYA WORLD
Archaeological data have demonstrated that prehistoric Americans had considerable influence on the structure of their environments; however, this influence often went unacknowledged by the accounts of European colonizers, who were struck by what seemed to them “pristine” landscapes. One proposed cause for this contradiction is environmental rebound: indigenous populations were so reduced by disease, violence, and other consequences of colonization that there was a rebound of resources to historically observed levels. Although widely invoked as an explanation for the pristine myth, environmental rebound in the protohistoric Americas is not well understood, in part due to the methodological challenges involved in exploring multi-causal explanations. How did disease, warfare, and other aspects of colonization combine to produce demographic change? Was rebound ubiquitous in the Americas? Did it occur after initial contact with non-indigenous populations or only after sustained colonization? In testing for rebound in the archaeological record, how do we disentangle the effects of climate change and in situ cultural change? This symposium will explore these and other challenges in identifying protohistoric changes in environment and subsistence.

In celebration of 20 years of the Geoarchaeology Interest Group (GIG) in the Society for American Archaeology, we seek to clarify the present and future contributions of geoarchaeology, in terms of practical techniques, analytic and interpretive methods, and theoretical approaches. Whether as its own field or hybridized multidisciplinary endeavor, geoarchaeology has grown over the last decades to encompass a multitude of research themes and operational procedures, but what unifies this diversity under the name of geoarchaeology? Furthermore, what are the current and emerging new challenges for practicing geoarchaeologists as relevant for today’s concerns of sustainable development, values of landscapes as heritage resources, and the place of human societies within a changing environment?

Archaeologists embraced radiocarbon dating almost immediately upon the validation of the technique, and many of the subsequent developments by radiocarbon scientists related to sample pretreatment, calibration, and statistical analysis have been driven by the needs of this specific community. Despite the close affiliation between these two groups the relationship often remains one of producer and user rather than collaborator, which has led not only to misunderstandings on both sides that create a drain on an archaeologist’s limited resources (time and money), but also to limit the interpretative power of 14C dates. This forum brings together radiocarbon scientists and archaeologists primarily engaged with using radiocarbon dating as a specific research tool for developing detailed site-based and regional chronologies. The session participants will present a few personal thoughts about this relationship, engage in discussion, and answer questions from the wider archaeological community.

Linear cultural resources, such as trails, canals, roads, railways, and transmission lines are ubiquitous across the landscape and pose a unique set of challenges to those who study and manage them. Linear resources can be difficult to identify using traditional survey techniques and large-scale linear resources are more likely to have segments destroyed or significantly altered. Linear resources often require additional research to properly document them, leading archaeologists to question how much of the resource they should record and how much detail they should provide. In addition, one linear resource may be managed by numerous groups, including regulators, volunteers, and for-profit organizations, and it may be associated with any number of other cultural resources along its length. This in turn leads to questions regarding jurisdiction, interpretation, and maintenance, or in some cases, repair. Participants in this forum will discuss some of the challenges they face in identifying, examining, and managing linear cultural resources, offering insights to those practices that have worked well in the past, with the goal of identifying a set of best practices for future researchers.
priorities. We examine this through two separate Indigenous and non-Indigenous field school settings. Students from the Barkley heritage conservation in coastal British Columbia that highlight how their field-based learning contributes to community interests and America and elsewhere. This poster session invites emerging research contributions from student scholars in archaeological and VICTORIA[263] Poster Session · STUDENT RESEARCH IN COASTAL AND COMMUNITY ARCHAEOLOGY AT THE UNIVERSITY OF between sites. Ethnoarchaeological studies have shown the value of studying human spatial arrangements to characterize group size, group relatedness, subsistence practices, and other economic activities. Over the years a number of Paleoindian sites in eastern North America have been excavated that contain precise spatial data on artifacts and features. These sites range from small ephemeral campsites to larger habitation sites with multiple loci. Through various analyses, presenters in this symposium present ongoing research focused on intrasite spatial patterning. As a whole these studies offer new directions in exploring spatial patterning at hunter-gatherer campsites and contribute to a larger goal of building spatial databases that will allow for future comparisons between sites.

[262] Poster Session · INTRASITE SPATIAL PATTERNING AND THE PALEOINDIAN RECORD OF EASTERN NORTH AMERICA

Community-driven archaeology is broadening its influence throughout anthropology undergraduate and graduate programs in North America and elsewhere. This poster session invites emerging research contributions from student scholars in archaeological and heritage conservation in coastal British Columbia that highlight how their field-based learning contributes to community interests and priorities. We examine this through two separate Indigenous and non-Indigenous field school settings. Students from the Barkley Sound project have investigated a precontact site in the Broken Group Islands in Pacific Rim National Park Reserve. Their work forms a collaboration with Nuu-chah-nulth First Nation. Students from the Heritage and Historical Archaeology field project conducted research at Emanu-El Cemetery, in Victoria, the oldest continuously used Jewish cemetery in Western Canada. The projects that they have developed and report on here are part of their contribution to the Synagogue and Jewish community. This poster session will explore how student projects can expand contemporary perspectives on the possibilities of community-engaged teaching and research.

[264] Symposium · INTEGRATING FUNCTIONAL ANALYSIS: CONTRIBUTIONS FROM USE-WEAR ANALYSIS WITHIN THE BROADER CONTEXT OF HUMAN BEHAVIOR IN PREHISTORIC NORTH AMERICA

Many studies of lithic technology have utilized the concepts of economy and efficiency but rarely do they integrate direct evidence of tool function in conceptualizations of raw material economy. Similarly, use-wear analysts have produced a body of literature on the function of stone tools but have rarely integrated their results into the larger context of human behavior. Stone tool use wear is often included as a separate section of archaeological reports and conclusions about tool function arising from use-wear analysis are rarely considered in conjunction with functional conceptions arising from tool morphology, assemblage composition, or spatial distribution. Recognizing the overall role that lithics play in complex economies requires a multifaceted approach to tool function. Function is not merely the physical use of a tool, but is contextual and complex, impacted by numerous factors, including climate, subsistence, and settlement strategy, inter- and intragroup communication and competition, demography, and ideology. This symposium is aimed at fostering a more integrated approach to functional analysis; one that utilizes multiple datasets and highlights the wealth of information derived from use-wear analysis when incorporated into broader interpretations of prehistoric lifeways.

[265] Symposium · THE INTERACTION BETWEEN POLITICAL AND ECOLOGICAL FRONTIERS

This session seeks to explore archaeological perspectives on the relationship between ecological and political frontiers. Sometimes, at least, ecological and political gradients may be largely coterminal. Prominent examples might include the pastoralist polities of the Eurasian steppe such as the Xiongnu and the Scythians, and their more agrarian neighbors to the south. In other cases, political
and ecological borders may often be starkly at odds with each other; the Inka Empire, for instance, successfully extended itself across the highly divergent ecozones of the Andes. Yet, even where political frontiers follow ecological boundaries, they only ever do so for a time. The pastoralist-agricultural boundaries of Eurasia were sharp political borders until they weren’t—and eventually polities emerged that transcended them. The point then is not to see ecological lines as determining their political counterparts, but rather to recognize that although ecological and political borderlands are always interacting, this occurs in complex and often unpredictable ways. Papers are therefore sought that explore such dynamic interactions between ecological and political frontiers, explicitly set within their historical contexts. The session is intended to be global in scope, and aims to include case studies of polities that vary in both scale and organizational character.

[266] Symposium · ARCHITECTURAL STUDIES IN THE U.S. SOUTHWEST: THEORY, METHODS, AND DATA
This session explores household architecture in the U.S. Southwest/Northwest Mexico by considering methodology, theoretical perspectives, and the strengths and weaknesses of regional datasets. The materiality of the house and the dynamic, recursive relationship between houses and people makes architecture an ideal medium for archaeologists to access the daily lives and practices of people in the past. Household architecture provides insight on social organization, economy, cultural transmission, migration, seasonal movement, and interaction. In addition, architecture provides access to the cultural meanings and cosmological significance attached to place and space. Big datasets present methodological challenges to the analysis of architectural data, but also great promise for understanding large patterns at a regional scale. In addition, theoretical perspectives such as materiality and agency are helping archaeologists reframe their consideration of the house and household. The “communities of practice” perspective has been particularly popular in recent Southwest/Northwest research. These perspectives are changing the way that patterns (or the lack of patterns) in the archaeological record are recognized and evaluated. Papers in this session draw on these themes to present recent research on methodology, theory, and data in the study of architecture in the Southwest/Northwest.

[267] General Session · CURRENT RESEARCH IN MESOAMERICAN ARCHAEOLOGY II

[268] Lightning Rounds · MODELING AGRO-PASTORALISM IN EURASIA
The objective of this lighting-round forum is to explore the theoretical and methodological strategies used by archaeologists to model the emergence and dynamics of agro-pastoral economies across time in greater Eurasia. Agro-pastoralism includes mobile or sedentary herding along with farming and/or management of wild plant resources. A main question we would like to address with this forum is, How, and under what conditions did Eurasian agro-pastoral systems achieve or maintain stability or resilience over time? In the forum, we will compare the vulnerabilities and strengths afforded by different variations and combinations of agro-pastoral demographic dynamics, land use, resource management, and economic strategies across diverse landscapes. We particularly wish to stimulate a discussion of how decision-making on the household, corporate group, or bureaucratic level, influenced the development of agro-pastoral systems over time. The new lightning-round format offers an excellent opportunity to bring together a wide range of current research, and to present, discuss, and compare regional studies of agro-pastoralism that use landscape, historical, or evolutionary approaches. We especially encourage discussion of how research into agro-pastoral systems can employ simulation, GIS modeling, or other advanced analytic techniques.

[269] Lightning Rounds · ENDURING CULTURE HISTORY: CONSTRUCTIONS OF PAST COMMUNITIES AND IDENTITIES IN THE TWENTY-FIRST CENTURY
Archaeological cultures and horizon styles are fundamental organizational units in archaeology; however, in many cases, regional culture-histories were established early on, with limited theoretical development. This panel involves a cross-cultural reappraisal of what constitutes archaeological cultures, how we define them, and what they mean. The aims are twofold: to critically evaluate how we define and apply archaeological cultures and horizons as tools and concepts, and to explore individual patterns of adaptations, resistances in different material classes within units. The lightning-round format will allow participants to provide examples of material culture used to define specific archaeological cultures and offer insights into the efficacy of these cultures or styles as archaeological frameworks for comparing regional sites and interpreting past human behaviors. The open discussion will consider the benefits and disadvantages of using these frameworks as they exist in the examples presented here and elsewhere. We seek to understand various circumstances and relationships that are possibly represented by shared sets of material culture, style, and technology across landscapes, and to what extent our present archaeological cultures and horizons represent political, economic, and social units and reflect emic constructions of past identity and community.

[270] Symposium · FORMATIVE INFLUENCES: A GATHERING IN HONOR OF J. SCOTT RAYMOND
Over a lifetime of work in South America, Scott Raymond has greatly contributed to the archaeology of the neotropics. Beginning with his dissertation on the archaeology of the Upper Amazon of Peru, under the supervision of Donald Lathrap at the University of Illinois, Champaign-Urbana, Scott later moved his focus to the Valdivia culture of Early Formative period Ecuador. During the span of his productive career, his interests have included ceramic classification methodologies, the nature of subsistence systems, settlement patterns, and the social formations of Early Formative Ecuador. Friends, colleagues, and students of Scott will present on some of the ideas, research areas, and influences he has had on our discipline.

[271] Symposium · RECENT DEVELOPMENTS IN EAST AND SOUTHEAST ASIAN ARCHAEOLOGY I: MATERIAL CULTURE STUDIES
The archaeology of East and Southeast Asia continues to grow with new scholars, projects, and methodological developments. The dialogue across borders keeps expanding as well, albeit modestly. As in previous years, we wish to bring together scholars to encourage cross-cultural, cross-border, and cross-disciplinary discussions regarding two world regions that have a long history of interaction. As always, the number of participants exceeds by far the number of slots available in one session, so there will be two symposia on recent developments in East and South Asian Archaeology focusing on different aspects of research. This first part brings together papers on material culture studies covering both a wide geographic area and range of time periods. These papers
explore recent research on metal technology, ceramic production, and beads, but also issues of looting and other questions of field research.

[272] Symposium · NEW PERSPECTIVES ON THE ARCHAEOLOGY OF SOCIAL MEMORY IN THE CENTRAL ANDES
For over a decade, social memory has been a mainstay of archaeological inquiry. Scholars have sought to trace the archaeological remains of history, ancestors, monuments, landscapes, and other cultural media reflected in constructions of memory by past societies. Syntheses of archaeologies of memory have been produced for many regions in the world; however, the Central Andes have eluded such an in-depth study. This session seeks to bring together diverse scholarship in order to gain comparative perspectives on both the overall history of memory in the region, as well as the diversity of theoretical and methodological approaches utilized in the study of ancient Andean memory. Related theories that have evolved out of social memory approaches such as persistent place, resilience, and landscape emplacement will also be explored in this session. Topics covered will include the memory of the dead/ancestors, materiality of place, place-making, and ritual landscapes. The purpose of this session is for researchers of this topic to come together in order to survey and synthesize the differing themes on memory and persistence throughout the Central Andes.

[273] Symposium · CONTEMPORARY ISSUES IN ROCK ART CONSERVATION AND PRESERVATION
Conservation and preservation of rock art is a goal of most rock art focused organizations as well as most government agencies tasked with protecting archaeological sites on lands they manage. The way these goals are accomplished varies throughout the world. Sharing information regarding steps taken to reach these goals, successes or failures of the steps involved, and lessons learned in the process can only lead to improved understanding of conservation activities and preservation results. Although conservation projects are often community initiatives spearheaded by an organized group or a government agency, individuals can also be the driving force behind site protection, and this session provides a forum to showcase projects of any size, at any location, using a variety of methods, and resulting in any level of success. The symposium seeks to provide an overview of contemporary actions being employed on behalf of rock art site protection.

[274] Symposium · ANTHROPIC ACTIVITY MARKERS: ARCHAEOLOGY AND ETHNOARCHAEOLOGY
People tend to recurrently use specific areas of their living space, producing an accumulation of evidence (chemical and/or physical) that represents the result of the activity performed. The possibility to identify and connect this evidence to the activity that generated the record is pivotal to our understanding of past human behavior. Ethnoarchaeology and experimental archaeology drive the inferential reasoning that creates the models connecting the distribution/concentration of proxies with specific activities. We define these models as “anthropic activity markers” and propose a transdisciplinary approach to reduce problems of equifinality whereby the same pattern might be caused by several activities. In particular, the analysis of the spatial distribution of the fingerprints under inferential reasoning that creates the models connecting the distribution/concentration of proxies with specific activities. We define these models as “anthropic activity markers” and propose a transdisciplinary approach to reduce problems of equifinality whereby the same pattern might be caused by several activities. Although conservation projects are often community initiatives spearheaded by an organized group or a government agency, individuals can also be the driving force behind site protection, and this session provides a forum to showcase projects of any size, at any location, using a variety of methods, and resulting in any level of success. The symposium seeks to provide an overview of contemporary actions being employed on behalf of rock art site protection.

[275] Symposium · OF DUNG AND HUMANS: THE ARCHAEOLOGY OF LIVESTOCK DUNG
Dung is a key interdisciplinary area of research as it provides valuable information on a wide range of environmental and ecological issues and socioeconomic and cultural aspects of human life. Livestock dung is commonly found in many settlements, especially after the domestication of herd animals. However, dung materials are regularly overlooked or missed using conventional excavation procedures, despite their worldwide economic importance as suppliers of fertilizer, fuel, and building material. This session showcases interdisciplinary approaches to debates surrounding the identification and interpretation of dung remains in archaeological contexts through multi-proxy analytical techniques in bioarchaeology, geoarchaeology and biochemistry. Additionally, the use of ethnography and experimental archaeology provide robust comparative data and models on factors affecting its composition, preservation, and taphonomy, as well as the environmental, management, and cultural practices influencing these. By bringing together participants working in a variety of geographic and temporal foci and from different fields of research, this session will review the state-of-the-art identification methods and approaches to further our understanding of archaeological livestock dung, and to identify avenues for potential future growth/developments in this key research area.

[276] Symposium · CURATING THE PAST: THE PRACTICE AND ETHICS OF SKELETAL CONSERVATION
The human skeletal remains curated within archaeological and museum collections belong to those who created the cultures that we seek to understand as archaeologists. Human and faunal remains recovered from archaeological excavations provide a wealth of information about past cultures, but also require the greatest care. The recovery, cleaning, and curation of bone often present one of the great challenges for archaeological projects as a bioarchaeologist or zooarchaeologist may not be on site. What is the best way to transport fragile materials to labs or to export them? How should they be stored until they can be analyzed, or over the long term? Should they be cleaned? Field labs, museums, and universities in remote locations are often only periodically monitored, can have extreme humidity or heat, be infested by insects or animals, lack financial support for collection maintenance, and/or be at risk due to natural disasters like earthquakes or hurricanes. This session describes techniques that osteologists have employed to address these problems as they have worked to curate and house skeletal collections from prehistory through the contemporary era in Europe, Asia, and the Americas in light of ethical and cultural considerations of modern populations.
[277] Symposium · SETTLEMENT SCALING IN ARCHAEOLOGY—NOT JUST MODERN, NOT JUST URBAN
The fact that cities become more efficient, innovative, and productive as they grow in population has been known for decades, but until very recently it was assumed that these properties were unique to modern capitalist economies. Three developments have cast significant doubt on this view. First, urban economists and economic geographers have had to make increasing use of insights from history and anthropology to account for features of contemporary cities. Second, a mathematical theory that predicts contemporary patterns has been developed, but it relies on very general properties of human networks embedded in space, not the specific properties of capitalism. Third, archaeological studies have discovered that many scaling properties of modern cities are also apparent in premodern and even nonurban settlement systems. These developments point toward a new way of framing human societies as complex networks, new avenues for the study of social evolution, and a new conception of the archaeological record as a repository of experiments in social and economic development. In this session we introduce settlement scaling theory to archaeologists, present a series of case studies from around the world, and critically assess its current strengths and weaknesses.

[280] Symposium · RECENT SHIFTS IN MAYA ARCHAEOLOGY: INVESTIGATIONS OF THE COLONIAL AND NATIONAL PERIODS OF THE YUCATÁN
This session seeks to highlight developments in the archaeology of the colonial and early national periods throughout the Maya regions. Maya archaeologists working in Mexico and across Central America have produced a rich body of scholarship exploring Maya society before Spanish invasion and settlement. Maya archaeology has been influential at both the regional and the international levels, generating standards for archaeological practice, introducing innovative scientific techniques, melding archaeology with ethnohistory and epigraphy, creating theories about the rise, maintenance, and collapse of state-level societies. However, the rich material record and cultural groups from the periods following Spanish-Maya contact have remained marginalized within the archaeology of this important cultural and geographic region. This session will bring together scholars working through the region at sites from the colonial through early national periods, and beyond. Historical archaeology across Mexico and Central America is only just gaining momentum. The scholars involved in this session are contributing not only to the expansion of knowledge about these marginalized time periods in Maya archaeology, but are also addressing some of the field's most pressing theoretical and methodological questions.

[278] Symposium · HOUSEHOLDS AND SOCIAL EVOLUTION: COMPREHENSIVE APPROACHES TO SOCIAL TRANSFORMATION
Social evolutionary transformation involves and affects all levels of human society, including households. Household and social evolutionary archaeological approaches, however, are often considered to have different goals and perspectives. Social evolutionary studies use a long-term and comparative approach to study how fluctuations and changes (both abrupt and gradual) in social, political, economic, and ideological systems can ultimately lead to the transformation and emergence of unprecedented sociopolitical organization. Household studies examine daily life as the locus of many important social, economic, political and ritual activities to understand some of the same systemic reorganizations and transformations. This session explores the relationship between social evolution and household archaeology in a global context. Bringing these two bodies of theory together involves taking a comprehensive approach to the study of societies and their internal systems and processes. This includes challenging commonly drawn divisions between the macro- and microscale, public and domestic domains, and ceremonial and quotidian activities. A more inclusive approach to the study of sociopolitical change can facilitate the effective use of temporal and spatial comparisons to better understand local regional developments and the dynamics of social complexity.

[282] General Session · EUROPEAN ARCHAEOLOGY: FROM THE PALEOELITHIC TO THE RECENT PAST

[279] Symposium · NEW DISCOVERIES AND MULTIDISCIPLINARY RESEARCH AT YANGGUANZHAI, CHINA
Yangguanzhai is the largest known middle Neolithic site in the Wei River Valley of China. Over ten years of excavation and research at the site have yielded data on pottery production, house structures, diet, burial practices, and the construction of an ancient moat. In this session, current and former project participants will present research project in ceramic analysis, geoarchaeology, bioarchaeology, paleoethnobotany, and other fields. This ongoing multidisciplinary research has generated significant new information and a greater understanding of craft production, settlement structure, and domestic life in prehistoric central China.

[281] Symposium · FLOODED ANCIENT MAYA SALT WORKS, PAYNES CREEK NATIONAL PARK, BELIZE
The session discusses research at the Paynes Creek Salt Works, as well as comparisons with other ancient Maya salt works. Excavations and sediment coring carried out between 2009 and 2015 investigated the nature of the Classic period (A.D. 300–900) salt industry that used wooden buildings preserved below the sea floor in a shallow, salt-water coastal lagoon. Salt was produced by evaporating brine in pots over fires as indicated by briquetage, the remains of pottery vessels and supports used in the salt production. Ten underwater salt works were selected for transect excavations. Land sites with earthen mounds were excavated to evaluate their role in the salt industry. Sediment coring, as well as collection of marine sediment from underwater excavations focused on the timing and rate of sea-level rise. Remote sensing using an automated research vessel, as well as air photography from a drone augmented the systematic flotation survey on Research Flotation Devices (RFDs). The Paynes Creek Salt Works, with evidence of infrastructure of production and distribution, provide a model for other salt works along the coast that lack preserved wood, as well as expanding the types of salt production known from inland and coastal salt works.

[283] Symposium · NEW INSIGHTS INTO MISSISSIPPIAN CULTURE AT CAHOKIA MOUNDS STATE HISTORIC SITE
Past and ongoing research at Cahokia, its satellites and outliers, has produced a plethora of information, old and new, which contributes to a better understanding of how this site was planned, organized, occupied, and evolved over several centuries. Current research also demonstrates how Cahokia related to and interacted with neighboring and distant sites, and how it reflected the cosmology of the Mississippian cultural tradition. This symposium will summarize the findings of current research in the greater Cahokia area, including the expansion of previous excavations, evidence copper technology, the relationship of Cahokia to its
outlying communities, new insights on community planning from geophysical tests, the astronomy and geometry of the site, and the internal reorganization and development of Cahokia proper.

[284] Symposium · METHODOLOGICAL ADVANCES IN ISOTOPIC ZOOARCHAEOLOGY
This session will explore new methodological advances in isotopic analysis using ancient animal remains to address key questions in human prehistory. Isotopic investigations in zooarchaeology have the potential to address diverse social and biological topics, including diet and foodway practices, hunting and procurement strategies, status and differential provisioning, exchange patterns, animal rearing and husbandry, biological consequences of domestication, and short- and long-term environmental changes. Examining these topics in past archaeological contexts is essential for understanding animal and human interactions in the present. Development of new methodologies in concert with traditional zooarchaeological analyses allow us to examine questions and issues regarding human ecology and environmental archaeology that were previously inaccessible.

[285] Symposium · ARCHEOLOGIES OF EMPIRE AND ENVIRONMENT
(SPONSORED BY ARCHAEOLOGY DIVISION, AMERICAN ANTHROPOLOGICAL ASSOCIATION)
This symposium brings together archaeologists studying environment and empire across time and space to discuss the role that agriculture and land use plays in imperial strategies. This session asks how plants, animals, and other environmental resources become entangled in imperial acts of conquest and colonization, exploitation, and inculcation. This archaeological approach invites theoretical and methodological perspectives that connect imperial strategies with their environmental settings and imbue the environment with political criticality. They include environmental archaeologies that investigate local/regional signatures of empire; historical ecologies that ask how land management affects imperial biographies; political ecologies that presume environmental regimes have political valence; and new materialisms that infuse the nonhuman world with agency. When archaeologists view imperial land use and environmental management as forms of statecraft, the political landscape moves from metaphor to unit of analysis, and ecofacts gain empirical heft as artifacts of empire. This perspective reinstates an appreciation for the political economies of agrarian states, with all the resource flows and divisions of labor that surplus cultivation entails. At the same time, this approach treats political economies as human-environment interactions, which opens up all kinds of new questions, challenges, and approaches to the intersections of empire and environment.

[286] Symposium · ARCHAEOLOGICAL PERSPECTIVES ON THE EVOLUTION OF FORAGER COOPERATION
Habitual cooperation among non-kin is biologically unusual and yet a defining behavior of the human species. Understanding how such altruistic behavior emerges and persists among human populations remains an active and heavily debated area of anthropological and ecological research. While ethnographic forager studies have played a particularly prominent role in the discourse, contributions from prehistoric forager studies remain sparse due to the inherent challenges of studying past populations who left few, taphonomically vulnerable material traces. Nonetheless, because prehistoric foragers were the very individuals who catalyzed and maintained human cooperation for thousands of millennia, the insights to be gained may be particularly salient in advancing evolutionary theories of cooperation. This symposium seeks to identify the diverse ways that archaeological forager research can contribute to the study of human cooperation and to inspire new analytical directions at the intersections of theory, method, and data.

[287] General Session · ADVANCES IN ARCHAEOLOGICAL METHOD AND THEORY

[288] Symposium · BUTTERFLIES TAKE WING: RITUAL AND SYMBOLISM IN PRECOLUMBIAN MESOAMERICA
Butterfly imagery has been present for thousands of years in Mesoamerica whether painted, modeled, or sculpted. Its life cycle, bright colors, and soaring flight captivated the mind of culturally diverse peoples in the Americas for its significance as a symbol of renewal, transformation, fire, war, and death. This session draws on a diverse range of methodological enquiries based on recent iconographic and archaeological research about butterfly representation in Mesoamerica: ceramics from West Mexico, Toltec sculptures, Zapotec effigy vessels, Teotihuacan ceramics and mural paintings, and Postclassic books (codices) and gold. The methodologically and thematically diverse papers aim to grasp the multifaceted nature of the butterfly, an insect that incorporated the ideology of this rich cultural area. Through the lens of several Mesoamerican specialists, this session will throw new light onto its context-related associations, identify processes of information transmittal and emulation, and thus elucidate its implications in each cultural milieu.

[289] Symposium · INTER- AND MULTIDISCIPLINARY APPROACHES TO ARCHAEOLOGICAL RESEARCH IN THE CARIBBEAN
The main objective of this symposium is to bring together researchers who study topics related to Caribbean archaeology from interdisciplinary and multidisciplinary approaches. These approaches not only allow the incorporation of a wide variety of sources of information and methodologies but also foster the revision of previous interpretations. Some of the questions that need to be posed are: To what extent are auxiliary disciplines helping to expand the construction of the stories being created by archaeologists? How can we use archaeological data in a way that the general public can relate to the research being carried out? Through case studies that employ methodologies that borrow from documentary archaeology, collections management, and hard science, this symposium will explore the possibilities of broadening the interpretations of our understanding of past human activities within the Caribbean region. Likewise, it makes it possible to revisit existing collections and expand traditional research questions. In this symposium, we want to bring forward the efforts being made to creatively use existing sources and methods in the development of new research projects in the Caribbean.

[290] General Session · UNDERSTANDING PALEODIETS THROUGH ISOTOPIC RESEARCH I
One of the many ethical responsibilities of an archaeologist is to demonstrate the relevance of archaeology and historic preservation to a diverse public in a meaningful way. Communication by archaeologists to the public is crucial to gaining support for archaeological resources, programs, and institutions. This is especially critical given recent trends at state and federal levels toward funding reductions and legislation that impacts archaeological resources. Additionally, skills in communication and outreach are increasingly valued in the archaeology job market. Anyone dealing with funding from public sources should be able to effectively communicate the value and relevance of archaeology to non-archaeologists. In today’s world, this often involves communicating information quickly, simply, and sometimes with little preparation. This lightning round is an opportunity for archaeologists to present, in three minutes or less, an “elevator pitch” focused on public benefits of archaeology, how archaeology addresses contemporary problems, what is archaeology, or responding to an enthusiastic collector. Presenters will get immediate feedback from a panel of archaeologists with expertise in public engagement. Participants are allowed one PowerPoint slide to accompany their presentation. A group discussion will follow the individual presentations, and the panelists will provide further information and resources for communicating with the public.

[292] General Session · COLONIAL-ERA ARCHAEOLOGY IN CENTRAL AND SOUTH AMERICA

[293] General Session · CURRENT RESEARCH IN MESOAMERICAN ARCHAEOLOGY III

[294] General Session · MORTUARY PRACTICES AND FUNERARY ARCHAEOLOGY II

[295] Forum · CARING FOR HOMELANDS, PART 2: TRIBAL HISTORIC PRESERVATION IN THE UNITED STATES

[296] Symposium · EXPLORING MOVEMENT ON WATER: A GLOBAL COMPARISON OF NAVAL TECHNOLOGY AND NAVIGATION TECHNIQUES

[297] General Session · WESTERN ASIAN ARCHAEOLOGY I

[298] General Session · POLITIES AND INTER-POLITY DYNAMICS IN THE MAYA WORLD II

[299] General Session · ARCHAEOLOGY IN THE AMERICAN MIDWEST II

[300] Poster Session · NORTH AMERICA: CALIFORNIA

[301] Poster Session · ARCHAEOLOGICAL PERSPECTIVES ON THE SOUTHWESTERN LANDSCAPE

[302] Poster Session · OCEANIA
[303] Poster Session · A FLURRY OF FIELD SCHOOLS IN THE UPPER GILA AND MIMBRES DRAINAGES
The Upper Gila, San Francisco, and Upper Mimbres drainages have seen several cycles of intense research and student training since the 1930s. Field projects directed by notable archaeologists and institutions, including Emil Haury, Paul Martin and John Rinaldo, James Fitting, Harry Shafer, and the Mimbres Foundation, have periodically focused professional attention on the area while providing fertile training grounds for students in U.S. Southwest archaeology. Currently the area is in the midst of another archaeological boom, with field schools from multiple institutions introducing new students to the area and changing our understanding of the region through new research programs that span much of the precontact period. This session presents research from five current field schools, bringing together established and emerging scholars to present new insights on the archaeology of southwestern New Mexico and southeastern Arizona.

[304] Poster Session · ARCHAEOLOGY ALONG THE PAINTED DESERT: CURRENT RESEARCH IN PETRIFIED FOREST NATIONAL PARK
While Petrified Forest National Park has been the subject of archaeological research for over 100 years, intensive field research in the last five years has greatly expanded what we know about the prehistoric and historic occupation of the area. In 2004 Congress authorized a boundary expansion, effectively doubling the size of Petrified Forest National Park. These lands are slowly being purchased and added to the park. Initial cultural resource inventory projects are being conducted to begin to better understand what is out there. The results of survey in the boundary expansion have found a stunning density and diversity of archaeological remains. Archaeological sites spanning the last 13,000 years of human occupation have been identified, including most notably extensive preceramic sites and lithic landscapes, large Basketmaker villages, and a densely settled Puebloan landscape. This work has been coupled with an additional season of survey work in the park’s pre-2004 core to contextualize previous research with these new areas. Also, over the last five years the NPS has taken this opportunity to use the park as a teaching laboratory, bringing in graduate student research and an extensive internship program. This session presents an update of the recent archaeology in Petrified Forest.

[305] Symposium · ECOLOGICAL PERSPECTIVES ON HOMININ LANDSCAPE USE DURING THE EARLY STONE AGE OF AFRICA
It is increasingly clear that Africa’s Early Stone Age (ESA) sites sample a diversity of behaviors and no one model is sufficient to explain every collection of archaeological debris. Behavioral flexibility was thus probably a key component of hominin adaptations, and the goal of this symposium is to identify the ecological parameters, or affordances (resources and hazards), that conditioned where, when, and how hominins chose to concentrate their archaeologically visible behaviors across Africa’s ESA landscapes. Papers in this session have a strong ecological focus and will contribute to an integrated examination of ESA hominin landscape use in Africa from faunal, lithic, paleobotanical, isotopic, and/or geological perspectives.

Previous survey by Gutierrez in the area had revealed numerous sites, but the past field season (summer 2016) of the PIPOG (Proyecto Interdisciplinario de la Prehistoria del Oriente de Guerrero) was the first reconnaissance focused on caves and rockshelters in the municipalities of Tlapa and Copanatoyac. In eastern Guerrero, cave sites have been used by humans since Paleoindian times to the present-day rain-petition rituals centered on the feast of San Marcos. This session reviews the preliminary findings of the PIPOG in a series of caves, including photogrammetric studies, pXRF elemental analysis of murals, and excavation.

[307] General Session · ADVANCES IN GEOARCHAEOLOGICAL RESEARCH METHODS I

[308] General Session · PERUVIAN ARCHAEOLOGY

[309] Symposium · REGIONAL CONNECTIONS IN NORTHERN ETHIOPIA AND ERITREA: RELATIONSHIPS BETWEEN THE EASTERN, WESTERN, AND CENTRAL HIGHLANDS
(SPONSORED BY SOCIETY OF AFRICANIST ARCHAEOLOGISTS)
Traditionally, archaeological research in the northern Horn of Africa has had a strong focus on external relationships. Connections with the Mediterranean, Sudan, and especially the Arabian Peninsula have been emphasized. On the other hand, little research has been done comparing different sites within northern Ethiopia and Eritrea. This is mainly due to the limited number of excavated and fully published sites in the northern Horn. Recently, there has been a surge of excavation, research, and publication, making it more possible than ever before to compare different sites and regions within the highlands. The German Archaeological Institute project at Meqaber Ga’ewa and Ziban Adi represents the new southern extent of excavation, while the University of California–Los Angeles project at Mai Adrasha represents the new western extent. The goal of this session is to foster cooperation and exchange between current excavation teams and discuss how our various sites may have related to each other in the past.

[310] Symposium · THE PRECOLUMBIAN ANTIQUITIES MARKET: REFLECTIONS, CRITIQUES, AND EFFECTING CHANGE
Precolumbian antiquities are among the most popular items on the international antiquities market. Because of the opaque nature of the antiquities market and the phenomenal growth of online and alternative sales platforms in recent years, it has become increasingly difficult for the scholarly community to monitor the precolumbian antiquities market. Studies into this market are limited, repetitive, or outdated; we may not have a real sense of the nature and function of the current market for precolumbian objects. Without this information it is unlikely that we will be able to positively influence policy in this area or effect substantive change. This session will explore past, current, and future policies and trends concerning the sale of antiquities from Central and South America. By exposing the developments through time, and reviewing some of the most prominent individuals and organizations that have
bought and sold at auction, a clearer understanding of the current state of research into the market for precolombian objects can be achieved. Having outlined gaps in our knowledge, this session seeks to identify the substantive steps that the academic community can take toward effecting transparency, accountability, and ethical practice within the precolombian antiquities market.

[311] PAST PRESIDENT SESSION · A CELEBRATION OF THE LIFE AND WORK OF DR. DENA FERRAN DINCIAUZE (1934–2016)
Participants in this forum will highlight the many achievements and contributions of Dena Dincauze. A distinguished scholar who specialized in the archaeology of northeastern North America, the peopling of North America, and environmental archaeology, Dr. Dincauze’s many achievements include having earned a PhD from Harvard University in 1967, a time when few women were completing graduate studies in archaeology. She was a research fellow at Harvard University, an assistant professor at SUNY Buffalo, and an assistant, associate, and full professor at UMass Amherst, where she retired as a professor emerita in 2001. Over the course of her career she significantly influenced the field through her scholarship, publications, conference papers, editorial board service, teaching, and mentoring. Over the course of her prominent career she served as the president of the SAA, editor of American Antiquity, president of the Society for Professional Archaeologists, and was the recipient of the SAA Distinguished Service Award in 1997. She was a dedicated mentor to several generations of archaeology students, many of whom have gone on to make their own substantial contributions to the discipline. She was an especially strong mentor for women in archaeology and, as such, has left an indelible impact on the field.

[312] Forum · CURRENT CHALLENGES IN USING 3D DATA IN ARCHAEOLOGY
3D technologies are integral to current practice in archaeology, and part of the daily work of a growing community of archaeologists in research and heritage management. Reality-based models, produced through techniques like laser scanning and photogrammetry, and virtual reconstruction models play important roles in many applications, impacting data collection, analysis, and presentation. As technical barriers are overcome, significant intellectual challenges remain for the full integration of 3D content in the field. This forum discusses three key challenges: (1) integrating 3D into scholarly publications, (2) scaling up data collection and maintaining appropriate accuracy, and (3) 3D work as a reflexive research process.

[313] Forum · ANIMAL ARCHAEOLOGY
Animal archaeology is an emerging discipline that uses the techniques and methods of archaeological science to study the past behaviors of nonhuman animals. Its applications to animal behavior are multiple. They include tracing the history of a species’ tool use, identifying a species’ past ranges that are no longer in use, and understanding how animals interact with objects in their daily lives. For archaeologists, it can help us to understand the evolution of the human species, distinguish human from nonhuman subsistence remains, and provide another outlet for archaeological skills. This forum brings together a diverse selection of animal archaeologists who are pushing the boundaries of two disciplines. We will openly discuss ways forward through the clashing of disciplines that is animal archaeology. Each participant will briefly present their work, and there will be ample time for discussion among the participants and audience.

[314] Lightning Rounds · BREAKING NEWS! LIGHTNING STRIKES CROWD OF ARCHAEOLOGISTS AT SAA ANNUAL MEETING: STUNNED SPECTATORS WALK AWAY WITH AMAZING STORIES OF ETHNOARCHAEOLOGY, EXPERIMENTAL, AND CULTURAL STUDIES RESEARCH
Lightning talks are meant to quickly orient an audience and inspire lively and meaningful discussion. Our lightning event focuses on current ethnoarchaeology, experimental, and culture studies research. Presenters will enliven this session with research tales from Africa and the Americas. The audience will learn of the material and social culture of Indigenous groups such as the Miami Tribe of Oklahoma, a local Greenlander community, and Western Namibian pastoralists, along with ethnoarchaeological investigations of Victorian English churchyard gravestones and prehistoric shell industries and cooking techniques in the eastern and midwest United States. Participants will be riveted by experiments on the making of sinew thread, cooking Alaskan king salmon, and beer production, and challenged to consider issues such as climate change and how can we use what we learn about the past and present to provide real, applicable solutions.

[315] Lightning Rounds · BREAKING GROUND WITHOUT A SHOVEL: COLLECTIONS-BASED RESEARCH IN THE FIELD OF ARCHAEOLOGY
(SPONSORED BY THE COMMITTEE ON MUSEUMS, COLLECTIONS, AND CURATION AND THE STUDENT AFFAIRS COMMITTEE)
Until recently, the value of collections-based research (CBR) within the field of archaeology has been underestimated. There is a perception that to do collections-based research is somehow less: less exciting, less rigorous, less groundbreaking. This session is designed to demonstrate to students and professionals alike that CBR is not only a viable and less expensive alternative to fieldwork, it is also a responsible way to ensure that collections are maximized as an existing resource. Archaeological collections have a long life span and limitless potential. Much of the time, collections are curated in a facility, ready to be rediscovered and used for dissertations, theses, and other research investigations. For students especially, it is critical to understand that CBR provides the tools for comparative research, to make new assertions about old sites, especially those which can no longer be actively excavated. Discussants will cover a variety of topics, ranging from exciting new CBR discoveries to new avenues of inquiry with long-standing collections. Recent graduates, current students, and professionals will speak about their experiences with collections-based research, highlighting the challenges and achievements, as well as the etiquette of gaining access to these collections.

[316] Symposium · MULTIDISCIPLINARY RESEARCH AT CASTILLO DE HUARMEY, PERU
The site of Castillo de Huarmey on the north coast of Peru is widely known for a spectacular 2012–2013 discovery—an intact tomb under the Wari imperial mausoleum where a large number of elite females along with their rich grave goods were buried. Along with
extensive excavations and surveys, the Polish-Peruvian archaeological project—Proyecto de Investigación Arqueológica Castillo de Huarmey (PIACH)—is engaged in multidisciplinary research on each aspect of the Wari presence on the north coast of Peru. This research includes analyses of the geographical, geological, and cultural contexts; architecture; artifacts and various techniques used for producing them; sources for textile, pottery, and metal production; as well as osteological, biogeochemical, and genetic analyses of the bioarchaeological individuals. As most of the work is still in progress, the session is designed to inform the scholarly world of this cutting-edge research and to generate a discussion on the results obtained to date.

[317] Symposium · COLONIAL CONSEQUENCES: RESULTS FROM THE ARCHAEOLOGICAL SURVEY OF COLONIAL DOMINICA
Brought into the foreground of anthropological concern through the works of Sidney Mintz, Eric Wolf, and others, the plantation is a spatial and economic category that is at once familiar and strange to archaeologies of environment, social complexity, and power. Through a concentrated examination of one landscape, Soufrière, a settlement enclave on the island of Dominica, and its evolution between the seventeenth and nineteenth centuries, this panel revisits and destabilizes the plantation as a socio-ecological form and explores the unique and dynamic configurations of identity, power, and social relations that such a space engenders. In its material and aspirational emergence, the plantation landscape left behind a material record that enables participants to interrogate three questions. What makes a plantation a plantation? How are social and economic inequalities built into its landscape? How does the material record of enslaved workers speak about, with, or against the plantation as a concept and socio-ecological form? This panel builds on archaeological studies that looking at the evolution of colonial society, demonstrated how domestic economies are essential to understanding the political economy of island colonies, and how ordinary people were linked through regional and interregional interactions in ways not expected by colonial elites.

[318] Symposium · MOBILIZING THE PAST: ARCHAEOLOGY AS ACTIVISM (SPONSORED BY QUEER ARCHAEOLOGY INTEREST GROUP)
Through studies of the past, archaeologists implicitly or explicitly influence the present. The impacts of archaeological research on everyday life range from government policy and legislation, to the reinforcement or subversion of societal norms through naturalization narratives, to the formation of community through a sense of shared past. Recognizing these impacts among others, archaeologists have begun to explore archaeology not just as a means of reconstructing the human past but also as a tool for shaping the present. This empowers archaeologists to heal the wounds and ongoing violence inflicted by colonialism, legitimize the identities or narratives of marginalized people, better care for our environment, represent the needs of living communities, and improve the world around us. This session will explore how archaeologists can extend their focus beyond academia in order to positively impact living people through investigations of history and material culture. Presenters will build on frequently discussed topics in archaeology including community and indigenous archaeologies, demonstrating how we can further our approaches to help heal trauma and build community and bringing to light less commonly discussed issues such as homelessness, gentrification, and LGBTQ rights, thus showcasing the versatile potential of archaeological approaches to activism.

[319] Symposium · TOWARD A SOCIAL ARCHAEOLOGY OF FOOD IN NORTHERN NORTH AMERICA
Archaeology in northern North America has long focused on documenting and modeling hunter-gatherer subsistence strategies within a framework that views the procurement, processing, and consumption of food in terms of peoples’ adaptations to the natural environment. While important, it is clear from the ethnographic record of the region that “food” embodied and offered more to hunter-gatherers than mere sustenance. This session offers case studies that highlight cultural dimensions of northern foods in antiquity. Papers address the social construction of edible and inedible foods; the preparation and presentation of food—cuisine; the transformation of plants, animals, and nonhuman persons into food; the role of food in the crafting of identity, the construction of gender, and status; food in trade, feasting, and ceremonial activities; and social and ideological aspects of the procurement, processing, consumption, and discard of food.

The Olmec and Epi-Olmec center of Tres Zapotes boasts a continuous occupation that spanned over two millennia. For over half that time, between 800 B.C. and A.D. 300, it ruled as the capital of one of the most resilient polities of the Mesoamerican Gulf lowlands, surviving and flourishing after the collapse of Olmec capitals to the east. Subsequently, the area supported a dynamic political landscape occupied by smaller competing polities. In 2014, with NSF support, we initiated a settlement study to place the rise, fluorescence, and decline of Tres Zapotes in its regional context, combining traditional pedestrian survey and surface collection with high-resolution lidar-assisted survey. This symposium presents results of the 2014–2016 fieldwork and ongoing laboratory analysis. Participants will present the theoretical foundations and methods of the survey, reflections on community engagement and the social context of regional survey, an overview of settlement patterns, and new information on interregional interaction, Classic period formal architectural layouts, variation in obsidian production and use, and an unexpectedly robust Postclassic occupation.

[321] General Session · MESOAMERICAN RITUAL STUDIES

[322] Symposium · LOCAL RESPONSES TO REGIONAL INTEGRATION IN POSTCLASSIC MESOAMERICA
An increase in militarism and exchange in Postclassic Mesoamerica brought along greater political, economic, and cultural integration of the region. Expansionist states warred, conquered, and brought into their sway smaller polities undergoing different processes as boundaries were redefined; buffer zones were created, expanded, and retracted; and alliances shifted in response to a changing geopolitical landscape. This session explores the different local and regional responses to the greater political and economic integration that took place throughout Mesoamerica in the Late Postclassic.
Craft production has long been a topic of major interest in archaeology. The spatial arrangement of these activities reflects important features in the social organization of production. Yet interpreting the social meaning of these spatial patterns is challenging, and the relationship between a given spatial distribution and particular type of social organization is not always clear. Considerations of space and craft production are also beset by methodological difficulties. Some kinds of craft production leave ephemeral or difficult-to-identify residues in the archaeological record, posing challenges for identifying the specific places where production occurred. In cases where identification of production contexts detailed excavation or laboratory analysis, moving from single contexts to broad spatial patterns is not a straightforward process. The papers in this session will offer new methodological and interpretive perspectives on how archaeologists approach spatial patterns in craft production. The session aims to bring analyses of craft production at all spatial scales into conversation with one another.

**Power from Below: Collectivity and Heterarchy in Global Perspective**

This symposium focuses on how ordinary people self-govern or co-govern, creating complex polities that maintain egalitarian structures, espouse egalitarian ideologies, or both. We focus on systems of governance engineered to balance power, but also how they continuously develop, falter, and are reshaped: some built directly on earlier egalitarian roots, others stemming from overthrow of authoritarian structures through a yearning for “return” to more balanced rulership—real or imagined. Archaeological concern with alternative forms of governance burgeoned after the “social turn” that took root in the 1980s, followed by convincing exploration of concepts like heterarchy and corporate organization in the 1990s and beyond. Today, the idea of differently organized distributions of power no longer needs to be justified, leaving room to expand study into collective action, subaltern political movements, self-organized production, public assembly places, and political cohesion based on principles other than kinship and coercion. Contributions delve more deeply into this multidimensional space, where complex politicized actors, from commoner to ruler, can be studied. These once-invisible people can be discovered through the use of new methods and theories, fundamentally changing our perception of how past societies were constituted.

**LandCover6k: Using Archaeology to Improve Climate Models**

LandCover6k is an international and interdisciplinary working group dedicated to reconstructing human land use across the Holocene. The goal of this initiative is to critically evaluate and improve models of anthropogenic land cover change used in climate science and historical modeling, work that is urgently needed. Current climate models make little use of the vast repository of evidence about human history, despite an awareness that humans are one agent of global change. Vegetation is known to change in response to many factors, including human land use, but the complex and variable relationships between land use and land cover are still insufficiently understood. Differing assumptions about these relationships have led to significant differences between models of anthropogenic land cover change, a shortcoming with immediate scientific and policy implications for work on global climate. Global climate models thus make use of quite problematic assessments about the subject matter of archaeology and history. In this session, we outline the goals and procedures of LandCover6k and report on preliminary work classifying, compiling, and mapping land-use data from several world regions. Archaeology turns out to be a critical discipline for understanding not only the past, but also the present and future.

**Nica News: Recent Archaeological Research in Nicaragua**

In 1881 John Bransford observed that “nowhere in the Americas was there greater potential for archaeological research than in Nicaragua.” Over 100 years later, that potential is being realized through numerous national and international research projects. Perhaps due to the relative stability of the country, and especially because of the openness to collaborative research, Nicaragua has become a popular destination for archaeologists. This symposium brings together Nicaraguan and international scholars to present their recent research. Potential topics include excavation reports, analyses, and new interpretations.

**Connectivity and Communities of Practice in Lowland South America**

The concepts of “communities and constellations of practice” are employed in archaeology to engage with the connectivity between material culture, knowledge, agency, structuration, and identity. These frameworks emphasize the socially situated and culturally transmitted nature of how to do and make, and seek to trace their empirical outcomes at different spatio-temporal scales. Archaeologists in Amazonia and circum-Amazonia have long sought to explain the occurrence of large-scale and persistent phenomena, while simultaneously accounting for the cultural-linguistic-ethnic diversity apparent across the regions in which they occur. In this context, how can understanding shared notions of practical action aid the study of generative processes underlying the material record? We propose that a crucial connection between historically and contextually specific processes (e.g., innovation, emulation, syncretism) and long-term trajectories (tradition, orthodoxy) within and between communities may be forged by considering practices and their circumstances of transmission. Moreover, identifying vectors of transmission (social networks, geography) can help suggest how they modified, amplified, or constrained historical outcomes. This session aims to unite scholars in discussion under this broad theme, and as a lens through which to view both variation and homogeneity. Challenges to the definition of the community, whether real, imagined, or archaeological, are also welcome.

**Protección del Patrimonio Cultural en México, a través de la Dirección de Registro Público de Monumentos y Zonas Arqueológicos e Históricos**

La Dirección de Registro Público de Monumentos y Zonas Arqueológicos e Históricos es una dependencia del INAH creada desde 1972, a partir de la necesidad de tener el conocimiento pleno de los bienes muebles e inmuebles del país como lo son: paleontológicos, arqueológicos e históricos, así como el conocimiento de su ubicación para su resguardo, ya sea por personas físicas, personas morales, y los que forman parte de los acervos del propio instituto. Con el objetivo de dar a conocer las tareas sustentativas de la Dirección de Registro Público y las condiciones bajo las cuales se protegen dichos bienes, se pretende exponer y difundir ante colegas nacionales y extranjeros las problemáticas, retos y logros en relación al patrimonio cultural mexicano y su
protección, además de hacerlos partícipes de la relevancia de su colaboración en la inscripción de los sitios y materiales, obtenidos como resultado sus investigaciones en México.

[329] Symposium · INTEGRATING AND DISINTEGRATING IN CENTRAL YUCATÁN: ARCHAEOLOGICAL APPROACHES TO SOCIAL CHANGE AT MULTIPLE SCALES
This session explores the dual processes of integration and disintegration primarily through research in the central Yucatán region of the Northern Maya Lowlands. From Formative through Colonial periods, central Yucatán was shaped by the convergence of distinct styles, variable household practices, intersite causeway systems, long-distance exchange, and cosmopolitan identities. We hope to show that integration and disintegration were not restricted to Classic period kings and elites, but date back to the emergence of monumental communities, through the historic period, affecting all levels of society. Archaeologists are often compelled to study integration, the processes and dynamics by which social entities (communities, cities, and states) came together to incorporate wider populations. Of equal importance, this session also focuses on disintegration, the processes by which those social entities, held together by kinship, tradition, and memory, splintered apart. This session investigates these dual processes across multiple scales of social entities, from individual actors and households to communities and regions. By studying both integration and disintegration as two ends of a continuum of social change, we gain a more dynamic perspective of what change meant for institutions, populations, and the daily practices and identities of people living in central Yucatán and beyond.

[330] Symposium · INVESTIGATING THE HUNTER-GATHERERS OF LAKE BAikal AND HOKKAIDO: INTEGRATING INDIVIDUAL LIFE HISTORIES AND HIGH-RESOLUTION CHRONOLOGIES (SPONSORED BY BAikal-HOKKAIDO ARCHAEOLOGICAL PROJECT)
The Baikal-Hokkaido Archaeological Project has been undertaking research on some of the richest hunter-gatherer archaeological records in the world. A particular focus has been on a range of bioarchaeological analyses, including AMS 14C dating, stable carbon and nitrogen isotope data, strontium isotope analysis, and ancient DNA, as well as human and faunal osteological analyses. This symposium presents new research emerging from the project, and assesses its importance for our understanding of past adaptations in the region, as well as for the implications for hunter-gatherer research agendas worldwide. Aspects of continuity and discontinuity are emphasized, particularly in the light of the increasingly high-resolution chronological framework that is becoming available, allowing us to consider historical processes among the hunter-gatherers of Baikal and Hokkaido in ways that were previously not possible.

[331] Symposium · STATUS AND IDENTITY IN THE IMPERIAL ANDES
From the fifteenth to the seventeenth century, Andean populations lived a tumultuous period of cultural contact and entanglement, resulting in a variety of interactions and negotiations between Inka, Spanish, indigenous, and African peoples. While the study of indigenous agency during Classic and Colonial periods has received an increase in deserved attention (deFrance 2003; Van Buren 1993; Wernke 2007, 2013), the role of status and power in shaping colonial interactions has received less consideration. Current archaeological research in the Andes has the potential to build on existing studies of domestic life and changing foodways to better understand complex power dynamics and social dimensions. By focusing on access and incorporation of both indigenous, African, and Spanish goods, as well as their determined quality and value, archaeological studies are well positioned to develop a more nuanced and intimate picture of colonial period social dynamics, especially in regard to the daily negotiations of status and identity. Building on household studies from Spanish Florida (Deagan 1996), this session examines how indigenous and African peoples selectively incorporated or rejected Imperial goods, and how differential opportunities of access to these goods may have influenced social status, health, and relationships with imperial actors.

[332] Symposium · OPEN AIR CAMPS OF THE TERMINAL PLEISTOCENE AND EARLY HOLOCENE: INTRA-CAMP SPATIAL ORGANIZATION, ACTIVITY AREAS, AND TECHNOLOGY
Open air camps from the terminal Pleistocene and early Holocene are rare and pose significant challenges in excavation, analyses, and interpretation. This international symposium brings together case studies of camp sites that provide a means to summarize and discuss current understandings of these important sites. This global discussion provides the opportunity to collaborate on challenges and interpretations. In this symposium we survey intrasite patterning of activity areas, including habitation structures, toward the goal of defining the diversity in site structure and activities.

[333] Symposium · RECENT DEVELOPMENTS IN EAST AND SOUTHEAST ASIAN ARCHAEOLOGY II: SITES, LANDSCAPE, AND ENVIRONMENT
The archaeology of East and Southeast Asia continues to grow with new scholars, projects, and methodological developments. Dialogue across borders keeps expanding as well, albeit modestly. As in previous years, we wish to bring together scholars to encourage cross-cultural, cross-border, and cross-disciplinary discussions regarding two world regions that have a long history of interaction. The number of participants exceeds by far the number of slots available in one session, so there will be two symposia on recent developments in East and South Asian Archaeology focusing on different aspects of research. This second part takes on the macro perspective by discussing human-environment and site-landscape interaction as well as long-distance exchange during prehistoric and early historic periods throughout East and South East Asia.

[334] Symposium · APPLYING INDIGENOUS FRAMEWORKS FOR ARCHAEOLOGICAL ANALYSIS AND INTERPRETATION
Archaeologists often apply interpretative frameworks that they derive from Western disciplinary contexts, even toward sites that were created and organized within non-Western or Indigenous cultural contexts. In this session, we offer contributions that concern Indigenous frameworks—whether as theory, linguistic concepts, oral histories, organizational principles, and/or cognitive or ontological categories—that can be applied toward the analysis and interpretation of archaeological sites. This requires gauging how to configure Indigenous concepts with archaeological strategies and testing methodologies. Such approaches also may involve considering ways to articulate Indigenous frameworks within existing or broadly framed theories, in order to translate from local
interpretations for greater import and applicability. Collaborative and community-oriented archaeologies have provided much groundwork for such approaches, yet some projects limit Indigenous collaboration toward its contemporary practice and contexts, and we seek to highlight avenues of analysis toward the archaeological record. Historically, archaeologists have often sought the theories of Western figures, whether the positivist scientists for processualists or the French poststructuralist theorists for postprocessualists. But, to evaluate the sites of Indigenous peoples, we will emphasize how the cultural ideas and traditions of Indigenous peoples can provide interpretive frameworks for analysis and interpretation to better understand archaeological histories.

[335] Symposium · WALLS, MOUNDS, AND POTS: EXAMINING THE CLASSIC PERIOD HOHOKAM
The Hohokam Classic Period is characterized as a time of change, social differentiation, and possible stratification. The ubiquitous use of towering compound wall, standardized platform mounds, and the widespread adoption of a new kind of pottery, Salado Polychrome, are some of the indicators that a new ideology had spread across the Hohokam region. Archaeological literature has shown that the Phoenix Basin, Tonto Basin, Tucson Basin, and other parts of the Hohokam world were a part of this shared ideology, but differed in how the ideology manifested. The goal of this session is to highlight recent work focused on the Classic Period. Paper topics in this session include ceremonialism and ideology, social and sociopolitical organization, social interaction, exchange, architecture and monumentality, and agriculture and subsistence. These papers, detailing aspects of the Classic Period in different parts of the Hohokam region, will provide a large-scale summary of current Classic Period research.

[336] General Session · MAPPING AND MODELING ARCHAEOLOGICAL DATA

[337] Symposium · THE DYNAMICS OF THE PRECLASSIC IN THE HEART OF THE MAYA LOWLANDS
Understanding the Preclassic period (900 BCE–150 CE), and in particular the Middle Preclassic (900–300 BCE), is essential for grasping the dynamics of Maya society. However, while our knowledge regarding the development of early communities in the tropical lowlands of the Maya region has advanced greatly in the past decade, important questions still remain. Since 2011, a multidisciplinary project at the site of Yaxnohcah, located in southern Campeche, has focused on the early processes that led to the emergence of massive, archaic city-states during the Late Preclassic (300 BCE–150 CE) and Classic (150 CE–850 CE) periods in the Central Karstic Uplands. How did early settlers adapt to the environment, which was dominated by seasonally inundated wetlands? How did inhabitants manage early infrastructure projects involving extensive landscape modification? What forces served to integrate dispersed communities? What processes led to the emergence of political centralization? What factors led to the development of a unique form of urbanism in the Maya area? The papers in this session address these and other questions, and situate Yaxnohcah in a network of Preclassic cities, including Calakmul, Nakbe, El Mirador, and Tintal, within the Central Karstic Uplands.

[338] Symposium · MANOT CAVE: IN SEARCH OF MODERN HUMANS
Manot Cave in Israel produced a 55,000-year-old anatomically modern human skull (Manot 1) and dense archaeological layers dated to the Early Upper Paleolithic period. Research on the human and the archaeological remains represent a major advancement in the understanding of the origin of our species and modern behavior in Western Asia. The aim of the proposed symposium is hence to present the public with the most updated interdisciplinary studies on Manot Cave to provide insights to the culture and environments of Early Upper Paleolithic modern humans in the Eastern Mediterranean region. Specialists working in excavation and analysis of the materials from the cave illustrate the results of their most recent work.

[339] Symposium · IMPLICATIONS OF THE PROMONTORY, DISMAL RIVER, AND FRANKTOWN ARCHAEOLOGICAL RECORDS FOR APACHEAN PREHISTORY
Earlier investigators—including Julian Steward, Waldo Wedel, Jim and Dee Gunnerson, and Mel Aikens—each voiced the suspicion that the Promontory Culture and the Dismal River Aspect reflected the presence of Proto-Apachean populations in the eastern Great Basin and Central Plains. The Gunnersons also saw notable similarities linking the two archaeological constructs. Although these suspicions saw relatively little subsequent attention, both archaeological records have received more intensive study in recent years. At the same time, linguistic, genetic, and anthropological studies have provided ever sharper focus for what we should expect for migrating ancestral Apachean populations in an era when opportunities for hunter-gatherers expanded. Papers in this session will explore search images developed from interdisciplinary perspectives for Proto-Apachean archaeological records, along with reports on renewed investigations of key sites, high-resolution chronologies, a focus on perishable artifacts (like moccasins) more apt to reflect cultural identity than lithic assemblages, a synthesis of the footwear “landscape” in late prehistoric period Great Basin and Plains records, insights into demography, a better understanding of subsistence activities and paleoenvironments through isotopic and zooarchaeological analyses, evidence of interaction with surrounding societies, and a clearer picture of ceramic assemblages derived from formal studies and sherd geochemistry.

[340] Symposium · WHERE THE WILD THINGS ARE NOT: HUMAN-ANIMAL INTERACTION IN THE SPACE BETWEEN WILD AND DOMESTIC
(SPONSORED BY ZOOARCHAEOLOGY INTEREST GROUP)
Western tradition has tended to view animals in a binary opposition of wild versus domestic, with limited appreciation for forms of cultural engagement with animals in the space between these poles and little recognition that these liminally placed relationships do not inevitably lead to animal domestication. Archaeologists no longer treat the wild-domestic transition as a threshold. Instead they have come to view domestication as a continuum or a range of possible pathways that may be followed. With this shift in perspective, growing attention has been devoted to the diversity of human-animal interactions that occur between the fully wild and fully domestic states, the cultural underpinnings of such relationships, and their zooarchaeological correlates. Significant questions in this area of scholarship are many. What social, political, and economic functions do non-wild, non-domestic animals fill? Under what conditions do such roles arise? What circumstances initiate a trajectory toward domestication, and, where this does not ultimately occur, why not? This symposium will explore these questions and related topics through examination of practices such as
taming, pet keeping, wild management, captive management, animal translocations, commensal relations, and other forms of human interaction with animals that are neither wholly domestic nor truly wild.

[341] Poster Session · NORTH AMERICA: MIDWEST I

[342] Poster Session · NORTH AMERICA: MIDWEST II

[343] Poster Session · NORTH AMERICA: PLATEAU

[344] Poster Session · NORTH AMERICA: PLAINS II

[345] Poster Session · NORTH AMERICA: PLAINS I

[346] Symposium · EROTETICS, GIS, AND DATA RESOLUTION: SPATIAL ANALYSIS IN ARCHAEOLOGICAL PRACTICE
Over the past two decades the use of geospatial analyses and GIS within archaeology has grown in popularity and analytical power. Crucial to this success have been advances in personal computing and the increased availability of geospatial data at varying resolutions. However, finer resolution data does not guarantee a superior result. The questions we ask often dictate our data needs and it is the responsibility of the researcher to carefully define the scale of analysis and units used. This symposium focuses on erotetics (the logic and theory of questions) and the role of data resolution, scale, and evidence in modern GIS-driven archaeological research. Drawing on case studies from Europe, Oceania, the Americas, and Africa, this symposium provides an opportunity for scholars to explore the pragmatic nature of geospatial research, and the diversity of methodological approaches currently available for answering geospatial questions of interest to archaeologists.

[347] Symposium · MUSIC ARCHAEOLOGY
The study of ancient music and sound-related activities is an interdisciplinary field that has become increasingly popular in recent years among scholars from around the world. A brief survey of music archaeological papers that have been presented at the SAA annual meetings during recent years, demonstrates the potential for research in this discipline. However, researchers are commonly spread across general sessions often reflecting the geography of their study area instead of the topic of their papers. In addition to presenting individual research, this symposium brings together scholars who are interested in archaeomusicology so that they can collaborate on new ideas, discuss issues with current research, and explore new avenues in the archaeological study of music/sound. Papers will encompass various aspects of ancient music that includes (but is not limited to) archaeologically recovered music instruments, music-related iconography, performance, and dance.

[348] Symposium · ARCHAEOLOGICAL PERSPECTIVES TOWARD MEDICINE AND GLOBAL HEALTH
With recent outbreaks of infectious diseases such as Ebola and Zika and rising rates of chronic disease such as asthma and obesity worldwide, there has been a growing awareness of the urgency to develop novel approaches to public health and the investigation of disease. As biomedical and genomic research generate new data, knowledge, and methods of treatment, many questions remain about the evolution, proliferation, and history of a number of conditions of global health concern. Archaeology, as both a methodological approach and an analytical framework, has a unique potential to contribute to these efforts. In particular, collaborations with the biological and ecological sciences can produce a finer-grained narrative of how specific diseases and health conditions proliferated in the past, and the ways in which humans have responded to these issues. When combined with social theory and history, these approaches offer a historical perspective that can inform preventative and treatment strategies for the future. This session aims to showcase archaeological research into issues related to global health and medicine to date, and to offer a creative space for archaeologists to shape discourse that will drive future investigations.

[349] Symposium · ARCHAEOMETRIC STUDIES IN THE MAYA AREA
In recent years a wide array of archaeometric studies has been used to approach questions regarding Maya cultural history. Research projects have been developed concerning both pre columbian and historical contexts. Quantitative techniques span interdisciplinary fields such as material sciences, geographical information systems, residue analyses, geoarchaeology, and environmental studies. Although methods might pertain to the so-called “hard sciences,” research topics focus on cultural issues such as technological development, settlement patterns, use of narcotics, or anthropogenic impacts on the environment. Presentations are welcomed both in English and Spanish.

[350] General Session · REMOTE SENSING METHODS IN ARCHAEOLOGY II

[351] Symposium · THE U.S. ARMY CORPS OF ENGINEERS’ REGULATORY PROGRAM AND HISTORIC PROPERTY MITIGATION
The U.S. Army Corps of Engineers’ (Corps) Regulatory Program is one of the oldest regulatory agencies in the federal government. Its mission is to protect the nation’s aquatic resources while allowing reasonable development through fair and balanced permit decisions under the authority of Section 10 of the Rivers and Harbors Act of 1899, Section 404 of the Clean Water Act of 1972, and Section 103 of the Marine Protection Research and Sanctuaries Act of 1972. Fulfilling its mission, the Regulatory Program must consider the potential effects of its permitting actions on historic properties in compliance with the National Historic Preservation Act
of 1966. When adverse effects to historic properties cannot be avoided, the Corps consults with the permit applicant and other consulting parties, in a collaborative effort, to develop appropriate mitigation measures. Increasingly, agencies, State Historic Preservation Officers, tribes, and the public are becoming dissatisfied with simple “document and destroy” mitigation. Stakeholders want relevant, nuanced, collaborative mitigation with tangible products that speak to their concerns. This session explores efforts by the Corps’ Regulatory Program, including the consultation process with stakeholders, to develop innovative and meaningful mitigation.

[352] Symposium · FAIRS, FEASTING, AND RITUAL IN NORTHERN MEXICAN CONTEXTS
Gatherings for ceremonies, pilgrimages, and commemorations have always formed an integral part of the lives of folks that lived in the various landscapes of northern Mexico. In this session, we consider ritual settings in several different social and temporal contexts that span from prehispanic sites of different scales in the modern-day states of Durango and Zacatecas, civic and religious celebrations in colonial Nueva Vizcaya, celebrations in a nineteenth-century mining village, and the yearly journey to the beach by folks in northern Sonora. For each setting, we consider the relationships between material culture, the locales, and the activities that make these gatherings both special and an integral part of the processes involved in identity creation and regional integration combining ethnographic analogy, historical research, interviews, and ethnography with traditional archaeological method.

[353] General Session · CURRENT RESEARCH AT TEOTIHUACAN

[354] General Session · ADVANCES IN GEOARCHAEOLOGICAL RESEARCH METHODS II

[355] General Session · ARCHAEOLOGY IN SOUTHEAST ASIA II

[356] General Session · WESTERN ASIAN ARCHAEOLOGY II

[357] Symposium · CRAFTING THE COMPLEX: MATERIAL CULTURE AND THE RISE OF COMPLEXITY IN FORMATIVE MESOAMERICA
Precolumbian Mesoamerica was home to several distinctive cultural groups. While these cultural groups were sometimes separated by hundreds of years, they were all united by several common features, including, but certainly not limited to, the creation and use of stylistic cultural and ritual objects, the construction of monuments such as stone pyramids, hieroglyphic writing, and a similar worldview conceptualizing ritualized blood sacrifice for the long-term benefit of the community. Before each of these cultural groups became the state-level organizations for which they are best known, they existed as small communal groups, likely bound to one another by kinship and reciprocal obligation. These cultural groups created similar types of artifacts and used them in similar ways in their daily lives. Over time, sometimes a long time, these cultural groups grew more and more complex, both socially and politically, eventually becoming the type of societies in which they are best known today. This session explores the creation and use of material culture among some of the various cultural groups that lived in Formative period Mesoamerica and how the use of material culture can illustrate growing social, economic, and political complexity.

[358] General Session · INCAN ARCHAEOLOGY II

[359] General Session · PERUVIAN ARCHAEOLOGY II

[360] General Session · CULTURAL HERITAGE ISSUES AND OPPORTUNITIES

[361] Forum · CROSSING THE LINE: THE INVESTIGATION OF PROBABLE BURIALS AT THE INDIAN SHAKER MOTHER CHURCH
In March of 2015 construction workers excavating the foundation of a new home site on property adjacent to the Indian Shaker Mother Church near Mud Bay in Thurston County, Washington, unearthed artifacts suggestive of a burial. Subsequent investigation of the site by the Department of Archaeology and Historic Preservation and Interested Affected Tribes with support by representatives of the Indian Shaker Church resulted in the recovery of additional artifacts and the delineation of a feature suggestive of a historic Native burial. Another possible burial was also identified. This forum gathers tribal and non-tribal cultural resource managers involved in the project to present and discuss the project, adversities and bureaucracies encountered, teamwork, and outcome.

[362] Forum · ADVANCES IN MANAGEMENT FOR MILITARY CULTURAL RESOURCES PROGRAMS
(SPONSORED BY MILITARY ARCHAEOLOGICAL RESOURCES SUBGROUP [MARS])
Although it is not widely known, many U.S. military installations have some of the most innovative and holistic cultural resource management programs in the country. This forum will explore in depth some of the successful cultural resource management strategies used by the military. The primary focus will be on cooperative and proactive approaches highlighted by technological advances in cultural resource management.
Collections contain more than cultural objects, also including items such as field documents, photos, and analyses in paper and digital form. The management of the entire collection as an archive presents many issues to the institution housing these materials whether inside a museum, repository, cultural center, laboratory, or so on. Issues around housing, access, usability, protocol, standardization, and preservation are just a few areas of concern that have ethical implications. This forum moves a conversation forward that began at the 2016 SAA meeting in Orlando by specifically targeting the ethical implications of archival work and how stakeholders affect and are affected by archival collections. Forum organizers are specifically interested in bringing together individuals with international experience knowing that particular issues are scalar and their solutions are not universal. It is important that different voices are heard and acknowledged to better understand what is at risk and how these issues might be addressed.

The reports included in this session represent some of the projects produced by participants in the NEH-funded Institute for Digital Archaeology Method and Practice, which included two in-person workshops in August 2015 and August 2016, and digital communication and support over the intervening year. Co-PI’s for the Institute were Ethan Watrall and Lynne Goldstein, and the workshops took place at Michigan State University. Projects represent many archaeological interests and skills, and participants included a range of archaeologists: graduate students, faculty, university administrators, museum professionals, CRM-practitioners, and government archaeologists. Each participant spent the year focused on a specific archaeological project, one of whose goals was to produce a forward-facing digital product accessible by the public (where public might be the general public or specific audiences).

A century (and a bit) of research has been conducted at Aztec Ruins and it is time for a new synthesis. This symposium fuses data both old and new to situate Aztec as the preeminent Southwest site of the thirteenth century. A multi-scalar approach with data from excavation, artifact analyses, and legacy data investigations are presented with an eye toward addressing gaps in our understanding and are situated in the twenty-first-century debate of Chaco (What Came After, and How Aztec Fits?). With our dramatically improved understanding of Aztec’s role in Pueblo history, these papers will evaluate the current state of Aztec archaeology; update on recently completed field, laboratory, and archive work; and evaluate the prospect of future research.

Human have been exploiting whales and other large marine mammals for thousands of years. Often initially focused on the opportunistic use of stranded carcasses, active whale hunting technologies and strategies emerged worldwide in different times and places. In spite of their importance as sources of food, fuel, and raw materials, there are fewer archaeological studies of cetaceans...
than any other hunted mammal group. Today, cetaceans are among the most threatened groups of mammals, due to dramatic global declines resulting from industrial overharvesting and other anthropogenic influences. Archaeology has an important role to play not only in deciphering the timing, sociocultural context, and technological developments of active whaling, but also in providing essential baseline information on the past geographical distribution and abundance of now-threatened species. This session will explore ongoing challenges and new perspectives for documenting past cetacean exploitation from a wide range of geographic areas and time periods. Potential examples include (but are not limited to) historical, archaeological, morphological, and molecular approaches for reconstructing the timing, intensity, technology, and socioeconomic importance of cetacean exploitation, and documenting both natural and anthropogenic impacts on large marine mammal populations worldwide.

**[379] Symposium · ADORNMENT, PERSONAL ORNAMENTATION, AND THE CONSTRUCTION OF IDENTITY: A GLOBAL ARCHAEOLOGICAL PERSPECTIVE**

Items of personal adornment are found in archaeological contexts all over the world. While the specific meanings ascribed to these objects likely varied widely in the past, their social values are generally interpreted in relation to individual or group identity. Recent research highlights the ways in which personal ornaments served integral roles in the creation, maintenance, and negotiation of different aspects of identity, such as gender, age, social status, ethnicity, lineage or group affiliation, and participation in ideological and power structures. In some cases, these objects were vital to social transactions, ritual performances, the creation of social memories, the legitimation of authority, or the renewal of the existing social order. In contemporary work, these research issues are increasingly examined within the frameworks of embodied practice and materiality. In these approaches, the production, circulation, and discard of material objects create, reproduce, and transform the contours of the social world, defining relationships between individuals, social segments of various scales, and both the natural and cultural landscapes. The papers in this session present recent research on objects of adornment from a variety of geographic and temporal contexts, focusing on the ways they were used to construct and negotiate different elements of social identity.

**[380] Symposium · TRAPS, WEIRS, PONDS, AND GARDENS: EXPLORING THE SOCIAL AND ECOLOGICAL SIGNIFICANCE OF AQUATIC SUBSISTENCE FEATURES**

Aquatic subsistence features are used cooperatively by cultural groups around the world; common examples include fish traps and weirs, clam gardens, and fish ponds. Aquatic foraging and aquaculture practices such as these are highly varied and operate in different dimensions that are structured by both social and environmental parameters. This perspective comes to us via multi-method anthropological approaches incorporating ethnography, oral history, and archaeology. As archaeological treatments have shifted toward aspects of practice, history, landscape, ontology, sociality, and human-environment interactions, our knowledge of customary fishing and shellfishing practices is now positioned to inform on much more beyond subsistence strategies. Recent topics include labor and community organization, ownership, territoriality, religion, ritual, technology, identity, landscape modification, resource management, and long-term change and continuity in practices. Also, in light of growing concerns regarding climate change and the potential loss of archaeological resources along the coast, there has been an increase in multidisciplinary research highlighting local indigenous knowledge and the role that maritime subsistence practices play in social resiliency and sustainability. This session explores the global diversity and the social and ecological significance of past and present aquatic subsistence features and practices, linking together common anthropological and archaeological themes in a holistic manner.

**[381] Symposium · ANCIENT CALIFORNIA: RECONSTRUCTING LIFEWAYS WITH BEHAVIORAL ECOLOGY MODELS**

Research in California has long been at the forefront in the adaptation of economic and behavioral ecology models for application to the archaeological record. This symposium presents a collection of new investigations of prehistoric foraging populations in California focused on reconstructing patterns of reproduction and population growth, subsistence, and intensification; settlement patterns; and the emergence of a monetized economy. Contributors employ a range of models to demonstrate the adaptive flexibility that resulted in unparalleled hunter-gatherer population density and diversity of sociopolitical complexity in California.

**[382] Symposium · LANDSCAPES OF CHANGE: INTEGRATED SOCIO-ECOLOGICAL HISTORIES IN THE CHICAMA VALLEY, PERU**

Growing research demonstrates that Peruvian coastal valleys are not static cases cutting the desert, but dynamic environments shaped by millennia of climatic variability and anthropogenic change. Despite rich cultural, climatic, and biotic data, we lack integrated histories that comprehensively synthesize the evolution of socio-ecological relationships. Importantly, we have little understanding of how recursive ties between environmental change (both natural and anthropogenic) structured societal development, nor how legacies of change resonate in modern ecologies. This symposium presents a socio-ecological synthesis of the Chicama Valley, a key Andean region. We develop a platform for integrating cross-disciplinary, multi-project information to develop new interpretations of the valley’s historical ecology as a cohesive entity. Thematic papers synthesize archaeological, paleoclimatic, geomorphologic, geospatial, and agronomic data. We discuss demographic and settlement dynamics, environmental change precipitated by premodern communities, and the impacts of climatic trends to understand the effects of path dependencies and disturbance socio-natural ecology of Chicama. We hope to establish a collaborative framework for effectively integrating information from independent research initiatives into a regional dataset, so that we can address broader socio-ecological questions. This symposium identifies crucial lacunae requiring future investigation so that the full importance of recursive socio-environmental dynamics can be better understood.

**[383] Symposium · TERRITORIAL BEHAVIOR AND ECOLOGY**

Human territorial behavior encompasses a broad range of variation. While basic territory development may begin simply by excluding others through the habitual or persistent use of the same location, such behaviors can extend to the active defense of resource patches and the emergence of stable boundaries. Anthropologists have long relied on ecological models to help explain this variation, and new approaches from behavioral ecology are beginning to expand our understanding of territorial behavior, its causes, and its effects. Here we assemble researchers focused on explaining variation in territorial behavior across western North
America through ethnographic and archaeological case studies. Papers in this session will offer new insights on territorial behavior, providing a foundation for future work on the subject.

[384] Symposium · THE CAIMAN’S (AND FROG’S) REVENGE: INTERSECTING PAPERS IN HONOR OF PETER G. ROE
Peter G. Roe earned his PhD at the University of Illinois, Champaign-Urbana under the direction of Donald W. Lathrap. Following in Lathrap’s large footsteps, over the past four decades Roe has carried out novel and pioneering research in a number of areas, including cosmology and religion; art, iconography, and design analysis; technology; ethnohistory; and ethnoarchaeology. Uniting these threads has been his abiding commitment to South American and Caribbean archaeology and ethnography. In this session, colleagues and former students present papers that relate to Professor Roe’s varied interests.

[385] Symposium · AN OTHER-THAN-HUMAN BEING: THE ARCHAEOLOGY OF BEARS IN NORTH AMERICA
Ever since Irving Hallowell’s classic 1926 ethnographic study of the special mythic status of bears in the Subarctic, anthropologists are generally aware that many peoples throughout the world have treated bears as far more than a subsistence resource, something more akin to another kind of human or an other-than-human being. Hallowell attributed that special relationship between Subarctic humans and bears to some striking parallels between bear and human behaviors and physiologies. If that were indeed the case, then one would expect to see similar relationships outside the Subarctic, although in fact Hallowell found little evidence for the special treatment of bears elsewhere in North America. Archaeological and historical research over the last nine decades, however, has produced a vast amount of as yet unsynthesized information on the roles of bears in Native American beliefs, rituals, and subsistence. Taking into account ecological variables of bear demography, reproductive rate, habitat use, seasonal availability, and trophic level, we invite participants in this session to draw on new and existing data to reconsider zooarchaeological and other evidence of bear hunting and use in light of the range of relationships that existed between bears and humans across the millennia in Native North America.

[386] Symposium · EMERGING FROM THE PLACE OF DARKNESS: SUBTERRANEAN ARCHAEOLOGY IN MESOAMERICA
Mesoamerican cave archaeology has continued to amplify its areas of interest, appropriating the study of a range of constructed features so that the term Subterranean Archaeology appears to be a more appropriate term. This grew out of investigators using the term “cave” in the sense of the Maya word ch’ē’en, which indicates not simply a cave but also a large number of other holes that penetrate the earth. It also recognizes that indigenous peoples show far less concern for whether the hole is of a natural or a human origin. Recent research continues to demonstrate that traditional caves are important landmarks in the landscape but, additionally, archaeologists have begun to show that many more features were marked by ancient peoples as having sacred significance. This session brings together fresh perspectives on the subject.

[387] General Session · CURRENT PERSPECTIVES ON PACIFIC NORTHWEST COAST ARCHAEOLOGY

[388] Symposium · FROM BIRDSEED TO SUPERFOOD: CHENOPODIUM CULTIVATION AND MANAGEMENT ACROSS THE GLOBE
Seeds of the genus Chenopodium are often ubiquitous and abundant in archaeological sites across the globe, yet our understanding of their role in human societies varies from region to region. Cultivation of chenopods has long been recognized in the Andes and Mexico, yet their diversity and unique histories of domestication are still being investigated. Through years of morphological and genetic work, researchers have demonstrated that the Native Americans of eastern North America independently domesticated their own chenopod species. Building on these advancements, researchers working across Eurasia and in other regions of the Americas are reassessing the status of the chenopods found in their sites. This session will highlight recent discoveries of both cultivated and intensively managed chenopod populations, shedding new light on a genus whose important role in human history has long been overlooked.

[389] Symposium · SHORT-TERM OCCUPATIONS IN PALEOLITHIC ARCHAEOLOGY
Critical aspects on the understanding of prehistoric lifestyles are how hunter-gatherers moved on the landscape and how they organize their technological and subsistence strategies in relation with climatic fluctuations and environmental changes. Ethnographic studies documented that in homogeneous environments, where resources are particularly scattered on the region, foragers tend to move frequently their central base. Conversely, in areas where resources are patchy due to seasonal climates, logistical mobility is preferred. In the last decades, many studies applied these ethnographic concepts to understanding the mobility patterns in archaic humans but, in several regions, it is still unclear how the environment influences hominins displacement strategies and whether biological and technological differences are also reflected in the management of the territory. This symposium aims to explore the issue of hunter-gatherers mobility focusing on short-term anthropogenic occupations. This type of mobility strategy might generate a variety of archaeological contexts such as residential bases, locations, hunting stations, or temporary camps. The comparison of these short-term occupations between different regions will contribute to a better understanding on how hunter-gatherers adapted and moved in different climatic and environmental areas. Speakers are very welcome to present new data, as well as theoretical and methodological approaches.

[390] General Session · CERAMICS IN SOUTHWESTERN ARCHAEOLOGY

[391] Symposium · MOLDING MATTER: TECHNOLOGIES OF REPRODUCTION IN THE PRECOLUMBIAN AMERICAS
Technologies of replication and reproduction are most commonly associated with the industrial advances of the recent past. Yet objects have been produced en masse for thousands of years across the globe, including in the precolumbian Americas. Rather than emphasize the economic or political implications of mold-made and stamped objects, however, this session focuses on their
cultural implications. Creating iterations of the same object from a shared mold implies an intended distribution beyond that of the individual patron or consumer, suggesting different motivations, contents, and intended uses. How did these processes compare to production of individualized objects that were often intended for a specific client, such as hand-painted ceramic vessels, feather capes, or woven mantels? What does the existence of such technologies suggest about indigenous concepts of an "original" vs. a "copy"? Despite the technological potential for large-scale reproduction, not all mold-made objects were created or distributed in equal quantities. What do differences in the proliferation of these goods indicate about their cultural value and use? Individual papers will examine the cultural significance of diverse objects replicated with molds and stamps in ancient Mesoamerica and South America.

[392] Symposium · A MATERIAL WORLD: COLLABORATIVE RESEARCH IN ART, ARCHAEOLOGY, AND MATERIALS SCIENCE IN THE STUDY OF THE ANCIENT AMERICAS
This session features collaborative research in art, archaeology, and materials science in the study of the ancient Americas. Collaboration between scientists and social scientists or humanists has long been a part of archaeological studies, yet recent decades have seen a flourishing in productive collaborations between archaeologists and art historians with materials and conservation scientists. This panel explores new directions in such interdisciplinary collaboration, particularly regarding how new scientific analyses can help us understand ancient technologies, artists' decisions in the choice of materials or modes of manufacture, and the meaning of materials to artists and users. In some cases, materials science reveals information that can confirm or refute what is suggested from stylistic or other analysis, particularly regarding sharing of materials and technologies across cultures. In others, new technologies of excavation, preservation, and analysis give insight into the use of organic materials, which allow us both to see a wider range of materials used by artists and to help re-create the ancient sensory world and ask new questions about the experience of artists and users in the ancient past of the Americas.

[393] Symposium · THE NORTH AMERICAN CONTINENTAL SYSTEM: INTERACTION AND EXCHANGE ACROSS THE CONTINENT
The precolumbian peoples of North America inhabited a "known world" that stretched, at a minimum, from Canada to Panama. Archaeological discoveries show that items such as shell, obsidian, and bead-types were conveyed over thousands of miles, while ethnohistoric accounts document the movement of people across equally vast distances. Just as important, shared stories, oral narratives, ideologies, and traditions point to histories of interaction between distant places stretching deep into antiquity. How should archaeologists deal with these long-distance connections, and what do these connections mean for cultural narratives and models of social change we construct for regions where we work? This session will bring together archaeologists working in different parts of North America to compare our continent's history of interregional interactions. By patching together a mosaic of different stories of interaction we will build toward a bigger history of North America's dynamic past that will help us understand its unique indigenous present.

[394] Symposium · COLLABORATIVE AND COMMUNITY ARCHAEOLOGY
This session addresses archaeology projects involving varied and innovative collaborative efforts that focus on partnerships with local communities.

[395] Symposium · MATERIAL ENCOUNTERS AND INDIGENOUS TRANSFORMATIONS IN THE EARLY COLONIAL AMERICAS
(SPONSORED BY ERC-NEXUS1492)
Early colonial encounters with Europeans initiated transformations in indigenous social, cultural, and material worlds. Archaeologists have recently come to investigate the varieties and complexities of indigenous colonial dynamics. Scholars increasingly emphasize indigenous agencies in negotiating colonial encounters and appropriating European material culture through gifts, trade, or imitation. This has resulted in exploring why indigenous people adopted or resisted foreign objects, and how such differential choices not only altered indigenous material assemblages, but also affected existing social, political, and economic structures. Over the past thirty years, our understanding of material encounters in the colonial Americas has advanced largely through studies based on cases from North America, using updated theories on, for example, consumption, hybridity, and entanglement. Building upon these efforts, this session will specifically target the hitherto underrepresented Caribbean and its surrounding mainland, including northern South America, Central America, and the southeastern United States, shifting the focus to fifteenth- to eighteenth-century Spanish colonialism. Participants will use indigenous long-term historical trajectories to discuss how foreign goods were differentially employed across time, space, and scale; how these were considered within indigenous ontologies and value systems; what implications their adoption had for larger indigenous society; and which theoretical trends best help us understand indigenous material practices.

[396] General Session · ARCHAEOLOGICAL APPROACHES TO RITUAL AND RELIGION I
Exploring the Viability of Geochemically Sourcing Elaborate Metates through XRF Spectroscopy

The Central American elaborate metate is a perplexing group of ground stone artifacts. Their function continues to be the subject of debate, with interpretations ranging from hallucinogenic and food preparation to ritual seating. It is difficult to deny, however, the substantial labor investment represented and likely symbolic significance. X-ray fluorescence spectroscopy has proven an invaluable tool in the nondestructive geochemical sourcing of archaeological obsidian, providing insights into exchange and the relationships between sometimes distant cultures. Less homogeneous materials, such as basalt and andesite, offer a distinct set of challenges compounded by the size of the artifacts themselves, however the possibility of illuminating the origins and mobility of ground stone merits study. The Archaeology Museum at the University of Calgary offered a unique opportunity to test and perfect a methodology to overcome these challenges prior to application in a less accommodating field environment. A selection of complete flying panel, effigy and elaborate basin metates with little to no provenience were selected for spectroscopy with a portable XRF unit. Cluster analysis was conducted with the produced spectra, as well as those recorded in the Rutgers University Central American Geochemical Database.

Preliminary Findings at the Quebrada de Oro Ruins: Shining New Light on a Classic Maya Site We Thought We Knew

The Quebrada de Oro Ruins comprise the remains of one of four known Classic Maya centers located in Bladen Branch region of the Maya Mountains of southern Belize. Initially recorded in the 1970s, the site has not garnered much attention by archaeologists due to its remoteness. However, this has not deterred cartographers from noting it as a significant landmark or archaeologists from asserting that it played an important role in ancient times. This contrasts with the views of the few archaeologists who have visited the site only long enough to report on the site’s rather typical layout containing modest-sized structures. So what do we really know about the Quebrada de Oro Ruins? Recent investigations of the site have been launched in pursuit of an answer to this question. This paper describes the preliminary findings of these investigations and touches on what they mean for our understanding of the Quebrada de Oro Ruins and the surrounding area during the Classic period.

Lithics and Learning: Toward a Heart-Centered Lithic Analysis

Both archaeologists and the knappers who created the lithics we recover are skilled practitioners implicated in a genealogy of technological practice. These living, thinking, and feeling beings make tools with their hearts and their minds—two inseparable components of the complete corporeal experience. A heart-centered approach to lithic analysis offers insights about the social and emotional contexts of situated learning in which ancient and contemporary makers of stone tools engage. The process of co-construction between the makers of material culture and the things they make means they actively shape each other across time and space. This has implications for communities of practice in the past as well as the present. Therefore, tracking the choices, movements, and gestures made along the chaînes opératoires of stone tool production positions the (re)creation of embodied knowledge within the materially, environmentally, and socially mediated world of learning and enskilmment. In this paper, I explore the findings of a diachronic analysis of three lithic assemblages from Quadra Island, British Columbia and propose a methodology for conducting a heart-centered lithic analysis. I incorporate qualitative and quantitative data of the artifacts themselves, their relation to communities of tool-makers, and my own experience of learning to make stone tools.

The Lithic Industries from Area C: Typo-Technological Characteristics

The lithic assemblages from Area C derive from a thick section reworked terra rossa soil of dark brown to reddish brown, loose clay to silty clay loam with abundant biogenic and anthropogenic materials subdivided into eight units. The depositional sequence of the units is in a chronological order as shown by radiocarbon and U-Th dates (Hershkovitz et al., 2015). A typotechnological analysis of the all units suggest a shift in industries though the sequence. Unit 2–3 are small assemblage which seems to be associated with post-Aurignacian/Aurignacian industry. Unit 4 is Aurignacian as it includes typical components such as twisted bladelets, carinated/nosed end-scrappers, flat end-scrappers, dourou blades, burins and bone and antler tools, and preference for flake production. Unit 5 contains both Aurignacian and Ahmarian components. The upper part resembles unit 4. While the rest show Aurignacian characteristics and some Ahmarian as well. Unit 6 the upper part is also mixed, but the lower shows more Ahmarian elements. Unit 7 represents a homogenous unit that shows a clear preference for bladelet production. The El-wad points and its variant are very common for the Ahmarian as well as a few MP artifacts that seem to extend to Unit 8.
Acabado, Stephen (UCLA)

[285] Zones of Refuge: Resisting Conquest in the Northern Philippine Highlands through Agricultural Practice

The origins of the extensive wet-rice terrace complex in Ifugao, Philippines have been recently dated to ca. 400 years ago. Previously thought to be at least 2,000 years old, the recent findings of the Ifugao Archaeological Project show that landscape modification for terraced wet-rice cultivation started at ca. 1600. The archaeological record implies that economic intensification and political consolidation occurred in Ifugao soon after the appearance of the Spanish empire in the northern Philippines (ca. 1575). The foremost indication of this shift is the adoption of wet-rice agriculture in the highlands, which served as zones of refuge for local populations. I argue that the subsistence shift was precipitated by political pressures and was followed by political and economic consolidation. Wet-rice agriculture was an expression of imperial resistance; it also facilitated political integration. Using paleoethnobotanical, faunal, and artifactual datasets, this paper documents the process that allowed the Ifugao to resist conquest.

Acebo, Nathan (Stanford University)

[98] Reassembling Black Star Canyon

The Santa Ana mountain landscape of contemporary Orange County, California, has been dichotomously characterized as “a wild frontier” and “a tamed indigenous space” where the material and social histories of indigenous communities are downplayed and legacies of Spanish, Mexican and American colonial society are both solidified and continued. Within this landscape, the Black Star Canyon Village site (CA-ORA-132) objectifies this binary historicity as the site constitutes a prehistoric/historic period landmark associated with the local history of the “Battle of Black Star Canyon,” in which Native Americans were accused of stealing horses and were subsequently massacred in 1831 by American fur trappers. This paper seeks to complicate the fractured modern narrative of the site by exploring how prehistoric and colonial era materialities of the mountain afford local and nonlocal indigenous practices of social and economic subversion while challenging dominant historical accounts of extinction and indigenous passivity.

Acevedo, Agustín [62] see Franco, Nora V.

Acosta, Jocelyn [11] see Saldana, Melanie

Acosta, Marcelo (CÉLAT—LAVAL University)

In this paper we will be discussing the iconography of the roof tiles found in the primitive missions of Nuestra Senora de Loreto and San Ignacio Mini located in the region of the Guairá. The aim is to analyze the material and symbolic universe that circulated in the primitive Jesuits missions (1610–1631). In order to achieve this goal, we will first analyze the technologies of production, the iconographic types and interpret the possible meanings acquired in the representations shown on the roof tiles. So far the archaeological research prioritizes the urban organization and the materials in the missions but omits the symbolic component that gave sense to the space and to the objects. The reductions were spaces of evangelization where circulated religious messages in two directions: from the evangelists to the Guaraní, and also from the Guaraní to the Jesuits. To accomplish this, they used different means of communication. The analysis of the technologies and the images on the roof tiles of both reductions allows us to analyze the technical and symbolic speeches of the material culture. We finally discussed above the discourse on the roof tiles and their symbolic role in the first period of evangelization.

[13] Prehispanic Plant Remains from Altica, Teotihuacán Valley, Mexico

Altica, situated in the southeastern sector of the Teotihuacán Valley, represents the earliest known farming community in this region. Its importance lies in the potential for the recovery of evidence for domestic plant use by these early inhabitants. Plant remains recovered over several decades in the Teotihuacán Valley provide an idea of the predominant plant communities in the area during the Early-Middle Formative, an indicator of local environmental conditions. Preliminary results from the analysis of macrobotanical remains recovered from excavation contexts, together with phytoliths and starch grains from selected stone tools contribute to an understanding of local economy and agricultural production in this community.

[131] The Cultural and Natural Landscapes of El Tintal, Guatemala: Preliminary Results of the Application of Airborne Lidar

In this paper, we present the results of our preliminary analysis of the application of lidar (light detection and ranging) imagery of the archaeological site of El Tintal in northern Guatemala. El Tintal is an extensive site with over 800 known buildings distributed in an area of about 12 km². From the Preclassic through the Late Classic Periods (ca. 400 BC to AD 850), the cultural settlement developed in direct association with the natural landscape marked by extensive bajos (seasonally inundated natural depressions). Initial mapping efforts and pedestrian surveys have revealed that in addition to having adapted construction to the natural terrain, the population of El Tintal also invested significant efforts in water management systems throughout the site.

Adderley, Paul (University of Stirling), Mitchell Power (University of Utah, USA) and Valery Terwilliger (University of Kansas, USA) increasing our understanding of the relationships between empire and environment.

Capital and provincial town in both pre- and post-collapse contexts. At the same time, I explore the possibilities and limitations these models hold for characterizing interactions between humans and the environment. Here, I use these models to facilitate synchronic and diachronic comparisons between the relationships between empire and environment. This analysis focuses on quantitative models commonly used by zooarchaeologists to characterize interactions between humans and the environment. Here, I use these models to facilitate synchronic and diachronic comparisons between capital and provincial town in both pre- and post-collapse contexts. At the same time, I explore the possibilities and limitations these models hold for increasing our understanding of the relationships between empire and environment.

Adcock, Sarah E. (University of Chicago)

Thinking through Zooarchaeological Approaches to Empire and Environment

In this paper, I explore the intersection of empire and environment in imperial and post-imperial contexts using the collapse of the Hittite empire and its aftermath in central Turkey around 1200 BC as a case study. More specifically, I mobilize zooarchaeological evidence from the Hittite capital of Hattuša and from Çadır Höyük, a rural town, in order to discuss how we might distinguish between political, economic, and climatic factors in our interpretations of the relationships between empire and environment. This analysis focuses on quantitative models commonly used by zooarchaeologists to characterize interactions between humans and the environment. Here, I use these models to facilitate synchronic and diachronic comparisons between capital and provincial town in both pre- and post-collapse contexts. At the same time, I explore the possibilities and limitations these models hold for increasing our understanding of the relationships between empire and environment.

Geoarchaeological Assessment of Long-Term Site- and Field-Management Characteristics at the Pre-Aksumite Site of Mezber, Tigrai Plateau

The ancient polities of the Tigrai Plateau and this region's pronounced climatic variations combine to create a research paradigm where social-environmental interactions can be considered over the long-term. Existing regional-scale indicators suggest that human responses to climate variability differed between peoples, polities and time-periods. Framed by an ongoing regional study designed to examine high-resolution climate and environmental markers at a broad-spatial scale, the study of the Pre-Aksumite (1600 BCE—1 CE) site of Mezber allows more refined a site-level understanding of anthropogenic interactions to be developed, both site-use and agrarian land management. This paper considers a set of geoarchaeological measurements and land-use proxies, including micromorphology, image analysis and inorganic chemical analysis of the sediments for this site. The complex dynamics between regional climate variations and indicators of past fire-husbandry and land management at this site are then explored.

Organic Residues from Durable Vessels in Prehistoric Southwest Alaska

Prehistoric people of coastal southwest Alaska used clay and stone vessel technologies for the past 3,000 years. Despite the challenges that the cold and humid subarctic climate posed to the procurement of clay and the drying and firing of pottery, people invested their valuable time and energy in the manufacture and maintenance of these durable vessels. Why? What role did container technologies play in the wider process of food procurement and processing? An increased focus on marine resources seems to have led to the emergence and spread of pottery in Alaska. Vessels may have been used for the rendering of marine mammal fats into oil to be uses as fuel. To test this hypothesis lipids, isotopes, and proteins from food residues of about 100 vessels from 32 archaeological sites in the Aleutian Islands, Alaska Peninsula and Kodiak Archipelago have been analyzed at the BioArCh laboratory of the University of York, UK. Establishing the contents of the vessels provides direct evidence for vessel function and contributes to the greater understanding of food technologies in prehistoric Alaska.

Adovasio, J. M. (Florida Atlantic University)

Perishable Artifacts from the Old Vero Site (8IR009), Indian River County, Florida

Despite depositional conditions inimical to the preservation of plant fiber or wood-derived artifacts, several such objects have been recovered during the ongoing re-excavations of the Old Vero Site (8IR009) in Indian River County, Florida. These include a minute fragment of charred, three ply, braided cordage with a contiguous underlying date of ca. 9,000 calendar years ago and a specimen of charred, flexible basketry or textile directly dated to 7989 ±19 calibrated radio carbon years ago. The technology of both specimens is consistent with analogous forms recovered from the celebrated Windover Bog site in Brevard County, Florida. The construction attributes of the Vero specimens are described and the potential significance is addressed.

[31] **Bone Remodeling Behavior across the Surfaces of the Skeleton as Biographical Windows**  
The morphology of the whole skeleton is crafted over the life course by bone remodeling across its skeletal surfaces: the endosteal surface of its trabeculae, and on the periosteal, endocortical, and intracortical surfaces of its cortex. The behavior of each of these surfaces differs between individuals and populations resulting in some understood differences in bone morphology across human groups. But the skeletal surfaces are also differentially influenced during growth, aging, reproduction, activity, disease, and other aspects of life experience. Analyzing aspects of bone quantity and quality at these various bone surfaces can provide windows into bone remodeling events of the once living skeleton. This paper will demonstrate how scaling between this record of cellular activity at the level of tissue, bone, skeleton, and community, bioarchaeologists have the potential to reconstruct aspects of past life history. An appreciation of the biology that undertakes the construction of the skeleton at its most basic cellular level extends the concept of the osteobiography. At the same time, an appreciation of the biocultural influences on this basic cellular activity provides a more humanistic perspective on our on reconstruction of the person from the skeleton.

Agenten, Courtney (Project Archaeology), Jeanne Moe (Project Archaeology/BLM) and Tony Hartshorn (Montana State University)  
[97] **Putting Archaeology Teacher Workshops to the Test**  
Students are assessed constantly throughout the school year. As teachers we ask ourselves how do I know that the students understand the concepts and skills? Archaeology educators should be conducting the same kind of rigorous evaluation of the professional development courses we offer teachers. Challenging our profession to know where teachers are coming from, what their needs are, where we want them to go, and how we know that they learned. What prior knowledge do teachers bring to a workshop? Have they been exposed to inquiry-based learning? How do they feel about teaching archaeology? How will they use the educational materials in their classroom after attending? These questions and more are necessary to understand the purpose and outcomes of archaeology-centered professional development. Project Archaeology conducted a study of ten teachers who participated in a five-day course on a developing curriculum guide, Project Archaeology: Investigating a Roman Villa. The results of the research will inform future studies on how archaeology educators can conduct similar assessments of teacher pedagogical content knowledge to determine the efficacy of professional development for educators.

[134] **Intervención de la Textilería Local como Estrategia del Tawantinsuyo para Vincular a las Poblaciones de Atacama con el Noroeste Argentino (1350–1535 Dc)**  
Los materiales textiles tienen la capacidad de contener información relacionada con situaciones de contacto cultural y el grado de intensidad de éstas. Bajo este principio se estudió en forma sistemática la textilería del sitio Doncellas en el Noroeste Argentino—tanto aquella que se encuentra en el Museo Etnográfico Juan B. Ambrosetti en Buenos Aires, como la porción depositada en el Museo del Pucará en Tíncara—y aquella proveniente de sitios del Salar de Atacama y de la cuenca del Loa, principalmente del sitio Cementerio Poniente de Quillagua. Esta tarea se realizó con el fin de obtener datos relevantes que ayuden a comprender la dinámica de las relaciones que existieron entre estos territorios vecinos durante los períodos Intermedio Tardío y Tardío. Los resultados de este análisis nos llevan a proponer que el nexo establecido entre ambos se habría desarrollado con mayor intensidad hacia 1350–1535 Dc, siendo posible asumir la existencia de un proceso expansivo que llevara a vincular ambos territorios, en asociación a los intereses del imperio Inka.

Aguero Reyes, Adriana (Independent)  
[267] **Architecture and Figurine Art in Central Veracruz**  
Terracotta figurine offerings as part of construction deposits are one of the traits that characterize the Classic period Central Veracruz culture. They are recurrent in both modest and monumental architecture, in sites of all ranks. In this they differ from ceramic figurine use in contemporary cultures, where they belong to the domestic and/or funerary sphere. This paper presents a case study on a series of figurine deposits of a palatial residence of the archaeological site of La Joya, showing that the qualities of size and finish and the form of disposing of the figurines will vary according to whether the they belong to the domestic and/or funerary sphere. This paper presents a case study on a series of figurine deposits of a palatial residence of the archaeological site of La Joya, showing that the qualities of size and finish and the form of disposing of the figurines will vary according to whether the

[34] **Seeking Strength and Protection: Tewa Mobility during the Pueblo Revolt Period**  
The Pueblo Revolt period (1680–1700) was a time of considerable social unrest and instability for Pueblo Indian people. The return of the Spaniards twelve years after the 1680 revolt required new strategies of resistance. Mobility became a key form of resistance and, the Tewa world in particular, provided a landscape in which pueblo communities could seek the strength and protection to survive. Many families left their home villages and took refuge with their relatives on mesa villages and in isolated mountain camps. In some cases, Pueblo leaders sent their women and children away for safety and security. In this paper, we consider mobility among the Tewa people, across their landscape during the Spanish Reconquest, as resistance strategy. Particular attention will be paid to the mobility strategies of San Ildefonso Pueblo to mesatop and upland areas during the reconquest.

Aguilar, Felisa (Centro INAH Coahuila), Ana Rugerio (Dirección de Registro Público de Monumentos y Zona) and Ulises Cano (Dirección de Registro Público de Monumentos y Zona)  
Fossils are physical evidence that provides important information in order to figure out and explain the origin and evolution of life on Earth. For this reason, an accurate collection and preparation are necessary. A precise data collecting also is required. Fossils must be preserved in scientific collections where they will be studied and where they will receive the status of specimens. In addition, for non-scientists these objects could be curiosities of the past from Nature which are also objects for collecting. In Mexico, fossils are recognized as national heritage, nevertheless it was not until 1986 that INAH was designated as the institution in charge of them, having modified its Organic Law and having added the article 28bis to the Federal Law of Archaeological Zones and Monuments, Artistic and Historical. According to this, INAH executes different actions to fulfill these responsibilities, for not only scientific collections, but private too and paleontological sites. Generating data sheets of records with the final goal to extend the legal declaration of the existence of these goods. This tool was developed to follow up and have control of specimen records and legal protection, key aspects for conservation and protection of this heritage.
Aguirre, Alejandra (Proyecto Templo Mayor/UNAM)

The Symbolism of the Animals Found inside Offering 125 of the Great Temple of Tenochtitlan

In the seventh field season of the Templo Mayor Project, we discovered various ritual deposits in an inverted pyramidal monument located west of the monolith of the Tlalocxuhtli Goddess. We determined that this space symbolized the threshold to the underworld, or realm of the dead. In this space we made the exceptional discovery of the Offering 125 associated with the ruler Ahuitzotl (1486–1502 CE). In this offering we found three flint knives that were dressed like Ehécatl-Quetzalcóatl (God of Wind). Two knives are decorated with spider monkey skin (Ateles geoffroyi) and in one case, a green stone duck effigy pendant. These elements were in association with two golden eagle skeletons (Aquila chrysaetos) and a wolf skeleton (Canis lupus). The employment of different symbolisms of animals refer to various aspects of Mexico cosmology. The animals occupy a specific location in the interior of the offerings and thus play a specific role within the offering’s narrative.

Ahern, Kaitlin

Reexamining the Identity of Reverential Termination Rituals in the Maya Lowlands

In the pursuit to understand ancient Maya ritual, researchers have commonly relied upon the analysis of termination rituals and caches. In the early 2000s, Jonathan B. Pagliaro, James F. Garber, and Travis W. Stanton introduced a clarification of the terminology, differentiating between reverential and desecration termination rituals. Following this publication, a surge of studies conceptualizing desecration termination rituals emerged, while the literature on reverential termination rituals remained sparse. Even today, the interpretation of reverential termination rituals remains particularly broad and unclear. Specifically, there is no clear demarcation separating reverential termination rituals from dedication rituals or even from desecration termination rituals. This ambiguity has made it difficult to properly identify the occurrence of this type of ritual in the archaeological record. Therefore, it is necessary to reconceptualize reverential termination rituals and establish a more concise definition of this ritual act. This examination draws from various case studies from across the Central Maya Lowlands to establish a list of characteristics associated with reverential termination rituals.

Ahrliechs, Robert (UW-Milwaukee)

Collecting Copper and Systematic Archaeological Analysis

The Old Copper Complex is represented by tens of thousands of copper artifacts recovered from locations widely scattered across the landscapes of the Western Great Lakes. Many of these artifacts continue to be collected and curated by avocational archaeology enthusiasts with characteristically poor contextual information. Traditional scholarly study of this complex has been restricted to the consideration of copper as a symbolically potent object and the construction of artifact typologies. This has resulted in a lack of emphasis on the role that copper played in the subsistence and economic systems of the people who depended on it. This research addresses the acquisition, use, and discard of copper artifacts through the systematic study of the Jim Bussey Collection from both northern and southern Wisconsin localities. Morphological artifact types, their relative distributions through space and time, LA-ICP-MS based sourcing data, and use-wear patterns are used to develop an archaeologically useful dataset despite poor provenience.

Analysis of Human Hair Bands from Old Man Cave, Utah

In the early 1900s, excavations conducted at Old Man Cave in southeastern Utah unearthed various Basketmaker II materials, including an incredibly well-preserved bundle of burden bands made from human hair, dog hair, and yucca cordage. Radiocarbon dating places the manufacture of these textiles between 170 BC and AD 135. The bundle, when unfolded, contained a complex set of artifacts, including two smaller fragments that appear to be carrying bands, and another far more unique woven artifact. Resembling a load-bearing strap, this wide-split woven band consists of two narrow tumpline-like bands joined at each end, displaying considerable upkeep and maintenance. Only one other artifact known to the authors bears a similar form, but the functions of both remain unknown. Regardless, these woven artifacts provide a case study for examining textile production methods and use in the San Juan region of the American Southwest. Analysis of fibers, twist, ply, weave, wear patterns, and predepositional repairs can help illuminate the method of skill transmission and cultural interactions that existed in preceramic Southwestern societies. The foundational knowledge for these and other analyses is established by a thorough examination of the artifacts at hand and relevant comparative pieces.

Maya E-Groups and the Nature of Science—Ours and Theirs

Maya E-Group architectural assemblages have attracted scholarly attention for about a century, and yet our ideas about them have become muddied through time. Since the beginning of investigations in the 1920s these structures have been thought to have had some astronomical function, but the exact astronomical significance suggested by archaeologists has changed though time. Today there is very little agreement about their meaning and function. In this presentation I will briefly review the history of the problem with an emphasis on the nature of the evidence that has been presented and how it has been presented. Rather than attempting to provide a definitive interpretation of the function of these buildings, I will argue that we have become increasingly, and perhaps dangerously, bold in our willingness to draw broad conclusions from limited evidence. The Maya E-Group problem sheds light on how interpretations become accepted as fact in archaeology, and the nature of scholarship in a fast-paced world.

Investigating Prehistoric Fisheries: Growth-Band and Stable Isotope Analyses on Otoliths of a Critically Endangered Species (Totoaba macdonaldi) in the Upper Gulf of California, Mexico

Over 700 fish otoliths were recovered during archaeological excavations at the Rancho Punta Estrella sites on the northern Gulf coast of the Baja Peninsula of Mexico; over 120 of these have been identified as totoaba (Totoaba macdonaldi, Sciaenidae), a critically endangered species due to...
pressures from commercial fishing and human alterations of the Colorado River. AMS radiocarbon dates on seven totoaba otoliths suggest two primary occupations at ~4900–5400 cal BP and ~800–1150 cal BP. This study incorporates several analytical techniques for totoaba otoliths including: growth-band analysis, stable isotopes, and morphometric measurements; which are used to establish age and size estimates, and reconstruct local environmental conditions (SST). Oxygen (δ18O) and carbon (δ13C) isotope ratios have been used to generate inferences on the local habitats and life histories of totoaba. determine the season of capture, and investigate seasonal shifts in water temperature and salinity in the upper Gulf of California. Comparisons of archaeological and modern specimens revealed that pre-dam juveniles grew faster and matured earlier than post-dam totoaba. Our study contributes to the prehistoric record for this species, expanding our knowledge of indigenous fishing practices in the region and species-specific impacts related to the divergence of major waterways like the Colorado River.

Ainsworth, Caitlin (University of New Mexico) [368] Late Spanish Colonial Subsistence Practices and Their Environmental Impact in the Middle Rio Grande Valley

In 1598, Spanish colonialists introduced European domestic fauna, including sheep, pigs, and cattle, into New Mexico's Middle Rio Grande Valley (MRGV). Sometime after this initial contact, Native residents of the MRGV shifted away from the use of a diverse set of native fauna and focused their diets on non-native domestic taxa. This shift had far reaching effects; reliance on domestic grazers ultimately led to overgrazing, erosion, and loss of native species—all of which characterize the modern Southwestern landscape. Knowledge of the timing of these changes is critical to understanding their impetus and effects. Recent research suggests the shift from exploiting a diverse resource base to reliance on a small number of domesticates occurred after the end of the seventeenth century but before the beginning of the nineteenth century. However, a lack of zooarchaeological data from sites occupied during the eighteenth and nineteenth centuries has thus far prevented more specific dating of this critical transition. Analysis of the faunal assemblage from Los Ranchos Plaza, occupied AD 1750–1904, is helping to fill this knowledge gap, and improve our understanding of changes in the nature of human and environmental interactions following the Columbian exchange.

Aitchison, Kenneth (Landward Research Ltd) [122] Discovering the Archaeologists of the Americas: Pilot Project

SAA has developed a plan to investigate the demographics of the archaeological profession in the Americas, looking to bring together knowledge and advice on how the profession of archaeology (in Cultural Resource Management, academic, government, museum, self-employed, and other contexts) is structured throughout North, South, Central America, and the Caribbean. This proposed Discovering the Archaeologists of the Americas Initiative intends to conduct a series of linked surveys that will gather, analyze, interpret, and share information on archaeological employment and education across all of the countries of the Americas. This will set up a process by which the survey can be conducted periodically to examine the development of the profession over time. This will also allow direct comparisons to be made between archaeological employment in the Americas with Europe, where previous work has been undertaken, and potentially other areas of the world. SAA, together with Landward LLC, have begun to undertake the Pilot phase of that overall project, carrying out targeted research in two geographic areas—the Republic of Chile and the USA State of New Mexico. This will then inform SAA's decision-making process ahead of the potential implementation of the full, overall Discovering the Archaeologists of the Americas Initiative.

Aiivalasit, Michael (Southern Methodist University) [368] Common Goods in Uncommon Times: Water, Droughts, and the Sustainability of Ancestral Puebloan Communities in the Jemez Mountains, New Mexico (AD 1100–1700)

The Jemez and Pajarito Plateaus of the Jemez Mountains share similar cultural, environmental, and climatic contexts, yet large Ancestral Puebloan communities of the Pajarito abandoned mesas-tops for lowlands of the Rio Grande during the sixteenth century while occupations of the Jemez Plateau persisted until the seventeenth century. Droughts are hypothesized as a driver of depopulation of the Pajarito Plateau, but if so why wasn't the Jemez abandoned as well? Prehistoric communities built water storage features (reservoirs) at most large villages. These common pool resources serve as archaeological proxies for how communities took collective action to reduce the risk of water scarcity. Geoarchaeological investigations at 15 prehistoric water reservoir features at 9 sites across both regions, combined with geospatial analyses of hydrogeology and settlement histories allow the close evaluation of relationships between resource management, climate, and population dynamics. Communities of the Jemez Plateau used their reservoirs for the entire length of occupation. Reservoirs on the Pajarito Plateau stopped being used during droughts in the mid-1400s. Subtle differences in precipitation and geohydrology made Pajarito communities more vulnerable to droughts, but key differences in social organization likely played a greater role in the divergent trajectories of this region.

Akmenkalns, Jessika (University of California, Santa Barbara) [203] Cultural Continuity and Change in the Wake of Ancient Nubian-Egyptian Interaction

This paper addresses the effects of long-term contact and colonialism among ancient Egyptian and Nubian communities during the Kerma period (ca. 2500–1500 BC) in northern Sudan. A wide array of theoretical perspectives on culture contact and colonialism has emerged in recent decades, highlighting the diverse range of outcomes that can result from extended periods of interaction and struggles for political control. Such cross-cultural interactions may occur in the context of information exchange, trade networks, military conflict, and interpersonal relationships, precipitating an ever-changing and fluid cultural milieu. I investigate these conditions at the sites of Hannek and Abu Fatima, both Kerma period sites located in the hinterlands surrounding the Kerma political and economic center. The results of this study stem from excavations conducted in 2015 and 2016 and indicate that while the Kerma residents of Hannek and Abu Fatima incorporated a small selection of Egyptian objects and practices during the period of contact, the archaeological evidence suggests that these communities largely adhered to indigenous cultural traditions, even in the later part of the Kerma period when Egyptian colonialism was at its apex. This research stands to contribute to our understanding of how interaction shapes the negotiation of identities in borderland regions.

Akoshima, Kaoru (Tohoku University) [42] Toward Standardization of Lithic Use-Wear Identification in Conjunction with Technological Organization and Raw Material Variability

The paper examines theoretical problems concerning characteristics of lithic microwear traces in the Paleolithic. Use-wear studies already experienced 40 years of research since the discovery of micro-polish varieties which reflect worked materials with wide applications to site structure analysis. However, global standardization of identification criteria still needs comparative efforts, especially on raw material variability and behavioral diversity among regional settlement and subsistence systems, hence experimental replication programs. The present research investigates comparative...
framework of use-wear classification and interpretation for both “low-power” (microfacking) and “high-power” (micro-polish) methods, with special reference to the “technological organization” concept by Binford. Use-wear data is evaluated in terms of complex human mobility patterns over the landscape and technological dichotomy between “curated” and “expedient” components with raw material availability and distributions. Case studies are selected from the Upper Paleolithic of Northeastern Japan. The Mogami River project in Yamagata Prefecture by Tohoku University (1984 to 2016) including the Kamino A site, the Marumori 1 site, the Takakurayama site, the Hakusan E site, and the Hakusan B site, provides concrete data bases for discussion. Experimental framework by the Tohoku University team since 1976 is utilized for wear pattern standardization.

Alaica, Aleksa (University of Toronto) [238] The Health of the Herb: Considering Camelid Herding from Late Moche Peru

The herding of camelids in the pre-columbian past impacted daily and ritual life of peoples residing there. During the Late Moche period of Peru, camelid herding was a major factor in the trade and exchange of goods, people and ideas. The extent of herding and the degree of camelid breeding in the coastal desert has been understudied. This paper will discuss the patterns in camelid age profiles and pathologies to inform the extent to which camelids where traveling along the coast and into the highlands. The broad age profiles evident from detailed analysis displays a broad range of herds coming to the Late Moche site of Huaca Colorada (AD 650–850). These data indicate that the long-held view that breeding of camelids was localized to the highlands needs to be revised. The osteological evidence from Huaca Colorada reveals the biological constraints imposed on Moche communities residing here and the demands of localized breeding to account for the numerous juvenile camelid burials uncovered in mortuary contexts and those uncovered in feast midden. In the end, the varied exchange from possible highland and coastal locations shows that individuals may have been coming from long distances to visit and engage with activities at Huaca Colorada.

Albanese, John (University of Windsor) [235] Skeletal Evidence Suggesting Biological Continuity in the Ruling Lineage throughout the Late Helladic, Sub-Mycenaean, and into the Dark Ages on the Greek Island of Kefalonia

The cluster of sites on Borzi Hill near the village of Tzannata on the island of Kefalonia includes several habitation areas and various tombs. The evidence suggests an extensive occupation during the Mycenaean (Late Helladic) Period, including the largest tholos or “beehive” tomb in the Ionian Islands. The tomb was built around 1350 BC at the same location as an older tomb that had collapsed. Although the tomb was looted in antiquity, excavations have yielded a number of notable finds including the remains of several dozen people. All the adult mandibles studied thus far in 2015 and 2016 that are not too damaged to be analyzed, fall into two very distinct patterns by sex. All the males, including the last individual buried in the tomb, have the same distinctive mandibular morphology. The last individual was interred in a distinct style that is not seen on the island until well into the Dark Ages, around the ninth century BC. If this morphology is inherited, the evidence suggests the royal lineage retained a prominent position in the community spanning various upheavals including the complete collapse and displacement of the Mycenaean civilization.

Albeck, María, Maria Amalia Zaburlin (Universidad de Jujuy, Argentina), Jose Luis Tolaba (Universidad de Jujuy, Argentina), Diego Martin Basso (CONICET—Universidad de Jujuy, Argentina) and María Elena Tejerina (Universidad de Jujuy, Argentina) [222] Far South: An Altiplanic Settlement in Northwestern Argentina

Pueblo Viejo de Tucute is the southernmost prehispanic (Late Intermediate Period) settlement with altiplanic roots so far recorded. It has nearly 600 dwellings installed in the mountain range southwest from Casabindo in the Puna de Jujuy, an altiplano like highland. The site is unique in the area, with particular architectonic features that differ from contemporaneous sites (Puna de Jujuy, Quebrada de Humahuaca, Valle Calchaqui). The houses are round, well built in cut stone with a diameter that ranges from 4 to 6 m. Several findings recovered during excavation resemble some from the Peruvian and Bolivian Altiplano, as described in colonial chronicles and ethnographic investigations although some characteristics are peculiar to the site. A brook clearly divides the settlement area in two, and in the middle rises a pucara presumably occupied only in times of conflict. 26 radiocarbon dates establish its occupation from the end of the tenth century to the first half of the fifteenth century. The early radiocarbon dating of the site outranges by a couple of centuries the moment proposed for the massive migrations of highland people in the Andes, due to climatic stress by drought during the twelfth and thirteenth century.

Albert, Rebecca (Michigan State University), Caitlin Clark (Michigan State University), Susan Kooiman (Michigan State University) and William Lovis (Michigan State University) [21] A-Maize-ing: Phytolith Evidence for an Early Introduction of Maize in the Upper Great Lakes Diet

There is no recorded maize (Zea mays ssp. mays) at Laurel or North Bay Initial/Middle Woodland sites in the northern Lake Michigan Huron or Superior basins of the western Great Lakes, despite the presence of maize microbotanicals in Michigan, New York, and Quebec as early as 400 BC. To evaluate the potential for an early maize presence in this region, samples of carbonized food residues adhering to sixteen ceramic vessels from the Laurel/North Bay Winter site (20DE17) were processed and analyzed. Low incidences of maize starches and phytoliths were present in multiple samples, three of which were dated to as early as the second century BC, 800 years before regional macrobotanical evidence. Compression damage to some starches as well as fine grit present in several samples support the proposition that the initial dispersal of maize in the region may have been through transmission of meal or flour, which was then incorporated into existing cooked dishes by local populations. The lack of maize macrobotanicals for centuries thereafter suggests that maize did not immediately become a significant component of regional cuisine until long after its initial introduction to the Upper Great Lakes.

Alcantara, Keltlyn (Vanderbilt University Department of Anthropology) [215] “Eating Locally” in Tlaxcallan: The Impacts of Political Economy on Postclassic Diets
Late Postclassic Central Mexico is defined by significant political change, with the Aztec Triple Alliance quickly dominating the political landscape. As the triple alliance materialized in the fifteenth century, Tlaxcallan simultaneously emerged as a key market center, connecting trade in the central highlands to the Gulf Coast. As the alliance expanded, Tlaxcallan remained a uniquely unconquered space, yet the conditions of its autonomy are unclear. Siege of trade routes and the manipulation of access to commodities (often foods key to diversifying local diets) was a central tactic used by the Triple Alliance. Through bioarchaeological analysis of dietary isotope, which reflect consumed foods incorporated into human bones and teeth, I discuss preliminary results from burials excavated in the city of Tlaxcallan’s Tepetipac district. Changes in local diets could disclose nuanced social and political relationships of market administration and economic embeddedness, and clarify the political and economic position of Tlaxcallan during this period.

Differential access to foods likely also occurred at a subgroup level (age, sex, occupation, or social group). This information can be used to reconstruct social structures within Tlaxcallan, and their relationship to broader geopolitical networks of trade in order to contextualize how local political architects confronted interregional politics.

Alcántara Salinas, Andrés Saul [183] El caso de la Parcela 28 del Ejido de Comala, Colima: La problemática del saqueo arqueológico y recuperación de una tumba de tiro El denominado Occidente Mesoamericano, presentaba características únicas que lo diferenciaban del resto de las culturas de esta súper área cultural; diferencias que son claramente observables en el sistema funerario que fue utilizado por estos grupos, al cual se le denominó como: “Tradición de Tumbas de Tiro.” El legado patrimonial que dejaron estos grupos se encuentra prácticamente todo el territorio del estado de Colima, desafortunadamente este se ha visto alterado por la práctica que realizan muchas pobladores y son quienes generan el saqueo de contextos con la intención de obtener las piezas cerámicas, artefactos de piedra entre otros muchos objetos depositados al interior de las cámaras funerarias. La destrucción y pérdida de muchas tumbas ha sido una constante a lo largo de poco más de 80 años. Uno de los trabajos que realiza el INAH, es el de atención a denuncias, con los cuales le permite la intervención de áreas o sitios que están siendo alterados por el saqueo; con estos trabajos se llega a recuperar objetos diversos e información novedosa e importante, que juntos enriquecen el acervo patrimonial arqueológico de México.

Alconini, Sonia (University of Texas At San Antonio) [231] Fertility, Water, and Rock Art on the Inka Imperial Fringes: The Valley of Mariana and Samaipata Samaipata was one of the largest centers of the Southeastern Inka frontier. Multifunctional in nature, it was an important advance point toward the tropical lowlands. Despite the intrusions of the Guaraní-Chiriguano, this region witnessed complex processes of settlement reorganization. This was particularly the case of the fertile valley of Mairana, an important breadbasket of this frontier outpost. Occupied by the Mojocoya and Gray Ware archaeological cultures, their inhabitants produced complex rock artistry and participated in vibrant interregional exchange networks. Based on a recent survey, this poster explores the occupational dynamics of this valley, and its later incorporation into the Inka imperial economy. It also discusses the importance of rock art in indigenous ritual practices associated with water and fertility.

Alcover Firpi, Omar A. (Brown University). Charles Golden (Brandeis University) and Andrew Scherer (Brown University) [118] Reconsidering “Sites,” “Features,” and “Landscapes” in the Maya Lowlands with Remote Sensing and Ground-Based Survey Etic distinctions between “sites” and “landscape features” and the limits of pedestrian survey have long influenced how scholars in the Maya lowlands model social and political dynamics of the region. The adoption of remote sensing technologies, particularly lidar, has improved our ability to identify anthropogenic features over wider areas. Yet remote sensing data collection remains centered on known “sites” and data serving to further expand the mapped boundaries of ancient “cities,” generally without challenging the notion of bounded settlements. Too often, research tends to emphasize a synchronic view of “sites,” whose edges are often defined not by emic understandings of boundaries but by the limits of archaeological survey. Moreover, the palimpsest of cultural features, including walls, terraces, and dams dispersed on the landscape reveal a complicated history of construction and use. We suggest that only if we revise theoretical conceptions of the relationship between “site,” “feature,” and “landscape” can these technologies be better used to answer new questions concerning landscape adaptation. This paper draws on recently acquired remotely sensed data and over a decade of ground-based survey data from the Usumacinta River valley of Mexico and Guatemala to offer new interpretations of landscape use and change among the Maya.

Aldenderfer, Mark (University of California) and Leslie Aiello (Wenner-Gren Foundation) [70] Wenner-Gren Foundation Funding for Archaeology Over the past 15 years the Wenner-Gren Foundation has received approximately 3,000 applications for research funding from archaeologists (students and established scholars) and have funded just under 500 of these requests (success rate = 15–16%; grand total of funds awarded = $3,050,000). The Foundation does not fundraise and thus the amount we can award each year is dependent on the financial markets. A particular challenge is to maintain and grow the spending power of the endowment, while continuing to fund as many worthy projects as possible. Although we are not dependent on the vagaries of donors or government policies, it is not an easy investment task to achieve the necessary level of return to meet the current requirements of the field let alone funding needs that may arise as priorities of government agencies and philanthropic sources change.

Alders, Wolfgang (University of California, Berkeley) and Abdallah Khamis Ali (Department of Museums and Antiquities, Zanzibar) [307] Preliminary Results of Geoarchaeological Sampling and Survey to Investigate Landscape History in Northern Unguja, Zanzibar We present the preliminary results of a study investigating long-term agricultural history in northern Unguja, the southern island of Zanzibar. In the summer of 2016, we excavated four test pits in modern rice fields to collect bulk, starch, phytolith, C14, and micromorphology samples, as well as samples from upland areas along watersheds, with the aim of characterizing contemporary and ancient land use in the rice-growing western side of the island. We also carried out brief archaeological surveys along three different watersheds, in the western, northern, and eastern parts of the island. Preliminary results suggest diverse strategies for agricultural production that varied in relation to urban development at Tumbatu and Mikokotoni in the
northwest, Zanzibar Stonetown in the southwest, and settlement on the northeastern side of the island. Productive diversity existed both between and within the two broad ecological zones in northern Unguja: the deep, clayey soils in the west where rice farming is possible, and the bare, rocky bedrock outcrops in the east where marginal banana, coconut and cassava farming exists through landscape modifications in the coral stone. We reflect on the implications of these differences for understanding long-term landscape histories in island East Africa.

Alderson, Helen (University of Cambridge)  
In Oceania, archaeologists have examined perishable ethnographic items to gain fresh insights into past people’s identities. This paper presents a new analysis of nineteenth- and twentieth-century Micronesian loinclothes from European and American museums, explaining how their construction offers insights into islanders’ sociopolitical identities during a period of rapidly intensifying global interconnectivity. On the island Kosrae, Micronesia, tol (loincloths) were the primary garment of every polynesian. Women wove tol on looms, using specific motifs to create identifiable styles. The German Southseas Expedition (1908–1910) recorded that each style materialized an individual social status, such as fisherperson or chief. I propose that in weaving, women created collective social identities, such as a gendered sense of self as traditional knowledge holder. While tol were indisputably Kosraean, their history is connected to a broader Micronesian weaving tradition. Tol motifs were not only passed from Kosraean mothers to daughters, but were also passed between interacting populations. This sharing accelerated after European contact (1824). In order to quantify this change, I present statistical analyses of motif transfer over time in tol, illustrating how Kosraean women used insider and outsider motifs to maintain old identities, and construct entirely new ones, in an increasingly cosmopolitan world.

Allard, Amelie (University of Minnesota)  
[128] “Little Hope of Much Trade This Year”: Merchant Capitalism and Community-making in the Late Eighteenth-Century Western Great Lakes Fur Trade  
While the North American Fur Trade has often been examined through economic lenses, scholarship from the 1980s onward has striven to demonstrate that this colonial phenomenon was more than mere trade and merchant capitalism: it also embodied a complex web of social relationships and practices that went beyond daily transactions. In this paper, I unpack the ways in which exchanges, of myriad shapes and forms, between Euro-Canadian fur traders and local Indigenous groups in the Western Great Lakes intersected socially and physically with other daily practices such as food procurement and mobility. Drawing from my research on the late eighteenth-century fur trade landscape of Minnesota and Wisconsin, I bring to light some of the ways in which Anishinaabeg and Dakota peoples (the two most powerful social formations of this area at the time) not only dictated the terms of their participation through trade and politics, but also controlled the movement of fur traders on their hunting grounds through a choice to share knowledge—or not. Lastly, I address the issue of accessing knowledge of Indigenous perceptions of this process through archaeological research, especially given the common mislabeling of post-Columbian Indigenous occupations as “fur trade posts” based on artifact assemblages.

[333] The Maritime Silk Route and Southeast China during the Han Dynasty: A View from Panyu, Hepu, and Lingnan’s Hinterland  
Consisting of the present-day provinces of Guangxi and Guangdong, the Lingnan region was from early on impacted by political and cultural forces centered to its north. Following Lingnan’s brief occupation by the Qin (214–204 BCE), the Qin general Zhao Tuo established the independent kingdom of Nanyue, whose defeat at the hands of Han armies in 111 BCE resulted in the region’s formal incorporation into the Han Empire. Importantly, various lines of evidence dating to the Han dynasty point to Lingnan’s increasingly extensive contacts with regions located further south along the so-called maritime silk route. Such evidence includes texts (indicating Lingnan’s likely interaction with the Indian subcontinent), grave goods (e.g., elephant tusks, frankincense, beads made of precious stones), nonlocal knowledge (e.g., granulation), and architectural elements (e.g., stone columns). Many of these ‘southern’ (or ‘western’) elements are well represented at Panyu (the Nanyue kingdom’s capital) and Hepu (a post-Nanyue kingdom coastal port), leading some archaeologists to emphasize the importance which such contacts played in Lingnan’s development during the Han dynasty. However, a closer look at these foreign elements’ spatial and sociopolitical patterning throughout Lingnan points instead to the likely limited impact which the Southern Maritime Route played in such developments.

Allen, Mitch (Mills College) and William B. Trousdale (Smithsonian Institution [retired])

The Helmand-Sistan Project, conducted jointly by American and Afghan archaeologists, was the first prolonged systematic survey and excavation of the lower Helmand River region of southwest Afghanistan. It identified over 200 sites dating from the third millennium BCE to the fifteenth century CE and conducted excavations at a dozen of them. Military action abruptly halted the project, caused the demise of its collection of material culture stored in Afghanistan, and limited publication to a few focused articles on specific sites and finds. After 40 years, we are now attempting to resuscitate the project and bring it to final publication, increasingly important because of the unlikelihood of further archaeological work in this area in the future. The challenges of doing so without the ability to recheck site details on the ground, without artifacts available for further analysis, and with project members scattered or deceased, will be the topic of this presentation. The paper will also highlight some key findings of the Project, notably in the canal-fed Sar-o-Tar region east of the Helmand River, intensively occupied and farmed only sporadically because of changing climatological and hydrological conditions.

[27] Halaf Seasonality and Mobility: An Archaeobotanical View from Fıstıklı Höyük, Turkey

Settlement patterns and mobility during the Halaf period (ca. 6000–5400 BC) are known primarily from Late Halaf sites. On the basis of the Late Halaf pattern, Halaf economies have been characterized as having segmentary organization with some degree of pastoral specialization reflecting a broad pattern of long-term mobility. However, the paucity of floral and faunal studies, particularly for the Early Halaf, limits the visibility of economic variability over the course of the Halaf. In this regard, archaeobotanical data from the Early and Middle Halaf site Fıstıklı Höyük (ca. 6000–5700 cal B.C.), located in southeastern Turkey on the eastern edge of the Euphrates floodplain, facilitates more nuanced reconstructions of Halaf mobility patterns that highlight their temporal and spatial variation. At Fıstıklı, the relative lack of weed seeds in midden and surface samples, together with the high frequency of cereal chaff and high proportion of dendritic long-cell phytoliths in many surface samples point toward the regularity of cereal threshing on-site and the use of threshing by-products as fodder for sheep and goats. The use of both dung and wood fuel in separate burning installations may indicate repeated short-term occupation at different times of the year.

[129] Kinship and the Self-Organization of Exchange in Small-Scale Societies

Circulation of material goods is common in small-scale societies. Even where exchange is not coordinated above the level of the household, goods produced in one area are consistently conveyed to distant settlements. Numerous ethnographic studies demonstrate that exchange transactions are common among kin, and that the circulation of goods in small-scale societies is structured by kinship ties. From an individual’s point of view, the number of kinfolk available to exchange with and where they live strongly affect access to nonlocal goods. This paper explores the interrelationships among kin networks, settlement organization, and exchange using agent-based modeling, ethnographic studies, and archaeological data.

[375] The Cultural and Historical Connection between Tefinagh Inscriptions and Rock Art Sites in Tadrart Acacus (Southwest Libya)

This paper discusses what kind of cultural and historical correlation between Tefinagh inscriptions and rock art in the Tadrart Acacus. The Tuareg alphabet, Tefinagh, is one of ancient African alphabets documented not only in Libya but also Algeria and Tunisia, among other countries. It is traditionally taught by a mother to all her children. This alphabet, which dates back at least to the second half of the first millennium BCE, is used by approximately 50% of the Tuareg for short messages and inscriptions. Furthermore, hundreds of Tefinagh inscriptions have been discovered in the Tadrart Acacus, some placed near or at sites with rock art. The rock art sites in the Tadrart Acacus dated from 12000 BCE to 100 CE. The study area, Tadrart Acacus, is an area of about 150 km in length and 50 km in width. It is located in the Fezzan region situated in southwest part of Libya. Tadrart Acacus hosts one of the richest concentrations of Saharan rock art and was included on the UNESCO list of World Heritage Sites in 1985. This paper attempts to undertake interviews with Tuareg people as per the questionnaire provided, and also uses standard recording sheets.

[209] Weaving Meaning into Mississippian Ritual
Fabric is rarely recovered from Mississippian sites, although there have been a few spectacular finds. There are however other lines of evidence that speak to the use and meaning of fabric in the Mississippian world. We have recovered the charred remains, or at times structured ash of what were once bags, mats, baskets or other fabric items during excavations at a few Cahokia related sites in the American Bottom region of Illinois. The Emerald Shrine Center in particular has produced these “ghostings” of fabric, particularly in buildings that were once shrines. The repeated burning fabric as part of the decommissioning of the shrines is striking at Emerald, as are the great numbers of spindle whorls that have been found at villages located near the shrine center. Weaving together meaningful interpretations of these fabric remains and spinning tools is possible by considering Mississippian art, ethno-historic accounts and by contrasting what is known of other Mississippian fabrics. My interpretations will be placed together with considerations of nonhuman actors and the enchained powers and forces that adhere to the material world and the raw materials of fabric construction.

Brother Bear: The Role of Ursus americanus in Cherokee Society  
Archaeological sites in the Southeastern United States often contain remains of the black bear (Ursus americanus), which, upon excavation, are placed into one of two general categories for further analysis: food or modified. The confines of these categories precondition interpretations of the bear remains, and limit possible crucial understanding of the roles of bears in the social life of the people who interacted with them. While the category of “food” can be further divided into quotidian or communal (feat) meals, the “modified” category is most frequently interpreted as “ceremonial” and left at that. Our paper, which is part of a larger series of papers, is a study in the ethnozooarchaeology of bears. We examine bears in the archaeological record from the pre-European Contact through Historic periods among peoples who lived in the region of the traditional Cherokee homeland. We compile archaeological data and combine their interpretations with information from ethnographic, ethnohistoric, and linguistic sources to offer a more robust construction of human-bear relationships, and their constancy through time into the present. By expanding the contexts through which bear remains are interpreted we offer new models for understanding the complex relationships between people and the animals whose world they share.

The Palace Group at Xochicalco, Morelos, Mexico  
Xochicalco is a hilltop site located in the mountain range of the western part of the modern Mexican state of Morelos. Archaeological investigations carried out in the upper part of the site between 1994 and 2009 have provided several breakthroughs in our understanding of one of the most representative sites of the Epiclassic period in Mesoamerica. The site’s major building complex, known as the Acropolis, is situated on the very top of the hill. Covering approximately a hectare, this group comprises ten structures interconnected by corridors and stairways. Excavations in this sector have provided multiple lines of evidence that have enabled us to identify this built space as a palace. Therefore, considering the location of the Acropolis, its architectural features, its dimensions, the recovered objects, and the evidence for a major destruction event, this paper will explain the configuration of this palace, as well as its implications and repercussions in the social space of Xochicalco.

Estudio petrográfico de la cerámica de Sihó, Yucatán, durante el Clásico Tardío y Terminal  
Sihó, sitio arqueológico localizado en el occidente de Yucatán, fue ocupado en distintos momentos de los períodos Preclásico y Clásico, aunque su ocupación más importante ocurrió durante el Clásico Tardío y Terminal. Es a este momento que corresponden gran parte de los edificios monumentales del asentamiento. La Universidad de Yucatán ha desarrollado en este sitio excavaciones que han permitido la recuperación de cerámica de diversos estratos socioeconómicos, tanto en contextos tipo estricto como en conjuntos de mediano y bajo status de los periodos Clásico Tardío y Terminal. El propósito de esta ponencia es presentar el análisis de petrografía enfocado en la textura de grano fino con el fin de obtener información de rasgos texturales que ayuden a identificar alteraciones de la arcilla para determinar parámetros de cocción en los artefactos culturales. Con base en lo anterior, discutiremos tanto los patrones de consumo y tecnología cerámica del sitio en un marco regional así como determinaremos las variaciones observables en los distintos contextos analizados enfatizando aquellas relacionadas con la forma de las piezas y su distribución en los conjuntos habitacionales del sitio.

Landscape, Settlement Patterns and Rain and Fertility Symbolism in Rock Art: A Comparative Analysis between Chalcatzingo and Cerros De Trincheras in Mexico  
In this paper we present a systematic comparative analysis of the most characteristic cultural traits of sites, apparently distant in time and space, that share fundamental aspects, concerning basic geomorphological and landscape features, settlement patterns, and rain and fertility symbolism depicted in rock art. The direct association between political power and religious authority, social prestige and the privilege of presiding ritual performances appears to be evident. While in Mesoamerica this historical and cultural processes took place from about 1500 BC. In northwestern Mexico they began to occur around AD 800. Nonetheless, as we will try to show, similarities are surprising.

African Ancestry or Neanderthal-Human Genetic Admixture in Eurasians? African Diversity Matters

Neanderthal and Denisovan genetic admixture with Eurasian modern humans, and a “signature” of Neanderthal admixture in African populations, are widely accepted “facts.” Inferences of admixture are based mainly on the assumption that Yoruba, San and/or Pygmy populations contain all African genetic variation. Variants shared among Neanderthals and modern Eurasians, but not present in these Africans, are assumed to reflect 2–4% admixture. However, genetic diversity and geographic structure are greater in Africa than Eurasia, so small samples are inadequate. Non-African ancestry lies in northern and eastern Africa. Therefore, excluding northeast African genomes automatically identifies them as “admixed” rather than as descendants of the common ancestors of Eurasians and northern/eastern Africans. For example, the Maasai of Kenya appear to have 1–3% Neanderthal admixture. How much would inferred archaic admixture with Eurasians be reduced by including Eastern and Northern Africans in admixture analyses? Adding Dinka from South Sudan to Yoruba and Pygmy datasets reduces Neanderthal admixture in modern French genomes from 2% to 1.3%. Conversely, using only Yoruba or Pygmy genomes increases estimates of Neanderthal admixture in Eurasians. Admixture should be considered unproven until more populations are used to ascertain African genomic diversity, and the alternative hypothesis of common ancestry is evaluated.

What Big Teeth They Have: Rethinking Mandibular Tooth Crowding in Domestic Dogs and Wolves Using Landmark-Based Metric Analysis

Tooth crowding is one of several criteria used for the identification of domestic animals in archaeological contexts, and is used frequently in dog domestication studies to support claims of early Paleolithic domesticates. Studies of crowding have varied in their quantitative approaches, and can be improved by more robust statistical testing and the incorporation of more specimens with secure wild or domestic identifications. Here we present a landmark-based method for analyzing tooth crowding, along with a statistical framework for describing crowding between populations. Our method expands on traditional metrics used to quantify crowding and is applied to a large dataset of modern dogs, modern wolves, and Late Pleistocene wolves to examine the prevalence of tooth crowding in these populations. Results show that both modern and Pleistocene wolf specimens exhibit more mandibular crowding than domestic dogs. This contradicts generally accepted assumptions regarding the nature of tooth crowding in dogs, and domestication in general, though future studies should specifically target archaeological material to investigate crowding within distinct archaeological populations. This shows that landmark-based methods offer powerful tools for recording and analyzing tooth crowding, and that assumptions surrounding tooth crowding in the identification of archaeological canids and other mammals should be critically reexamined.

A Multi-Proxy Site Formation Analysis of a Late Middle Pleistocene Occupation in the Azraq Wetlands of Northeastern Jordan

The Azraq Marshes Archaeological and Paleoen ecological Project (AMAPP) aims to understand and evaluate the importance of the Azraq wetlands for Pleistocene hominin populations. Ongoing research since 2009 indicates that the northern wetland, the Druze Marsh, acted as a desert refugium for hominins throughout the Middle and Late Pleistocene. Excavations in the southern marsh—known as the Shishan Marsh—began in 2013 and uncovered a rich assemblage of bifaces, small tools, and flakes, along with fragmentary faunal remains. The Shishan Marsh 1 (SM1) occupation, which dates to approximately 250 ka, is embedded in a complex sedimentary sequence indicative of a transitional environment, from a lake to marshy ponds that formed at the edge of an alluvial fan. This paper summarizes the results of sedimentary and microbotanical analyses of the site’s stratigraphy, as well as site formation indicators from the lithic and faunal remains recovered during the 2013, 2014, and 2015 field seasons. We conclude with a discussion of the depositional history of the Shishan Marsh occupation, and implications for deciphering how the area was used by the late Middle Pleistocene inhabitants.

An Archaeological Test of a Settlement Pattern Shift Recorded in Tsimshian Oral Records

We archaeologically test a hypothesis derived from the Tsimshian oral record. That record recites a long history of settlement movement and conflict culminating in an invasion of coastal Tsimshian territory by northerners. This conflict reportedly caused the Tsimshian to temporarily abandon their coastal territories and retreat inland. We tracked settlement shifts through a site taxonomy and intensive analysis of a large 14C sample acquired by percussion coring. We found an occupational hiatus in the study area and hence cannot disprove the hypothesis. We conclude the archaeological data are best explained by the history described in the indigenous oral record.

Island, Mainland, and the Space Between: The Role of Geography in Shaping Community Historical Trajectories of Nineteenth- and Twentieth-Century Ireland

This study looks at the relationship between geographical “islandness” and community formation in Western Ireland. In this paper we investigate to what degree geography shapes the social, economic and political experiences of a community. Furthermore, we examine to what extent these elements of community composition strengthen or diminish their influence on each other. We compare the nineteenth- and twentieth-century island communities of Inishbofin and Inishark, Co. Galway against the complementary mainland townlands of Streamstown, Co. Galway and the Killary, Co. Mayo. This paper traces the extent to which social dynamics (community constitution and development through time), degree of political engagement (local implementation of regional and national policy), and economic opportunity (types of local industry and extent of trade network) impact development on island communities in relation to their mainland counterparts. Using historical documents, archaeological excavation and survey data, as well as digital mapping, this comparative study shows how communities of similar historical composition, but with varying geographic situations, can result in different social, political, and economic mentalities which ultimately shaped the experience and development of the present day island and mainland communities.

[336] Multispectral Photogrammetry of Cultural Landscapes on the Northern Plains from Unmanned Aerial Vehicle Platforms

As early adopters of technology, especially for creating accurate maps, archaeologists have been using Unmanned Aerial Vehicles (UAVs) to discover and record archaeological features, landscapes and excavations since they became commercially available. This project tested the use of visual (RGB), near-infrared (NIR) and thermal sensors mounted on UAV platforms (fixed wing and multi-rotor) to discover and record archaeological features in their landscape context with georeferenced, high resolution imagery of two landscapes on the Northern Plains that contain a variety of cultural features, including stones circles, boulder alignments, stone cairns and medicine wheels. We created digital layers to compare with the results of conventional archaeological survey, in cooperation with an ongoing archaeological survey in the vicinity of the forks of the South Saskatchewan and Red Deer Rivers in southwestern Saskatchewan. We applied both Object Based Image Analysis (OBIA) and desktop visual examination of the imagery captured in this project in order to determine whether interpretation results were similar to conventional survey and whether conventional survey and UAV-based multispectral imagery recognized different features.

[337] Preclassic Complexity in the Central Karstic Uplands: Yaxnohcah and its Neighbors

The Preclassic (900 BCE—150 CE) was the period during which the earliest sedentary communities in the Maya lowlands were founded. Acts that initiated these early civic centers, such as the construction of E-Groups and communal platforms, were followed quickly by rapid expansion of communities throughout the landscape, involving population growth, monumental architecture, massive waterworks, and a high degree of sociopolitical complexity. It was also during this period when ideologies and practices in religion, statecraft, and commerce were firmly established. In this context archaeological research has been shifting its attention to the Preclassic in order to address the still impervious questions on how this growing complexity led to the advent of Maya culture. Recent archaeological excavations at Yaxnohcah and other Preclassic sites have centered on those topics that endeavor to shed some light on this complex process. In this paper we will present a review of such efforts at Yaxnohcah and situate them in relationship to the development of complexity in the Central Karstic Uplands. We focus on the adaptation of the earliest settlers to the wetland landscape during the Middle Preclassic and the subsequent early appearance of low density polycentric cities in the region.

[227] PIDBA (Paleoindian Database of the Americas): Long-Term Collaborative Research at International Scales

Compiling and making accessible primary archaeological data from multiple sources and across large areas is one of the grand challenges facing archaeology in the twenty-first century. The Paleoindian Database of the Americas (PIDBA) has been operating for over 25 years to make Paleoindian data openly accessible online to all interested parties. Data from more than 100 scholars, including locational data on over 30,000 projectile points, has been made available in digital form that has been variously used for analyses and display. PIDBA serves as a model for collaborative interaction between professional and avocational archaeological communities across the Americas. Analytical challenges include rendering data from disparate sources interoperable, assuring the security of sensitive data, and maintaining networks of researchers providing information. PIDBA is now linked with DINAA, making the information within it even more widely accessible, and hopefully it, or a data source something like it, will continue to exist long into the future.

[212] Esoteric Spiritualities and Archaeology: Bridging Alternative Understandings of the Ancient World

Practitioners of esoteric religious traditions express profound interest in the ancient world as a source of wisdom. Yet the view of the ancient world forwarded by these groups is often one that archaeologists struggle to understand. It is a worldview that blends perceived ancient traditions from a variety of cultures into a new milieu that results in practices such as Kemetic Yoga and beliefs in Atlantis as a spiritual home for all humanity. This paper will focus on a case study of the beliefs, practices, and history of the Theosophical Society founded by Helena Blavatsky. The ways in which this esoteric spiritual group embrace notions of the ancient world reveal opportunities for archaeologists interested in promoting heritage preservation. I will argue that archaeologists can in particular use notions of shared global heritage to advocate for archaeological preservation among esoteric audiences.

[257] Exploring the Development and Spread of Arctic Maritime Traditions through Bayesian Radiocarbon Analysis

To address the question of why arctic maritime traditions developed and spread in the North American Arctic during the mid- to late Holocene, we applied Bayesian analysis to a large radiocarbon database (n = 1202) for northwest Alaska and the Bering Strait region. We used Oxcal to create and analyze demographic patterns in summed probability distributions. We also used Bayesian calibration models to clarify the probable timings and
Overall, its assemblage and architecture appear to be totally different from the nearby Classic lowland capital of Cancuen, or any other lowland site. Yet, Verapaz highland trading partners, has a unique architecture and material culture of highland Verapaz style but with significant lowland elements. Evaluating how the Calixtlahuacans got their obsidian is important for understanding how the Postclassic market system was organized outside the Basin of Mexico. By whatever means Calixtlahuaca's citizens got their blades, it is clear that after the Mexica conquest of 1474, less obsidian reached the city than was previously the case. This change is likely to have had a detrimental effect on the well-being of the city's inhabitants. Andrus, Bradford (Pacific Lutheran University)

[322] A Postclassic City with No Blade Workshops: How Did the Calixtlahuacan's Get Their Stone Tools? Analysis of the obsidian artifacts recovered from households in the city of Calixtlahuaca (AD 1130–1530) indicates that prismatic blade production was not a domestic affair. Furthermore, intensive survey did not reveal evidence of onsite blade workshops anywhere in the city. This finding is at odds with what has been reported for many other Postclassic urban centers. This paper discusses why the blade-core data are not consistent with onsite blade production. It then evaluates three models for explaining how the Calixtlahuacans provisioned themselves with blades: finished blade trade, long-distance itinerant craftsmen, or local craftsmen working outside the city limits. The discussion examines why the quantity and quality of blade production artifacts do not indicate onsite blade production, and what the ratios of proximal, medial, and distal blade sections might indicate about provisioning. Evaluating how the Calixtlahuacans got their obsidian is important for understanding how the Postclassic market system was organized outside the Basin of Mexico. By whatever means Calixtlahuaca’s citizens got their blades, it is clear that after the Mexica conquest of 1474, less obsidian reached the city than was previously the case. This change is likely to have had a detrimental effect on the well-being of the city's inhabitants.

[382] Productivity in a Human Context: Creating and Applying Proxies Relevant to Chicama Valley Archaeology El Niño-related changes in marine and terrestrial productivity impacted Chicama residents in several ways, including altering available marine species, soil productivity, and by extension, the technological and economic innovations necessary to adapt. The combination of marine and terrestrial resources were central to the economy of people living in the Chicama Valley throughout the Holocene. Estimates of El Niño’s effects on past marine productivity typically rely on proxies that are distant to where people may have lived and fished, and may not accurately reflect the day-to-day reality of people living in a particular area. Similarly, El Niño-related flooding affected terrestrial productivity through both erosion and deposition. Therefore archaeological research would benefit from new proxies focused on the times and places relevant to human economies. Such proxies are now being developed and applied to a limited extent, and will be discussed as relevant to the Chicama Valley, with particular focus on productivity changes that may or may not have impacted people over time. For example, it is unlikely marine productivity near the Chicama Valley ever diminished to the point where a lack of resources was a meaningful threat until the advent of modern industrial fishing.

[356]  
**Building Agent-Based Approach** 

The relation between the main variants of preindustrial economic production in arid Eurasia, from nomadic pastoralism to irrigated agriculture, is known to have been unstable, with abundant examples of conflict and shifting patterns of land use right up to contemporary times. We present the latest development of a six-year effort, within the SimulPast project, in experimenting and generating theory that could help explain the different land use patterns. Using Agent-Based simulation models, we progressively put together mechanisms hypothesized to be relevant factors in shaping the balance of farming and herding land use within this type of setting and observe their simulated consequences under a wide variety of conditions. We will present the design and results of two models, NomadFrontier and NomadBorder, which were built on the exploration of two previous models, Musical Chairs and Nice Musical Chairs, and introduce new aspects: 1) an explicit penalization based on spatial distances, 2) territorial marks that regulate the access to pasture, 3) a two-level institutional structure, comprising corporate groups and political associations between these, and 4) a parametric representation of terrain constraints. Last, we will compare the simulation experiments with our assessment of several historical and archaeological case studies in Eurasia.

**Survey Says?!?! A GIS-Based Comparison of Site Locations and Settlement Patterns in the Gunnison Basin, Colorado** 

In comparison to the Late Paleoeindian period (10,000–8,000 BP), the Early Archaic (8,000–6,500 BP) in the Gunnison Basin, Colorado is a poorly understood time because of its relatively light archaeological signature. Not only do we have a lighter archaeological record, but we also see a change in technologies, such as projectile point types in this transitional period. Some archaeologists explain these observations as a result of changing environments and shifting settlement processes as new populations move into the basin. Others suggest the results may be due to survey bias, as archaeologists continue to survey portions of the basin. I will investigate whether there is a possible difference in site selection and settlement patterns between the two time periods that may indicate a reason for this lighter signature. Using R and ArcGIS, I will create a predictive model for both the Late Paleoeindian sites and Early Archaic sites and then compare the results. These results will then be plotted against previously surveyed areas in an attempt to determine the reason for the relatively small Early Archaic record in the Gunnison Basin.

**The Central Maya Highlands during the Postclassic: A Marginal Region on the Eve of the Spanish Conquest?** 

Compared to its Guatemala counterpart, the region of the Chiapas highlands is known to have a marginal history in the Postclassic period. This misrepresentation is due to limited investigations since the 1960’s and to inexistente ethnographic resources, which could provide clues for the interpretation of ethnic and settlement patterns on the eve of the Conquest. However, Spanish documents described “cacicazgos” as Chamula and Zacancatan near Jobel Valley, which is the focal point of our study. Complex colonial reorganization in the region, in addition to a delicate current social and political context, make archaeological ruins survey difficult. However, ceramic analysis from two sites and archival studies allow us to strengthen, and provide results which contrast with the previous prehispanic model for this cultural area, giving rise to interesting discussions and perspectives abroad about interactions at a regional level.

**Hadíyá:wa: Do You Hear What Traditional Pueblo Cultural Advisors Are Saying?**

Archaeological collaboration with traditional Pueblo communities faces many practical challenges. Archaeologists typically expect cultural practitioners to accept what archaeology entails as a scientific discipline and its approach to understanding the past. Within traditional Pueblo perspectives, archaeological excavation might not be an appropriate measure for mitigating adverse effects in the federal Section 106 compliance process. Rather than asserting the primary of their preferences and values, archaeologists should be receptive to indigenous perceptions and attitudes about what archaeology is and what archaeology does. Hearing can facilitate the opening of communication avenues for cross-cultural explorations into the multiplicity of truths about the past.

**Rancheras: Historical Archaeology of Early Colonial Campsites on Margarita and Coche Islands, Venezuela**

Little is known from the present-day archaeological perspective of early colonial realities of Margarita and Coche islands located in north-eastern Venezuela, in the state of Nueva Esparta. Moreover, the island of Coche has never been surveyed archaeologically. This paper discusses the preliminary results of systematic archaeological surveys of Coche and the southern coast of Margarita Island, carried out within the frame of the Nexus 1492 ERC research project coordinated by Leiden University. Colonial materials and sites were located on both islands. All sites yielded pre- and post-1550 Spanish and other European ceramics, as well as Amerindian pottery and possibly intercultural hybrids. Activities related to pearl fishery and goat breeding are most probably responsible for the presence of the ephemeral settlements or rancherias that were located in these places. These were contemporary with and also slightly posterior to the core Spanish town of Nueva Cádiz that flourished on the island of Cubagua between 1528 and 1542.

**“Winged Worldviews”: Human-Bird Entanglements in Northern Venezuela, AD 1000–1500**

Drawing from archaeology, zooarchaeology, ethnohistory, ethnology, and avian biogeography, this paper aims at reconstructing the interrelations between indigenous peoples and birds in north-central Venezuela, between AD 1000 and 1500. Amerindian narratives and premises of perspectival ontology from the South American Lowlands suggest that certain birds were more closely interrelated with humans then other beings. The analyses of nearly 3,000 avian bone remains recovered in six late Ceramic Age sites located on the Venezuelan Caribbean islands and on the adjacent mainland indicate that the uses of birds as food, a source of raw material, and a symbol were culturally contingent. Formal and contextual analyses of bird imagery...
crafted in pottery, stone, and shell also suggest culture-specific uses and entanglements. Differences are especially visible between the Cariban-speaking Valencio pottery makers from north-central Venezuela and their neighbors from the north-western coast, the Arawakan-speaking Dabajoid, during the last centuries before the European Conquest.

Anthony, David (Hartwick College) [221]  
**Ancient DNA Analysis and the Indo-European Dispersal**  
New methods for analyzing ancient human DNA are introducing a new “molecular archaeology.” aDNA permits us to detect mating networks, to see ancestry evolve across generations as populations expanded or died out, to track migrants and their genes across geographic space, and to say whether and with what frequency migrants and the indigenous population mated at the destination. aDNA analysis is an unprecedented tool for the study of ancient migrations, kinship, and biological adaptation. This paper reviews recent studies of the aDNA of more than 300 prehistoric people from Europe, the steppes, the Caucasus, and Central Asia that revealed a massive migration of steppe pastoralists westward into agricultural central Europe and eastward to the Altai Mountains, previously occupied by foragers, dated about 3000–2500 BC. The dispersal of the Indo-European languages can be dated independently to the same period, after the invention of the wheel and before the IE languages differentiated in the second millennium BC. Genetics suggest a delay in intermarriage at the destination, and archaeology suggests an initial material contrast, so language shift in agricultural Europe might not have happened with the initial migration but developed later after the mobility patterns and resources of the two populations converged.

Antonelli, Caroline (University at Albany—SUNY) [44]  
**The Myth of a Marginal Environment: Redefining a Yucatecan Landscape**  
This paper examines shifting environmental paradigms in the Maya realm. Using Mayapán as a case study, a site long-considered to be located in a “marginal” environment for agricultural productivity, I will evaluate site resilience, sustainability, and self-sufficiency and use these concepts to create a more nuanced perspective of human-environment interactions. Data from Mayapán will be cross-referenced to other similar sites across the Maya region. I will show that assumptions about the environment in the Northern Yucatán Peninsula is rooted partly in culture historical interpretations of the previous century. Modern investigative techniques from the last twenty years have allowed for more robust scientific research that contrast the environmental perspectives of the past, challenging these long-held beliefs and opening up new avenues of research. These new investigations show that the environmental history of the Maya in the Northern Yucatán Peninsula is even more complex than previously understood. Occupation in this area is both highly adaptive and stable at different points in time.

Antonites, Alexander (University of Pretoria) [161]  
**Building a Network: Territorialization and Deterritorialization in Thirteenth-Century Northern South Africa**  
Regional social complexity in southern Africa is closely tied to the rise and development of the Mapungubwe polity of thirteenth-century South Africa. Expanding political power and influence meant that Mapungubwe increasingly articulated with communities on its periphery—a relationship that is reflected in shared material culture. These hinterland sites are all located in areas where there is an absence of earlier twelfth century occupation, which suggests a process of active settling of these areas rather than extant local communities adopting the trappings of Mapungubwe material culture. The maintenance of social hierarchy at Mapungubwe is widely believed to be based in the ability of elite to attract followers and monopolize long distance trade goods. This process of concentration required spatial expansion to draw in distant resources such as gold and ivory. Paradoxically, ongoing research on hinterland sites suggest that this territorial expansion resulted in a weak hierarchical control over these remote areas, resulting in a concomitant deterritorialization as distant communities enjoyed growing autonomy and authority.

Appleby, Jo (University of Leicester) [31]  
**Osteobiography as Local Biology**  
Osteobiography is an increasingly popular approach, but one that can have the effect of producing unproblemitized, individualized approaches to the life course. In this paper I wish to explore how we can create a theoretically informed osteobiography. I propose two strands to this. Firstly, rather than osteobiography being something that “happens to” individuals living in a society, I suggest that it constantly emerges through inter-relations with culturally specific understandings of the person that are deeply contextualized. Secondly, I bring in the concept of “local biology” to explore how, rather than tracing events that happen to bodies, osteobiography can be better conceptualized through the continual interaction of genes, environment, culture and society. This interaction shapes not just immediate responses to disease or stress, but changes the potentials of the person throughout the life-course. These ideas are explored through a consideration of the process of ageing.

**Comparison of a Community-Scale Classic Maya Political Adaptive Cycle with a Bimonthly-Resolved Paleoclimate Record from Uxbenká, Belize**  
In studies of human-environment interactions, the conceptual framework of panarchy and its associated resilience theory posit that periods of stability and transformation are inevitable in what has been termed an “adaptive cycle.” This presentation discusses the reconstruction of a community-level political adaptive cycle for Uxbenká, an ancient agrarian polity in the Maya hinterlands, and explores its linkages with the broader political ideology of divine kingship and climate stress. Employing Bayesian age modeling of more than 60 radiocarbon dates associated with construction events and data on a potential dynastic lineage, along with the introduction of original, bimonthly-resolved local paleoclimate data, we assess cycles of growth, maintenance, decline and renewal in the built environment history of the civic-ceremonial precinct as proxies for the stability or instability of political power and authority. Furthermore, while multiple studies have compared cultural records with rainfall abundance and deficits, we discuss the important role of short- and longer-term climate unpredictability from an ultra-precise speleothem paleoclimate record. This work produces insights on some of the conditions that confert or erode the resilience of political actors embedded in a coupled sociocultural landscape.

Salvage Excavation: NMSU Summer Field Project at the South Diamond Creek Pueblo in the Northern Mimbres Region

New Mexico State University (NMSU) anthropology students spent the summer of 2016 getting to know a bit more about the Mimbres people who lived more than 1,000 years ago, and along the way helped preserve their history. Eight NMSU students joined community volunteers for four weeks to explore and excavate areas of the South Diamond Creek Pueblo (SDCP) in the Gila Wilderness of New Mexico. The project had three major goals: 1) to contribute to our understanding of cultural trajectories in the northern Mimbres region, 2) to assess the damage to the site by erosion and looting activities, and 3) to learn about being stewards of cultural resources for the public at large. This project was remarkably successful and several NMSU students have used data from the excavations for their own research. Their projects are diverse and include studies of ceramic exchange, lithic toolstone procurement, and environment-human relationship on this landscape. In collaboration with NMSU students and volunteers, the SDCP project helps us improve our knowledge of when and how the Mimbres people inhabited southern New Mexico from AD 900 to 1150.

Restoration of Sandia Cave, NHL, New Mexico

Sandia Cave is a National Historic Landmark that has played an important role in the history of archaeological thought about the Paleoindian period and Southwestern archaeology. The cave is also a designated traditional cultural property that is culturally significant to numerous Pueblo groups. Despite its cultural and historical significance and popularity as a tourist destination, the integrity of the cave has been severely diminished by heavy and repeated acts of vandalism over the years. It was severely blackened with soot from fires illegally lit in its interior and extensive graffiti was spray-painted inside the cave. The graffiti was thought to potentially obscure valuable information (historic and precontact markings) located on the rock surface. In 2015, a grant funded restoration work in the interior of the cave. A collaborative team of cave specialists and archaeologists (with input from tribal governments) developed a series of innovative restoration techniques to ensure that the natural and cultural significance of the site was maintained during the restoration process. This presentation will discuss the techniques that were developed and the success of the project as a way of deterring future vandalism at the site.

Archaeological Investigations on the Lucy Islands, Near Prince Rupert, BC, from 2010 to 2013: New Evidence Relating to the Development of North Coast Culture

In the summer of 1966, George MacDonald launched the wide-ranging North Coast Prehistory Project. One of his goals was to document the broader patterns of human settlement along the north coast of British Columbia, and in 1968, this led to the first test excavations at GbTp-1, a small seasonal encampment on the Lucy Islands, 19 km west of Prince Rupert, in the open waters of Chatham Sound. The data from that excavation showed that this remote site was already inhabited by about 2,500 years ago, placing it firmly within the Middle Period (3500–1500 BP) in the emerging local sequence. Recent work at this site, from 2010 to 2013, shows that the occupation actually began as early as 9,500 years ago. At that time, sea levels were higher, and the archaeological evidence is therefore located well above the modern shoreline. Although limited in scope, the latest research offers several new insights into that poorly known early period in the development of north coast culture.

Archila Montanez, Sonia (Los Andes University, Department of Anthropology), Mónica Berón (CONICET, Museo Etnográfico), Gabriela Musaubach (CONICET, Museo Etnográfico), Martha Mejía (Los Andes University, Department of Anthropology) and Eliana Lucero (Universidad de Buenos Aires, Museo Etnográfico)

Ancient Woods Used in a Ritual Context at Chenque I Cemetery (Pampean Region, Argentina)

Empirical evidence of ancient ritual practices is not often found in many archaeological sites. This complex ideological aspect of past human societies has usually been reported in association with the presence of monuments such as sculptures, tombs, funeral mounds, temples and shrines and also with particular artifacts used during ceremonies and rituals such as ceramic, stone or metal vessels, musical instruments and so on. Archaeobotanical evidence could contribute enormously to the study of ritual practices particularly in contexts where ritual practices involved many other different paraphernalia including plants, animals, minerals and artifacts made of perishable materials such as wood and fibers. Identification of plant remains in itself constitutes a source of information about cultural choices. Chenque I site is a cemetery, which includes several human burials and was used between 1050 and 290 BP by hunter-gatherers groups inhabiting western Pampean region in Argentina. We studied and identify charcoal from burial structure 28 in which funerary practices such as burning of human remains have been recorded.

Ardagna, Yann (UMR 7268 Marseille) and Marc Maillot (Section Française de la Direction des Antiquités S)

The Medieval Necropolis of Mouweis (Shendi Area, Sudan): Bioarchaeological Insights

[219]
The site of Mouweis is a Nilotic city of the Meroitic period excavated by the Louvre Museum since 2007. This settlement includes a first-century AD palace, later destroyed and reduced to a hill-shaped ruin. During the medieval period, a cemetery was created in the demolition level of this palace. Radiocarbon dating reveals a funerary occupation between the eighth to the fourteenth century. Burials were mainly individual with a uniform typology and follow the same orientation as the structure of the Palace, and excavations highlighted a concentration of seven burials at the center of the Palace. The particular layout suggests a funerary layout from the center to the periphery, and this (according to social status, age-at-death, sanitary state, sex ...) is the basis of our paleobiological study. The sample represents 21 individuals (17 adults, 4 juveniles). The central group covers a largest number of pathological conditions and one of the most significant results of the paleobiological analysis is a case of leprosy. Although the presence of this infection in that particular region was known, paleopathological cases remain particularly scarce in medieval Sudan.

New Indicators of a “(Much) Older-Than-Clovis” Cultural Presence at Chiquihuite Cave Archaeological Site in Zacatecas, Mexico

The systematic search for ancient human presence in the Zacatecas semi-desert of central-northern Mexico continued with new field explorations and excavations during 2016. A new season at the Chiquihuite Cave was meant to verify the weak signals of older-than-Clovis human presence obtained a few years ago. The new extended excavation inside the high-altitude cave revealed two old, clearly differentialed cultural components that had not been acknowledged before. The upper component is clearly laid upon a well-defined occupation floor far away from the entrance, next to the rear walls of the main chamber. It consists mainly of a relatively rich lithic assemblage, while the study of other proxies is under way. It is true that several questions must be made about the assemblage, especially due to its raw material and the technological attributes, but its cultural origin is self-evident. Multiple radiocarbon dates yielded matching results of an age much older than 14,000 cal BP. Another component, much weaker in its characteristics, seems to exist below the upper one, manifested as cultural finds distributed vertically to a considerable depth. Several radiocarbon results suggest an apparent age for the oldest cultural presence going beyond currently accepted dates.

Densidad poblacional y sus implicaciones socio-económicas en la primera capital olmeca de San Lorenzo, Veracruz

En los últimos años, los análisis de densidad poblacional y distribución espacial conforman un tema medular en torno al desarrollo de las sociedades, ya que la forma en que se distribuye una población humana en el espacio conlleva determinantes efectos en la estructura interna de la sociedad y, viceversa, la interrelación de los factores económicos, administrativos, políticos y culturales en la sociedad son el reflejo de la organización espacial. El presente cartel muestra los resultados de un estudio que permitió reconstruir el número y tamaño de las estructuras arquitectónicas ubicadas en los diversos sectores del sitio y, a partir de éstos, estimar el número total de pobladores en el asentamiento con el fin de llegar a inferir tendencias en el desarrollo de la primera capital olmeca de San Lorenzo, Veracruz.

Gender and Obsidian Economy in Mesoamerica

Obsidian tool production in Mesoamerica has been considered primarily the work of men. It is important to examine the roles that women might have had in obsidian crafting. This paper uses results from a study of an obsidian assemblage from an unusual burial excavated at Puerto Escondido, Honduras, to explore the implications of women possibly being involved in stone tool production. In this burial one person was laid out on a bench, wearing an obsidian mirror, in a below-ground chamber, that was then filled with ashes and carbon from incense burning, smashed ceramics, and obsidian tools made from flakes and blades. Analysis of chemical composition using XRF shows that obsidian flakes at the site mainly came from local sources, while blades were imported from centers of specialist production. The use of local obsidian for expedient tools (confirmed through study of residues as used to process plant material) suggests other recorded examples of women making stone tools they use for common tasks. The mixed economy of obsidian at Puerto Escondido, with blades acquired from specialist centers and flake tools made from local material, could correspond to a division between a male gendered specialty and expedient production that included women.

Arksey, Marieka (University of California, Merced)

Politicized Use of the Spaces outside of Caves during the Terminal Classic Maya Collapse

This paper investigates the use of caves as performance spaces for water and agriculturally focused rituals during the Maya Late Classic period (~ AD 750–900) and the events of the “collapse.” Although the “collapse” of the social, economic, and political systems during this period has been the subject of much study, the majority of research has focused on the environmental factors with little consensus as to how rulers attempted to maintain order, social solidarity, and political power during this time of crisis. Drawing on perspectives grounded in performance theory, ethnography, and traditional archaeology, this paper examines how the use of caves was expanded during the collapse to include the more visible and accessible exteriors of caves for the first and only time in over 2,000 years as rulers attempted to garner favor with the increasingly dissatisfied general populace.

Glimpses of Promontory Tradition Settlement Practices and Social Networks: The Ceramic and Faunal Assemblages from Site 10-Oa-275

The West Fork Rock Creek site (10-Oa-275) is a late prehistoric-aged seasonal camp in southeastern Idaho containing 11 occupational surfaces dating between AD 750 and 1800. Several living floors and nonliving floor deposits contain both Promontory Gray and Great Salt Lake Gray ceramics, along with the butchered remains of bison and pronghorn. This paper explores associations between site occupants and Promontory groups to the south,
especially those of the Promontory Peninsula, and considers Promontory and Fremont interactions more generally. Various Promontory groups incorporated eastern Idaho within their home range, perhaps primarily to exploit large-game herds and obsidian sources of the upper Snake River region. The 10-Oa-275 assemblage has improved our understanding of Promontory settlement systems and socioeconomic interactions in areas beyond the Wasatch Front, two important topics that have received sparse attention from previous researchers.

Armit, Ian (University of Bradford), Lindsey Büber (University of Bradford), Rick J. Schulting (University of Oxford), Laura Castells Navarro (University of Bradford) and Jo Buckberry (University of Bradford) [139] Postmortem Interactions with Human Remains from Sea Caves in Northeast Scotland

As liminal places between the above-ground world of daily experience and the underworld, caves form a persistent focus for human engagements with the supernatural. As such they have frequently been used as places for the dead, whether as final resting places or as places of transformation. Late Bronze Age human remains were recovered from the Sculptor’s Cave, on the Moray Firth in northeastern Scotland, during the 1920s and 1970s. They suggest the curation and display of human bodies and body parts, associated with wooden structures and a range of objects dominated by small personal ornaments. Recent fieldwork at the nearby Covesea Cave 2 has revealed similar evidence, as have other caves along the same stretch of coast. The Cave 2 assemblage displays evidence for excarnation, trauma, selective redeposition and processing of bodies and body parts. Although individuals appear to have entered the cave whole, certain elements were subsequently removed, while others appear to have been displayed. In this paper we consider the ways in which the Late Bronze Age communities of this region interacted with their dead and consider the role of the Covesea sea caves as a coastal mortuary landscape.

Armitage, Spencer [263] Vertebrate Analysis of Column Samples Taken from Hup'kiskuu7a (93T, DfSh-43)

Hup’kiskuu7a (93T, DfSh-43) is a small precontact site in Tseshahit territory. This site was excavated in 2015 and 2016 in order to determine to what extent smaller sites in Barkley Sound were being used during the late and mid-Holocene (ca 5000–200 cal BP). Two 2 x 2 m units were excavated. A column sample was taken from the north wall of each unit in 2016. These column samples reached a depth of 120 cm DBD in unit 1, and 137 cm DBD in unit 2. The sediment recovered was screened through 6.35 mm and 2 mm mesh. In this poster I present vertebrate analysis of the samples recovered from these column samples. This analysis was done to determine spatial site use, environmental variability and ensure accurate representations of fauna were recovered from different areas of the site. My findings from Hup’kiskuu7a are then compared to column sample data from three larger sites in Barkley Sound; Huu7ii (DfSh-7), Kakmakimilth (306T, DfSh-17) and Ts’ishaa (204T DfSh-16). This comparison determines Hup’kiskuu7a has a lower NSP per liter than its larger counterparts.

Armstrong, Alan (Northwestern University) [317] Chronological Evidence of Material and Landscape Changes Associated with a Shift in Colonial Control at the Morne Patate Plantation, Dominica

Morne Patate Plantation in southern Dominica (occupied between the 1740s and 1950s) provides us with an opportunity to examine a setting that underwent major changes in social organization and economic engagements associated with the shift in colonial control of the island from the French to the British in 1763. This paper presents an overview of the chronology of the archaeological contexts at the site and changes in settlement organization. This material record provides evidence for discrete phases of occupation which can be tracked through the changes in the altered landscape and the footprint of the plantation. This study examines changes in chronologically sensitive ceramic assemblages that correlate with modifications in the landscape, and changes in buildings constructed at the site. Morne Patate has two main phases of occupation with distinct patterns of material culture and use of space. This change in settlement organization paired with the site chronology provides an important archaeological context to observe different uses of materials and varying domestic production strategies that occur in separate phases of the plantations occupation.

Armstrong, Chelsey Geralda [77] Unique Ecologies of British Columbia

It is widely understood that humans have varying degrees of influence on a wide range of ecological patterns and processes. In British Columbia an array of landscape management practices have been documented among Indigenous communities resulting in novel ecosystems. Yet, little is known about the range and extent of these eco-human dynamics in pre-settler colonial contexts. We explore the concept of “unique ecologies” as a way of better understanding the untold past of ecological and cultural factors that result in the landscapes we see today. We define unique ecologies as anthropogenically managed landscapes that support the succession and maintenance of culturally important plants including, crab-apple (Malus fusca), black hawthorn (Crataegous douglasii), hazel nut (Corylus cornuta), red elderberry (Sambucus racemosa), and dominant sub-canopies surrounded by important berries, roots and fibers. The association of unique ecologies with significant archaeological habitation sites, such as houses and large processing features, help us document how Indigenous people created equitable climates, fertile forests, and reliable supplies of foods and medicines. The ongoing documentation of unique ecologies in BC expands our understanding of subtle historical social-ecological relationships, while also forming and reifying oral histories and traditions, and offering lessons on how to live well on the land.

Armstrong Oma, Kristin (University of Stavanger) [35] Long Time—Long House: Dwelling with Animals in Scandinavia in Prehistory

The three-aisled longhouse is one of the most long-lived forms of dwelling-place known from prehistory, with its span from the Early Bronze Age (1500 BCE) until the Viking period (10.000 CE). During some 2,500 years, the architectural outline and form remained surprisingly similar. The three-aisled longhouse is, in terms of human culture (albeit not in geological terms), a longue durée institution, a materialization of a particular lived space, where humans and domestic animals lived under the same roof. The aim of this paper is twofold: First, I explore the tenets of this lived space, and its
implications in terms of social practice with a particular regard to the life-space shared between humans and animals inside the longhouse. Further, I examine the dynamics between patterns of change in prehistoric societies and the longhouse that endures as a basic building block for the farming household. I use the ontological turn as a framework for thinking through both of these topics. I mainly focus on the archaeological record from early Bronze Age until the Viking period in Rogaland, SW Norway.

Arnaud, Charlotte (CNRS) and Mélanie Forné (associated researcher CNRS)  [125]  Multiscale Diversity in Classic Decorated Pottery in the Hix Witz kingdom of the Western Maya Lowlands

A political entity defined mainly on epigraphic evidence, the Hix Witz kingdom includes at least three head centers, Zapote Bobal, El Pajaral and La Joyanca, all located south of the San Pedro Mártir River. The architecture, sculpture and ceramics of the three sites were subjected to extensive studies from 1999 to 2006, also in 2012, suggesting that this entity consisted of relatively heterogeneous components that must have entertained distinct relations with neighboring regions of the West-Central Petén Zone. The goal of this study is to assess the subregional (Hix Witz) and intersite (the three centers) diversity in service polychrome types and decorative modes of domestic ceramics. Correlating this diversity with possible population movements, trade routes, market networks, and fluctuating political relationships with surrounding polities may open new ways for the identification of major Classic players in West-Central Petén politics.

Method and Theory in the Archaeology of Interior Salish Rock Art Sites on the British Columbia Plateau.

Interior Salish rock art sites on the British Columbia Plateau are multicomponent assemblages which include the geomorphology, the rock art and other surface and subsurface elements such as trails, manuports, petroforms, hearths, lithics, radiocarbon dates, flora and fauna. Defining the interrelationships of these components is essential to understanding the site formation process. In addition, direct historical and cultural continuity between these sites and Interior Salish descendant communities allows conventional archaeological methods to combine with intergenerational knowledge of place and time (indigenous theory) to give finer resolution to the interpretation of site activities.

Arnh, Anna (Hamilton College), Nathan Goodale (Hamilton College), Alissa Nauman (Hamilton College) and Bruce Wegter (Hamilton College)  [343]  Ea-IRMS and the Isotope Ecology from Faunal Remains at the Slocan Narrows Site, Upper Columbia River Area, Interior Pacific Northwest

Isotope ecological signatures can add to the overall understanding of terrestrial and aquatic species’ diets that are present at an archaeological site. In this paper we analyze fauna specimens from across the breadth of species found at the Slocan Narrows site, an aboriginal pithouse village occupied from 3,100 cal BP to the late eighteenth century in the Upper Columbia River area of the interior Pacific Northwest. We utilize EA-IRMS to measure δN, δC, and δO isotope ratios to obtain an understanding of the dietary ecological landscape of the local habitat at Slocan Narrows. Fauna specimens used in this study come from well documented pithouses dating to 1065 cal BP, 533 cal BP, and 405 cal BP, providing a temporal examination of the isotope ecology of the site through the later phases of the village occupation.

Arnold, Bettina (U. of Wisconsin-Milwaukee)  [324]  “And Make Some Other Man Our King”: Mortuary Evidence for Labile Elite Power Structures in Early Iron Age Europe

“... we have been set free ... by our most tireless prince, King and lord, the lord Robert ... Yet if he should give up what he has begun, seeking to make us or our kingdom subject to the King of England or the English, we should ever afterwards at once to drive him out as our enemy ... and make some other man who was well able to defend us our King” (Declaration of Arbroath April 6, 1320). The Romans in first-century BC Gaul and the English in fourteenth-century AD Scotland described the political structures of the Celtic-speaking European peoples they encountered as chaotic and decentralized. Historians and archaeologists have tended to represent such sociopolitical lability as a weakness in the struggle of indigenous peoples against the often superior military strength of highly centralized and hierarchical state-level societies. Based on the evidence for secondary elites, the pares rather than the primus, a case study drawn from the mortuary record of early Iron Age southwest Germany demonstrates that the political structures characteristic of such tribal states were both fluid and highly stable. Built on a foundation of heterarchical relationships, they have proved extremely resistant to millennia of external imperialist pressure.

Arnold, Dean (Field Museum)  [216]  Finding Prehistoric Sources of Ceramic Raw Materials in Ticul, Yucatán, Mexico: Traditional Knowledge, Materiality, and Religion

Up until the tourist market and piped water forever changed the practice of making pottery in Ticul, potters’ raw materials came from sources in a unique socially perceived and spatially restricted landscape that served them well for at least a thousand years. Revealed by ethnographic research, potters’ traditional knowledge and utilization of these sources indicated that the unique sources of potters’ clay, palygorskite, and pottery temper were ancient and dated to the Terminal Classic Period. Although potters no longer associate any religious meaning with these sources, ethnographic research since 1965, and comparative ethnographic and archaeological data indicate that each of these sources probably had religious meaning for the potters in the past. These sources and the materials that come from them were materialized, distilled, and encapsulated in the required use of pottery for properly performing the annual Day of the Dead ceremonies when the spirits of the dead ancestors return from the earth to the land of the living.

[275] Dung Use before Animal Domestication in Southwest Asia: Evidence from Early Natufian Shubayqa 1 (Northeastern Jordan)

In southwest Asia the use of dung as fuel has so far only been attested at agricultural sites, which relied on the exploitation of domesticated plants and animals. In this presentation we report the first evidence for dung use by hunter-gatherers in southwest Asia 15,000 years ago. Charred dung remains were found inside two stone-made hearth structures at the late Epi-Paleolithic Natufian site Shubayqa 1. This evidence suggests that dung was recurrently gathered and used as fuel. The macro- and microscopic analyses of the dung pellets suggest that they probably derived from ovicaprids (like sheep), or alternatively, gazelle. In addition to dung pellets, fragments made of a mixture of dung and grasses were found, which may represent the remains of ‘dung cakes’ or parts of compacted floors from penned areas. This suggests that raw dung may have been processed for the purpose of burning. The wood charcoal analyses from the two hearths indicate that the tree cover at the time of occupation was scarce. We therefore propose that at Shubayqa 1, dung was probably used as a supplementary fuel resource. Overall, these finds suggest that the use of certain animal by-products predates the appearance of domesticated animals in southwest Asia.

New Perspectives on the Maya Highland Site of Kaminaljuyu, Guatemala

Recent data has been unearthed on Kaminaljuyu during the last five years. Despite Guatemala City’s growth, much information is still under the ground. A continuous program has allowed for the piecing together of various research programs carried out at the site. An effort to integrate most of the research and rescue programs has been done to obtain a comprehensive perspective of the culture history of the site. This paper will present data on recent research, focusing on the significant developments during the Preclassic period and its connections to other sites in the highlands and beyond. New data on the ceramic sequence and chronology, exchange, commoners’ roles in the society, hydraulics systems beyond agriculture, environmental impact of Lake Miraflores changes, and others will be presented. A short summary of the relationships with the community will be presented to emphasize the role of present day society for the conservation and protection of the site.

North American Late Pleistocene Bear: Diversity and Resource for Early Peoples

North America had a large and varied bear diversity (Mammalia, Carnivora, Ursidae) during the late Pleistocene. At least seven species occurred from southern Mexico and Belize north, as far as Alaska and the Yukon, constituting the subfamilies Tremarctinae and Ursinae. Tremarctinae had at least four species: two short-fanged bears pertaining to the genus Arctodus; the spectacled bear Tremarctos floridanus; and an undescribed species, probably within the genus Arctotherium. All of which are extinct today. The three ursine species are extant, but their populations and distribution ranges have diminished from the late Pleistocene into the Holocene. The polar bear Ursus maritimus now is at high risk for extinction, and the grizzly bear U. arctos is threatened. The black bear U. americanus, however, is increasing its populations in some areas of its range. Few records of human-bear interaction in the Late Pleistocene are known. Those records are focused on bear being a subsistence resource for early peoples. Primary evidence is based on bone modifications. Their procurement and possible impact that such an interaction had on the diminishing bear diversity, based on the extinction patterns, is explored.

Assessing the landscape impact of past settlement and subsistence systems in space and in time is essential to reconstructing precolumbian land use in the Amazon basin. In this paper we consider archaeological and landscape evidence for past land use by examining the strengths and limitations of archaeological radiocarbon evidence as a proxy for broad demographic patterns in precolumbian Amazonia.

Beer, Porridges, and Feasting in the Gamo Region of southern Ethiopia

Porridges and beer make up a majority of the household diet throughout much of rural Africa and could possibly be some of the earliest foods produced. In Africa, pottery is one of the primary culinary tools used to make both porridges and beer. This ethnoarchaeological and archaeological research explores pottery using use-alteration and morphological analyses from the Gamo of southern Ethiopia to indicate the use of pottery as a culinary tool. Beer and porridges are considered luxury foods among the Gamo and are associated with feasts. Through the combination of ethnoarchaeological and archaeological analyses of Gamo pottery, as well as interviews of living descendants, we are able to determine that large scale feasting was occurring at the original Borada Gamo settlement of Ochollo Mulato. The identification of beer and porridges could lead to deciphering social, economic, and demographic changes in the Gamo region and beyond.

Arthur, Kathryn (USF St. Petersburg)

Knowing My House: An Indigenous Theory and Practice of Being

The Gamo, who live in the highlands on the edge of the southern Ethiopian rift valley, are known for their unique and beautiful household architecture. Tourists ogle their oval basket-like grass houses and peer inside for mere minutes hoping to observe some secret moment or practice previously unknown to them. Similarly many archaeologists long to feel beneath their trowels a widespread hard surface indicative of a house floor. We remove the tangible aspects of the home, bit by bit, hoping to discover a preserved moment, day, or life time from the past, as a door to understanding how the house and its materials were interdependent with their residents’ activities and identities. In the Gamo way of knowing the world, the entangled entities of humans, homes, and household materials are living beings and as such they all engage and experience the life process together. This article offers an
alternative way of knowing and being in the world as a theory for understanding the daily lives of farmers and craft specialists as materialized in and near their homes—an ontology of the house.

[344] Gunflints from the Central Plains: Technological Characteristics and Chronological Implications

The time-sensitive characteristic of gunflints makes them important chronological markers at archaeological sites. This poster reviews gunflints from select sites primarily within the eastern Central Plains that have known dates and well documented histories. Lithic materials, origin of manufacture and method of production, as well as technological characteristics of gunflints are discussed. English, French, and Native made gunflints are considered. Native produced gunflints offer an opportunity to explore the influence of culture contact on material culture change during a dynamic period of trade, interaction, and resultant modifications to traditional chipped stone technologies.

Ashley, Ceri (University of Pretoria)

[161] Creating the “Imagined Community” of Mapungubwe

Mapungubwe’s influence spread deep into the regional hinterland, drawing in far-flung communities, trade networks and people. The traditional picture of a centripetal economy however has been challenged recently by work at these so called peripheries, indicating unexpected levels of autonomy and material wealth. While the place of these newly explored hinterlands need to be re-theorized and their agency acknowledged, there is danger in swinging the interpretive pendulum too far toward a centrifugal social structure of loosely linked political groupings. In this paper, as a complement to the idea of deterritorialization, I will argue that alongside the uncoupling of hinterland economies from the putative core, there were nevertheless, continued iterations of belonging and community that bound the disparate entities. Drawing on the concept of the ‘imagined community’ that acts and articulates beyond the proximate, face-to-face contacts of the ‘natural’ community, I will explore how material culture consumption helped reinforce and maintain this network of ties and belonging.

Ashley, Michael (Codifi, Inc.)

[70] The Benefits of B Corps for Building Sustainable Social Enterprises in Archaeology

Within the slender margins of academic archaeology, our funding options are extremely limited. The accepted pathways to sustainability have been institutional support (the academy) or starting a nonprofit. In both cases we all must battle over an ever shrinking grant and philanthropic pool. The alternative is to go for-profit, which has historically meant to become a CRM firm. In the past few years, Benefit corporations (B Corps) have become an alternative to this, offering an opportunity for community benefit enterprises to be held to a higher standard than either nonprofits or academic projects in that they should expressly seek change in the world, conduct business as if deterritorializing, I will argue that alongside the uncoupling of hinterland economies from the putative core, there were nevertheless, continued iterations of belonging and community that bound the disparate entities. Drawing on the concept of the ‘imagined community’ that acts and articulates beyond the proximate, face-to-face contacts of the ‘natural’ community, I will explore how material culture consumption helped reinforce and maintain this network of ties and belonging.

Ashlock, Phillip (CIRCA/University of Aberdeen)

[394] Fortifying a Community through Public Archaeology: The Collaboration of Public and Private Organizations to Preserve, Protect, and Promote a Spanish-American War Fort on a South Carolina Sea Island

In a collaborative partnership among the surrounding community, local government, private nonprofit groups, and professional organizations, the first archaeological investigations involving Phase III data recovery excavations were conducted at Fort Fremont in advance of the development of a local government sponsored interpretive center. Enframed in a maritime forest along the Port Royal Sound, Fort Fremont is listed on the National Register of Historic Places and enhances the coastal landscape of Saint Helena Island, South Carolina. It is an Endicott Period coastal defense fortification constructed during the Spanish-American War. Throughout its history, the fort has had a complex relationship with the surrounding community. When the fort was garrisoned between 1899 and 1921, there were well-documented conflicts with the surrounding African American community, known as the Gullah people, who occupied the region long before Fort Fremont’s construction. Through collaboration with local nonprofit and professional organizations, public archaeology is being used to strengthen ties with local residents and the Gullah community. The archaeological investigations and public outreach based initiatives utilized both social media and conventional means to enhance awareness and support the archaeology and history of Fort Fremont within the local community.

Astudillo, Fernando J. (Simon Fraser University)

Colonization of the Galápagos Islands started soon after Ecuadorian separation from the Gran Colombia in 1830. During this decade the Islands were legally claimed by the Republic of Ecuador and colonization projects started. Exploiting concessions were approved to national and international companies. One of these concessions was assigned to Ecuadorian businessmen Manuel J. Cobos and José Monroy to create an agricultural colony on San Cristóbal Island; 1,000 km west from the Ecuadorian coast in the Pacific Ocean. They were able to create and manage an industrial-scale plantation called El Progreso in the highlands of the Island. El Progreso operated for three decades generating significant impacts to both the terrestrial and maritime ecology. In this paper we present what we know about the past social relationships occurring inside the plantation during the second half of the nineteenth century. During the past years we have been integrating the analysis of historical written records and archaeological remains in order to explore the daily life of the plantation owners and the workers in this remote location.
Can Archaeology Help Decolonize the Way Institutions Think? How Community-Based Research Is Transforming the Archaeology Training Toolbox and Educating Institutions

Community-based research requires systemic shifts within institutions, from the way research is funded, protection of human subjects/IRB reviews, ethical guidelines, and what is legible/valued in tenure and promotion decisions. Some of the most important yet least discussed changes must happen in the classroom, in terms of what and how we teach. For community-based archaeologists, we know that process matters. How we conduct research with community partners is essential. The relationships and trust we build; how we design and carry out projects in a participatory way; and the formats we choose for sharing results often need to be retooled. In this paper I consider these issues in two parts. First, I examine how community-based archaeological research is helping decolonize institutions by introducing new ways of thinking about the goals, processes, and outcomes of research. Second, I consider the skills and training that community-based archaeology requires, and I present my recent encounters and experiments in cultivating literacies and competency in these areas among undergraduate and graduate students. I close by examining our responsibilities as scholars to bring about curricular change in our departments, universities, and professional organizations; including suggestions of next steps for the SAA in this area.

Visually Linking the Ritual and the Quotidian at Tiwanaku, AD 500–1100

Residential complex of Mollo Kontu. Based on this evidence, I argue that these ceramic vessels provided visual links between the large-scale public rituals in the vicinity of the site’s monuments and the small-scale rituals and meals of people living outside of the monumental core. These links, in turn,

The Origin of Human Creativity

The recent discovery of cave paintings in Sulawesi dating to at least 40,000 years ago has altered our understanding of the origins and spread of the first painting traditions. This suggests that both rock art developed independently in Europe and Southeast Asia at about the same time, or that our species invented this trait prior to its initial expansion from Africa. Here I will discuss the implication of this discovery as well as new evidence from Borneo with the aim to deepen our knowledge of a major turning point in early human prehistory.

Modeling Conditions Necessary to Detect Gene Flow in Humans from Archaeological Contexts

Gene flow between ancient human groups is difficult to detect. In a closed deme, variance in a morphological trait should decrease over short time periods due to genetic drift. Previous studies have thus regarded increases in within-site trait variance over time as a possible indicator for new genetic variation through flow or the physical movement of individuals. This interpretation depends on archaeological context, as diachronic changes in population variance may also arise from selection, sampling differences, or population structure changes. This study applies genetic cline theory to investigate limitations in modeling changes in trait variance due to flow over three time periods among multiple sites. We fit simulated data based on parameters obtained from archaeological dental metrics to models of genetic isolation and flow. The model for no gene flow is that trait means shift stochastically but do not change, and variances decrease over time. Departures from these conditions argue for gene flow. Changes in trait means occur when gene flow is asymmetric between groups with previously distinct trait means. We show that at least three sites from each temporal horizon are necessary to achieve an unambiguous model fit for gene flow among groups within and between time periods.

Determination of Burial Locations Using Soil Analyses at the Loyola Plantation in French Guiana, 1668–1763

Our paper discusses the approach used to determine the location of burials in an equatorial environment where organic preservation is nil. Before using the space of the plantation cemetery to preserve the memory of the enslaved who lived at the plantation we had to demonstrate the extent of the cemetery using soil analyses. Memory of that period is a fleeting souvenir among local residents and we want to use archaeology to address issues with which they are confronted in order for them to appropriate the spirit of the plantation. The Loyola Habitation under Jesuit rule reached nearly 500 enslaved whom toiled at the production of a number of cash crops such as sugar, coffee, indigo, rum, etc. under the supervision of a handful of Jesuit missionaries whose goal was to open reductions in Guaraní country. From the cemetery where approximately 1,000 people (Slaves, Amerindians and White land owners) have been interred, our motivation is to make a lasting lieu for a dialogue with history.

INDIVIDUAL ABSTRACTS OF THE SAA 82ND ANNUAL MEETING
had a political effect on the residents of the city, as they served as reminders of those rituals in which peoples’ social statuses and obligations to the broader community were most vividly manifested.

Aura Tortosa, J. Emili (Universitat de València) [165] Walking before Running: Late Paleolithic Regional Dynamics in the Spanish Mediterranean Region Previous to the “Last Big Transition” (17–10 ky cal BP)
The lapse of time between the end of the Last Glacial Maximum (LGM) and the Holocene 8.2 cold event can be considered as a Long Transition, in which global diachronic changes and regional processes are combined. Between 17–10 ky cal BP important ecological changes (increased temperatures, forestry and presence of some species of herbivores, variations in sea-level and coastline, etc.), techno-economic transformations (abandonment of osseous weapons, active and passive grinding stones related with food processing, economic trends to intensification and diversification, etc.) as well as testimonials configuration of group identities (end of parietal art, changes in personal ornaments and funerary practices). These changes are accompanied by an important continuity in sites occupation, which shows a break on the Mesolithic (ca. 10 ky cal BP), starting a fast cycle that ends with the Neolithic (ca. 7.5 ky cal BP), the “last big transition.”

Averett, Erin (Creighton University), Derek Counts (University of Wisconsin-Milwaukee), William Caraher (University of North Dakota) and Jody Gordon (Wentworth Institute of Technology) [37] From Trench to Tablet: Field Recording, Interpreting, and Publishing in the Age of Digital Archaeology
Since the arrival of robust mobile tablet devices in 2010, archaeological documentation has increasingly become born-digital. The adoption of digital tools and practices has not gone unnoticed, with reactions ranging from enthusiastic acceptance to outright skepticism. Significantly, scholars are beginning to offer more critical and reflexive views of the issues surrounding the use of mobile devices in archaeological fieldwork, interpretation, and dissemination. The ability to disseminate digital data directly from connected devices to a global audience threatens to destabilize traditional standards of archaeological documentation practices, which, in part, used media to define the stages of knowledge production: handmade, paper documents defined the provisional character of field documentation, and the printed, bound, publication marked definitive results. Digital media blurs these distinctions by making trench side data indistinguishable from its final form. By drawing on examples from current archaeological publication schemes, this paper will show how new digital tools and techniques can highlight the potential for mobile computing in archaeology, but also demonstrate how these new methods will challenge and transform institutions that shape archaeological knowledge.

Awayda, Conner and Leslie Aragon [303] Site Analysis and Excavation of the Gila River Farm Site in Cliff, New Mexico
Archaeology Southwest and the University of Arizona’s Upper Gila Preservation Archaeology (UGPA) field school excavations at the Gila River Farm Site (LA 39315) produced interesting results from the 2016 field season. The Gila River Farm Site is a Cliff Phase (A.D. 1300–1450) Salado site located on the first terrace of the Gila River, in southwestern New Mexico. It was recorded by archaeologists in the 1980s but had never been excavated. Although now protected on land owned by the New Mexico Nature Conservancy, the site has been subject to mechanical disturbance associated with agricultural activity as well as looting in the past. Despite this history, test excavations revealed more intact deposits throughout the site than had been anticipated. This poster presents the results from this season’s field school and suggests future directions for preservation archaeology at the Gila River Farm Site.

Awe, Jaime [395] Exotics for the Gods: Lowland Maya Ritual Consumption of European Goods along a Spanish Colonial Frontier
As a number of researchers who have focused attention on Maya–Spanish interaction along the Belize colonial frontier have noted, the relationship between these two contrasting cultures was anything but amicable. As a result of this bellicose relationship, few material goods of European origin were traded into frontier settlements. The only exceptions were a few objects that were brought in by overzealous friars as gifts to the “heathen” Maya they sought to convert to their Christian faith. And while ethno-historic reports of the missionizing adventures of Spanish priests provide us with important data on Maya life during the early colonial period, the Spanish entradas provide precious little information about the material goods they gifted to the Maya, and even less about how the Maya utilized these foreign goods. In this paper, I discuss how archaeological discoveries in Belize have been filling this void, and how the evidence suggests that a variety of objects of European origin were ritually decommissioned in sacred places.

Azar, Madelaine [283] Quantifying Variation in Ramey Incised Motifs: A Stylistic Evaluation of Cahokian Authority across the American Bottom
Ramey Incised jars, often considered to be indicative of Cahokia’s twelfth-century Stirring Phase fluorescence, are characterized by angular shoulders, polished exteriors, and incised symbolic motifs arranged around the vessel orifice. Thought to be for ritual or symbolic use, the ceramic type is not only present at Cahokia, but ubiquitous across sites in the American Bottom. However, the process through which these vessels were manufactured and then disseminated is still not fully understood. An evaluation of temporal and spatial variation in Ramey Incised motifs throughout the American Bottom was conducted in order to better understand levels of standardization, elite control, and Cahokian influence involved in the production and distribution of Ramey Incised ceramics. Motif data indicate that the Ramey Incised manufacturing process was not likely concentrated within one central site. Many
Ramey Incised vessels may have been created at the site from which they originate. The results may also suggest the existence of stylistic and political autonomy, as well as cultural diversity, among many of Cahokia's satellite settlements. Contrary to proposed models of far-reaching, hierarchical Cahokian authority, American Bottom social organization during the twelfth century may be better understood in terms of a decentralized heterarchy.

Subconsciously Expressions of Identity in Migrant Communities: A Look at Lithic Debitage

Subconsciously expressions of cultural identity can be found in low-visibility attributes of everyday processes such as lithic production. In the late thirteenth century, Kayenta migrants into the southwestern New Mexico maintained or adapted many archaeologically visible traditions. This research examines lithic debitage assemblage morphology and attributes from three archaeological settings: southwestern New Mexican sites, Kayenta sites, and Salado sites (representing post-migration communities) during the thirteenth and fourteenth centuries to identify potential patterns of continuity and adaptation among the migrant communities. Previous research has demonstrated continuity in Kayenta traditions in Salado communities in the form of home and ceremonial structures, ceramic production and stylistic patterns, and in projectile point style. As Kayenta populations migrated in new regions, lithic production patterns changed when they were introduced to new raw material and went from having primarily chert resources to having access to abundant obsidian nodules. This research hypothesizes that low visibility attributes in the form of lithic debitage will demonstrate continuity in lithic production patterns as this migrant community engages with local raw materials.

Metagenomic Analysis of Precontact Diet Using Ancient Dental Calculus from Prince Rupert Harbour, British Columbia

Prior to the displacement caused by European colonization, the Coast Tsimshian harvested an array of terrestrial, freshwater, and marine dietary resources as they moved between coastal settlements and the nearby Skeena River valley. Conventional paleodiets analysis using faunal analysis and isotopic values has provided valuable data which, when paired with the knowledge of First Nations communities, can help reconstruct how ancestral communities utilized food resources prior to the cultural disruption caused by European contact. However, these methods of analysis are limited in their ability to pair the consumption of specific species with specific individuals, potentially resulting in an incomplete analysis of how individuals in these communities interacted with their environment. Building on previous archaeological analyses, this paper will present the results of a metagenomic study which used next-generation DNA sequencing methods to identify plant and animal DNA preserved in the dental calculus of ancient human remains from several sites across the Prince Rupert Harbour area. The results of this study provide an exciting new lens through which to examine traditional resource use and food-related culture within the ancient communities of the Prince Rupert Harbour area waterways.

Narratives of Quiechapa in Light of Material Evidence from Survey

Our knowledge of the prehispanic past of Quiechapa and the surrounding regions has been largely based on a combination of historic sources, modern day linguistic classifications and previous archaeological work in nearby regions. El Proyecto Arqueológico de Quiechapa (PAQuie) recently completed a 99 sq. km pedestrian survey of the Quiechapa region in the Sierra Sur of Oaxaca, Mexico. In this talk, I discuss major findings from the survey in the Quiechapa region within the context of broader narratives of prehispanic southern Mexico. I combine spatial analysis of archaeological sites and architectural features with analysis of ceramic and lithic materials in order to compare and contrast the material evidence from specific sites with current narratives. I address the occupation history of the region as well as Zapotec military presence based on the initial pedestrian survey. Finally, I discuss directions for future investigations.

Indicios de poder, la estrategia de control de la guerra de castas: Arqueológica e historia de la posición de las fuerzas armadas porfírianas en la Campaña militar de Yucatán de 1899–1901.

En el contexto de la última época de la guerra de castas. El gobierno de Porfirio Díaz manda a construir un sistema de fuertes en la zona centro oriental del estado de Yucatán, con el objetivo de tomar el control del territorio que por más de cuarenta años había estado dominado por los mayas “rebeldes.” Excavaciones realizadas, así como recorridos en la zona revelan la planeación, ubicación y arquitectura de puestos militares, los cuales sugieren por una parte la estrategia del gobierno para llevar a cabo la ocupación de la región, y por otra parte el grado de peligrosidad que percibían las autoridades frente a los mayas conocedores de la zona. La evidencia arqueológica de la guerra en conjunto con documentos históricos apoyan a
reconstruir la política de reducción y los cuatro distintos frentes de operación por mar y tierra que planeó el gobierno de Diaz para retomar la soberanía del territorio de los mayas.

Hitchhiking to the New World: Archaeoentomology and the Study of Introduced Insect and Ectoparasite Species.
This paper presents an overview of North American archaeoentomology, focusing on the study of introduced species. Seminal works on the introduction of plant and animal species during colonization suggested that more than just crop plants were imported to colonize the Americas by Old World species (Lindroth 1957) and introduced the term “European biological imperialism” (sensu Crosby 1972) to our vocabularies in environmental archaeology. Research in archaeoentomology, focusing primarily on beetles and ectoparasites found in archaeological contexts, has permitted the documentation of species introduction and dispersal in the New World during the Colonial Period (fifteenth–eighteenth centuries). While plant species and seed crops were imported intentionally, insects and ectoparasites were almost always hitchhikers, unintentionally imported during colonization. Recent archaeoentomological research suggests the early and intensive occupation of suitable ecological niches by Old World species (Bain and King 2011) however, small and relatively modest datasets have limited our understanding of the displacement of native species. Case studies will be presented from sites in Newfoundland, Quebec City, Boston and Virginia. These studies suggest that colonists continued to combat Old World pest and ectoparasites species here in the New World as they re-created European niches through settlement practices.

Anthropocene: a hotly debated geological epoch entangled with climate change, the Industrial Revolution, and the perceived deleterious effect of humans on the natural world. A dialectic surrounds the Anthropocene because identifying this epoch, geologically, has real implications for global politics and the future of humanity in a changing global environment. Crossland (2014) suggests that to understand the palimpsest of global human action that resulted in the Anthropocene requires us to consider a broader network of relational events that move beyond the Industrialized West. This necessitates a reorientation from a human-centric view of the world to one that considers human and other-than-human relations. Archaeology is uniquely situated to examine the Anthropocene; we are concerned with the multi-scalar interactions of humans with the natural world. In this paper, I examine the concept of urbanism at Cahokia, a pre-columbian North American city, and its relationships with the Anthropocene. I discuss the implications for and results of ‘city-life’ that have had unique impacts on the global environment (e.g., excess garbage, modifying the natural environment, development of agriculture). My data concerns the construction of monumental earthworks and neighborhoods with the natural environment and their impact on the environment.

Baitzel, Sarah (Washington University in St. Louis) [202] A View from the Past: A Reanalysis of Archaeological Collections from the Sama Valley and Its Implications for Current Models and Chronologies of the Southern Andean Valleys
Although limited in area compared to the neighboring Moquegua, Caplina, and Azapa valleys, the Sama valley (Departamento Tacna, Peru) with its warm temperature, perennial water sources and arable flood plain creates hospitable conditions for highlanders who settled the valley as early as Late Horizon period. In his 1567 visita, Garcia Díez de San Miguel notes the presence of a Luqapa colony and an Inca Tambo at the site of Sama Grande near the modern town of Sama-Inclan. In addition, survey and test excavations by German and Peruvian archaeologists under the direction of Hermann Trimborn between 1972 and 1975 registered Formative, Middle Horizon, and Late Intermediate period sites throughout the valley. In this paper I present the results of a reanalysis of materials collected by Trimborn and his collaborators. The goal is to compare the original project notes and artifacts with current ceramic chronologies for this region, and to reevaluate past and present interpretations and models related to presence of highland populations in the Western coastal valleys of the southern Andes.

Baker, Brenda (Arizona State University) [219] Mortuary Variability and Identity Upstream of the Fourth Cataract
Fieldwork upstream of the Fourth Cataract in northern Sudan reveals substantial variation in mortuary practices among roughly contemporaneous sites on both local and regional levels. Cemeteries in the Bioarchaeology of Nubia Expedition (BONE) concession on the right (north) bank of the Nile River near el-Qinefab include intervisible clusters of graves from the Kerma period (c. 2500–1500 BC) and into the subsequent period of Egyptian colonization of Nubia. These sites constitute a mortuary landscape on the desert terrace distinct from mortuary activity in the Merotic (c. 350 B.C.-350 AD) through Christian (c. AD 550–1400) periods that is confined to the floodplain. Grave architecture and treatment of the dead in this presumed hinterland show inclusion of imported grave goods in all periods that indicate integration into extensive trade networks rather than marginalization from state-level core areas. Identities among those interred in the desert cemeteries may be reflected by grave styles and burial treatment, including presence or absence of ceramic vessels or imported objects, or inclusions that may reflect activities conducted during life (e.g., a bone implement likely used in pottery production) or more subsistence strategies. This research advances our understanding of ancient Nubian social organization, identity, and interaction.

Baker, Kristen [41] World War II Battlefield Archaeology of Tarawa
A central tenant of military philosophy is "adapt, improvise, and overcome." Navigating battlefields requires constant adaptation to dynamic surroundings due to the interplay of several variables such as 1) preexisting landscape and terrain, 2) enemy defenses, 3) enemy opposing forces, and 4) friendly and enemy fire. To successfully navigate the archaeology of a historic or prehistoric battlefield, archaeologists must attempt to understand the variables (such as those listed) that contributed to their battlefield of interest and be willing to constantly adapt their search and recovery strategy to their findings. This presentation will detail the archaeological methods employed by History Flight specifically for battlefield archaeological purposes, and the corresponding findings that resulted from search and recovery activity in the World War II battle site of Tarawa that occurred in what is now the Republic of Kiribati, Tarawa, Betio Island. From 20 to 23 November 1943, the battle of Tarawa resulted in the loss roughly 1,200 U.S. service men and approximately 5,500+ Japanese military and Korean laborers. While the historical record details much of the events that occurred, careful forensic and battlefield archaeology has brought to light data that in some cases contradicts and in others cases confirms the historical record.

[381] Identifying the Drivers of Central American Rainfall Shifts: Implications for Past, Present, and Future Human Behavior

Yok Balum Cave’s location at the northernmost extent of the Intertropical Convergence Zone (ITCZ) combined with its abundance of aragonitic stalagmites make the site an exceptional archive of paleoclimatic information. Additionally, Yok Balum Cave is located at the heart of the Maya Lowlands, and speleothem-based paleoclimatic records from the site can provide invaluable information for archaeological research. Although the Yok Balum record and most other regional climate records strongly suggest that the fragmentation of the Classic Maya Civilization was contemporaneous with a series of decadal-scale droughts, the cause of these droughts remains enigmatic. A suite of geochemical records from Yok Balum Cave stalagmites imply that the ITCZ migrated southward at that time, but this behavior is inconsistent with elevated Northern Hemisphere temperatures thought to characterize the Medieval Climate Anomaly. The solution to this paradox likely involves the complex interplay between solar activity, explosive volcanism, and the North Atlantic climate state. Furthermore, reconstructions spanning the last 500 years identify modern industrial activity as a driver of southward ITCZ migration. Considered together, the records from Yok Balum provide an excellent example of how climate change affected past civilizations and underscore the challenges faced by modern societies.

[337] New Perspectives from the Late Preclassic Period in the Mirador-Calakmul Basin

The Late Preclassic period (350 BC–AD 150) in the Mirador-Calakmul Basin is characterized by innovations in various aspects of ancient Maya society which are the reflections of an complex ideological, sociopolitical, and economic power. These ingredients were responsible for the conception and creation of large and diverse works of architecture and engineering achievements. This paper will discuss the importance of the Late Preclassic period in El Mirador and contemporary cities within the Basin as an evolutionary process, and the data provide a reflection of the sovereignty radiated during the Preclassic period within the Basin and other surrounding cities.

Balco, William (University of North Georgia)

[103] Excavating the Yahoola High Trestle: Spanning Past and Present in Dahlonega, Georgia

Archival research and subsequent test excavations at the site where the Yahoola High Trestle once stood in Dahlonega, Georgia, has explored the construction, use, and abandonment of an important component of America’s first gold rush. This structure supplied high-pressure water to hydraulic mining operations in the area, facilitating sophisticated mining techniques to extract gold from the surrounding landscape. This paper presents the results of archival research and archaeological testing conducted in 2015 and 2016 by student volunteers and members of the local community. The results of these excavations suggest that the trestle was likely not the imposing structure it was originally intended to be and that it was likely disassembled for scrap after it became obsolete. Regardless, the construction and operation of the trestle helped shape the developing economy in rural north Georgia during the mid- to late-nineteenth century.

[162] Identifying the Drivers of Central American Rainfall Shifts: Implications for Past, Present, and Future Human Behavior

Yok Balum Cave’s location at the northernmost extent of the Intertropical Convergence Zone (ITCZ) combined with its abundance of aragonitic stalagmites make the site an exceptional archive of paleoclimatic information. Additionally, Yok Balum Cave is located at the heart of the Maya Lowlands, and speleothem-based paleoclimatic records from the site can provide invaluable information for archaeological research. Although the Yok Balum record and most other regional climate records strongly suggest that the fragmentation of the Classic Maya Civilization was contemporaneous with a series of decadal-scale droughts, the cause of these droughts remains enigmatic. A suite of geochemical records from Yok Balum Cave stalagmites imply that the ITCZ migrated southwest at that time, but this behavior is inconsistent with elevated Northern Hemisphere temperatures thought to characterize the Medieval Climate Anomaly. The solution to this paradox likely involves the complex interplay between solar activity, explosive volcanism, and the North Atlantic climate state. Furthermore, reconstructions spanning the last 500 years identify modern industrial activity as a driver of southward ITCZ migration. Considered together, the records from Yok Balum provide an excellent example of how climate change affected past civilizations and underscore the challenges faced by modern societies.

Ball, Christopher (University of Toronto)

[371] Reassessing Perspectives on Environmental Management in Southern Ontario
Archaeologists in southern Ontario have taken up a number of diverse perspectives for coming to an understanding of past human-environmental dynamics. While these disparate perspectives all produce something of value and contribute to the bigger picture of human-environmental relationships in the region there has been little work done in synthesizing their contributions or consolidating said perspectives into something more cohesive. This discussion is therefore focused largely on the consideration of paleoethnobotanical work in southern Ontario ranging from strict archaeobotanical reporting to the search for the origins of agriculture and ultimately to current trends observed in the shift toward more synthetic historical ecology or niche-construction based theoretical perspectives. This discussion will argue that while current trends have been almost entirely positive for our understanding of past human-environmental relationships, with special attention to the benefit of their application in southern Ontario, there is still considerable room for improvement as we strive to approach a more holistic, and nuanced view of this critically important dynamic of past societies.

Vidal Montero (University of Chicago) [216] Pigment Mining for Color Meanings: El Cóndor Mine from Atacama Desert (AD 300–1500) The mineralogical richness of the Atacama Desert allowed for the development of an important set of mining-extracting and metallurgical, lapidary and pigment productive activities, which became significant activities in the sociocultural dynamics of desert dwellers. El Cóndor mine, an important hematite source located in the middle section of the Loa River, was exploited from the Formative Period (~AD 300) until Inka times (~AD 1500). In contrast to other mining sites in Atacama, El Cóndor presents a variety of activity areas: extraction pits, processing areas with multiple anvils and grinding tools, semicircular structures, and combustion zones—in addition to large dispersion of red powder spread across its surface. The production was initially developed as a craft, intensifying during later periods (since ~AD 1200) due to the increase in pigment values and the scale of consumption at regional and also supra-regional levels. El Cóndor mine constitutes an interesting example of a large-scale hematite operation because it articulated important exchange and relationship networks, and also serves as a relevant case for evaluating and discussing local miners negotiations during the productive reorganization after the Inka expansion to the region.

Baltus, Melissa (University of Toledo) and Sarah Baires (Eastern Connecticut State University) [283] Building below the Surface: Earth Moving and Caching at Cahokia’s CABB Tract Human engagement with the world includes forging and maintaining relationships with social agents, both visible and invisible. Among Native North Americans, these relationships are simultaneously religious, social, and political. We explore these relationships using data from our 2016 excavations at Cahokia’s CABB (Courtary Area Between Borrow) Tract, located southeast of Woodhenge and west of the Grand Plaza. The CABB Tract is situated north of two known borrow pits (Fowler’s 5–5 and 5–6) and includes an additional, previously unidentified borrow pit. Using evidence resulting from our limited excavations and geomorphology cores, we examine how Cahokians engaged with the natural and the supernatural through earth-moving activities while contributing to the construction of the urban landscape. We explore the “doings” (after Fowles 2013) of building and shaping the landscape through the borrowing of earth, creation of low spaces, and layering of soils and special materials as a means of engaging with and relating to other social agents. Additionally, we consider practices of re-excavation into special buildings and deposits of pottery in borrow pits and buildings in this area of Cahokia to demonstrate the ways in which the supernatural intersects with daily life.

Bamford, Bree (University of Victoria) [263] Preliminary Vertebrate Faunal Analysis of Hup’kisakuu7a (93T): Results from 2015 and 2016 Excavations Excavations conducted at the site of Hup’kisakuu7a (93T), in partnership with the Tseshaht First Nation, unearthed a variety of fauna that merit zooarchaeological analysis. Unlike the major ancient village sites previously excavated, such as Ts’ishaa and Huu7i, the shallow shell midden of 93T is representative of a small-scale site, potentially occupied over a long period of time, comparable to that of the aforementioned major sites. The faunal assemblage is small in comparison to those of major village sites and differs notably in its consequent composition. Data from two separate excavation seasons have been quantified by weight, number of specimens and volume excavated per cubic meter. The datasets have been integrated to assess intrasite temporal and taphonomic trends, as well as intersite variation. Analysis reveals discernible intrasite variation that is consistent with house floor deposits and associated midden refuse. Intrasite comparisons indicate that the characteristics of Hup’kisakuu7a are unique and provide context within a larger archaeological understanding of subsistence practices in Barkley Sound. These results contribute to the ancient and continuous cultural history of the Tseshaht in the Broken Group Islands of Barkley Sound.

Bánffy, Eszter [95] Adapting to Harsh Environment Resulting Changes in Culture That Led toward a New Perception of the Outer World: The Birth of the Central European Neolithic In the sixth millennium BC, first farmers reached the area between south east and central Europe, soon spreading into central Europe. About the character and identity of these first farmers at the boundary area, a series of new research results is available. At the boundary, harsh environmental conditions made their long well-working subsistence system unstable, as the ‘package’ of farming and mainly sheep and shifted to cattle keeping. Yet, it
has hardly been investigated, what reflections of the changing character of nature and landscape caused in their minds. The paper gives two examples for the perception of the previously unknown, northern natural environment, resulting in changes in cognition. The first one is about settlements amid forested hills. A different perception of social arena evolved, the original clay architecture turned to wooden house structures. The second example focuses on monumental clay figural art: female upper bodies emerging from large podiums are found in domestic contexts. In the northern margins, females turn to horned cattle figures. This shift reflects a growing importance of cattle keeping that permeated in domestic ritual life. The new pattern, different social places created and changes of rituals affected their perception of the natural environment around.

Banks, Kimball (Metcalf Archaeological Consultants Inc. and Combined Prehistoric Expedition Fdttn), Linda Scott Cummings (PaleoResearch Institute), Signe Snortland (Combined Prehistoric Expedition Foundation) and Maria Gatto (Aswan-Kom Ombo Archaeological Project) [229] Turning the Desert Green: Reconstructing Late Paleolithic Vegetation at Wadi Kubbaniya, Upper Egypt
Wadi Kubbaniya is the largest wadi extending from the Western Desert to the Nile in Upper Egypt. The Combined Prehistoric Expedition devoted four seasons in the late 1970s-early 1980s investigating Late Paleolithic (20,000–12,000 BP) settlement-subistence in the wadi. The Expedition documented one of the most complete occupational sequences for this period in Upper Egypt. Because of excellent preservation, the Expedition was able to reconstruct the vegetation and identify floral resources exploited during the Late Paleolithic. In 2012, the Combined Prehistoric Expedition Foundation in collaboration with the Aswan-Kom Ombo Archaeological Project returned to excavate WK26, which dates to the end of the Late Paleolithic sequence, with the objective of continuing vegetative reconstruction and identifying exploited floral resources, applying recent technology. This paper addresses vegetation during and plant use in the Late Paleolithic and techniques for identifying such resources.

Banning, Edward (University of Toronto) [191] Percolation Theory and the Effectiveness of Adaptive Sampling in Subsurface Survey
Percolation theory, used mainly in physics and materials science, describes the behavior of interconnected clusters in spatial lattices, but is also relevant to an age-old problem in archaeology: how best to detect buried sites with subsurface testing. It can provide insights into adaptive sampling protocols applied to two-dimensional clusters of artifacts. Our research focuses on adaptive sampling’s impacts on our understanding of underlying distributions of artifacts and sites in survey by shovel tests, augering, or coring. Does adaptive sampling improve our ability to detect and recognize sites? Does it help us define site’s boundaries or estimate their sizes? Or do we risk defining “sites” that are simply a creation of the research method? We evaluate adaptive subsurface sampling and compare it to simple subsurface survey through simulation. This allows us to control for artifact density and clustering, size or definition of the “neighborhood.” The simulations and comparison to predictions based on percolation theory help us evaluate the utility of current survey protocols and to suggest improvements for future work.

Baquedano, Elizabeth (University College London, Institute of Archaeology) [288] Gold (Tumbaga) and Butterfly Symbolism
When metals were introduced in Mesoamerica ca. AD 850 they were used with both utilitarian and decorative purposes. Copper artifacts were turned into fishing hooks, tweezers, or axes. However, silver and gold were mostly used in jewelry production. Several deities were fashioned in gold as well as animals associated with gods. They included pendants, nose-rings, necklaces, etc. Warriors were also depicted as pendants, and there are examples in discs too. The context where the objects have been found is particularly important. There are good examples of butterflies made to represent fertility goddesses and there are representations of warriors wearing pectorals in the shape of butterflies. This paper will focus on the symbolic importance of butterflies in warfare as well as in agriculture.

Barba, Luis (Universidad Nacional Autonoma de Mexico), Linda R. Manzanilla (Universidad Nacional Autonoma de Mexico), Agustin Ortiz (Universidad Nacional Autonoma de Mexico) and Alessandra Pecci (Universidad de Barcelona) [274] Residue Analysis of Plastered Floors and Function of the Rooms at Teopancazco, Teotihuacán
Teopancazco is a neighborhood center at Teotihuacán. It was excavated in the framework of the project Teopancazco “Teotihuacán, Elite y Gobierno” directed by Linda R. Manzanilla between 1997 and 2005). Samples from the plastered floors of the compound have been analyzed at the Laboratorio de Prospección Arqueológica of the UNAM (Mexico) in order to understand the chemical enrichments of floors and the spatial distribution of activities. We show here the results of the analyses of the Xolalpan phase of the compound, integrating the information coming from the residue analysis and other archaeological evidence at the site, in order to provide a hypothetical reconstruction of the use of space.

Barbar, Sarah (University of Central Florida) [82] The Symbolism, Use, and Archaeological Context of Masks in Formative Period Coastal Oaxaca, Mexico
Mesoamerica has a long tradition of masking, as evidenced by representations of masked individuals, and the masks themselves, extending back to at least the Early Formative period. In the lower Río Verde valley of Oaxaca, evidence for masking exists throughout the pre columbian sequence, from the
earliest villages to Postclassic settlements. This evidence often consists of figurines depicting masked individuals or representations on ceramic vessels and carved stones. Recent excavations have also uncovered a small number of masks and mask fragments. In this paper, we focus on the early history of mask production and use during the Formative period (1900 BCE—CE 250). We discuss the symbolism and archaeological context of masks and their representations in other media such as figurines. We suggest that masks played an integral role in communal performances that likely also included music, dance, and oration. A means of bringing together people and the divine, masks in ancient Oaxaca (like masks in Oaxaca today) imply animistic and nagualistic aspects of Mesoamerican cosmology. These ancient masks shared broad similarities with those used elsewhere in Formative period Mesoamerica, including the incorporation of transformative capacities into relations of inequality and authority by the first centuries of the common era.

Barbier, Brian (University of California, Santa Barbara) [381] Beads All the Way Down: Reassessing the Economics of Shell Bead Production on Santa Cruz Island Marine shell beads played an important role within broad interregional exchange networks in California for several millennia. Previous scholarship has demonstrated the relationship of shell bead production and exchange to increasing sociopolitical complexity in the Santa Barbara Channel region during the Late Period, ca. 900 BP. However, this relationship is less understood for earlier periods. Additionally, the morphologically-distinct bead types produced during the Late and preceding Middle and Early periods leave different signatures in the archaeological record. Through experimental replication of Olivella shell beads, I assess differences in bead production labor rates and debitage signatures for the predominant bead types produced during the Early, Middle, and Late periods. I compare these findings to the bead production patterns at CA-SCRI-236, a site on Santa Cruz Island that was occupied during all three time periods. Results suggest that previous interpretations are inconclusive: socioeconomic complexity as underwritten by bead production may have developed much earlier and may have experienced brief nulls during times of social or environmental stress. Analysis of the long durée at one location provides greater insight into the evolution of sociopolitical complexity in the region.

Barcelo, Juan (Universitat Autònoma de Barcelona) and Florencia Del Castillo Bernal (Centro Nacional Patagónico-Conicet) [286] The Emergence of Cultural Consensus in Hunter-Gatherers: Toward a Computer Model of Ethnogenesis in the Past In this contribution we present the results of a computer simulation of an “artificial society,” implemented to understand how cultural identities and cultural standardization may have emerged in a prehistoric hunter-gatherer society as a consequence of restricted cooperation. The aim of the model is to explain how diversity and self-identification may have emerged in the small-scale societies of our prehistoric past. The computer model explores some possible consequences of theoretical assumptions about cooperation, communal hunting and cultural diversity and the process of ethnogenesis. We have not modeled the decision process from the point of view of individuals, but at the level of the population, modeling social dynamics as a set of factors that constrain social actions. The agent does not decide as a rational individual, but probabilities for action at each cycle are taken into account as soon as local conditions change. Computer results are then compared to ethnoarchaeological data from Patagonia to evaluate the explanatory capability of the theoretical model.

Bardolph, Dana (University of California Santa Barbara), Brian Billman (University of North Carolina, Chapel Hill), Jesus Briceno (Ministerio de Cultura, Peru) and Gabriel Prieto (Universidad Nacional de Trujillo) [222] Reconsidering Farming and Foraging in the Pre-Moche World This paper examines the relationships between food, identity, and social inequality on the Prehispanic Peruvian North Coast through a paleoethnobotanical perspective. We reconstruct household culinary practices to address the roles that food played in the migrant experience of highlanders that settled in a traditionally coastal river valley. This migration occurs just prior to the consolidation of the Southern Moche polity, one of the earliest state polities in the Americas and characterized by unprecedented social stratification. Regional subsistence reconstructions based on primary plant data from large-scale household excavations are now beginning to bear fruit. We consider changes in plant foodways during the Early Intermediate Period (400 BC—AD 1) through a diachronic analysis of macrobotanical data from highland and coastal residential sites in the Moche Valley, to explore how highland-coastal contact, competition, and alliance formation, and a broadly changing sociopolitical landscape impacted plant production at the household level. We aim to show how careful microscopic research can complement the current studies of political, economic, and ideological phenomena at larger ceremonial centers, on the Peruvian north coast, in the Andes, and beyond.

Barkwill Love, Lori (University of Texas at San Antonio) [303] Revisiting the Mogollon Early Pithouse Period The beginning of the Early Pithouse period in the Mogollon region, around AD 200, was marked by a fundamental shift in material culture and lifeways. This major shift included the introduction of ceramics and the construction of more substantial habitation structures as well as communal structures. Yet, relatively speaking, few Early Pithouse period sites have been excavated, and many of the sites that have been excavated were excavated 30 or more years ago. This poster presents new data from existing Early Pithouse period collections as well as the preliminary results of test excavations at Two Boots, an Early Pithouse period site excavated as part of the 2016 UTSA Southwest Archaeology Field School. The implications of these new data on our current understanding of the Early Pithouse period and directions for future research will be discussed.

Barlow, Robert (BAKOTA Project/University of Alabama), Hajnal Szász (Babes-Bolyai University), Györgyi Parditka (University of Michigan) and Paul R. Duffy (University of Toronto) [196] Spiraling Like a Bass: Exploring Elements of Bronze Age Ceramic Style at the Micro-Regional Level Fortified tell site excavations in the twentieth century formed the basis for construction of a Bronze Age chronology in the Carpathian Basin. Typological and stylistic elements observed on these sites were used to create archaeological cultures for large areas, whose distributions changed over time. However, the use of large archaeological groups obviously masks internal regional variation, both chronologically and stylistically. Different river-valleys, as micro-regions, may have formed the basis for regular interaction, community activities and social practices, and thus may have left distinctive material culture. In this poster we compare stylistic elements of four different micro-regional areas in Eastern Hungary during two Bronze Age cultural phases. We evaluate the possibility that the large culture area names “Öttomány” and “Gyulavarsánd” mask internal variation recognizable among the surface collection material for 17 sites in the Lower Kórös Basin. By considering other settlement types as well, we also investigate whether fortified tell sites provide a representative picture of regional ceramic manufacturing practices.

Barnard, Hans (Cotsen Institute of Archaeology at UCLA) [309] Cultural Continuity along the Western Red Sea Littoral
The study of the ancient cultural history of northern Ethiopia, modern Tigray, often includes an interpretation of the obvious connections with the Arabian Peninsula, to the east, and the Nile Valley to the west. Less attention is usually given to contacts with the African heartland, to the south, and the relatively arid region between the Nile Valley and the Red Sea, usually referred to as the Eastern Desert, to the north. The cultural connections with the latter are reflected in linguistic and material traditions (basketry, ceramics, headrests, etc.) and more recently in the central place of coffee in daily life. In this presentation the long-term cultural continuity along the western Red Sea littoral will be illustrated. Given the limitations of the data currently available, this will be from a theoretical and more or less anecdotal perspective.

Barnes, Gina (Durham University) [148] Moderator

The Xwisten (Bridge River) community has had an ongoing collaborative relationship with the University of Montana, exploring the archaeology of the Bridge River Village, site Ear4. The latest series of inquiries at the Bridge River Village focused on the excavation of Housepit 54, a single, mid-sized, semi-subterranean pithouse with 17 anthropogenic floors from occupations spanning 1800 BP–ca. 1850s CE. The goal of this research is to explore the perceptions of the discipline of archaeology, the dissemination throughout the community of archaeological findings and scientifically held beliefs regarding Housepit 54 and the ancient village, and the impacts that this project has had within the Xwisten and surrounding communities, including consideration of existing differences in world views and belief systems. The final outcome of the research is intended to facilitate greater understanding of conducting community collaboration, provide an opportunity to better understand community needs and desires with regard to archaeological research, and allow the Xwisten Community a place to provide feedback and valuation with regard to the experiences had as of the end of the 2016 field season and the final excavations at Housepit 54.

Baron, Joanne (University of Pennsylvania), Liliana Padilla, Christopher Martinez and Arielle Pierson (University of Pennsylvania) [125] Ceramics of La Florida-Namaan: A Preliminary Report
The Guatemalan archaeological site of La Florida, located on the San Pedro River near the Mexican border, was home to the Classic Maya polity known as Namaan. Hieroglyphic inscriptions from La Florida and elsewhere reveal the polity’s widespread political contacts with sites in western Petén, Tabasco, and beyond, as well as a dynastic history spanning three centuries. While known to archaeologists since 1943, the site has only recently been the subject of a multiyear research project. In this paper, we will present the ceramics recovered during the 2016 season of the La Florida Archaeology Project, our first season of excavations. We aim to explore, in this season and in future excavations, the role of La Florida in commercial exchange along the San Pedro and between Classic Maya communities in Petén and the Tabasco Plain.

Baron, Natalie (Trent University) and Gyles Iannone (Trent University) [214] Investigating the Religious Landscape of Epicenters in Preindustrial Tropical States
The landscape of an epicenter has been built and modified to suit the needs of the people, both nonelite and elite. Epicenters consist of administrative, ceremonial, and residential features within a central precinct, often encircled by a moat or wall. Rulers of early tropical states would use religious propaganda to promote their power and legitimacy, which in turn created the purposeful and sacred design of the epicenter. By using the comparative method, this paper will examine the geographical relationship of the epicenter and the religious background of preindustrial state formations in South and Southeast Asia (800–1400 CE) and Mesoamerica (250–900 CE). This method will allow for a greater consideration of the similar characteristics exhibited by tropical states across different historical contexts. On-site visitations and an extensive literature review of the datasets place an emphasis on architectural features and the monumentality of the epicenter.

Barrier, Casey (Bryn Mawr College) [278] Towns and Household Groups during a Period of Urban Transition in Native North America: A Case from the Early Mississippian Era in the Cahokia Region
The development of large, complex settlements and the organization of associated institutions and social groups are major topics of research for anthropological archaeologists. The realization that precolumbian inhabitants of the central Mississippi Valley instigated complex social arrangements at urban scales makes Native North America a site of research that can contribute to the comparative study of urbanism. In this paper, previous and ongoing work near the site of Cahokia is discussed. A program of research has been started that is examining demographic shifts associated with the
growth of large settlements during the period of urban transformations. As part of the process, an emerging view is one of social groups aggregating at various scales and creating complex arrays of communities, institutions, and settlements ranging from village, to town, to city. This view includes a real-time history of movements and constructions suggesting that these settlements were in flux, and that the sites and settlement "types" we study are a product of the dynamic urbanization process in the region. As a case in point, the construction then rapid abandonment of an early mound-town by coalesced household corporate groups is provided that gives a rare look into one aspect of urbanism in this region.

Barrios, Edy (CUDEP-USAC) [71] Community Resilience in the Rio Amarillo East Pocket: Commoner Occupation around Rio Amarillo and Quebrada Piedras Negras at the end of Late Classic through Postclassic Periods
Recent and ongoing research at residential groups at the sites of Rio Amarillo and Quebrada Piedras Negras are providing a better understanding of the lives of commoners and of the population dynamics during the Late Classic through the Postclassic period in this area. These sites share the second-widest pocket of the Copan River Valley, and lie in the middle of one of the main trade routes between Copan and Quirigua. The excavations and mapping of the household groups distributed in this landscape provide an increased understanding of the people who inhabited this region close to the Copan metropolis during a time of complicated political, economic, and environmental change. Of particular interest are some of the differences found in the material culture of these sites, which all lie within the visual limit of each other. This paper will discuss both results of specific households and those of a larger mapping program.

Barse, William (Smithsonian Institution) [220] Orinocan Prehistory and Its Wider Relationships
The archaeological sequence developed in the Upper Orinoco in the vicinity of the Atures Rapids has not only local continuity through time but exhibits broader relationships with northern South America. The earliest preceramic components in the region, dated to ca. 10,000 BP, can be linked to comparable occupations that have been documented in the Sabana de Bogota. Slightly later preceramic components represented by distinctive contracting stemmed projectile points show links to sites in central Brazil and to the El Inga related sites in Ecuador. The lengthy Barrancas Tradition and sequent Arauquin horizon also exhibit stylistic links to other ceramic complexes in northern South America. These ties through time will be examined and related to anthropological models of trade and exchange in northern South America.

Bartusewich, Rebecca (University of Massachusetts Amherst) [132] Understanding Interactions between Iron Age Polities in Cyprus through the Microscopic Lens
This paper will address economic and political interactions of two Cypriot polities during the Iron Age prior to political transitions in about 450 BCE. Idalion is a polity in the interior, near the copper-bearing Troodos Mountains and Kition is a port town on the southern coast. These polities are separate by 20km of rolling hills and plains. By 450 BCE, Kition had obtained political control of Idalion, but there has been little research about these two urban areas interactions prior to this event. I have performed preliminary analyses of 100 thin sections to determine if in a mineralogically similar region one can differentiate between production locations and determine types of interaction. Using this data I have found that production characteristics such as the type clay processing, sieving, the speed of the wheel, and firing temperature were most informative. I applied a chaîne opératoire analysis to understand the way potters learn and adapt. Periods of stasis and change in production styles over several hundred years suggest a long-time relationship between the two localities, long before one politically overtook the other.

Bar-Yosef, Ofer (Harvard University) [33] Early Cultivation in China: Where and When
For over 2.6 million years foragers did not demonstrate that cultivation was a way for obtaining food stability although occasional events may have escaped the archaeological records. Cultivation by hunter-gatherers across the continents (except for Australia) emerged during the Terminal Pleistocene and early Holocene as a response to limitation on mobility due essentially to competition among growing populations conceived archaeologically as “relative demographic pressure.” The paper will consider the impacts of the loss of a major land due to the Pacific sea rise and Holocene environmental and social fluctuations in North and South China as triggers for millet and rice cultivation. The hypothesis concerning “where” and “when” in the Chinese mainland will be discussed based on current evidence.
While there is much interest in issues of cosmopolitanism, or the making of a "world citizen" or a "world community" as drawn from eighteenth- to nineteenth-century conceptualizations, such issues become difficult to study on the African continent given the strong emphasis on personhoods configured around local, corporate contexts. Burial practices from ancient Aksum demonstrate particularly strong corporate personhoods, even while the kingdom was engaged in extra-local trade. Instead, using network theory, this paper looks at how the social dynamics implied by Aksumite burial practices would configure Aksum's regional connections across Tigray. In doing so, this paper seeks to understand what African case studies tell us about cosmopolitanism, and how these understandings highlight a wider range of ways that societies may be cosmopolitan.

**[338] Early Upper Paleolithic Shell Beads and Shellfish from Manot Cave, Israel**

The Early Upper Paleolithic (EUP) cave site of Manot, western Galilee, Israel yielded remains of the Ahmarian and Levantine Aurignacian technocomplexes. The malacofauna assemblages from the two technocomplexes were analyzed (NISP=1180). Dozens of ornamental shells, mostly deriving from the Aurignacian assemblages, include perforated Nassarius gibbosulus, Columbella rustica and Antalis spp. as well as two cowrie beads found in association with human bones. The comparison of the Manot assemblage to the few published Levantine Early Upper Paleolithic shell assemblages reveals Aurignacian trends characteristic of circumb-Mediterranean shell beads. Further research is necessary in order to characterize the Ahmarian shell assemblage. Edible mollusks include Patella caerulea and Phorcus turbinatus from rocky Mediterranean shores and Levantina land snails found as a shell midden. Mollusks were collected from the immediate vicinity of the site and from the nearest Mediterranean shore, about 15 km away. The consumption of shellfish and snails also represent an EUP trend characteristic of the Mediterranean region.

### Barzilai, Omry (Israel Antiquities Authority)

**[338] The Dan David Expedition to Manot Cave: 2010–2016**

Manot Cave is a unique relict karst cave located in the western Galilee, Israel. The cave was inhabited from the Late Middle Paleolithic through the Early Upper Paleolithic periods until its main entrance collapsed some 30 thousand years ago. The cave consists of an elongated main hall and two side chambers. The topography of the main hall is composed of a long steep talus (ca. 30 m long) inclining from the original entrance of the cave to the center; a leveled area at the lowermost point of the main hall; and a smaller talus inclining from the eastern end of the cave. Seven excavation seasons (2010–2016) have been conducted so far at the Cave. The excavations revealed dense accumulations of Early Upper Paleolithic deposits by the cave entrance (Area E), at the center (Area D), at the base of the western talus (Area C), and at the leveled area (Area A). The aim of the symposium “In search for modern humans at Manot Cave” is to present the most updated interdisciplinary studies on Manot Cave which provide insights to the culture and environments of the Early Upper Paleolithic populations in the Eastern Mediterranean region.

**[90] The Earliest Architectural Remains in Anatolia**

The occupation of man has played an important role on cultural innovation; at the same time this process has always been a requirement of daily life for generation continuity. Since the start of human life history, choosing of places for occupation species has had different features. For example, the cave or rockshelters were preferred by Paleolithic man and they have hot style caves and/or shelters due to the period; this developed in Pleistocene climatologic conditions that were cold because of glaciers on the earth. At that point, we have to take a look at the transitional periods such as the Epipaleolithic. In 2016, different architectural remains obtained in Direkli Cave which is located on the slopes of Delihöbek Mountain in Central Taurus, Kahramanmaraş. Direkli Cave occupation has been described as part of the Epi-paleolithic period, and especially by Natufian Culture. Basically, Natufian culture contains pre-farming components such as geometric microliths, circular structures in caves (as in Hayonim Cave), axes and some traces of domestication. At that point, we can say that there are close relationships between settlement and/or occupational development and the origin of architecture in human life.

Bates, Brian (Longwood University), Walter Witschey (Longwood University), Craig Rose (Longwood University), Mary Farrell (Longwood University) and Erin West (Longwood University) [224] The Black Sea as a Fluid Frontier: Connectivity, Integration, and Disarticulation from the Fourth to First Millennium BCE

Recent years have witnessed increasing scholarly attention to the Black Sea, a region often considered peripheral to better known “cores” of cultural activity, such as the Mediterranean, Europe, the Near East, and even the Caucasus. Challenging conventional views of the Black Sea as largely disarticulated prior to the arrival of Greek colonists in the seventh century BCE, this paper argues that ongoing, informal networks of interaction existed throughout the millennia. Networks of connectivity over the millennia. It is hypothesized that these phases occurred in response to broader interregional dynamics of connectivity between the Near East, southeast Europe, and the Mediterranean.

Battilo, Jenna (Southern Methodist University) [229] Paleofecal Analysis from a Human Behavioral Ecology Perspective

Paleofecal research has benefited from many recent methodological advances, such as SEM and high-throughput DNA sequencing. However, as our results grow both more robust and more precise, our interpretations have not always followed suit. Researchers are eager to establish what was on the menu, but often more cautious in exploring the biocultural and evolutionary implications of those findings. Some scholars have argued that it is difficult to apply human behavioral ecology (HBE) models to archaeological data due to its incomplete nature. Although as Tim Riley (2012) points out, paleofeces represent a set of a single person’s subsistence choices within a constrained time period, making them an ideal vehicle for the application of diet-breadth and other optimality models. This presentation will address how paleofecal analysts can apply HBE models to discern subsistence choices and provide a theoretical base for understanding the motivations for those choices. To that end, I will use examples of paleofecal research from the American Southwest, including my own work applying diet-breadth and patch-choice models to the analysis of 44 Basketmaker II period paleofeces from Turkey Pen Ruin, Utah.

Batty, Sylvia (Institute of Archaeology, NICH), Rebecca Friedel (University of Texas at San Antonio) and Leah McCurdy (University of Texas at San Antonio) [7] To the Mountain: Heritage Preservation through Archaeological Literacy in San Jose Succotz, Belize.

Maya archaeology has seen a steady shift to the integration of community heritage interest and ownership in the design, execution and outcomes of research and preservation efforts. This poster describes a heritage outreach project focused on archaeology literacy development among grade school children in the community of San Jose Succotz, Belize, adjacent to the Xunantunich archaeological reserve. We authored a fully illustrated book entitled To the Mountain (2016) for the Succotz community, incorporating information on two sites that have been extensively investigated with the assistance of Succotz community members. To the Mountain is written in English, Spanish, and Yucatec, the three main languages spoken in Succotz. We distributed one copy of the book to each grade school child and made an eBook available online for download. By monitoring the use of this book by educational institutions and community members the changing perceptions of heritage and the effectiveness of heritage preservation through literacy campaigns can be established and observed. We expect that the familiar concepts in the book will make it an ideal educational tool for history and language education. We hope it will foster a culture in which Maya ancestry and language are not points of shame or social stigma.

Batuń-Alpuche, Adolfo I. (Universidad de Oriente), Maia Dedrick (University of North Carolina at Chapel Hill) and Patricia McAnany (University of North Carolina at Chapel Hill) [280] Identifying Farming Strategies within Changing Regional Contexts at Tahcabo, Yucatán

Colonial- and national-period studies of agricultural practices in Yucatán can provide useful case studies to address current theoretical concerns in political ecology. Perspectives on livelihood strategies today are broadly comparable to household-level studies of economic activities accessible through archaeology, especially given historical archaeology’s attention to market integration and technological innovations. The time depth available through archaeological study complements contemporary analyses that address decision-making processes and the connections between global and local phenomena. In particular, archaeological study may contribute perspectives on the possible outcomes, sustainable or otherwise, of specialized and intensive production. This presentation examines Colonial-period strategies based on evidence from two contexts at Tahcabo: households and rejolladas (limestone solution sinkholes that contain deep soils). Given the sociopolitical, environmental, and demographic dynamics known to have existed at the time, we consider farming choices and their implications for risk management and long-term sustainability.

Bauer, Alexander (Queens College, CUNY) and Owen Doonan (California State University Northridge) [265] The Library Is on Fire, Now What? Assessing the Damage and How to Approach It: A Case Study from the Chesapeake Bay

The Chesapeake Bay, ecology, and archaeological sites are threatened by the effects of multiple interrelated environmental change such as sea level rise, land subsidence and erosion and the impacts that such change has on the archaeological record. Using shoreline analysis, empirical observations and predictive modeling of four counties along the Bay, this project seeks to establish an understanding of the impacts on known archaeological sites in the study area as well as to assess potential high-probability site locations. The resulting data can be employed by government agencies, policy-makers, conservationists and others to determine the threat level posed by environmental change at the shoreline, thereby empowering informed decision-making about the allocation of resources to address the most urgent needs first.

Bauer, Alexander (Queens College, CUNY) and Owen Doonan (California State University Northridge) [265] The Black Sea as a Fluid Frontier: Connectivity, Integration, and Disarticulation from the Fourth to First Millennium BCE

Recent years have witnessed increasing scholarly attention to the Black Sea, a region often considered peripheral to better known “cores” of cultural activity, such as the Mediterranean, Europe, the Near East, and even the Caucasus. Challenging conventional views of the Black Sea as largely disarticulated prior to the arrival of Greek colonists in the seventh century BCE, this paper argues that ongoing, informal networks of interaction existed across the region during the previous millennia, networks that both facilitated and challenged later colonial and imperial processes. Presenting a technological study of pottery from recent investigations at the Black Sea coastal site of Sinop, Turkey, and other Black Sea coastal contexts, this paper presents the argument that the appearance of shared traditions may both reflect and have served to reinforce an emergent “Black Sea” identity at different phases in the region’s prehistory, suggesting that alternating cycles of integration and dis-integration waxed and waned across Black Sea networks of connectivity over the millennia. It is hypothesized that these phases occurred in response to broader interregional dynamics of connectivity between the Near East, southeast Europe, and the Mediterranean.
Bayham, Frank (California State Univ., Chico) and Kasey Cole (California State Univ., Chico)  

Local and academic level.

Evidence of remodeling and final destruction of Aztec precipitated upheaval at the end of the Chacoan system and the conversion of the site to a mortuary and trash-fill context. Finally, while some great house rooms burned on small scales, Aztec burned catastrophically. This destruction coincides with upheaval in the adjacent Mesa Verde region, increased frequency of habitation of rooms, and the notable conversion of Chacoan rooms to both mortuary and trash-fill contexts. Therefore, we argue that data indicate skewed sex ratios, unrecognized high status individuals, violence—particularly toward women and children—the practice of witchcraft, and that the state played—if any—in the functioning of the settlement and in the region in general.

Baxter, Erin (University of Colorado, Boulder)  

Aztec at the End of Days: Great House to Crossroads

New investigations of primary source material reveal that the final days of Aztec were extensively recorded (but not published) by Earl Morris. This paper will present analyses of burial, feature, architectural and artifactual data that indicate a chaotic and tumultuous end at Aztec preceded by behaviors that differed drastically from Chaco Canyon or in other tenth century great house sites. These practices are seen in mortuary data, in room remodeling the increased frequency of habitation of rooms, and the notable conversion of Chacoan rooms to both mortuary and trash-fill contexts. Finally, while some great house rooms burned on small scales, Aztec burned catastrophically. This destruction coincides with upheaval in the adjacent Mesa Verde region, which also experienced high levels of violence, and trends toward aggregation followed by migration and regional depopulation. We argue that data indicate skewed sex ratios, unrecognized high status individuals, violence—particularly toward women and children—the practice of witchcraft, and that evidence of remodeling and final destruction of Aztec precipitated upheaval at the end of the Chacoan system and the conversion of the site to a refugium during the depopulation of the Mesa Verde region.

Tales from the Trench: An Analysis of Artifacts Salvaged from Two Western Thule Sites in Kotzebue, Alaska

Monitoring and salvage archaeology is often viewed as an anathema to the archaeological record. Nevertheless, both situations frequently occur within CRM contexts. Here, we present analyses of lithic material, organic tools, pottery, and fauna from two subsurface house features in Kotzebue, Alaska. Radiocarbon dates indicate that the two sites are roughly contemporaneous, dating to the end of the Medieval Warm Period, and are associated with the Western Thule tradition. The materials were recovered during trenching activities for a fiber-optic cable and retain little provenance integrity. However, we argue that the analysis of “salvaged” artifacts, even without ideal stratigraphic or spatial information such as these, can be informative for the archaeological record and CRM companies should encourage contractors to support analysis and research that can contribute to knowledge at both the local and academic level.

Bayham, Frank (California State Univ., Chico) and Kasey Cole (California State Univ., Chico)  

Territoriality, Intertribal Boundaries, and Large Game Exploitation: Empirical Evaluation of a Spatial Bioeconomic Model of Conflict in the Western U.S.

Being a high-ranking prey item, large game are often desired for their economic and prestige values, both of which may be converted to an individual’s status. As such, big game can serve as a potential axis for competition between linguistic or ethnically distinct groups particularly under conditions of population stress leading to resource depression. This dynamic has been modeled using an evolutionary ecological approach that combines an amalgam of standard economic models with the added cost of intergroup conflict (Bayham and Bayham 2016). This study identifies several archaeological correlates of the model and explores its empirical applicability and testability in various areas of western North America. We specifically focus on localities in northern California and adjacent regions which utilize large artiodactyls, have conflict with neighboring groups, and buffer zones. Preliminary results are promising and we suggest the model may prove beneficial in the construction of regional research designs.
Bayman, James
[129] From Hohokam Archaeology to Narratives of the Ancient Hawaiian “State”
The analysis of material correlates to interpret cross-cultural variation in ancient political economies is a conventional and time-honored tradition in world archaeology. The material correlates that archaeologists use to gauge degrees of social stratification include evidence of subsistence intensification, hierarchical settlement patterns, craft specialization, large-scale monumentality, and differentiated mortuary programs. Ironically, recent claims for the rise of ancient states in the Hawaiian Islands confound prevailing models of political economy among the Hohokam in south-central Arizona. My comparison of Hohokam and Hawaiian archaeology reveals that although their material records were comparable in scale, many archaeologists have concluded that Hohokam society (unlike Hawaiian society) was governed by a marginally stratified non-state political economy. These findings challenge anthropological archaeologists to ponder the theoretical ramifications of relying on material correlates to construct cross-cultural models of ancient political economies.

[83] The Critical Zone Revolution from 2016 Lidar and Two Decades of Multi-proxy Geoarchaeology around the Programme for Belize
Over the last two decades we have studied agroecosystems in the Programme for Belize (PfB), a valuable and privileged reserve for an exceedingly wide array of research efforts. Aspects of the agroecosystems preserved in the PfB include terraces, wetland fields, aguadas, ecology, and curious wall features under the canopy of this tropical forest with some savannas. We based these studies on excavations along multiple transects across this karst region’s uplands, escarpments, bajos, floodplains, and terraces and on hundreds of soil and water chemistry analyses. This paper appraises these excavations and their findings in light of a new, 300 km² swath of lidar that covers each of these landscapes in the PfB and its surroundings, especially the Blue Creek area. We focus on three main topics based on our 2016 field and remote data that reflect these decades of study: wetland fields, agricultural terraces, and soil-human forest interactions. The lidar imagery shows us new evidence for wetland field systems, terracing, and the critical zone (from rock to soil to forest to the lower atmosphere), which creates unprecedented resolution on this remarkably florid region’s history of human and landscape interaction.

[276] Field Conservation of Skeletal Remains: Techniques, Materials, and Implications for Future Analysis
The information potential of skeletal remains—as for any excavated material—is impacted by the conditions of archaeological burial, and the environments and actions encountered during subsequent excavation, laboratory processing, study, and storage. A conservation approach emphasizes the mitigation of threats to material stability and integrity, which for excavated collections are often most critical at the point of archaeological exposure and recovery. Techniques and materials in use by conservators for stabilizing, lifting, and providing protective housings for skeletal remains in the field are discussed, using case examples primarily from terrestrial archaeological projects in Mesoamerica. Implications for the use of various modern synthetic consolidants and adhesives will be included, based on results of recent experimental work carried out at the Smithsonian’s Museum Conservation Institute examining their effects on results of biomolecular instrumental analysis of skeletal material.

[153] Tool Use across Space in the Middle Pleistocene: Novel Techniques of Edge Damage Analysis at Elandsfontein, South Africa
Although studies of lithic technology have been ongoing for over a century our knowledge of what tools were used for is still poorly resolved. Detailed analysis of microscopic damage has been the major focus studies of tool use. However, these studies are often limited to a subset of tools that have not undergone post depositional damage and can be studied microscopically. Recently new approaches to damage patterns on the edges of simple flaked tools have been used to develop assemblage scale analyses of tool use in a variety of Paleolithic contexts. Here we apply these techniques to a large assemblage of stone artifacts from multiple excavations at Elandsfontein (1 Ma—780 Ka) from the Western Cape of South Africa. We incorporate experimental tool use to develop possible hypotheses about what certain patterns of damage represent. Measures of damage location, continuity, and extent provide intriguing insights into the variability in tool use patterns. Results indicate that tool use patterns are largely heterogeneous across a relatively large landscape. This research was supported by the National Science Foundation Research Experience for Undergraduates (NSF-BCS-1620907).

[342] Grave Markers of Infant Burials in Historical Cemeteries in West-Central Minnesota
Roughly one in eleven individuals buried in historic-period cemeteries in Stevens County, Minnesota, died before reaching one year of age. This paper examines the grave markers of a subset of the 913 infants buried between 1870 and 1970, looking at both chronological and contemporary variation in style, production, and information recorded. Explanatory factors examined include religion (using the cemetery of burial as a proxy), evidence of associated maternal mortality, and when available, documentary evidence of parental socioeconomic status, ethnic origin, other children, and so forth.
**Bebber, Michelle** [342] *A Petrographic and Material Science Approach to Understanding Temper Selection in the Prehistoric Ceramic Sequence of the Scioto River Valley, Ross County, Ohio*

This research elucidates the complex nature of pottery tempers used in the Scioto River Valley of south central Ohio. The data suggest that during the Late Prehistoric Period indigenous potters began using composite temper types with concretionary hematite as a secondary temper—most often found alongside shell as the primary temper. This project involved two phases: 1) petrographic research and 2) mechanical properties testing. The initial research phase involved a detailed analysis of the clay matrix using polarized light microscopy. Precise temper densities were determined using point counting procedures. The second phase involved the production of test samples based on the petrographic data, followed by compressive bend testing of the experimental samples. The test samples were evaluated for mechanical strength, fracture toughness, and rate of thermal expansion. It was shown that hematite tempered samples exhibited significantly higher strength values—however, these samples fractured in a catastrophic manner signaling low post-peak toughness. The shell tempered samples exhibited the weakest strength values—however, they exhibited the most elasticity and most resistance to post-peak failure. Based on the data, it is suggested that these two distinct temper types were being used in complement.

El ejercicio del poder en Mesoamérica puede ser medido y estudiado de diferentes formas. Una de estas formas tiene que ver con los despliegues políticos ligados a los programas arquitectónicos y las estrategias políticas implementadas a partir de estos elementos. En este trabajo se pretende mostrar de forma visual los resultados de un estudio que evaluó la centralización del trabajo de la arquitectura pública como un índice de poder político.

**Becerra Alvarez, Marimar (Universidad Veracruzana)** [10] *Sistemas de almacenamiento en un puerto prehispánico: Consideraciones generales*

Un sitio con características portuarias, en el cual se da una dinámica de un flujo constante de bienes, personas, información, etc., no sólo necesita captar y distribuir, sino también cerciorarse de la preservación de dichos bienes. En este panorama, los sistemas de almacenamiento son eje fundamental, ya que preservan los bienes hasta el momento en que son requeridos por el usuario final, lo que implica que los sistemas de almacenamiento deben estar equipados y estructurados para coincidir con los objetivos del consumo.

**Beck, Charlotte (Hamilton College) and Amanda Taylor (Pacific Lutheran University)** [51] *Bear Creek and the Pacific Northwest Western Stemmed Tradition*

The lithic assemblage from Bear Creek (4SKI839), a late Pleistocene-early Holocene site in King County, Washington, is representative of the Western Stemmed Tradition (WST), likely the oldest lithic tradition in most areas west of the Rocky Mountains. It is followed in the Pacific Northwest by the Olcott Tradition. Although some argue that Olcott represents an intrusion from Alaska, archaeological evidence supports a situ development from the WST. In the Great Basin the WST is biface oriented, represented by a relatively standardized reduction sequence present in assemblages across that region. On most of the Columbia Plateau, however, the WST appears to be a composite blade/pseudo blade technology, which is well suited to the reduction of tough, coarse-grained materials so prevalent in that area. Biface reduction is only one of several core reduction strategies represented in the Bear Creek assemblage; others include multidirectional unpatterned, centripetal, and unidirectional core reduction. In this poster we demonstrate that the Bear Creek assemblage identifies more closely with the core and flake/pseudo blade strategy of the Columbia Plateau than the biface-oriented strategy of the Great Basin.

**Beck, Jess (University of Pittsburgh—Center for Comparative Archaeology)** [139] *Post-Mortem Manipulation, Movement, and Memory in Copper Age Iberia*

Post-mortem manipulation of human remains played a critical role in mortuary practices in Copper Age Iberia (c. 3250–2200 BC). During this period in Spain and Portugal, individuals were buried communally in tholos-type tombs, as well as natural or artificial caves and rockshelters. Evidence from across Iberia suggests that mortuary practices included the manipulation and movement of previously interred bodies, either in order to clear space for new individuals, or to facilitate secondary reburial in new locations. I focus on evidence from the site of Marroquías Bajos (Jaén, Spain), which at 113 ha is one of the largest villages known for the Iberian Copper Age. Marroquías contained at least seven different mortuary areas, and shows evidence of multiple funerary processes, including secondary burials and communal burial in mortuary structures or artificial caves. The latter two treatments suggest that at specific points in time, members of the community came into repeated and deliberate contact with human remains. By contextualizing Marroquías Bajos mortuary practices within a broader regional pattern of post-mortem manipulation across the Iberian Peninsula, it is possible to explore the ways in which these mortuary practices influence the construction of communal and individual identities in Copper Age societies.

**Becker, Hilary (Binghamton University)** [132] *Branding the Mediterranean: Naturally-Sourced Products and Their Containers in Greece and Rome*

The ancient trade in olive oil and wine is well understood thanks in no small part to typologies established for their transport containers. A synthetic survey of the containers used to transport other naturally-sourced products, such as pharmaceuticals, perfumes, and pigments, is lacking. Such products were subject to counterfeiting and adulteration in antiquity, thus packaging and labeling were often valuable tools for ancient consumers to help them identify the product’s origin, which could serve as a guarantee of quality. Containers for herbs, pigments, and perfumes, as well as surviving examples of labeled products themselves, facilitate our understanding of how naturally-sourced products traveled (often at great distances). Exploring this system not only broadens our understanding of the trade in naturally-sourced products, but also provides insight into what an ancient consumer would have known at the marketplace.

**Becker, Rory (EUO), George Holley (Minnesota State University Moorhead) and Jakob Jensen (University of Utah)** [375] *Use of Ultraviolet Imaging to Enhance Analysis of Incised Stone Artifacts*

Monochrome ultraviolet (UV) photography provides a new method in the analysis of incised imagery on stone artifacts. In this study, the technique is used to enhance the interpretation of figures on a collection of finely incised catlinite tablets from the Red River Valley of Minnesota and North Dakota. The nine hand-sized tablets included here are commonly associated with the Onoca tradition, although these display designs rooted in Plains themes. These tablets are ideal for the interpretation as they bear multiple, sometimes overlapping, incised designs that are subsequently marred by scratching/cutting. A comparison of traditional methods with the monochrome UV imagery shows a high level of detail in the UV photography that is not
Becker, Sara (University of California, Riverside)

Osteoarthritis in Hands, Feet, Spine, and Temporomandibular Joint from Individuals Buried at Tiwanaku Sites in Moquegua, Peru

This study evaluated evidence of osteoarthritis in the multiple joints of the wrist and hand (ulnae, radii, carpals, and metacarpals, finger phalanges), ankle and feet (tibia, tarsals, metatarsals, foot phalanges), spine (cervical, thoracic, lumbar vertebrae), and temporomandibular joint from human skeletal remains previously excavated from Tiwanaku sites within the Moquegua Valley of Peru (AD 500–1000). Osteoarthritis, a type of degenerative joint disease with a complex etiology, has been shown to occur in situations where movements are repeated frequently enough to damage joint surfaces. This skeletal condition was used to understand patterns and levels of activity from five Tiwanaku colony sites (M1, M10, M11, M43, M70). Data were collected from older juveniles and adults (n = 183), cross-evaluated by age-at-death and sex, and preliminary results show differences, especially in hands, feet, and spine, between individuals from these sites. In addition, evidence of osteoarthritis in the temporomandibular joint, especially among younger folk, may be related to artificial cranial modification. Overall, these results support the idea that the site groupings represent spatial differences in occupation and that repetitive labor likely began among older subadults (10+ years) in the prehistoric Andean culture of Tiwanaku.

Becks, Fanya (Stanford University)

Archaeology as Meditative Practice

In this paper I will illustrate how my research praxis necessarily altered as a product of close collaboration and consultation. The Muwekma Tribe of the San Francisco Bay Area (California, USA), is a community that has been eager to engage with respectful researchers in the analysis of their ancestors remains, once they have been disturbed. As a non-indigenous researcher collaborating with the tribal community, aspects of proper respect and care toward ancestors, and materials associated with them, in the form of focus, love, respect and acknowledgement, have been integral in my engagement with plant remains from ancestral Ohlone graves. The ethics of calm, careful, and one pointed focus throughout material analyses have deeply altered the way that I have engaged with archaeological materials, and have illustrated a necessity to transcend secular and materialist ontologies when interacting with, and thinking about, Muwekma’s ancestral heritage.

Beckwith, Laurie (Douglas College)

A Late Formative Period Site in Chimborazo Province, Ecuador

Compared to the coastal areas of Ecuador, the central highlands of Ecuador are not well-known archaeologically, especially for the Formative Period. This paper will report on preliminary survey and excavation research carried out in the Chibungu River Valley, to the south of the modern city of Riobamba, during the 2009 and 2012 field seasons. Test excavations were carried out at the site of Collay, located on a mesa at 3,100 masl, to obtain a sample of material culture and material for dating. The site produced a series of Late Formative Period radiocarbon dates and evidence of a well-developed ceramic tradition that while unique to the site, shows a clear relationship to coastal Late Formative Period ceramic styles and to those from Cerro Narrio to the south. In addition the presence of exotic materials, such as spondylus, obsidian and green and alabaster-like ground stone bowls, demonstrates the site’s participation in substantial trade networks. Finally, the location of the site in relationship to nearby mountains and the presence of standing stones with pecked bowls are suggestive of the ritual nature of the site.

Bedford, Stuart (Australian National University)

The Archaeology of Colonialism and Capitalism in the Southwest Pacific: The Compagnie Calédonienne Nouvelles-Hébrides (CCNH) on Malakula, Vanuatu

Much of the European mapping of the South West Pacific occurs relatively late in terms of global history. In Vanuatu (ex New Hebrides) the first visits were Spanish ships in 1606. The wider archipelago was not further explored until the visit of Cook in 1774 but soon afterward it had been incorporated into the rapidly infilling global map. The geography, climate and people had been described as had hints of the economic potential and the islands could now be discussed and dissected among the parliamentarians, business houses, proselytizing churches and learned societies of Europe and beyond. The tenancies of global capitalism, intertwined with colonial and missionary encroachment were soon to follow. One of the early drivers of European encroachment, and its associated introduction and distribution of exotic wares and technologies, plants and animals and disease was the Compagnie Calédonienne Nouvelles-Hébrides (CCNH). This paper outlines how archaeology can contribute to the understanding of this period in this region which saw radical change to traditional societies over a relatively short time.

Bednar, Sarah

The Baalche’ Group: An Investigation of a Preclassic Maya Palace at Yaxnohcah, Campeche, Mexico

As part of the ongoing research into the development of sociopolitical complexity at the Maya site of Yaxnohcah, the Proyecto Arqueológico Yaxnohcah has been conducting investigations in the Baalche’ Group, a large courtyard group located at the center of the site. The group sits adjacent to many prominent architectural features, including a Preclassic period E-Group assemblage, a ball court, and a water reservoir. Radiocarbon dating and ceramic analysis has revealed that the Baalche’ Group itself was founded during the Late Preclassic period and was continuously occupied until the Terminal Classic period. Furthermore, our research suggests that the group likely functioned as an early palace, a place where the emerging rulers of Yaxnohcah resided and governed. This paper will present the findings from the investigations in the Baalche’ Group, with a particular focus on the factors that led to the early emergence of a palace complex at Yaxnohcah during the Preclassic period.

Beekman, Christopher (University of Colorado Denver) and Verenice Y. Heredia Espinoza (Colegio de Michoacán)

In the Land of the Blind, the One-Eyed Man Is King: Los Guachimontones, Jalisco

The site of Los Guachimontones was occupied from the late Middle Formative to the end of the Postclassic period. It had a bimodal history of occupation, with the first peak corresponding to the Late Formative period (100 BC–AD 200) and the second to the Late Postclassic (AD 1400–1600). It had an estimated population of 4,000–6,000 people in the Late Formative, when most of the public architecture was constructed. This makes it a very modest settlement in comparison to other Mesoamerican capitals, but it was the primate center for the Tequila valleys, and likely all of far western Mexico at the time. Assessing its role has thus been complex. Here we consider the activities reconstructed for the site to date—a preference for community ritual over private ritual, cooperation over aggrandizement, and an orthodox interpretation of ideology—to characterize Los Guachimontones as an exemplary center that dominated the southern Tequila valleys. Beyond that zone however, lineage ritual increased in importance, highlighting the limits on the site’s power.
Beggen, Ian (North Carolina State University) and Joseph A. M. Gingerich (Ohio University) [262] EXPLORING ARTIFACT TRAMPLING AT AN EARLY PALEOINDIAN CAMPSITE

Taphonomic processes such as trampling can have a major impact on the interpretation of site formation, artifact distribution, and use-wear analyses. This poster presents a preliminary spatial and lithic analysis of artifacts from the Shawnee-Minisink Paleoindian site in Pennsylvania, USA. Using a high resolution point-provenience database of Paleoindian artifacts, possible trampling damage is mapped and analyzed in order to distinguish if high foot traffic areas exist at Shawnee-Minisink, such as between hearths or zones of specialized activities. Trampling of lithic debris by human activity can be difficult to assess in the archaeological record. Evidence of trampling, however, is explored through multiple assessments: the vertical distributions of artifacts, the horizontal dispersion of different artifact types and sizes, and an analysis of artifact edge damage. Graphical displays of damaged artifacts and distinct spatial distributions allow for a better interpretation of activity areas and site occupation. In combining artifact metrics, artifact edge damage, and the spatial distributions of artifacts we expect to identify incidents of cultural disturbance at Shawnee-Minisink. These data contribute to a larger body of spatial analysis research aimed at better understanding the occupation of mobile hunter-gatherer campsites.

Beldados, Alemseged (Addis Ababa University) and A. Catherine D’Andrea (Department of Archaeology, Simon Fraser University) [171] AGRICULTURAL HISTORY OF THE HORN OF AFRICA: NEW ARCHAEOBOTANICAL EVIDENCE FROM MEZBER

Archaeobotanical analysis of samples from the site of Mezber are underway with the goal of investigating the early agricultural history of northern highland Ethiopia. Mezber is a Pre-Aksumite site excavated by the Eastern Tigrai Archaeological Project (ETAP) with cultural deposits dating from 1600 BCE to CE 1, and occupied over four phases. In 2014–2016, a total of 59 soil samples ranging in size from 1.8 to 7.5 liters was processed by manual flotation. Macrobotanical remains were obtained from light fractions with the help of comparative collections at the Archaeology Laboratory, Addis Ababa University. Identified crop species include barley (Hordeum vulgare), emmer (Triticum dicoccum), lentil (Lens culinaris), linseed (Linum usitatissimum) and the indigenous staple crop teff (Eragrostis tef). Direct AMS dates were obtained on charred barley and barley recovered from the earliest occupational phase, with determinations of 2810±30 BP (1050–895 cal BCE) and 2780±30 BP (1004–844 cal BCE), respectively. These AMS determinations constitute the earliest directly dated evidence for crops in the Horn of Africa. In addition, the extended occupational sequence at Mezber provides a window on changing agricultural practice throughout the Pre-Aksumite period.

Beliaev, Dmitri (Kronozov Mesoamerican Center, Russian State University for the Humanities), Philipp Galeev (Kronozov Mesoamerican Center, Russian State University), Sergei Vepretskii (Lomonosov Moscow State University), Camilo Luin (Universidad de San Carlos de Guatemala) and Alejandro Garay (Universidad de San Carlos de Guatemala) [298] DEVELOPMENT OF A CLASSIC MAYA SECONDARY POLITY AT ITZIMTE

Itzimte (municipio La Libertad, Department of Petén, Guatemala) is a medium-sized Maya site in the savanna region in Central Petén. It was first described by Theobert Maler in 1908 and later visited by Sylvanus Morley in 1915 and 1921. In 2002 it was studied by Atlas Arqueologico de Guatemala team led by Hector Mejia. Itzimte consists of 6 principal plazas and 16 dispersed patio groups occupying about 50 ha. Monumental corpus of the site included 20 stelae (13 carved) and 12 altars (4 carved). During the fieldwork of the Atlas Epigrafico de Petén project from 2013 to 2016 we redocumented major part of Itzimte hieroglyphic inscriptions. Dynastic count recorded on Stela 7 implies that the ruling house of Itzimte was founded in Protoclassic (75–100 AD). Although Early Classic (250–600 AD) history is unknown, we identified names of Late Classic rulers. Late development of Itzimte comparing to other neighboring polities seems to be related to its alliance with Ik’a (Motul de San Jose) kingdom around 760–770 AD.

Belkin, Sara (Boston University) and Daniel Plekhot (Brown University) [260] POTENTIAL FOR SPATIAL “BIG DATA” IN HISTORICAL ARCHAEOLOGY: A DEMONSTRATION OF METHODS AND RESULTS

Historical Archaeology has seen a steadily increasing embrace of Geographic Information Systems (GIS) for the purposes of site recording, preservation and management, but has seen little to no use of the plethora of spatial datasets already publicly available. Such datasets include census, tax, and immigration records, property and housing maps, and archived aerial and satellite imagery, which when properly integrated in a GIS, have great potential for further contextualizing historical archaeological data and analyzing them at geographically broader scales. In this poster we present some of these publicly available data sources with a case study examining the consumer practices of an Irish-American family in early twentieth-century Milton, Massachusetts. We draw on data from excavations at the M.B. Wakefield Estate, U.S. census records, and other sources to plot where they purchased their household goods and to determine if these places are best characterized as Irish neighborhoods. Through this we can explore questions related to transnationalism, alienation practices, and the importance of community. This case study will illustrate the potential of these sources for use in archaeological studies, the ease with which they can be accessed and utilized with conventional archaeological data, and their use in answering broad anthropological questions.

Bell, Ellen (California State University, Stanislaus), Marcello A. Canuto (M.A.R.I., Tulane University) and Cassandra Bill (Langara College) [39] PUSHING THE LIMITS OF POWER: COPAN EXPANSIONIST STRATEGIES IN THE EL PARAISO VALLEY, WESTERN HONDURAS

The reign of K’ahk’ Uti’ Witz’ K’awil, Copan Ruler 12, has been rightly hailed as a pivotal time in Copan’s political history. Given that no monumental constructions on the Copan Acropolis have as yet been securely attributed to his patronage, this long-lived ruler appears to have turned his focus outward, expanding the Copan kingdom into a multiethnic polity with a long geographic reach. In this paper we explore Ruler 12’s administrative strategy in one region of the Copan kingdom, the El Paraíso Valley. Stratigraphic evidence, radiocarbon dating, pottery and other portable material culture, and stylistic analysis of mosaic architectural sculpture suggest that the site of El Paraíso was established as a Copan-style administrative center in the mid-seventh century AD, nearly 20 years after Ruler 12’s accession. In this paper we bring recent analyses to bear on questions about the timing, function, and affiliation of this center and its founding.

[139] The Histotaphonomy of Human Skeletal Exposure within a Neolithic Long Cairn at Hazleton, UK
The total excavation of the Cotswold-Severn Neolithic long cairn at Hazleton was unusually meticulous and represents an excellent example of long term skeletal exposure. Some discussion exists around the nature of bodies prior to deposition in these long cairn structures and histotaphonomy is here used to consider this question. The human remains at Hazleton were recovered from two spatially distinct stone-lined chambers in a highly disarticulated and commingled state. During excavation each element or fragment were individually numbered, totaling over 9,000. Later anthropological assessment managed to re-assemble partial individuals, permitting a spatial understanding of scattering within each chamber. Two individuals from each chamber were assessed microscopically using confocal and backscattered electron imaging, to identify the histotaphonomic changes and their spatial relationships. The results indicate that different trajectories for disarticulation and body status at the point of interment may shed light on burial practices i.e., was the body intact at the point of interment or not? This group exhibited no cutmarks, and so the commingling, which contemporaneously extended over a 300-year period of use, needs some discussion. The histotaphonomy indicated, in this case, that bodies were likely intact at the point of interment.

Bell, Martin (University of Reading UK)
Archaeologists focus on sites. This paper looks at ways of identifying patterns of habitual movement that made those sites part of a living landscape. It draws on paleoenvironmental evidence, ethnography from the American northwest coast and the microscale of human footprints. Patterns of movement by people and animals create structures within landscape, which influence the activities of subsequent generations and the perspectives from which they encounter and perceive landscape. Paths thus constitute a significant aspect of niche construction. Examples from British and European prehistory demonstrate that there are ways of identifying and dating prehistoric routes using the spatial relationship between monuments. Negative features, such as hollow ways, can be dated by their relationship to colluvial sediments from associated agricultural terraces using various scientific techniques (artifacts, mollusks, U-Series and OSL). The results challenge existing assumptions that the main prehistoric routes in Britain were rideways on hill crests. There is more evidence for the early origins of parallel systems of hollow ways crossing the grain of the landscape. It is proposed that these were associated with the activities of seasonal pastoralists. The paper outlines key themes from the writer’s recently completed forthcoming book Making One’s Way in the World.

[121] Raw Material Characterization and Lithic Procurement in the Azraq Basin, Jordan, During the Middle Pleistocene: Preliminary Results
Recent excavations at Shishan Marsh 1 in the Azraq Basin, Jordan, have uncovered several artifact-bearing layers that date to the Middle Pleistocene. A paleoecological assessment of sediments from this period indicates predominantly warm and dry conditions in the region, similar to those of the present. Hominins living under these harsh conditions were forced to contruct around a receding spring- and wadi-fed water source for subsistence. In this way, the distances they could venture to acquire resources were limited. Consequently, Shishan Marsh 1 presents the opportunity to investigate lithic procurement strategies practiced by Middle Pleistocene hominins in a water-stressed and arid environment. A macroscopic evaluation of the lithic assemblage revealed a nearly homogenous raw material composition with chert as the dominant stone type. A pilot provenance study of lithic sources in the region and a sample of artifacts are conducted using ICP-MS. The preliminary results indicate that local procurement of stone extracted material from predominantly one chert formation. The operation of the regional wadi-system as a potential secondary source are also considered, as it may have transported nodules toward the Azraq Basin.

[347] The Materiaility of Sound: Detecting Performing Patterns on Two Mesoamerican Bone Rasps
This presentation focuses on some results of an interdisciplinary study carried out on two scraping idiophones made of human bones from ancient Mesoamerica (omichacahuaztli). Both the instruments are today on exhibit at the Museo Nazionale Preistorico Etnografico “Luigi Pigorini” in Rome. The detailed analysis of the bone surfaces allowed us to reconstruct the taphonomic processes that affected the bones and the steps employed to transform them into musical instruments. Our research team organized marks into an operational stratigraphy, reconstructing the sequence of stages in production and use, raw material procurement, cleaning, shaping, decoration and finally use-wear patterns. Marks related to this last stage were useful in detecting the performing pattern of the instruments. Once we obtained these material data, we could play both the instruments in a recording session, using their original scraping tools, which are an Oliva shell and a human fibula. This allowed us to analyze the acoustic characteristics of the instruments and to replicate their sound in the exhibiting space, giving museum visitors the possibility to “listen to,” and not only “look at,” both the omichacahuaztli, although behind a museum glass.

Bellorardo, Benjamin Aaron (University of Arizona)
[373] Sandals from the Center Place, Footprints on the Pots: Continuity and Change in Twined Sandal Tread Designs from Chaco, Aztec, and Beyond
Twined sandals were important components of Ancestral Pueblo ritual paraphernalia for a millennium. They were expensive and time consuming to make and many had patterns of raised knots woven into their treads that stamped footprints with complex geometric designs on the ground when worn. Scholars have postulated that twined sandals were likely used in communal rituals, dance performances, and even foot races. During the Pueblo II period, their use appears to have been connected with communal activities at Chacoan civic-ceremonial centers. After the collapse of Chaco, these sandal making and wearing traditions disseminated into disparate communities of the San Juan Basin, including the Middle San Juan. In this presentation, I discuss ongoing analyses of twined sandal collections, documenting continuity and variability of attributes of sandal shapes and tread design layouts from Chaco Canyon, Aztec Ruins, and other post-Chaco communities in the region. While few sandals have been dated absolutely, I compare sandal designs with well-dated Pueblo II-era decorative styles from painted pottery and other media to date them relatively. With this research, I hope to shed important light on how twined sandals functioned similarly or differently at these two centers of Ancestral Pueblo society (and beyond), over time.

Taphonomic Analysis of the Small Mammal Assemblage of Hayonim E: Implications for Paleoeocology of the Southern Levant During MIS 6

This study presents the taphonomic history of the small mammal assemblage of Hayonim E, Israel, and compares it to those of other Middle Paleolithic (MP) sites. Levantine paleoecological changes during the MP have implications for hominin dispersal into the region. It has been suggested that a comparison of faunal assemblages from Hayonim (160–130 Kya), Qafzeh (120–90 Kya) and Amud (75–45 Kya) indicate a shift between glacial and interglacial fauna which mirror dispersals by Neandertals and modern humans. However, these analyses do not account for possible differences in the predator accumulating the fauna among the sites studied. Analyses of the taphonomic history is critical before inferring the paleoecology of the site and only sites that were accumulated by the same predator may be compared with rigor. Results suggest that the assemblage from Hayonim and Qafzeh were accumulated by barn owls while the assemblage from Amud cave was accumulated by Eagle owls. Barn Owls (Tyto alba) take prey in proportion to its abundance in the environment and thus, fossil assemblages derived from this taxon are excellent indicators of the environment; although comparison among sites should only be done with caution, given their different taphonomic histories.

Residues Analysis of Bedrock Mortars of the Limari River Valley (IVth Region, Chile): Evaluating Plant Exploitation among Late Holocene Hunter-Gatherers

For an integral understanding of bedrock mortars, as a product and producer of social practices, we have carried out research in the Limari River valley (Chile) (Fondecyt Grant N°1150776). One dimension of this research was directed to answer the following questions: were these cupules used to grind plants? And if so, what plant resources were used by these hunter-gatherer groups? Do these include cultivate domesticated plants? And how does it relate to the association “initial pottery/horticultural practices” in the area. In an initial analysis we confirmed the grinding of local wild plants in five sites in the area and the presence of starch grain of Zea mays in one site. Now we shall extend the morphological and residue analysis of the cupules of a total of 10 bedmortar sites. This consists in the recovery and identification of microfossil evidence in use residues of the cupules, plus the registration of the morphological attributes of the cupules. The objective is to reach a better comprehension of late Holocene hunter-gatherer groups of this area, and have an insight of their plant exploitation strategies, referred to the use of wild plants and the possibility evaluating the use of domesticated plants.

Open-Air Camps of the Terminal Pleistocene and Early Holocene: An Introduction

Open-air camps from the terminal Pleistocene and early Holocene pose significant challenges in excavation, analyses, and interpretation. This international symposium provides a formal setting to continue a series of discussions on site formation, analytical trends, and interpretations. Key topics include defining site boundaries, contemporaneity of activity areas, population estimates, and the possible effect of thresholds in the arrangement and longevity of site use. Of particular interest is the question of what is the diversity represented in site layout and function during this time period.

Karakorum, Mongolia, a Complex Urban Site in a Nonurban Society

It is undisputed that Karakorum was founded by the Mongol Emperor/Khan, saying this means we analyze a top-down planned large city in a non-sedentary, nonurban society. Therefore we will address the question of the layout of the city and the spatial organization. How are activities and people ordered, is there common space, what kind of infrastructure is provided by the city founders and how is it maintained during the nearly 200 years of the existence of the city. At which areas were landmark buildings erected, where did the emperors place public monuments like propaganda stelae, how did they use architecture as a symbol of power? Are there any changes in the layout of the city, traces of decay? Was the master-plan of the city planners ever finished or do we see a rapid decline after the city lost its status as a capital? What criteria do we have to differentiate town quarters? Where are the cemeteries and are there any indicators for elite burials? Share locals and foreigners the same cemetery or has each ethnic or religious group its own cemetery? What social status did the inhabitants have and where did they come from?

Collection of Crustaceans and Echinoderms during the Middle Holocene on the West End of San Nicolas Island, California

We present the preliminary results of crustacean (crab) and echinoderms (sea urchin) remains from CA-SNI-40, a large Middle Holocene (~4440–3650 cal BP) dune site located on the West End of San Nicolas Island, California. Our study provides detailed identifications and quantitative analysis of crab and sea urchin remains that will contribute to previous faunal studies at this site, which identified over 88 shellfish taxa including dietary and non-dietary species. Preliminary results indicate that seven taxa of crab (Brachyura) and two indistinguishable species of sea urchin (Strongylocentrotus spp.) are present in fairly high densities. A dense urchin lens is present throughout much of the site, indicating that people harvested this resource in extremely high numbers during the time of occupation. We compare density values based on weight and minimum number of individuals (MNI) between two excavated loci to examine differences in harvesting patterns at this site. Morphometric measurements of crab dactyls indicate that people were collecting specimens of all age classes from littoral and kelp forest habitats. Our results suggest that the marine ecosystems on the West End of San Nicolas Island served as a productive and diverse site for human harvesting during the Middle Holocene.

[296] **Faring the Sweet Sea: Simulating Prehispanic Raft and Canoe Navigation in Lake Cocibolca, Nicaragua**

Before 1492, the human communities that inhabited the shores of Lake Cocibolca in Central America engaged in dynamic interactions and exchange networks, traveling across the land and canoeing or rafting on the lake and rivers to trade goods and communicate with their neighbors. Evidencing this travel network, archaeological studies have documented an abundance of ceramics and carved stone that the past inhabitants of the Lake Cocibolca region produced and traded widely during the later prehispanic periods (AD 300–1550). To shed light on this interaction and exchange network, I use a geographic information system to predictively model the optimal aquatic communication routes among the nearshore and island-based settlements of this lake. This model utilizes seasonally averaged environmental variables of surface current and wind patterns and cultural variables of navigator skill, vessel shape, and propulsion method to simulate a series of lacustrine voyages. Through this model, travel times and probable routes are estimated. These simulations indicate that Lake Cocibolca is navigable by dugout canoe and raft under average conditions and it is likely that canoe travelers would have taken advantage of the prevalent current and wind patterns to contact their neighbors via this large freshwater lake.

[185] **Life during Wartime: Children, Violence, and Security at Morton Village**

Children are not immune to the violence of war. They can be incidental victims, prime targets, active participants, beneficiaries of fierce protection, or the recipients of warfare-related symbolic action. Though not subject to the same high rates of violent trauma as their adult counterparts, the available osteological data show that a small number of children interred in the late prehistoric Norris Farms #36 cemetery in Fulton County, Illinois did suffer traumatic injuries, both fatal and nonfatal. Some children were victims of scalping, while at least one was potentially the recipient of a human trophy as part of associated mortuary ritual. We revisit the osteological and mortuary evidence for children’s involvement in warfare at Norris Farms #36 and seek to contextualize it within the ethnographic literature on childhood in times of war. We also consider the somewhat obvious observation that some individuals in this skeletal series—including most children—bear no osteological evidence of physical violence. Consequently, we broach the concept of security as we consider children’s day-to-day lives at the associated Morton Village site and the broader landscape; How might this community have created secure spaces for the physical protection of children and other vulnerable people in the face of danger?

[25] **The Archaeological Study of Cities in East Asia**

This paper explores the study of cities in China and the implications for their archaeological investigation. Walled settlements developed in China during the Neolithic and by the Bronze Age many had already grown to considerable size and complexity. While scholars in China and East Asia often consider cities to be a form of settlement organization starting at this early date, the concept of city used in their study is frequently unexamined, and historical examples of cities in the Chinese heartland are used as models to understand earlier sites, or sites outside of this region that may have developed differently or had different uses. These long-held concepts of what premodern cities were and who lived in them developed from the study of rich historical documentation but have now come to limit understandings of cities by constricting the available range of interpretation.

[370] **An Analysis of Historic Glass Containers from St. George’s Caye, Belize**

From 2009 to the present, an abundance of whole and partial glass bottle remains of various types have been recovered throughout excavations on St. George’s Caye, Belize. Much of the glass collection has been found within the island’s cemetery among an assemblage of various other historic artifacts. The majority of the bottles and bottle fragments have been identified as eighteenth- and nineteenth-century English cylindrical bottles. In 2016, artifacts. The majority of the bottles and bottle fragments have been identified as eighteenth- and nineteenth-century English cylindrical bottles. In 2016, an analysis of this assemblage commenced in order to determine a date range for manufacture of the bottle sample using analysis methods designed by Jones (1986) and Carillo (1973) to estimate manufacture date through measurement. Jones and Carillo’s methods were used to date six whole dark green glass cylindrical bottles that have been recovered from the island. Bottle base and finish fragments have been dated based on physical indicators of style and method of manufacture present on the bottle fragments as described by Jones (1986). This evaluation includes lip to string lip ratio, lip and string rim style and style of base and pushup among other features. The results of this analysis will help to provide a relative date range for the deposit of the assemblage from the cemetery at St. George’s Caye.

[160] **Mississippian Occupations at the Ravensford and Iotla Sites**

Recent large-scale excavations at the Ravensford and Iotla sites, and elsewhere in western North Carolina’s Cherokee “heartland,” have documented Mississippian components that include architectural remains as well as artifact assemblages. But while Late Mississippian occupations have been found on many sites, Early and Middle Mississippian households and settlements have been difficult to isolate. Increased numbers of systematic surveys and excavations in recent years have uncovered evidence of these less visible occupations. Early and Middle Mississippian phases in western North Carolina have not been formally defined, but include both Early Pisgah and Etowah related phases. Mississippian influence appears to have been present during Early Pisgah in the form of flexed pole architecture, use of shell tempered ceramics, and maize agriculture. No evidence has yet been recovered that mounds were built during the Early Pisgah phases. By the Early Qualla phase, which includes later Pisgah ceramics, all of the hallmarks of Mississippian culture appear to be present. It is unclear if a chiefdom level of sociopolitical organization was present, however, and individual Mississippian towns and associated dispersed communities in the mountains may always have been relatively independent, as was true of the later Cherokee towns.

[267] Turquoise Mosaic Skulls: Understanding the Creation of an Object Type

In 1932, Alfonso Caso and his team found a human skull decorated with turquoise mosaic tesserae during their well-known excavation of Monte Albán’s Tumba 7. To this day, this is the only artifact of this type to have been found in a documented excavation. Nevertheless, at least twenty turquoise mosaic-decorated human skulls are currently held in museums and private collections. Many of these have been considered forgeries, others are considered authentic. Within this group, there are clear iconographic and stylistic differences, an indication that these ‘mosaic skulls’ were not all made by the same original culture, or forger. In this presentation, I will present an overview of the corpus of mosaic skulls known to date and trace their object biographies. Through this study of provenance and iconography, I will try to answer the question “Are mosaic skulls a twentieth century invention, or are they a genuine Mesoamerican artifact type?”

[38] Testing Social and Ecological Drivers for the Initial Spread of Agriculture on the Iberian Peninsula

Much initial research into the arrival and dissemination of agriculture in Europe has focused on identifying the speed and direction of the arrival of Neolithic subsistence. More recent work has begun to examine the chronological and spatial patterning of the spread of agriculture with the goal of identifying important sociological or environmental factors that affected the timing and location of agricultural settlement. In this context, agent-based computational modeling is emerging as a sophisticated platform from which to test social and ecological drivers for the neolithization of Europe. In this case study, we use the Iberian peninsula as the setting for a computational model of Neolithic spread in order to test multiple processes that have been proposed as mechanisms for the spread of agriculture in Europe. The inclusion of state-of-the-art crop models, based on downscaled paleoclimate models allow us to more accurately simulate ecological conditions that individuals or groups may have favored when establishing a settlement in a new location. The results from these computational hypotheses are evaluated against a high resolution chronological dataset for the arrival of agriculture to the Iberian peninsula. The integration of paleoenvironmental and conceptual models provides a unique perspective for the evaluation of Neolithic spread mechanisms.

[68] The Ambivalence of Caves and Rockshelters in Medieval Norway

Caves and rockshelters occur frequently in Norway and they were extensively used as dwelling-sites for humans in most periods of the prehistory. During the transition to the medieval period (AD 550–1500), however, archaeological excavations show that their use changed significantly. From then on, they mainly served as offering sites, burial sites and as workshops for metal smiths and stone masons. This change may have been related to a change in the perceptions of caves and rockshelters. One gets a glimpse into these later perceptions when studying the medieval saga texts and eddic poetry from Iceland. In these texts, there is a marked ambivalence concerning these places. Caves are, on the one hand, portrayed as scenes for negative actions and incidents, and are associated with dangerous and threatening beings and powers in the Norse mythology. On the other—when people communicate with these beings—caves and rockshelters are places where wisdom, wealth, and status can be achieved. It is argued that the ambivalence led to a general avoidance of the shelters for dwelling purposes, and to a favoring of them as arenas for worship and ritual.

[338] Site Formation Processes at Manot Cave, Israel

Manot Cave, represents today one of the richest Upper Paleolithic assemblages in the Levant. The site has produced a 55,000 year old anatomically modern human skull, as well as Middle Paleolithic to Post-Aurignacian lithic and bone artifacts. The rich assemblage is found in an “unusual” situation, with an in situ occupation area at the top of a talus and close to a currently blocked entrance. The occupation area defined by in situ combustion features is replete with artifacts, and so is the talus slope. Understanding this site requires a basic untangling the processes responsible for the formation of the talus slope, in addition to the occupation area. Here we present the results from an extensive microarchaeological investigation and high resolution 14C dates conducted in several excavation areas.

[378] Rome and Cetaceans: Archaeological Evidence from the Strait of Gibraltar
Over the past 10 years, bones from whales and other marine mammals have been uncovered from archaeological excavations of Roman cities around the Straits of Gibraltar (Baetica and Mauritania Tingitana coasts). The high frequency of archaeozoological remains and their location within fish-preserving contexts (cetariae) has suggested the active exploitation of cetaceans throughout the Roman Imperial period (II BC–V AD). This paper reviews the evidence from Baeto Claudia, Julia Traducta, Septem Fratres and Tamuda, the sites from which the majority of the finds are located, and where the use of salted whale meat and other products has been proposed within fish-salting factories, as noted by some classical authors (Galien, among others). This is the area of the Atlantic-Mediterranean region in which the most archaeological, zooarchaeological and iconographic evidence has been documented, and which is currently being investigated to demonstrate that whaling, traditionally attributed to Basque in the Cantabrian in the Middle Ages, began in classical antiquity.

\[3\] Olmec Masks in the Region of Arroyo Pesquero
In a detailed analysis of some figurines of the offerings of 4 of La Venta, we observed that some of them were carved wearing a mask. This is hardly visible because the shape of the part that forms the human face is almost entirely covered by the stone masks found a few kilometers from La Venta, in the site of Arroyo Pesquero, Veracruz, a site of Olmec offering reported in 1969 by the archaeologist Manuel Torres where a lot of lithic material was discovered. Among these there are axes, figurines and masks of stone, which reproduce realistic human faces with particular characteristics, as if they were trying to represent a particular individual. In other collections we have found identical trait in some figurines in Olmec style, which have the same representation as if they were wearing a mask. This evidence reveals the use of masks in rituals by living people and not just as part of funerary paraphernalia. What was the meaning of these masks? Are they related to a particular period and region? These are some of the subjects addressed in this presentation.

\[75\] Elite Domestic Spaces and Daily Life in a Reducción
The archaeology of Spanish colonialism in the Andean region is coming into increasing focus with the documentation of Spanish colonial doctrinas and reducciones, along with the excavation of religious structures, public spaces, and elite and common indigenous households. However, we still lack a clear comparative diachronic perspective of how Spanish colonialism affected the daily lives and values of indigenous Andean peoples. This paper presents the results of the 2016 excavations of three large stone structures and two smaller associated structures in the Spanish colonial reducción of Santa Cruz de Tuti, in the Caylloma Province of Arequipa, Peru, occupied from the precolonial era until its abandonment in 1843. We argue that various of these spaces were in use from near the founding of the reducción in the late sixteenth century to its abandonment in the mid-nineteenth century. As such, our excavations yield valuable comparative data on the domestic lives of the elite indigenous classes of Spanish Colonial Peru and their changing values, lifeways, and bodily habitus over the course of Spanish Colonialism and into the early Republican period.

\[75\] Elite Domestic Spaces and Daily Life in a Reducción
The archaeology of Spanish colonialism in the Andean region is coming into increasing focus with the documentation of Spanish colonial doctrinas and reducciones, along with the excavation of religious structures, public spaces, and elite and common indigenous households. However, we still lack a clear comparative diachronic perspective of how Spanish colonialism affected the daily lives and values of indigenous Andean peoples. This paper presents the results of the 2016 excavations of three large stone structures and two smaller associated structures in the Spanish colonial reducción of Santa Cruz de Tuti, in the Caylloma Province of Arequipa, Peru, occupied from the precolonial era until its abandonment in 1843. We argue that various of these spaces were in use from near the founding of the reducción in the late sixteenth century to its abandonment in the mid-nineteenth century. As such, our excavations yield valuable comparative data on the domestic lives of the elite indigenous classes of Spanish Colonial Peru and their changing values, lifeways, and bodily habitus over the course of Spanish Colonialism and into the early Republican period.

Bernes, Thomas  
\[385\] Bear Imagery and Ritual in Midwest North America
The American black bear figured prominently in the visual arts, rituals, ceremonies, and cosmological beliefs of Native peoples inhabiting Midwest North America through antiquity. Bears are almost universally perceived as great Lower World spiritual beings possessing the power to cause or cure illness, maintain life, and change its form where bears become people and vice versa. Their remains and images are often found in mortuary ritual contexts—a powerful means of communicating emotions and central themes of the culture. Drilled bear canines (metonymies of power) and effigy pipes occur in such traditional religious contexts. The importance of the black bear’s head in ceremonies and rituals is documented in the historic and archaeological record, which involved the consumption of brains at feasts, public display of skulls on poles, and use of skull masks at ceremonies. Late Woodland Period (1400–750 BP) bear effigy mounds also provide visual aesthetic evidence of group identity and cosmological beliefs, indicating that monumental architecture (like all Native art) cannot be separated from religious practices. This study provides archaeological evidence of religious traditions shared cross-culturally in antiquity regarding the bear, which elicited power over the human imagination and spirit.

Berry, Alexander  
\[46\] Sea Level Fluctuations of the Southern Salish Sea: An Assessment of the Archaeological Potential for Sites Dating from the Last Glacial Maximum to the Holocene
Following the last glacial maximum, coastlines around the world drastically changed. This occurred through a complex combination of geomorphological processes, which were compounded by global sea level rise. While these fluctuations took place, humans adapted to an aquatic subsistence lifestyle along coastal regions. This study focuses on the southern Salish Sea (located in North America’s Pacific Northwest) and human-environmental interactions during the terminal Pleistocene. Through the use of a predictive model (reevaluated for international application), a holistic methodological framework developed in the Baltic Sea was utilized to address questions regarding archaeological potential in the southern Salish Sea. A dataset was compiled incorporating environmental, ethnological, and archaeological information—for an analysis of the region and its inhabitants. This data enables
the production of paleo-landscape reconstructions at 14,000 BP, 11,000 BP, and 6000 BP, which illustrate the prehistoric coastal configurations influx caused by sea-level fluctuation. Concluding from this research, the sea-level history of the southern Salish Sea is defined in accordance to the amount of dynamic change that has occurred over the past 14,000 years. With precontact sites ranging from inland to completely inundated, the data provided in this study yields information regarding the varying degrees of Paleoindian and Archaic archaeological visibility.

Berry, Meg (Centre for Rock Art Research and Management—University of Western Australia)

It’s All a Bit Retro: Investigating Early Phase Rock Art on the Dampier Archipelago, Northwest Australia

Murujuga, located off the northwest coast of Australia, possesses one of the largest and most vibrant open-air rock art galleries on the planet. On Murujuga, low erosion rates, durable geology, and growing evidence from the wider region has allowed for archaeological contextualization of rock art into deep time; giving researchers the opportunity to investigate both the changing social dynamics of groups and the stimuli for this change over thousands of years. The main objective of this paper is to report on the findings from research undertaken over the past three years within the ARC funded Dynamics of the Dreaming Project investigating how early cultural lifeways on Murujuga are evident in the associated rock art phases; and to examine shifting social geographies during periods of extreme social and environmental pressure. Through the tethering of a stylistic analysis focused on rock art motifs associated with early phase rock marking on Murujuga, with archaeological, social, and chronological indices this paper aims to illustrate and discuss how rock art evolved and was mobilized within the natural and social landscape throughout time.

[22] Arts and Sciences of Ancient Plants at McMaster University

Since 2013, the McMaster Paleoethnobotanical Research Facility (MPERF) has explored questions surrounding the relationship between humans and plants, including plant cultivation and collection, consumption and social uses of flora, and interactions between people and landscape. Active projects address human-plant dynamics throughout different regions of Mesoamerica, South America, and Ontario, at time periods ranging from the Late Pleistocene through historic periods. With recent support from the Canada Foundation for Innovation, laboratory work has turned toward refining techniques for microbotanical analysis and applying Raman spectroscopy to botanical residues. This presentation centers on the study of macrobotanical and microbotanical remains to address three foci: meal production and everyday practices in the Late Formative Lake Titicaca basin of Bolivia; foodways and ethnobotany at Southeastern Mesoamerican sites; and changes and continuities in Mxtec lifeways during the Early Spanish Colonial period at the site of Achiltula in the Mixteca Alta region of Mexico. We highlight collaborations with broader networks and institutions, as well as the ongoing training in paleoethnobotanical techniques and interpretative strategies currently taking place at the MPERF. These efforts fit into a long tradition at McMaster of the application of novel methodologies in archaeological sciences to answer social questions.

Bestel, Sheahan and Tianlong Jiao (Denver Art Museum, USA)

[229] Plant Residues from the Pre-Austronesian Tanshishan site (c. 4300 BP) and Their Interpretation

A mid-Neolithic expansion of farming cultures into the coastal areas of Fujian province, located opposite Taiwan on the other side of the Taiwan Strait, occurred around c. 4300 cal BP. Crops including foxtail millet and rice formed part of these farmers’ diet, and plant remains such as bamboo, possibly used for wooden cooking implements, were also common in sediments and residues at these Longshan-period sites. Plant residues from pottery fragments excavated from the Tanshishan site, located in Fujian Province, eastern China, have the potential to shed light on the subsistence and diet of the proto-Austronesian seafaring people who occupied Taiwan and subsequently spread across parts of the Pacific and into Australia. Despite the suggested ancestry of the Tanshishan culture to proto-Austronesian sites such as Damaoshan and Huangguashan, plant remains recovered from the proto-Austronesian sites were poor and crops were difficult to identify. The implications of the results from the research on residues and plant remains on the public understanding of Austronesian origins will be discussed.

Bethke, Brandi (Oklahoma Archeological Survey)

[127] Domesticated Animals as a Source of Cultural Change during the Contact Period on the Northwestern Plains

Despite functioning as pack animals, guards, religious figures, and even companions, dogs were never as integral to Blackfoot culture as the horse became. To date, researchers have most often characterized the relationship of Blackfoot people and their horses by framing the horse as an “upgraded version” of the domesticated dog—a “new and improved” dog. While prior experience with domesticated dogs did facilitate the incorporation of horses into the daily lives of Blackfoot people, this paper argues that the fundamental differences between dogs and horses prove to be one of the greatest sources of cultural change between the pre- and postcontact periods. Through a framework that integrates archaeology, history, and contemporary ethnohistory this paper will identify these key differences in order better understand how the horse fostered new and dramatically different conceptions of domesticated animals that in turn had significant effects on the value of dogs within equestrian Blackfoot culture.

Bettencourt, Luis

[277] The Intellectual History of Settlement Scaling Theory

There is a long history of comparative empirical studies of settlement sizes in relation to evidence relating to nature and scope of built environments and human socioeconomic activities. However, only recently have consistent theories of settlements been developed that yield specific predictions that can be tested against archaeological evidence. In this paper, I present a brief intellectual history of these ideas to show how they incorporate concepts from various disciplines with an emphasis on archaeology and sociology, as well as urban economics and geography. Specifically, I will show how ideas of socioeconomic “agglomeration,” developed originally to explain modern cities and interpreted in light of social activity over built spaces, have a much larger scale and provide a general logic that can be tested in any settlement system throughout history. Archaeological evidence in favor of such theoretical predictions allows important inferences about the structure of social networks of communication and exchange between people and their intensity and efficiency in specific places and times. These ideas also provide connections to mechanisms of cultural evolution and “economic growth” in ancient societies, such as the division of labor and knowledge in settlement systems, and lead to new uses and interpretations of archaeological evidence.

Recontextualizing the Dead: A Geospatial Approach to Synthesizing Bioarchaeological Data at Çatalhöyük

Two decades of excavation at Çatalhöyük have produced a skeletal assemblage of approximately 555 individuals from primary, secondary, and primary-disturbed Neolithic (7100–6000 cal. BCE) deposition contexts. As personnel and digital technology have changed, integration of the large body of legacy bioarchaeological data with current research has posed many challenges. Often, analyses of osteological data patterns have relied on broad comparisons of temporal and spatial categories drawn from nominal data in the site database, such as comparisons between individuals buried within different types of houses, or groupings of earlier and later stratigraphic layers. However, as Geographic Information Systems (GIS) software has been incorporated into site-wide research methodologies, new opportunities have arisen to explore more fine-grained geospatial patterns in the skeletal record at Çatalhöyük and provide new insights into diet, nutrition, disease, growth, development, and other aspects of life and death at this complex Neolithic settlement. This study explores the benefits and challenges of using GIS to integrate legacy data from the site database, (i.e., age, sex, and long bone measurements), with recently collected data, such as dietary isotope results and dental stress indicators, to develop new understandings of demographic and osteological patterns based on spatial visualisation and tools of geospatial analysis.

Basket Case? Finding Funding for Archaeological Projects: A European Perspective

The competition for funding is increasing, as demand increases but the sources of funds diminish, especially if there is a research element in any proposed project. This paper will explore the possible routes for funding and the potential and pitfalls of using a “basket” approach to raising funds for archaeological projects in the public sector (i.e., charities and noncommercial), including universities. It will also look at different approaches for funding significant heritage-based projects (including national lotteries). I will also briefly use the Endangered Archaeology in the Middle East and North Africa Project as an example of what can (and what can’t) be achieved.

2000 Years of Eating: Continuity and Change in Food Practices Among the Puuc Maya

This paper examines the evidence for what and how the Maya of the Puuc region ate during the long history of occupation of this region. Data collected from almost two decades of research by the Boloenche Regional Archaeological Project and covering close to two millennium of occupation are used in this exploration of eating. Household archaeology primarily from the site of Kiuic and the suburban site of Stairway to Heaven, and ceramic data from throughout the BRAP study area provide insights into continuities and change during the Maya occupation of the Puuc region. Among the most important findings is the evidence for dramatic changes in daily practices of eating that took place from the Preclassic to Classic periods at the household level. These changes are argued to reflect significant differences in how Preclassic and Classic Maya saw their social relations between themselves, other family members and the larger social world. Ethnographic data and comparative archaeological data are used to further examine what these patterns in Maya ceramics may mean.

Power and Purpose: The Role of Animals in Ritual Context at a Mid-Continental Site in the Fourteenth Century

A variety of ritual contexts are documented at the Oneota and Mississippian Morton Village site and the associated Norris Farms Cemetery in Fulton County, Illinois. These include multi-scalar mortuary contexts, communal ritual structures, and smaller domestic-related facilities. Animal remains from both food and faunal tools, along with artifacts that are imbued with animal symbolism, were found in each context. This paper explores the variability and looks for patterning of animal use within these ritual contexts to better understand the linkages between animals and religion within a social context of ethnic interaction and cultural negotiation.

Bevin, Amanuel (University of Louisville), Hong Wang (Illinois State Geological Survey, Prairie Research), Mary Prendergast (St. Louis University, Madrid) and Katherine Grillo (University of Wisconsin–La Crosse)

Lake Turkana in northern Kenya has played a central role in generating archaeological and paleoclimatic datasets relevant to studying key transitions in human prehistory. Generally, despite its rich Plio-Pleistocene hominin fossil record, the later prehistory of the basin, particularly the period between 50 and 10 ka, remains comparatively underexplored. In this paper, we discuss new radiocarbon dates from two recently excavated sites in West Turkana, namely Kokito 01 (GcJh11) and Kokito 02 (GcJh12). The sites span the terminal Pleistocene and early Holocene (14–10 ka), a time of substantial ecological and cultural changes globally. Site chronologies are interpreted with reference to fluctuating lake levels during the African Humid Period. Well-dated sites from this timespan are scarce in the Turkana Basin, and the new radiocarbon dates are important for establishing human settlement history and associated cultural developments in the region during shifting climatic conditions at the Pleistocene-Holocene transition.

Bezy, Philippe

Maya Shell Trumpets: An Interpretive Pivot

For the ancient Maya, the use of music was often depicted as central to ritual activity. One of the longest lasting instruments, the shell trumpet, provides ample material for analysis. My three-pronged interpretive approach is made possible by the shell’s use in ancient ritual contexts, its appearance in Classic era iconography, and its organic origins. Archaeologically provenanced trumpets, for example, yield deposition data, while art historical methods address both unprovenanced trumpets and their depictions in Maya art. Malacological information about marine mollusks and their ecological niche offer a supplementary layer to interpretive efforts that impacts our understanding of ancient Maya shell selection. The conjunction of the three approaches emphasizes the ritual function shell trumpets fulfilled and further indicates an association between specific species and specific ritual practices. What is more, some examples suggest a concerted effort to coordinate the species chosen with other ritually important components like directionality and color.

Biagetti, Stefano (CaSEs—Univ. Pompeu Fabra [Barcelona, Spain])

Remote Sensing for Late Holocene Archaeology in Central Sahara: A Multi-Scalar Approach
At the end of the African Humid Period (c. 5,000 years ago), the Sahara became dry. Yet, in spite of the onset of current arid conditions, human societies found successful strategies to cope with reduced rainfall and patchy natural resources. Archaeological evidence from the arid Sahara, dated from the last five millennia, can be studied by means of Earth Observation techniques. In this paper, we will present the results of our research from central Sahara, aimed at the remote reconstruction of the geomorphology, environment and archaeology of selected areas. We will focus on multiple-resolution remote sensing based upon multispectral and panchromatic imagery (e.g., Corona, Landsat, ASTER, Worldview) to understand the development of cultural trajectories in arid lands, complementing data collected from previous fieldwork and implementing the knowledge of currently inaccessible areas.

Bicho, Nuno (Universidade do Algarve) and João Cascalheira (ICArEB—Universidade do Algarve)  
[389] A Critical Review of the Meaning of Short-Term Occupation in Early Prehistory
One of the main elements in prehistoric research is the study of settlement patterns. In the last five decades, stemming partially from Binford’s research on the topic, the idea of settlement is based on site typology, including the traditional residential and logistic concepts. The latter is certainly marked by the notion of short-term occupation. This concept, used freely by many archaeologists, tends to rely on two main ideas—that of an occupation lasting a short span of time, and subsequently resulting in a limited amount of material culture. Our aim, based on various archaeological case studies from the Stone Age records of Portugal and Mozambique is to show that neither idea is necessarily correct (i.e., there may be short-term occupations with the production of large amounts of artifacts such as lithic workshops; there might be very small collections, such as lithic caches, resulting from short occupations but with very long uses of the site; and most times both are hardly differentiated within complex palimpsests). We will present a critical review of the definition of short-term occupation in Prehistory and will try to define both the criteria for definition and the concept of short-term occupation in the archaeological record.

[136] Ritual Power and Politics in Mesopotamia
In times of political and societal instability public ritual acts as a stabilizing force. During the first millennium BCE with the rise and collapse of several powerful empires, ancient Babylonia witnessed much of this political turmoil and instability. Kings of each succeeding empire appropriated long-established Mesopotamian religious ideology to cast themselves as divinely selected rulers. They manipulated the celebration of the akitu, a twelve-day religious New Year’s festival, to legitimate and gain popular support for their rule and to stabilize a declining society. Despite the social and economic problems facing a collapsing empire, political power expressed via the religious rituals of the akitu festival, displayed the new ruler’s ideology as divinely sanctioned, and therefore normative to Mesopotamian society.

Biehl, Peter F. (SUNY Buffalo) and Arkadiusz Marciniak  
[95] The Entanglement of Nature and Culture in the Neolithic and Chalcolithic of Central Anatolia: The Transition of Çatalhöyük East to West
Prehistoric communities need to be seen as firmly embedded in their ecosystem and landscape where the nature is a very real factor in the decision making processes. The human-environmental relationship is complex and nonlinear, which different societies shape it in variable ways. Responses to nature are always of social character made of a number of intertwined explicit and implicit elements. They ultimately have far reaching consequences for the condition of any group including a survival in the face of food shortage or lack of critical resources. The entanglement and nature and culture becomes particularly complex in a period of climate change such as the 8.2k cal BP climatic event. This paper argues that how humans respond to climate change plays a crucial part in the formation of society. Çatalhöyük offers a microcosm that may help us unlock some of the key questions surrounding the period of the transition from the East to West mound around 6000 cal BC. By revealing the entanglement of nature and culture on a microscale, the paper aims to investigate the character of this major threshold in the development of Anatolian societies of that period from a hitherto unexplored perspective.

[71] Material Culture Correlates of Polity Restructuring and Decline: Changes in Ceramic Production and Use at the End of the Late Classic Period in the Copan Valley
Features of material culture can be actively constructed and transparently manipulated to various sociopolitical ends, with the installation of elaborate monuments and possession of ornate goods making bold statements of power and authority. While other more common elements of material culture may provide perhaps less conspicuous commentary on the “state of the union,” they can also be equally symbolic of the conditions under which they were created. This paper examines the material culture (specifically, ceramic) correlates of the Copan polity’s decline at the end of the Late Classic period and what specific patterns of ceramic production, distribution and use may reveal about the effects of the sociopolitical, economic and demographic changes that characterize this era of Copan’s history.

[339] Insights into Prehistoric Footwear Landscapes

In earlier research, we used Promontory moccasins dimensions to chart predictable relationships concerning moccasin length, foot length, stature and age. A high proportion (83%) of the discarded moccasins in the Promontory caves came from children and subadults. While a discard bias concerning adults males (who were likely to discard moccasins outside of domestic contexts) must be acknowledged, the predominance of children and subadults suggested the presence of a growing population, consistent with other data suggesting that Promontory Culture peoples flourished in comparison to their terminal Fremont neighbors. The precision of the Promontory formulae in predicting stature and age from moccasins can be employed in assessing site function for a variety of footware instances, including the Yukon ice patch moccasin from an area in or near the Proto-Athapascan homeland, Franktown Cave in Colorado, Kenton Caves in Oklahoma, and Ross Rockshelter and Daugherty Cave in Wyoming. We also contrast our findings with other large assemblages of footwear, including sandals from Antelope House in Arizona. The presence of children or subadults informs our understanding of the nature of different sites, suggesting occupations by small residential groups in some cases and individual larger moccasins consistent with migratory activities like adult male scouting in others.

[273] Rock Art Site Protection: Lessons Learned in 50 Years of Trying

The shared attributes of two successful rock art site preservation projects near metropolitan areas will be discussed. They started with different backgrounds. The Adams School Site (now Chitactac-Adams Heritage County Park) in California was a neglected and vandalized park whose property had been donated. Picture Canyon (now Picture Canyon Natural and Cultural Preserve) in Arizona was neglected State Trust land being used as an illegal dump that needed to be purchased to become a preserve. Both projects benefited greatly from proactive public servants and volunteers who were dedicated to preservation goals. They partnered with Native American communities, documented their resources first, worked with conservators, and held public meetings to educate the stakeholders. They applied for grant funding, met with decision makers on all levels—local, state, and federal, and had perseverance to jump through all legal hurdles. Picture Canyon benefited from a successful National Register of Historic Places nomination, and matching grants from Arizona Growing Smarter and Flagstaff Open Space funds, while Chitactac-Adams benefited from an Intermodal Surface Transportation Act grant. Projects that failed were located within multiple jurisdictions where no one took the lead, had a lack of funds, and/or people who cared.

[219] Life in Times of Change: A Bioarchaeological Perspective on Health and Living Conditions in Upper Nubia in the Late Second and Early First Millennium BC

With the end of the Pharaonic Egyptian colonial occupation c. 1070 BC and the increasing deterioration of climatic conditions, communities in Upper Nubia faced significant changes, both to the political structure (which may have affected trade networks), and to the agricultural potential of the region (e.g., availability of arable land). This presentation aims to elucidate if, and in what ways, these alterations impacted upon the living conditions of the people in the area, using the skeletal human remains from the cemeteries of the colonial administrative center at Amara West (N = 180). Analysis of markers of physiological stress and disease (stature, orbital changes, dental disease, nonspecific infection, respiratory diseases, endocranial changes, trauma, osteoarthrits), and oxygen and carbon isotopes, are complemented by contextual data drawn from the cemeteries, settlement and surrounding habitat. Despite limitations due to the bias in sample size, a systematic analysis reveals several tentative trends such as decreasing stature, increased levels of osteoarthrits, dental pathologies, pulmonary diseases, post-cranial fractures and higher subadult mortality. Embedded within the environmental, isotopic, historic and archaeological data, they point to an overall degeneration in living conditions of the population reflecting the impact of severe changes to the environmental, settlement structure and subsistence affecting the region.

Binning, Jeanne (California Department of Transportation)

[100] Identifying Pressure Flakes in Lithic Assemblages

Most lithic technologists would agree that pressure flakes cannot be reliably identified in debitage assemblages by their size and morphology. Analysts using fractography have had success identifying pressure flakes by determining crack velocity via microscopic features on the ventral surface. However, this technique is time-consuming and is most successful on glassy materials. Native Americans of the western continental United States, extensively used one pressure flaking technique for 8,000 years. This pressure flaking produces flakes that are diagnostic of the approach. The distinctiveness of these flakes provides a means of identifying pressure flaking in the Holocene archaeological record of the western United States.

Birch, Jennifer (University of Georgia)

[277] Settlement Scaling in the Northeastern Woodlands

In the late precontact Northeastern Woodlands, processes of aggregation, migration, and geopolitical realignment led to the formation of settlements which give the impression of being too large to be called villages but possessed organizational structures associated with segmentary societies. This paper utilizes empirical data generated from Iroquoian community plans to present a study of scaling relationships in Northern Iroquois. The results are then considered in the context of the historical development of Northern Iroquoian societies and ongoing considerations of how settlement scaling theory can be applied to aggregations in middle-range societies which were clearly not urban in scale.

Bird, Douglas [302] see Price, Michael

Birge, Adam (University of Texas at San Antonio)

Ritual trails and geoglyphs in the Andes date back as far as 400 BC and are perhaps best represented in the Nasca lines and the ceques of Cusco. In western Bolivia, the Sajama lines are a network of ritual trails that cover an estimated 22,000 km² and connect pucaras, chullpas, villages, and chapels. Although this ritualized landscape was heavily modified during the Colonial (1532–1820) and Republican (1821–1952) eras, these pathways had prehistoric use by the local Carangas. These lines may have facilitated social and ritual behaviors but also allowed for negotiation of Spanish and Inca colonization. Understanding these pathways and their features and artifacts allows for inferences to be made about the creation and change of social, political, and ritual life. In this paper, I present a model for investigating the material remains of the Sajama lines that would allow it to be comparable to other ritualized landscapes. This model was based off of a pilot project in 2015 where I identified and surveyed a group of nine ritual pathways around the mountain of Nevado Sajama. This model will be applied to a larger sample of the Sajama lines in future fieldwork.

Birkmann, Joseph and Michael W. Graves

Resiliency in Hawaiian Irrigated Agricultural Systems: A GIS Approach

Precontact Hawaiian agriculturalists created irrigated cropping systems of considerable complexity across all of the Hawaiian archipelago. While many of these systems are concentrated in short but broad alluvial valleys, the windward coast of the big island of Hawaii presents a unique hydrological landscape. Here the geologic youth of the island presented Hawaiian agriculturalists with a landscape dominated by relatively small, narrow gulches with limited space for cultivation and a propensity for flooding. This paper examines issues of resilience and stability in small-valley irrigated agricultural systems using high-resolution lidar data and advanced techniques in GIS-based hydrological modeling. We will attempt to evaluate the role of extreme flooding events in influencing decision making and maintenance needs within the various drainages of the windward Kohala peninsula. In doing so we emphasize the utility of adopting a regional approach to landscape based analysis, as well as the analytic possibilities of high resolution GIS data for assessing ecological resiliency in agricultural systems.

Bischoff, Robert

A Spatial Analysis of San Juan Red Ware Using Least Cost Paths

A fundamental part of interaction is distance. Distance can be calculated in many ways. GIS applications allow the calculation of least cost paths between locations. Often the length of this path is used as the distance between points; however, the amount of time it takes to traverse a path may differ for paths with the same length that traverse different topography. In this poster, I use the distribution of San Juan Red Ware in a portion of the southwestern United States to examine the differences between using Euclidean distance, the length of least cost paths, and the length in time of least cost paths. San Juan Red Ware was produced in southeastern Utah between approximately AD 750 and 1100 and was widely traded.

Bishop, Katelyn

Social-Ceremonial Organization, Ritual Practice, and Ritual Use of Fauna in Chaco Canyon, New Mexico

Chaco Canyon, located in northwestern New Mexico, is widely believed to have formed the religious, economic, and political core of a large regional network that thrived during the Pueblo II period. However, debate continues to surround Chacoan ceremonial and sociopolitical organization. One approach to understanding the social-ceremonial organization of Chacoan great houses is through an understanding of the nature of ritual practice and the scales at which it was organized. Pueblo peoples, past and present, have incorporated animals into ritual practice, with a special emphasis on avian fauna. Given the well-documented ceremonial importance of animals, explorations of the use, treatment, and spatial distribution of their remains can inform researchers’ understandings of past ritual behavior. This poster examines ritual practice through an analysis of articulated faunal burials and avifaunal remains at several great house sites in Chaco Canyon. Relying upon excavation records made available through the Chaco Research Archive, we investigate the nature and significance of these remains, their associated materials, and architectural settings. Through the consideration of the differential contents and contexts of structured deposits containing faunal material, we address the flexible negotiations of social relationships that existed at great house sites in Chaco Canyon across space and time.

Biskos, Michael

Paleolithic Survey on the Upper Luangwa Valley, Zambia

The northern half of the Luangwa Valley, Zambia, a southern branch of the East African rift system, is archaeologically unexplored territory in an area that may have served as an important biogeographic corridor between eastern and southern Africa during the Plio-Pleistocene. This paper summarizes the first systematic survey in this region. Paleontological reconnaissance in 2013 incidentally revealed multiple Paleolithic sites which may range from the Acheulian through the MSA. Representative artifact samples from sites are described, their age estimated based on techno-typological criteria, and the potential of the area for future excavation and/or landscape archaeology is assessed.

Bisulca, Christina

Characterization of Minerals on Hohokam Palettes

Hohokam palettes are a unique artifact found at several important sites in southern Arizona. The Arizona State Museum (Tucson) has an extensive collection of Hohokam palettes from Gila Bend dating from the Santa Cruz and Sacaton periods (AD 850–1150). Most of these palettes have white lead-containing minerals on the surface. This project aimed at characterizing the composition and isotope signatures of these minerals using noninvasive and minimally destructive methods, including multi-collector ICP-MS, XRF, Raman spectroscopy, and VP-SEM/EDS. The lead-containing accretions were
characterized as a mixture of ground galena ore with white clay and/or calcite, and several explanations for this will be discussed. Isotopic analysis of the lead on the palettes indicates that the same lead source was exploited throughout the region; lead from this same source was also found at Valshni Village, a Hohokam site in southern Arizona, indicating movement of lead throughout the region. There have been many proposed uses for palettes in Hohokam culture. This mineral identification supports Haury’s early theory that these palettes were used for pigments.

Biwer, Matthew (University of California, Santa Barbara)
[230] Preliminary Results of Paleoethnobotanical Analysis at Quilcapampa, a Middle Horizon site in Arequipa, Peru
In this poster I present preliminary results and interpretations of paleoethnobotanical investigations at the site of Quilcapampa, located in the Sigua Valley, Department of Arequipa in south-central Peru. Recent AMS radiocarbon dates indicate Quilcapampa was occupied for a short period during the mid-eighth century AD, which places the site within the Middle Horizon (AD 600–1000). Based on site architecture and ceramic evidence, the site may represent a colonial installation of Wari Empire (AD 600–1000) in the region, though further analysis is needed to characterize the relationship between residents of Quilcapampa and the Wari Empire. As relatively little is known about Middle Horizon foodways in the Sigua Valley, this poster provides preliminary macrobotanical (desiccated/carbonized plant remains) and microbotanical (starch grains and/or phytoliths) data excavated during the 2015 summer field season. While these results are preliminary, they represent a first step in characterizing knowledge of Middle Horizon foodways for the region and may add to our understanding of Wari foodways and colonialism.

[365] Mica Symbolism from a Late Irene Mortuary Site
Recent excavations at the Fallen Tree Mortuary Complex (9U18) on St. Catherines Island, GA have recovered over 20 shaped mica artifacts and dozens of fragments associated within three Late Mississippian adult male burials. This nonlocal material was purposely shaped and interred with the individuals. In this poster, I will discuss what the symbolism of the mica and examine the location and orientation of the mica discs on the individuals. In addition, I will compare the mica to several other artifacts types that may have overlapping symbolism within the site.

[21] Investigating Hunter-Gatherer Earth Oven Intensification: a view from the Lower Pecos Canyonlands
Foraging societies in the semi-arid Lower Pecos Canyonlands of southwestern Texas intensified the use of desert succulents over a span of 9,000 years or more for food, fiber, and other uses. Food plants including Agave lechuguilla, sotol, and prickly pear were baked in earth ovens with stone heating elements, an iterative process that left massive residual by-product in the form of fire-cracked rocks and burned and unburned plant refuse in and around baking facilities. The archaeological signatures of earth oven cookery are pervasive and found in almost all settings in the region including open sites in the uplands and river terraces and protected rockshelters in the canyon walls. We have developed a systematic strategy focusing on stratigraphic excavation, 3D modeling, rock quantification, geoarchaeology, radiocarbon dating, and macrobotanical identification to document earth oven cookery at two dry and two wet rockshelters in Eagle Nest Canyon, a short box canyon off the Rio Grande. The resulting data offer an unparalleled look at this characteristic form of landscape intensification. This presentation highlights the archaeological context, our methodological approach and results to date.

[318] Activist Archaeology and Queer Feminist Critiques in Mesoamerican Archaeology
One of the strengths of prehistoric archaeology is its ability to document the full range of human variation. For Latin America, activist archaeology has the potential to inform postcolonial and Third World feminist critiques that challenge white supremacist legal systems that marginalize women of color and indigenous peoples. The false universalisms and cultural essentialisms found in human rights debates ignore the diverse experiences of women’s oppression, especially the indigenous, poor, rural, disabled, and queer. Hegemonic models of the Mesoamerican past naturalize the oppression of women by employing colonial narratives regarding sex, gender and sexuality. The advocacy and activism of present day feminist archaeologists focus on decolonizing the discipline by documenting the fluid and contextual nature of precolumbian sex/gender systems, and demonstrating the agency and power of indigenous women in politics, religion and reproduction. In this paper, we ask the following questions: how do modern assumptions around sex, gender and sexuality find their ways into archaeological discussions of ancient Mesoamerican states? How do these narratives then become naturalized into discourses that perpetuate homophobic, sexist and racist legal systems? How can activist archaeology in Latin America both transform the discipline and potentially inform modern political debates?

[379] Linking Beads, Linking People: A Social Network Approach to Exploring Identity in the Colonial Southeast  
Beads and other ornaments were important objects involved in early colonial entanglements between Europeans and Native Americans, with the color, texture, and physical properties of these objects fostering the embodiment of new social roles within changing colonial worlds. In this paper I discuss how such objects were involved in the material manifestation of social identities as pluralistic native communities aggregated in the Spanish missions of La Florida. Looking specifically at the aggregated population of Mission Santa Catalina de Guale, a seventeenth-century mission located on St. Catherines Island, Georgia, I use the methods of social network analysis (SNA) to explore how mission neophytes utilized European glass trade beads to both foster the persistence of social identities and to create new communities in the context of population aggregation. Presenting a bipartite network reconstruction of the Santa Catalina community, I discuss how both individuals and objects of adornment acted together to materialize changing colonial identities.

Blakeslee, Donald (Wichita State University)  
[345] Etzanoa: A Northern Caddoan Town  
Documents associated with the Juan de Oñate expedition of 1601 allow identification of the proto-Wichita (Quiviran) town that he visited. Described by natives as taking two or three days to walk through, the Spanish saw only parts of it. Still, they counted 1,700 to 2,000 houses in the southern end of the community, which was described as about two leagues (five miles) long. Above that point, the Spanish traveled away from the river for another three leagues, and when scouts returned to the river, they reported that the town “continued on” upstream. Today, the archaeological record of the town consists of over 25 separate recorded sites strung along about 14 river miles, with unsurveyed ground between them. The town consisted of clusters of houses 30 to 40 houses each, separated at distances of 300 to 400 paces by agricultural fields. Survey between recorded sites has begun, and eventually it may document this as the largest prehistoric site in the United States.

[233] Faces of the Feast: The Spatial Organization of Face-Neck Jars in the Jequetepeque Valley, Peru  
Chicha was consumed in large quantities during social gatherings and feasting events at a number of ceremonial locales including hinterland sites, in the Jequetepeque River Valley, Peru, during the Late Moche. Face-neck jars were used in the brewing and serving of corn beer and depict supernaturals and elite lords with elaborate headaddresses and earspools. This research showed the degree to which face-neck jars were standardized in manufacture and design and how this may have contributed to the materialization of a regional Moche identity that possibly transcended sectarian social and political differences. The faces were impressed on the necks of the vessels with the use of one-piece molds and formed part of a shared manufacturing technique in a river valley that was characterized by political and religious decentralization. At San lidefonso the use of these standardized Moche wares depicting male elites and supernaturals appears to have anchored the feasting rites of separate but possibly confederated communities. This made chicha production central to the political and ritual economies of ancient Andean polities, and the face-neck jars likely symbolized the generosity of local lords who sponsored feasts and religious events.

[370] Unraveling Global and Local Ceramic Production Networks: An LA-ICP-MS Analysis of Ceramics from Barbados, Jamaica, and Great Britain  
A wide variety of ceramics are recovered in plantation contexts on Barbados and Jamaica, from hand-built coarse earthenwares to refined tablewares, as well as industrial wares for sugar production. The origins for these ceramics are often uncertain. In addition to the importation of ceramics from Great Britain and elsewhere in the Americas, many potters and workshops existed on the islands to produce both quintessentially Caribbean pots as well as European-
style vessels. To better understand this complex history and ceramic distribution, we present the results of elemental analysis of 250 coarse earthenwares from plantations on Barbados and Jamaica, analyzed via LA-ICP-MS. These results demonstrate how ceramic sources for both locally made wares and imported wares changed over time within Trent's Plantation on Barbados, and across multiple plantations on Jamaica. Through this analysis, it becomes possible to visualize the overlapping production networks, from global to exceedingly local, that generated these diverse ceramic assemblages.

Blomster, Jeffrey (George Washington University) [391] Inscription, Replication, and Production of Olmec Imagery and Regional Identities
The Early Formative period exhibits dramatic transformations in imagery and identity throughout Mesoamerica. Focusing on a time period before techniques for mold made and mass produced objects had been achieved, this paper explores replications that involved copies, iterations, and emulations of designs and imagery. At select sites in Mesoamerica, objects have been documented with Olmec-style imagery, some of which have been linked to the Gulf Coast Olmec society; in most cases, the Olmec imagery forms a minor component within a larger panorama of regional design systems. Excavation data from Etlatongo, in the Mixteca Alta of Oaxaca, Mexico, contribute to understanding the cultural impact of the replication of imagery by looking at four classes of ceramic data: vessels, figurines, masks, and cylinder seals. Focusing on contrasts between imported originals and locally made replicas revealed through chemical compositional data, this paper explores the various techniques deployed to craft imagery and the media through which different designs were inscribed on objects and bodies, exploring the salient impacts on social identities. While some objects could have been employed for the mass replication of imagery, in other cases, imagery and identity were constructed and negotiated through more variable and contested means and techniques.

Blong, John (Texas A&M University) [371] Prehistoric Landscape Use in the Upper Susitna Basin
This paper presents the geomorphological and paleovegetation record of the upper Susitna River basin in the central Alaska Range, and discusses late Pleistocene and Holocene landscape and vegetation change and how this affected human use of this upland landscape. Geomorphological data suggest that the last significant glacial ice sheet covering the upper Susitna basin receded by 14,000–13,000 cal BP. Following deglaciation, there is evidence for high-energy aeolian activity spanning the late Pleistocene and early Holocene. There are at least three Holocene tephras recognized in the upper Susitna basin. Initial human occupation occurred by 11,000–10,500 cal BP, at least 2,000 years after the end of full glacial conditions, and 1,000 years after first evidence of landscape recovery. Initial early Holocene use appears to have been ephemeral, but human activity in the study area intensified in the middle and late Holocene as modern vegetation patterns were established. There are preliminary indications that vegetation may have been affected by Holocene tephra fall. There is evidence for a hiatus in human occupation of the upper Susitna region during the middle Holocene, but it is unclear whether this was directly related to tephra deposition, or broader climate instability during the Neoglacial Period.

Blue, Kathleen (Department of Anthropology, Minnesota State University, Mankato) [120] Migration and Interaction in the Epiclassic of the Tula Region: Preliminary Data as Evidenced by Dental Nonmetric Analysis
Dental nonmetric data provide a means for the analysis of genetic affinities and relationships of individuals, and can therefore be used to reconstruct past migration and interaction patterns, both within and between sites. The dental traits of 16 individuals, along with 21 individual teeth, from Cerro Magoni, an Epiclassic site in the Tula region, were collected in this preliminary analysis. Additionally, 13 individuals from two Xajay sites, El Zethe and Huesamenta, were also assessed. The collected traits are previously defined dental nonmetric traits of the deciduous (n = 8) and permanent (n = 29) teeth. Teeth are ideal for this type of assessment as they are more likely to be preserved and are under tighter genetic control than the cranium or postcranium, and are less prone to environmentally induced variation. Multivariate analysis of principal components (PCA), following Irish and Guatelli-Steinberg (2003), provides the clearest picture of genetic relatedness, or lack thereof, among the individuals/sites in this study. In addition to the nonmetric analysis, data on the dental health of the individuals will also be presented. Very little evidence of stress-related dental enamel hypoplasis was present, but several individuals suffered from significant periodontal abscesses. Evidence suggesting extra-masticatory activities involving the teeth was also common.

Bobolinski, Kathryn (University of Montana) [50] A Zooarchaeological Analysis of Housepit 54 at the Bridge River Site (EeR1), Middle Fraser BC
Housepit 54 at the Bridge River pithouse village in south-central British Columbia provides a glimpse into the complex cultural practices that occurred at this area in the past. This village, which includes approximately 80 semi-subterranean structures, was occupied during four periods, approximately 1800–1600 cal. BP (BR 1), 1600–1300 cal. BP (BR 2), 1300–1000 cal. BP (BR 3), and 610–45 cal. BP (BR 4), firmly placing the site within both a historic and a precolonial context. It is situated in the Middle Fraser Canyon region of the Canadian Plateau, which encompasses the Fraser and Bridge
Rivers as well as the adjacent talus slopes, terraces, mountains and high valleys. The Mid-Fraser offers a plethora of fauna that could have been exploited spanning fish to large ungulates. This study incorporates data from the 2013–2016 excavations at Housepit 54 to examine the zoological remains in order to test alternate hypotheses regarding relationships between animal predation, processing strategies, household population and social dynamics.

Bocherens, Hervé (University of Tuebingen), Dorothée Drucker (University of Tuebingen, Germany), Martina Láznicková-Galetová (University of West Bohemia, Czech Republic), Mietje Germonpré (Royal Belgian Institute of Natural Sciences, Bruss) and Christoph Wissing (University of Tuebingen, Germany)

Isotopic Tracking of Trophic Relationships (Predation, Competition, Commensalism) between Paleolithic Humans and Predators

Predators are usually considered not so informative in zooarchaeological investigations, except when their bones carry cutmarks. They are more viewed as a disturbing factor for the bone assemblage. However, tracking their paleoecology using stable isotopes in their bones can yield valuable information on several key aspects of their relationships with paleolithic human populations. Especially carbon and nitrogen stable isotopic composition in bone collagen of predators compared to those of humans and the available prey species can be used to quantify proportions of consumed prey through Bayesian mixing models. This novel approach allows an evaluation of competition or niche partitioning between large predators such as wolves, cave lions and cave hyenas, and Neanderthal or modern humans between around 50,000 and 8,000 years ago. Moreover, the possibility to determine which predator had access to which prey can tell us about availability of large mammal carcasses, in the case of mesopredators unable to hunt large prey themselves, and possibly document cases of commensalism between small predators (e.g., fox, wolverine) and human settlements. Finally, stable isotopic investigations can provide a crucial contribution to the debate about domestication of wolf during pre-LGM Paleolithic in central Europe.

“Constraint and Freedom” in the Era of Big Data

Twenty-seven years ago, Bruce Trigger presented a “new synthesis of archaeological explanation,” seeking to harmonize neo-evolutionary explanations dominant in the 1970s with sociohistorical perspectives of the 1980s. Central to his thesis was the distinction between “external” constraints that structure human agency independent of humans themselves, and “internal” constraints that are historically and culturally constructed. Here, I critique Trigger’s formula by acknowledging that even external constraints have histories, and I propose a useful classification of structural constraints as “static,” “dynamic,” and “complex.” The Era of Big Data in archaeology has enabled us to identify and test the importance of structural constraints on human behavior at unprecedented spatial and temporal scales and across traditional cultural boundaries. As an example, I present new data that define complex structural constraints on maize agriculture in the southwestern United States and northwestern Mexico—the evolution of traditional maize landraces—and I attempt to use these data to track the relationships between contemporary and ancestral Pueblo people via their corn. These data are presented as part of SKOPE—Synthesizing Knowledge of Past Environments—an initiative to deliver “big” paleoenvironmental data to researchers and the public.

Attempt of Modelization of the First Settlements in America at Pleistocene Based on the New Archaeological Sequences in Piauí (Brazil)

The research teams are conducting the park of Capivara in Brazil since 2008 lead to reveal 6 new Pleistocene archaeological sequences. The sites are all located within a 20 km area and stem from different sedimentary and topographic environments including open air, rockshelter, cave at the bottom of cuesta, or in karst. Each of the sites shows different sedimentary sequences, including different archaeological horizons and different typotechnical compositions. The dating that we have obtained by crossing C14, TL, and OSL data lead us to identify accurately each of these archaeological sites, hence permitting to attempt a comparative approach with the major climate changes observed during the isotopic states 2 and 3. Based on this study, at a large-scale reading, there is no evidence of a correlation between major climate changes and periods of occupation. Nevertheless, we can notice a concordance of vacancy within the group of investigated sites. Technically, those vacancy periods correspond to clear technical changes. All those observations reflect the fact that our region of research witnessed different Pleistocene occupations beginning from isotopic states 2 and 3.

Bogemanns, Frieda, Rindert Janssens and Cecilie Baeteman

Unearthing Holocene Lowland Landscapes as Tool to Detect Archaeological Sites: A Case Study from Lower Khuzestan (SW Iran)
Over the past century, archaeological research in Upper Khuzestan has shown a long history of settlements in the alluvial plains. The Lower Khuzestan plain has barely been studied with research that has restricted to superficial surface surveys. The nearby presence of the Persian Gulf and the downstream parts of the rivers Karun and Jarrahi, the first one being the largest river in Iran, offer great potential for human settlements and activities. In lowlands, however, processes of sedimentation inevitably bury former landscapes, and therefore make geological investigations crucial for understanding the location of archaeological sites. Knowledge of the processes provides insights into the environmental nature, the impact of geomorphological events, and the chronological framework. The southwestern part of the Khuzestan plain, northeast of Khorramshahr will be presented as case study. The study shows the effects of both terrestrial and littoral processes on the nature of the sedimentary environments, the influence of the Holocene transgression on the sedimentary environments and, the effect of external forces on the dynamics of the sedimentary systems and landscapes.

Testing the Robustness of NISP and MNE: Results of a Blind Test

Archaeozoologists generally consider that counts are replicable data accurately representing the initial abundances of elements, individuals or taxa. However, few studies have examined these assumptions with control data. To test the robustness of NISP (Number of Identified Specimens) and MNE (Minimum Number of Element) counts, we conducted a blind test that involved the analysis of two large experimental samples composed of known red deer (Cervus elaphus) and cattle (Bos taurus) elements. The two samples differ in fragmentation levels, ranging from simple marrow extraction to extensive comminution for bone grease rendering. Our results suggest that NISP and MNE are accurate and replicable measures of abundance for whole assemblages and for samples limited to non-long bones, even at the ratio scale. However, when analyses were restricted to long bones or long bone portions, both quantification methods poorly predicted abundances, including the ordinal level. Moreover, the blind test indicates that MNE is more robust at predicting skeletal abundances than NISP. The poorer performance of NISP in the blind test probably results from substantial variations in rates of long bone fragmentation and identification.

Settlement Organization of Paleoindian Caribou Hunters: Inferences from the Israel River Complex, Jefferson, New Hampshire

A long-term research project in northern New Hampshire has identified nearly 20 Paleoindian components within a 1 km by 0.5 km space overlooking the Israel River. Consideration of the spatial distribution of tools and debris within the components and the distribution of these components on the landscape suggest a rigorous organization of migrating bands of Paleoindians who focused on caribou hunting. Site specific topography appears to be an essential element in the selection and use of various components in the cluster of sites.

Island Colonization and Ecological Transformation in Prehistoric Eastern Africa

Until recently, the small islands lying off the coasts of Tanzania and Kenya have seen little systematic archaeological investigation. Their biogeographic diversity, reflecting various processes and chronologies of formation, nonetheless offers an ideal opportunity to examine processes of prehistoric colonization and anthropogenic impact. We explore the earliest evidence for human activity on three different islands, Pemba, Zanzibar and Mafia, and provide the first evidence for early human alterations of these island ecosystems. While the datasets remain preliminary, we are able to show that the types of anthropogenic impacts also seen on other regional island systems, including extinction, extirpation and habitat alteration, were also a feature of early settlement in island east Africa.

Analysis of Easmobranches from Offerings 126, 141 and 165 Found at the Great Temple of Tenochtitlan

Numerous fish from diverse species have been found inside the Great Temple offerings. These were transported from the coast to Tenochtitlan. During the seventh field season of the Templo Mayor Project, five sawfish rostra were found inside three offerings. By analyzing macro and microscopic structures, and through the comparison with modern specimens from the Ichthyology Collection of the Institute of Marine Sciences and Limnology, at the National Autonomous University of Mexico, these animals were identified as Pristis pectinata y Pristis pristis. Nowadays, these fish are distributed in the Gulf of Mexico, the Caribbean coast and the Mexican Pacific Ocean. Individuals selected by the Mexica priest were adults, measuring almost 4 m in length. Contemporary specimens are no longer of this size, since the species is in critical danger of extinction, worldwide. Through a biological and an archaeological analysis, this paper contributes to getting a better understanding of elasmobranch biodiversity during prehispanic times, as well as their use, symbolism and importance.

Bolnick, Deborah [344] see Hard, Robert

Bond, Julie [224] see Maher, Ruth

Bondura, Valerie (Columbia University)

Borders often imply two-dimensional lines on a map, a naturalized “over here” and “over there.” This is reified in places where political boundaries appear to follow ecological ones. But the nature of these lines, even apparently clear environmental ones, is always arbitrary, and the recognition of
these lines is always dependent on subject position. The word “frontier” highlights this politics of definition and recognition; frontiers are defined in history and anthropology as the edges of colonial projects, and thus frontiers are recognized and experienced differentially. Drawing on several seasons of fieldwork in northern New Mexico, I discuss the ontological problem at the heart of studying ecological and political frontiers in archaeology. I seek to understand how ecological and cultural difference across space was conceptualized and experienced by examining a location that was a frontier for some (Spanish, American) and a center place for others (Pueblo, Jicarilla Apache, vecino). I look to historic ceramics and other materials to understand how the Sangre de Cristo Mountains along the Rio Grande Gorge corridor were simultaneously a border and a center, and suggest that these archaeological remains speak to the inherent tension in the overlap of marginal/central places.

Bone, Christopher (University of Oregon) and Ha Beom Kim (Department of Anthropology, University of Oregon) [24] A Landscape-Scale Spatial Analysis of Neolithic Settlement Patterns in Jeju Island, Korea

Intensive archaeological research in Jeju Island, Korea, conducted over last three decades have produced a rich set of spatial data on archaeological sites and feature distributions across the island. While these spatial data have high potential for improving archaeological understanding of past human activities, a systematic analysis of spatial data from Jeju has yet to be fully undertaken by archaeologists. In this study, we employ spatial analysis on high-resolution topographic data to enhance our understanding of landscape-driven subsistence strategies and settlement patterns. While we limit our scope to Neolithic data for this study, we anticipate that spatial analysis will contribute to a long-term understanding of human-environmental interactions on the island.

Bonham, Katie Mchugh, Christymynn M. Darwent (University of California, Davis) and John Darwent (University of California, Davis) [257] A Thousand Years of Bone-Tool Production at Shaktoolik, Alaska

Osseous tools and debitage collected from three middens at the Shaktoolik Airport site during excavations in the summers of 2014 and 2015 were analyzed using the chaîne opératoire rather than a typological approach to assess site use over time. Relative frequencies of raw materials, tool types, and production debris were analyzed from different periods. The Early Thule/Proto-Yup’ik portion (ca. AD 1200) of the assemblage came from a midden associated with a men’s house (qasgiq), and is characterized by high relative frequencies of specialized tools production debris. Samples from later middens deposits had considerably less manufacturing debris than the men’s house. Midden samples from Late Thule/Proto-Yup’ik (ca. AD 1400–1600) are lacking in sea-mammal bone as a raw material but have a high relative frequency of caribou bone and antler. However, Late Prehistoric Yup’ik samples (ca. 1700–1800) have high frequencies of sea-mammal bone for tool production. This difference was initially hypothesized to be the result of climatic changes, but more likely is due to differences in the season of occupation. The Historic Iñupiaq midden sample has a lack of hunting/fishing tools but presence of more exotic materials and nonutilitarian objects, which is likely associated with Russian-American contact.

Bonneau, Adelphine (Université Laval/CELAT), Réginald Auger (Université Laval), Bernard Gratuze (IRAMAT, Centre Ernest-Babelon) and Jean-François Moreau (Université du Québec à Chicoutimi) [178] Trading around the Saguenay River (Sixteenth and Seventeenth Centuries): New Insights from Trade Glass Beads Typology and Chemical Analysis

Hundreds of pounds of glass beads were imported among other goods by European traders to exchange with First Nations communities and to acquire fur, during the sixteenth, seventeenth, and eighteenth centuries. Once traded, these beads were used as bracelets, necklaces, cloths ornament, etc., or bartered with other Native groups. Nowadays, thousands of these beads are found on archaeological sites in Canada and can be a privileged tool to investigate trade networks in North America. As a starting point, the Saguenay River area (from Tadoussac to St John Lake) has been chosen. Beads from trading posts (Chicoutimi, Metabetchouan, Ashuapmsuak) and from Amerindian settlements (Ashuapmsuak River, Anse-à-la-Croix, Ste-Marguerite River) were classified according to available typology and analyzed with microscopy, Raman spectroscopy, LA-ICP-MS, and LIBS (Laser Induced Breakdown Spectroscopy) to reconstruct trading networks from Europe to Quebec, and around the Saguenay River. Preliminary results indicate a diverse provenance of imported glass beads (France, Germany, Italy) and obvious relationships between trading posts and local Native sites. How were the beads chosen by the Europeans? To meet Native people “fashion” tastes? Were there different qualities of glass? This study can only provide preliminary answers but it emphasizes the diversity and complexity of trading in New France.

Bonsall, Clive (University of Edinburgh) and Adina Boroneanţ (Senior Researcher, Romanian Academy Institute of A) [68] Filling the Gap: Caves, Radiocarbon Sequences, and the Meso-Neolithic Transition in SE Europe

Radiocarbon sequences from some cave sites in the Balkan and Italian peninsulas show a temporal gap between Mesolithic and Neolithic occupations. Some authors have seen this as a regional phenomenon and have sought to explain it in terms of a general population decline in the late Mesolithic, which facilitated the replacement of indigenous foragers by immigrant farmers. In this paper, we reexamine the evidence and consider alternative explanations for the Meso-Neolithic “gap,” focusing on taphonomic, economic, social, and ideological factors.

Booher, Ashley (Texas Tech University) and Brett A. Houk (Texas Tech University) [11] Peri-abandonment Deposits at Chan Chich, Belize

This poster details peri-abandonment features from the Maya site of Chan Chich in northwestern Belize. The term peri-abandonment relates to deposits or features dated to around the time of abandonment of the site. Previous research in the southern and eastern lowlands has documented widespread above-floor terminal artifact deposits in primarily episcopal centers thought to have formed at or near the time of abandonment at many sites in the region. Excavations at Normans Temple complex at Chan Chich in the late 1990s encountered above-floor terminal deposits at the base of Structure C-1 and on the steps of Structure C-2. Excavations conducted in 2016 uncovered two additional features—an above-floor artifact deposit and graffiti on a wall in a collapsed room—at the Normans Temple complex. Both features are thought to have been created near the time of the abandonment of the site.

Boomert, Arie [364] Origin of the Pitch Lake: An Amerindian Myth from Trinidad
Although Trinidad is referred to in various myths of the Warao and Arawak of the Orinoco delta and the Guiana coastal zone, only one mythical tradition is known which was documented among the Amerindians formerly living on the island. Explaining the origin of the major asphalt seepage known as the Pitch Lake in southwest Trinidad, this myth appears to be closely related to part of a mythological cycle related by the Lokóno (Arawak) Guyana and northwest Suriname which narrates the viciissitudes of Arawanini, the first Arawak shaman, believed to live on an island, kaieri, in primordial times. Besides, there exists a systematic correspondence between the Lokóno myth of Arawanini and the mythological cycle centering on the culture hero Guahayona, recorded by Pané among the ‘Taino’ as early as the 1490s. Clearly, the ‘Taino’ myth is derived from the Lokóno one or, more likely, from a prototype to both. They illustrate the close relationship, most likely going back to Saladoid times, between the cosmological views of the Lokóno (Arawak) of the mainland and the ‘Taino’ of the Greater Antilles.

Booth, Donald [283] The Mitchell Site: An Upgrade
In the spring of 2015, SCI Engineering, Inc. was contracted to conduct archaeological investigations ahead of the expansion of the Cedar Creek Lumberyard situated in the northeast portion of the Mitchell site (11MS30) in Madison County, Illinois. These investigations resulted in the delineation of multiple wall trench structures of varying size and shape. Most of what is known of this important Mississippian mound center comes from James W. Porter’s dissertation on his 1960s excavation at the Mitchell ahead of the construction of an interstate highway that ultimately destroyed all but two of the ten mounds at the site. This work, and a small scale investigation in the mid-1970s and minor testing in the 1990s, constitute the extent of modern archaeological investigations previously conducted at the Mitchell site. In an attempt to put the 2015 structures into a broader Mitchell context, an effort was made to bring all of these investigations into a GIS format resulting in an overall site map depicting all of the previous excavations and all of the cultural features that have been identified to date. This GIS mapping project provides opportunities to draw new insights into this major Mississippian center in the northern American Bottom.

Borck, Lewis (Leiden University/Archaeology Southwest) and Leslie Aragon (Archaeology Southwest/University of Arizona) [74] Using a Sexualized Ritual Landscape to Ontographically Examine Hohokam Gender Stereotypes
Between approximately AD 800–1450, politically oriented religious movements flourished and withered throughout the Hohokam world of the Greater Southwest. The public architecture associated with these movements is one of the only remaining evidence that archaeologists have for their occurrence. While researchers have started to investigate how these movements were politically intertwined, in this paper we lay out an argument that their physical remains can also be used to ontographically examine gender stereotypes in the pre-textual past. To do this, we link sexual characteristics embodied by the public architecture of the Hohokam Ball Court Society and the subsequent Platform Mound Society with the structure of each Society’s associated social and political organization to approach an ontographic understanding of gender stereotypes during those periods. An intersectional archaeology recognizes that multiple cultural dimensions and categories reflexively impact society at all scales, including at the individual scale. We argue that gender biases can be used to more effectively analyze archaeological data and interpret the experience of individuals who created the archaeological record.

Boren, Courtney (University of West Florida) [249] OSL Dating and Chronology in Pensacola, Florida’s Contact Period
New research on the history of the Pensacola Bay region from the late Mississippian to the Protohistoric period is clarifying previous understandings of cultural sequences. Two recently discovered sites have created opportunities to apply new dating technologies to culture historical questions. The first site is in an incredibly dynamic area of sand dune formations on a barrier island. The second site is associated with the Luna Settlement of 1559–1561 here during the sixteenth century.

Borenstein, Gabrielle (Cornell University) [221] Motif and Milieu: Deconstructing the (Re)production of the Kura-Araxes Culture (3500–2400 BC)
How do material remains—and the imagery that adorns them—inform our understanding of past landscapes? How does knowledge of landscapes enrich our understanding of the objects produced within them? This paper explores the relationship between iconography and environment in the Early Bronze Age Kura-Araxes (3500–2400 BC) culture. The Kura-Araxes was arguably the most widespread archaeological horizon in the ancient Near East, extending from the Caucasus to the Levant to the Zagros Mountains. Marked by a common material assemblage, research to date has prioritized the degree of uniformity and geographical extent of the culture across the diverse topography. Using new data from the site of Gegharot in Armenia as a lens, this paper quantitatively and qualitatively investigates the relationship between motif and milieu. It examines the imagery present on ceramic vessels, plaques, and hearths as a means not only of assessing regional variability throughout the ecumene, but also of deconstructing the co-constitutive nature of people, pots, places, and politics. Moving beyond categorical and typological systems of classification, this paper considers how communities of practice are formed, in part, as a result of common experiences in a shared landscape.

Boric, Dusan (Cardiff University), Marija Edinborough (University College London), Emanuela Cristiani (University of Cambridge), Doug Price (University of Wisconsin, Madison) and Olaf Nehlich (University of British Columbia) [290] Social Bioarchaeology of Forager-Farmer Transition in the Balkans
In Europe, Greece and the Balkans were the first areas to be reached by expanding Neolithic, agricultural lifestyles. The Danube Gorges of the central Balkans represents one of the best case studies in Europe for studying bioarchaeological consequences of the change from foraging to farming thanks to abundant settlement and mortuary record found here. It also provides a good regional anchor point for the contextualization of other contemporaneous sites across the Balkans. A large number of skeletal remains, in the excess of 500 individuals from a dozen sites found along the River Danube in this region provide best insights into how the arrival of new populations along with the adoption of agricultural lifestyles affected human biology. A large suite of now available isotope data, including carbon and nitrogen, sulfur, and strontium, along with data on sex and age profiles, dental calculus, tooth wear and microstructure, paleopathology, and musculoskeletal stress markers allow for fine-tuned reconstructions of human physical
plasticity in the Early Holocene. This paper reviews the current state of knowledge on the bioarchaeological consequences of the transition in the light of the Neolithic Demographic Transition model.

Borrero, Luis (CONICET), Fabiana Maria Martin (CEHA-Instituto de la Patagonia-UMAG), Manuel J. San Román (CEHA-Instituto de la Patagonia-UMAG), Flavia Morello Repetto (CEHA-Instituto de la Patagonia-UMAG) and Dominique Todisco (Université de Rouen) [226] Southern Patagonia: Coastal versus Interior Human Migration

In spite of the ca. 14,000 Cal BP or more at 41º S, the oldest human occupations in southern Chile below 52º S are not easy to explain as a result of a Pacific coastal migration. The oldest Late Pleistocene occupations recorded at Ultima Esperanza and Tierra del Fuego are all focused on the exploitation of terrestrial resources and have ties with sites located in the eastern steppes, such as Fell Cave, Piedra Museo or Cerro Tres Tetas. The oldest maritime oriented human occupations of the western archipelagos are only of Mid-Holocene age. However, discussion is still open, since this region is still poorly explored.

Stone (Arizona State University) and Johannes Krause (Max Planck Institute for the Science of Human Hist) [143] Tuberculosis in Past Peruvian Populations

Due to its arid climate the Atacama Desert has an exceptional preservation of ancient biomolecules. In an archaeological context, this allows for genetic analyses of both past human populations and the infectious diseases they experienced. Precontact Peruvian cultures are among the first New World populations to show skeletal indications of tuberculosis, and recent molecular analyses have revealed that three individuals were afflicted with a rare zoonotic form of the disease acquired from marine mammals. This form is no longer circulating in the human population, and it appears to have been replaced by the European variant after contact. While the ancient disease was presumably acquired through either the consumption or manipulation of tissues from affected seals or sea lions, little is known about its range in the human population and whether or not it subsequently became human-adapted. This talk will explore our recent work on the molecular evaluation of additional skeletal material from the Americas that show physical evidence of tuberculosis infections. Our analyses are conducted with the aim of exploring the different forms of tuberculosis that were circulating in the New World before contact, their relationship to the Peruvian form, and the potential evidence for human adaptation.

Boswell, Alicia (Bard Graduate Center and Metropolitan Museum of Art), Ellen Howe (Metropolitan Museum of Art), Joanne Pillsbury (Metropolitan Museum of Art) and Deborah Schorsch (Metropolitan Museum of Art) [164] Variations in Moche Metalwork

In the last thirty years, archaeological investigations on the north coast of Peru have produced a wealth of new information leading to nuances in our understanding of Moche sociopolitical organization (AD 200–800). These discoveries have included excavations of intact tombs of Moche male and female elites, interred with their ritual regalia and other grave goods. Metal ornaments made up an important part of this regalia, yet our understanding of Moche metallurgy technology and its relationship to sociopolitical organization remains under-explored. In this paper we will carry out a systematic comparison of the metal objects and techniques employed to create them from multiple Moche sites. With this comparison we will further document the diverse technologies used throughout the Moche world with the goal of furthering our understanding of Moche metalworking artisans, techniques, and organization. This comparison will document the degree of standardization in Moche metalworking techniques to identify the nature and scale of differences between regions, and how these may shed light on workshop practice and social relations in the Moche world.

Boutin, Alexis (Sonoma State University) [31] Scales of Analysis and Modes of Interpretation in Osteobiography: An Example from the Dilmun Bioarchaeology Project

Bioarchaeologists have traditionally prioritized statistically significant patterns in large skeletal assemblages to document major biocultural trends in human populations. But in the last 15–20 years, the osteobiography approach has returned to favor, encouraging bioarchaeologists to focus on the specifics of the human scale, reconstruct an experiential prehistory, and restore an identity to those “genderless, faceless blobs” (Tringham 1991:97) who people so many traditional interpretations of the past. My “Bioarchaeology of Personhood” model argues that alternative modes of interpreting osteobiographical data can provide a more humanizing view of past personhoods and can communicate effectively and accessibly with a broad range of academic and public audiences. Unlike the outlier-oriented, case study approach of decades past, osteobiographies should draw from—not substitute
for—the context provided by population-based approaches. To illustrate these points, I will present a fictive osteobiographical narrative about a subject from ancient Bahrain, whose remains are studied by the Dilmun Bioarchaeology Project.

Bouman, Abigail [219] see Breidenstein, Abagail

Bovy, Kristine (University of Rhode Island) [228]  Predicting and Assessing the Impact of Environmental Events on Seabirds at Tse-whit-zen Village
Seabird remains, especially murres, scoters, loons, grebes, shearwaters and gulls, are abundant in the Tse-whit-zen faunal assemblage. There is considerable biological research on the effects of climate change on seabirds, especially in light of recent climate trends; for example, responses of seabirds to increased sea surface temperatures associated with El Niño events are well documented. In contrast, there has been relatively little research on the effects of recent earthquakes on marine birds. One might predict that nesting habitat could be altered due to coastal subsidence or tsunamis. However, effects on non-nesting birds, may be considerably more subtle, due to the obvious mobility of marine birds (compared to shellfish or other smaller animals). One possible effect could be a decline or change in the availability of seabird prey such as shellfish or small fish, due to substrate changes or eelgrass destruction. At Tse-whit-zen, herring is one of the major components of the fish assemblage, and many of the seabirds recovered were likely hunted while feeding on herring spawn. I examine the relationship between herring and seabirds at the site through time in response to past earthquakes. Spatial differences in taxonomic composition and taphonomy will also be examined.

Bowen, Corey (Vanderbilt University) and John Janusek (Vanderbilt University) [230]  Felines and Condors and Serpents, Oh My! Cataloging Zoomorphic Imagery in Tiwanaku Ceramics
A regimented canon of ceramic production emerged at the site of Tiwanaku in the fifth–sixth century AD, coinciding with the transformation of the site from a local ritual center to a regional political authority. The highly standardized range of forms and painted imagery it produced presents great potential for an extensive analysis of both complete and fragmented Tiwanaku-style vessels. To date, most analyses of Tiwanaku ceramic vessels have categorically centered on form in order to facilitate quantitative comparisons of archaeological contexts. Our recent studies of ceramic vessels from mortuary contexts in the Tiwanaku heartland, under the aegis of an archaeological project directed by Deborah Blom and Kelly Knudson, have sought to develop iconographic classifications to assist out understanding of Tiwanaku’s material culture. We seek to create a comprehensive catalog of the zoomorphic representations depicted on Tiwanaku vessels. This assemblage will constitute the foundation for a broader analysis of animal imagery as potent symbolic media on Tiwanaku vessels and other materials, such as stone sculptures.

Bowie, Kristina (University of Victoria) and Jillian Harris (Penelakut First Nation) [17]  Traditional Practices That Inform Cultural Competency in Archaeological Studies and Cultural Safety for First Nation Communities
While Canada’s Truth and Reconciliation Commission on Indian Residential Schools completed its mandate in December 2015, pursuit of the truths and movements toward reconciliation of past residential school practices continue. Efforts to identify missing former students and locate unmarked cemetery, grave and burial sites are continuing at the former Kuper Island Industrial School on Penelakut Island. This work is structured as both a collaborative and community based archaeology and is being conducted at the request of the Penelakut First Nation to address contemporary concerns. Contemporary archaeological methodologies, including noninvasive ground-penetrating radar survey, are informed by oral histories of residential school survivors, and by traditional skedelich rituals conducted by First Nation community members. As a traditional methodology, skedelich rituals provide cultural safety as a valued method of healing for First Nation community members, a result which is pursued, but for which contemporary Westernized archaeological methods may be inept. In addition to providing an Indigenous framework for analysis and interpretation of this site, cultural traditions and community members must be included in this search journey. This points to cultural competency on part of the archaeologist wanting to help, required before any form of reconciliation of the past can follow.

Bowler, Victoria (University of New Mexico), Emily Lena Jones (University of New Mexico) and Cyler N. Conrad (University of New Mexico) [127]  The Canids of Arroyo Hondo: A Reanalysis
Domestic dogs were an important part of human cultures in the prehistoric American Southwest; the significance of these animals is apparent from ceramic decorations and clay figurines, as well as faunal remains. But how these animals functioned within Southwestern cultures is less well-understood. Prehistoric dogs’ roles in some cases seem to have been similar to those of modern dogs: protector, worker, and pet. However, zooarchaeological data have shown that dogs, like turkeys, were also used as a food resource and might have sometimes been sacrificed or killed as offerings. The use of stable isotope analysis has the potential to clarify the relationships between humans and dogs in the prehistoric American Southwest. In this paper, we present preliminary data from our reanalysis of the canids from Arroyo Hondo Pueblo, a Pueblo IV community in the Northern Rio Grande.

Boyd, Carolyn (Shumla/Texas State University) and Kim Cox (Shumla) [126]  Burning Water: Time and Creation in the Rock Art of the Lower Pecos
The White Shaman Mural (~2000 BP) is a planned composition with rules governing the portrayal of symbolic forms and the sequencing of colors. Using digital microscopy we determined that all black paint was applied first, followed by red, then yellow, and last white. Complex images were woven together to form an intricate visual narrative detailing the birth of the sun and beginning of time. One of the key figures in this creation narrative is a small anthropomorphic figure bearing red antlers tipped with black dots. The juxtapositioning of red antlers and black dots is ubiquitous in Pecos River style rock art, as is the painting sequence of these two pictorial elements. In each example, the black dots were applied prior to the red antlers. “Burning Water” explores the significance of this motif in the White Shaman Mural and in the graphic vocabulary of the Lower Pecos. It is a visual pun or couplet metaphor joining two opposing forces—fire and water—to initiate creation and the beginning of human time.

Prestige Foods and the Adoption of Pottery by Subarctic Foragers

In the last two millennia before European contact, pottery technology was adopted by foragers across much of the southern Canadian Boreal Forest in response to the spread of Woodland (~100 BC—AD 1700) cultural influence. However, the function and importance of pottery in these northern societies remains unclear due to a combination of poor organic preservation, thin and disturbed stratigraphy, and limited archaeological exploration. In this study, we summarize the results of food residue analyses from 177 archaeological sites distributed across central Canada. We show that pottery was closely linked to the consumption of domesticated plants, especially maize (Zea mays ssp. mays), which in most areas of the Subarctic were probably only rarely available through trade or local cultivation. This, combined with other lines of evidence, suggests that pottery was reserved for socially-significant meals such as feasts and imbued with special ritual, culinary, and/or social meanings. We speculate that the spread of pottery technology across the region marks a subtle change in the symbolism, and perhaps importance, of intergroup reciprocity and cooperation during the Woodland period.

A Dynamic Social Landscape: Recent Investigations at the Hacienda Guachalá, Northern Highlands of Ecuador

The area of Cuyabeno in the northern highlands of Ecuador is marked by the physical remains of successive waves of Inca and Spanish imperial expansion and their enduring consequences. Across the landscape high altitude fortifications evidence the drawn-out struggles between expanding Inca and local forces during the fifteenth century. Similarly, elite haciendas that transformed the rural countryside in the interests of imperial and state power continue to dominate the social and political landscape. In this paper, we review recent work carried out by the Proyecto Arqueológico Pambamarca (PAP) in the area of the Hacienda Guachalá, where archaeological investigations have contributed new perspectives on the continuous cultural history of the region. Archival, geophysical, and material evidence have generated both new questions and a greater understanding of the ways in which communities navigated the profound changes that characterize this important region of the northern Andes.

Market Economy Solutions to Funding

Traditional funding structure to support archaeological research consists of grants from public or private organization or donations from individuals, public or private entities. But as these traditional sources are shrinking their allocations for basic research in general, and for the social sciences in particular, archaeologists can harness the power of the market and find market solution to funding of research. This paper will examine one such case—the institution of field schools and the significant way in which they create market incentives to all to generate significant funding, great research and strong commitment to pedagogy.

Polyvalent Monumentality: Analyzing Geospatially the Interplay of Fortification and Hydrology at the Maya site of Muralla de León

Dissertation fieldwork since 2014 at Muralla de León has documented, mapped, and partially excavated an integrated system of earthworks that appears to have served both large-scale defensive and hydrological functions. Located on the shores of Lake Macanché, the site sits atop a steep-sided natural rise, artificially augmented in height by an encircling stone rampart wall, or enceinte. A defensive function for the enceinte is hypothesized, though it also appears to serve as a means of water control within and around the site. Additionally, an artificial channel just outside of the wall likely functioned both for navigation and as a defensive moat. In order to explore the proposed functions for these features, a system of detailed mapping and targeted excavation has been deployed. The mapping effort has utilized a total transit station and handheld GPS unit to produce a high-resolution DEM. This level of detail has allowed for GIS analyses of movement, using tools like least cost path, and of the hydrology of the site interior and adjacent channel. These analyses have informed the major hypotheses of the project, offering useful but not unequivocal insight. Here, the contributions of this spatial component of the project are weighed and discussed.

The Repeated Replacement Model Reexamined: Methodological Considerations and Dataset Improvements

Five years ago a general explanation model was introduced regarding the observed dynamics during the Upper Paleolithic timeframe on the Iberian Peninsula. In doing so, a scenario of repeated replacements of human groups was established, reflected by fluctuations within the radiocarbon chronology and changes within the archaeological record. Incorporated into the “Adaptive Cycle Model,” this model assumes a strong relationship between the constant changes of stadial-interstadial environmental conditions and the trend of human resilience to, especially external, stressors. In doing so, the recurring rapid shifts from interstadial to stadial conditions can be understood in the context of a release phases. Only on that account could the soon-succeeding second release impact, the climate deterioration during Heinrich Stadials, have affected the abandoning of the Cycle, i.e., a “breakdown of the meta-population.” Accordingly, the resilience threshold was reached by an environmental “double-punch.” After several years of intensive research in the fields of Upper Paleolithic research we will test the key assumptions of the model a second time, incorporating the enhanced

[28] **Embodiment and Relatedness: The Rock Art of Muluwa, Wulibirra, and Kamandarringabaya**  
As an interpretive tool for rock art studies, the concept of embodiment has much to offer especially when used in conjunction with ethnographic data. In this paper we focus on embodiment in the context of relatedness using a case study involving Yanyuwa rock art from three sites—Muluwa, Wulibirra, and Kamandaringabaya—in the Sir Edward Pellew islands in northern Australia’s southwest Gulf of Carpentaria region. Although not stylistically similar, the rock art from these sites is intimately connected to the travels, events, networks and bodily transformations involving the White-bellied Sea Eagle and Dugong Hunter Ancestral Beings (Dreamings) as well as other spiritual beings known as namurlangiangkju. Using ethnographic data collected over a 30+ year period we highlight how these sites and motifs are part of a network of nonhuman entities to which human entities then become involved—the images found here embody the network of relations that Yanyuwa find themselves within. More specifically, we explore the interrelationship between Ancestral and spiritual beings, place, embodiment, kinship, and rock art to better understand how Yanyuwa rock art is perceived and experienced, as well as the role it plays in shaping Yanyuwa identity and relationships with neighboring groups.

Brady, James (Cal State L.A.)  
[386] **An Interpretation of Motifs on Protoclassic Polychrome Pottery from Naj Tunich Cave**  
A good deal of academic attention has been focused on the iconographic analysis of Maya painted ceramics, principally from the Late Classic Period and to a lesser extent from the Early Classic. The tradition, however, begins in the first century AD during the protoclassic ceramic stage. Virtually no analysis has been undertaken on these earliest Maya artistic expressions probably because the motifs are largely geometric and figurative representations are rare. I compiled a motif inventory from Ixcanrio Orange Polychrome sherds recovered from Naj Tunich Cave, Guatemala. Comparisons with ceramics from other sites indicate that the motifs are widely distributed indicating that the symbol set was understood throughout the southern lowlands. The message appears to be a fundamental one in that the same motifs continue to be used all the way through the Classic Period. The message is related directly to earth and water.

[240] **Provenance and Distribution of Neo-Punic Ceramics at Zita, Southern Tunisia, and Beyond**  
The site of Zita is an urban mound located in southern Tunisia and situated along an ancient trade route from Carthage to Tripoli. It is the highest point on a peninsula jutting into the Mediterranean Sea across from the Island of Djerba, often identified as the Island of Calypso of the Lotus-Eaters from the Odyssey. Established as a Carthaginian settlement around 500 BCE, the city became a Roman regional center in the first century CE. Zita still has industrial features such as ceramic kilns and metallurgical zones. The ceramics and presence of kiln zones provide the opportunity to characterize the full spectrum of production and/or import and the site. In this study a high resolution geochemical analysis by ICP-OES/MS (n = 145) has been carried out in order to detect the provenance of these ceramics and provide an analytical reference set of data for ceramic production in this part of North Africa. This paper emphasizes provenance of these materials as a key concept to understand the development of trade and technology through time.

Braje, Todd (San Diego State University)  
[251] **Trophic Cascades, Kelp Forest Dysfunction, and the Genesis of Commercial Abalone (Haliotis spp.) Fishing in California**  
For over 12,000 years, hunter-gatherers of coastal California harvested abalone as an important subsistence and raw material resource. Archaeological evidence from the Northern Channel Islands suggests that human-induced reductions of local sea otter populations may have triggered a trophic cascade beginning 8,000 years ago and released abalone and other shellfish from predation pressure, helping to sustain intensive human harvest for millennia. With the arrival of the Spanish in AD 1542 and the Mission Period in AD 1769, abalone were quickly released from nearly all predation as sea otters were locally extirpated and indigenous shellfisheries were severely disrupted. For decades, abalone populations exploded, reaching unprecedented sizes and densities. By the 1850s, however, Chinese immigrants recognized the potential of abalone and founded the first commercial shellfishery in California. Although the fishery was predicated on ecosystem dysfunction, Chinese fishers harvested black abalone relatively sustainably for decades. Ironically, it was state and federal claims of overharvest that resulted in targeted legislation of Asian fishers and the subsequent collapse of the commercial fishery by Euro-American interests. Today, California abalone communities are a shadow of their former selves, but restoration targets based on historical hyper-abundance and lacking perspectives from deep history may only compound the problem.

[171] **Temporal and Spatial Variability in Pre-Aksumite Lithics from Mezber, NE Ethiopia: Social and Economic Implications**  
With over 33,000 total excavated flaked stone artifacts and >18,000 analyzed from deposits in primary context, Mezber offers a unique opportunity to understand the role of lithics in Pre-Aksumite societies. Using multiple raw materials and reduction sequences, knappers produced a wide array of LSA/Neolithic tools for domestic use, and a narrower range for specialized activities. Locally available chert was the most common raw material, although pXRF results indicate ≥3 as yet unknown distant sources for obsidian, the second most frequent toolstone. Significant temporal and spatial variability in lithic type and frequency over ~1,400 years of continuous Pre-Aksumite occupation at Mezber, suggests important changes in community
practices that incorporated lithics. Sparse during the Initial Phase, lithics become more frequent and typologically diverse in the Early Phase, reflecting their importance in domestic activities. Lithics experience a dramatic increase in frequency during the Middle Phase. Some fields are dominated overwhelmingly by only one artifact type (scrapers), suggesting more intensive craft specialization. Lithic frequencies decline markedly during the Late Phase, and especially at those locations with previous high scraper frequencies. We conclude by discussing the economic and social roles that lithics played in early state formation in the northern Horn of Africa.

[38] Density, Discard, and Distraction: How Do We Form Inferences of Behavior from the Early Pleistocene Record

The discovery and excavation of dense patches of lithic artifacts has spurred discussion about how such features form. Interpretations are often based around the assumption that these reflect locations of targeted hominin use. Despite their assumed significance, there remains the possibility that high density scatters may reflect the vagaries of the formation processes of the Early Pleistocene archaeological record. Here we use a neutral model of the formation of the archaeological record to investigate the significance of archaeological densities at local and global scales. Even when the underlying processes driving the discard of lithic material are random, there is the possibility that high artifact densities can form. Moreover, when investigated at a local scale, distributions of artifact frequencies can appear nonrandom. These results suggest that while hominin behavior was not stochastic, the overprinting of behavior due to time-averaging may cause it to appear so. As such we suggest that Early Stone Age archaeologists should investigate formational processes at multiple scales when using artifact density to develop behavioral inferences.

[178] Ceramic Technologies and Technologies of Remembrance: An Iroquoian Case Study

The patterned deposition of certain objects, often in association with materials or structures that are seen to have symbolic associations, is an act of memorialization seen in many Neolithic and broadly shamanic societies throughout the world. This paper uses petrographic and contextual data to explore how objects manufactured with certain material qualities may have served as symbolic referents to memories related to Ontario Iroquoian ritual and social practices, both at the object level, and in the built environment of the Iroquoian longhouse. Through these associations, Iroquoian encounters with “bundled” material qualities precipitated remembrance. The participatory experience of creating (and by extension, re-encountering) structured deposits containing such objects resulted in the creation, modification, or destruction of other social relationships. For its occupants, the spaces inside an Iroquoian longhouse were filled with unseen subterranean deposits, containing materials and memories that reflected and reified Iroquoian cosmologies, and influenced quotidian social practices.

Bray, Tamara (Wayne State University)
[331] A View from the Hinterlands: Early Colonial Objects in Mortuary Contexts in Northern Highland Ecuador

In this paper I revisit a particularly interesting find made in the Pimampiro District of northern highland Ecuador a number of years ago. It consisted of a traditional shaft tomb burial that contained an unusual assemblage of items, which included seemingly obvious Late Period Caranqui and Panzaleo wares together with a set of four Nueva Cadiz beads. How and why did these precious European objects penetrate this seemingly remote region at such an early date to be inserted into such a basic ritual context? What does their presence within an otherwise completely “precolumbian looking” context indicate with respect to temporality, materiality, and archaeological assumptions? In this paper, I analyze this mortuary assemblage with respect to regional, historical, and social context, as well as in light of networks of meaning, the notion of value and material agency.

[219] Christian Life in Medieval Nubia at el-Kurru, Sudan

The Nubian site of el-Kurru (modern Sudan) lies along the Nile River about 140 km upstream of Old Dongola, the capital of the Medieval Christian kingdom of Makuria. In 2015–2016, a cemetery adjacent to the settlement was excavated, containing 26 skeletons. Here, I will present current bioarchaeological work on these individuals. Biological profiles were developed, including sex and age ranges, health markers evaluated, and indicators of pathology and trauma identified. Those interred span all ages, from infants to older adults, with an equal distribution of sexes. No indications of interpersonal violence are present. Age-related pathologies (i.e., osteoarthritis, advanced dental wear) are evident in a quarter of the sample population, while signs of probable disease (i.e., periostitis, cribra orbitalia) are present in another quarter. Archaeological evaluation of the burials, directional organization, and scarce grave goods indicates these individuals were Christians. Further analyses include extraction and sequencing of ancient DNA, stable isotope analysis, AMS Radiocarbon dating, and additional development of biological profiles to include stature and ancestry markers. Compared to a wealth of physical anthropological work on Medieval Lower Nubia, this sample population provides a means to understand life in the relatively less-studied kingdom of Makuria using archaeological and bioarchaeological data.

**Birch Island: The Archaeology and Memory of Resettlement**

Archaeology has the ability to bring people together and assist communities in creating their own historical narrative so it can be passed on and acknowledged, corrected and recorded, within and outside of their community. My work in Happy Valley-Goose Bay, Labrador on an archaeological site that only ended occupation in the late 1960s facilitates the formalization of the historical narrative of the former Birch Island community through archaeology, historical research and personal interviews. Community members who once lived on the island will be invited to excavate with us in addition to participating in formal and informal interviews to get a better picture of what life was like when the community flourished. All the information gathered will be available for public use and historical plaques will be placed at the site to inform and commemorate the area. By actively seeking out these open lines of communication and engagement, we are decreasing our own bias and allowing for a more engaging, meaningful and accurate interpretation of places that have a living history for those connected to it.

**Prehistoric Settlement Patterns of the Los Alamitos Bay, Southern California**

The details of prehistoric settlement patterns in the Alamitos Bay area of southern California are not well documented. Due to rapid urban development throughout the twentieth century, the archaeological record has been explored with only limited excavations. The lack of systematic investigations has limited our knowledge about prehistoric populations and their variability in terms of subsistence practices and settlement patterns. Using a review of information gleaned from archaeological studies conducted over the last 60 years, I generate a model of settlement pattern that summarizes our current understanding of how communities were temporally and spatially distributed across the environment of Alamitos Bay as a function of the available subsistence resources and how these communities responded over time.

Breslawski, Ryan (Southern Methodist University)

**Seasonal Bison Exploitation in North American Prehistory: A Probabilistic Approach Using Fetal Prey Osteometry**

Bison remains often serve as evidence for seasonal food exploitation in archaeological investigations of the Great Plains and adjacent regions. Interpreting this evidence relies on discrete rutting and calving periods that allow zooarchaelogists to link ontogenetic data to a specific time of year. However, ecological data on modern bison show that the timing of rutting and calving behavior varies between herds and even within the same herd between years. To address this problem, this study models variability in conception dates across modern bison herds. In combination with metric data from fetal prey remains, these conception models are then used to create intra-annual probability distributions for the timing of a hunting event. Using intra-annual probability distributions obtained through this approach, this paper assesses seasonal subsistence hypotheses at three Late Holocene sites: Big Goose Creek (Wyoming), Baker Cave III (Idaho), and Upper Tucker (Texas). Unlike efforts to infer seasonality from fetal bison remains with other methods, this study provides easily interpretable probabilities showing the level of agreement between data and hypotheses.

Breukel, Thomas (Leiden University)

**Jade Axes from the Site of Pearls, Grenada: A Field-Based Microwear Analysis**

This paper reports upon the wear trace analysis of 20 ground stone axes from the Ceramic Age site of Pearls, Grenada. The selection contains several exotic lithic materials including twelve jadeitites, for which the nearest known source is over 1,100 km away. Pearls is a heavily disturbed site on the Atlantic coast of Grenada, of which much of the material record is held in private custody. Yet, the site holds central importance in the wider interacting region, as a lithic, ceramic, and ornament production center with suggested exchange ties to many source areas and partner sites. A biographical study was undertaken in order to obtain information about the context in which the jadeite materials arrived at the site, where and how they were manufactured, and if they had been put to use. Collections from the Windward Islands have thus far not been analyzed using microwear analysis, making this study a first. Further, the analysis was enabled by transporting a DinoLite digital microscope and a Nikon Optiphot metallographic microscope to the field. The methodological complications with a study of archaeological records accessible solely through non-institutional sources will be evaluated.

Brewer, Katherine (University of New Mexico)

**Religion and Death: Missionization and Its Effects on Puebloan Burial Practices during Spanish Colonization**

For the Spanish, conversion to Catholicism was an important part of the colonial strategy in the New World in order to have more perceived control over the indigenous groups they encountered there. In New Mexico, conversion of the Puebloan peoples became the main reason for remaining in the territory after little to no material wealth was found. Much of this conversion was forced, and the question remains as to exactly how many Puebloans converted and how many converted in public while practicing their native religion in private. By analyzing burial patterns pre- and postcontact, it is possible to see changes in burial ritual related to the conversion process. Catholic burial ritual involves a specific set of steps, from the last rites to the interment, while the Pueblos had their own burial rituals that differed from Catholicism in many ways. Both of these can be compared to Puebloan mission burials to see what, if any, changes occurred due to missionization.

Bria, Rebecca E. (Vanderbilt University)

**Rethinking Assemblages in the Digital Age**

Archaeologists have long drawn on technological advances from other disciplines to create new ways of visualizing and classifying data. Relational databases in particular have been a cornerstone of archaeological inquiry into material assemblages, whether sets of artifacts and their attributes or constellations of sites across regions. But how have new technologies (e.g., spatial, three-dimensional, mobile, and digitally collaborative platforms) enhanced archaeologists’ ability to trace, and ultimately understand, complex networks of social and physical relationships between humans, things, and spaces? How can new materialist theories, with their sharp focus on the matrices or assemblages of materials that constitute any archaeological object or subject, lead us to rethink how we develop and apply digital technologies in archaeology? This paper offers insights from multiple years of
digital archaeological research in the highland Andes to combine recent developments in digital and theoretical archaeology. It argues that the relational structure and ontology of many digital data applications can enhance archaeological understanding of human-material dependencies. It contends that digital archaeology, with its unique ability to trace human-material relationships across time and space, can greatly contribute to contemporary debates regarding the social and physical environment.

New Perspectives on Past Vitamin D Deficiency

Less than half of the current world population is estimated to have adequate vitamin D status and potential consequences are much debated. For those engaged in addressing the challenges that vitamin D deficiency poses, information on past deficiency provides an important time dimension to current debates. Over the last 15 years I have undertaken extensive collaborative work on past deficiency. Investigations at St. Martin’s, a nineteenth-century UK site, established diagnostic criteria and revealed the sociocultural complexity of deficiency. Work undertaken at McMaster has demonstrated that contrary to popular belief the condition is not just associated with Northern European cities in the Industrial Revolution. In the largest-scale project undertaken to date (3,426 individuals) vitamin D deficiency has been shown to be widespread across the Roman Empire (third–sixth c. CE). Although latitude plays a role, levels of urbanization and social complexity are clearly also factors. New work on defects in dentine linked to vitamin D deficiency offers the opportunity to determine the number and severity of episodes of deficiency. Dentine defects are preserved indefinitely and in combination with skeletal features can illuminate the individual experience of deficiency in the past and contribute to current debates on health.

Briggs, Rachel (University of Alabama) [142]

A Gendered Approach to Assessing Differences in the Hominy Foodway in Central Alabama

Between AD 1000–1120, groups living in the Black Warrior Valley of west-central Alabama adopted maize agriculture and began practicing an ancestral hominy foodway that not only included nixtamalizing culinary steps, but also included the use and production of a new ceramic technology, the Mississippian standard jar, as well as a new cooking technique, hot coal cooking. Curiously, while groups to the east of the valley also adopted maize and began cooking hominy, they forewent other material and practice-based signatures characteristic of the foodway in the Black Warrior Valley. While this rejection has traditionally been interpreted as a broader, active refutation of a Mississippian lifeway, this paper draws on settlement, subsistence, and ceramic data to assess whether differences in gender roles and seasonality may instead be more useful for understanding the development of these two coterminous hominy traditions.

Analyzing Wood-Use Behavior at Wupatki Pueblo

Wupatki Pueblo is one of the best known prehispanic settlements in northern Arizona. Unfortunately, very few excavation reports exist and only a couple of successful dendrochronological analyses have been published. Through a reexamination of wooden construction elements, legacy data from previous publications, and unpublished field notes, stored at the Laboratory of Tree-ring Research, this paper presents the results of the first wood-use behavior analysis at Wupatki Pueblo. The use of a holistic methodology (i.e., the use of statistical analyses and Exploratory Data Analyses) revealed that tree type allocation and consumption, particularly the utilization of both high and low elevation conifers, maintained throughout the construction sequence at the pueblo. Through the combination of modern and post-modern indigenous theories and analogical models (predicated upon wood-use behaviors displayed among one of the primary descendent communities), wood-use behavior at Wupatki Pueblo is interpreted as an example of learned behavior through enculturation, guided by a shared cultural system of meaning based in ritual. The emphasis of this paper is not only on the results of this analysis, but also on the importance of considering both the culturally defined and scientifically explained contexts when interpreting wood-use behavior.

Bright, Lisa and Joseph Hefner (Michigan State University) [300]

A Different Kind of Poor: A Multi-Method Demographic Analysis of the Santa Clara Valley Medical Center Historic Cemetery

From 2012–2014 excavations at the Santa Clara Valley Medical Center (SCVMC) Historic cemetery (circa 1875–1935) resulted in the exhumation of 1,004 individuals. The cemetery, which served as one of several county burial grounds for the indigent and unknown individuals of the area, provides a glimpse into the growth and development of Santa Clara County, California. To date no cemetery records have been located, leaving the identity of these individuals a mystery. To better understand this population, a demographic analysis employing various Siler and Gompertz mortality models, as well as correspondence and transition analysis was used to compare the osteological age-at-death assessments at SCVMC to other historic bioarchaeological samples (Milwaukee County Institution Ground, Alameda Stone, and Voegtly). Additionally SCVMC is compared to known age-at-death data from Mission City Memorial Park, a contemporaneous historic county burial ground in Santa Clara County, whose data was scraped from a local genealogy website. The results indicate that individuals interred at SCVMC were likely recent immigrants into the area, and experienced higher mortality risk than the comparative sample. Interestingly males and females at SCVMC experienced identical mortality risks, contrary to the comparative sample. Demographic analysis allowed for a better understanding of county burial practices.

Working on the Margins of the Modern World and Within Archaeology: The Historical Archaeology of Late Nineteenth- and Early Twentieth-Century Ireland

In Ireland, historical, post-medieval, or modern world archaeology as a discipline is located on the margins. The time period and material comprising our research is argued by many to be relevant only to the pursuits of historians and folk studies. In this paper I discuss the importance and relevance of a discipline on the margins and the study of Ireland’s impoverished class during the last decades of the nineteenth and early twentieth centuries. This marks one of the most dynamic periods in Ireland’s political, economic, and cultural history which includes the complexities of identity during struggle and conflict. The material culture from two archaeological sites associated with The Archaeology of Ireland’s Early Modern History research program in Skibbereen, County Cork, structures this paper. The sites date from the early 1840s to the late 1920s and serve to illuminate the importance of historical archaeology to modern heritage formation, as well as the intricacies of this transformative period of Irish socioeconomic and cultural history.

[156] Archaeology of Religion in Nicaragua

This past summer I was given the opportunity to participate in an archaeology field school conducted in the country of Nicaragua. For the past 15 years, archaeologists have excavated sites along the shore of Lake Cocibolca in search for Mexican colonization. During my participation in the field school, we continued this quest through investigations at the site of El Rayo, the most significant site for studying the potential impact of outsiders on indigenous cultural traditions. The core theoretical perspective focused on the interpretation of culture change, especially ethnicity, in the centuries leading up to the Spanish Conquest in 1522 CE. As such, the results are of fundamental importance to developing claims of cultural identity by existing indigenous groups in the region. Ethnohistorical accounts from the sixteenth century CE describe the indigenous cultures of Pacific Nicaragua, including strong evidence for shared Mesoamerican cultural and linguistic traits. Using the ethnographic information, ceramic analysis, and research I collected during my time in Nicaragua I will attempt to interpret the religious aspects of precolombian indigenous cultures, bolstered by a cultural comparison of precolombian indigenous cultures of Nicaragua to that of Mesoamerica.

Brite, Elizabeth Baker (Purdue University)

[285] Irrigation Canals as Subaltern Agents of Resistance: An Example from Nineteenth-Century Russian Turkestan

In the mid-nineteenth century, Imperial Russia established domination over “Russian Turkestan,” a large territory in Central Asia. A core part of the colonial mission was the transformation of Turkestan’s arid environments into productive farmland. Though this was eventually achieved by the Soviets who constructed massive new irrigation systems in Central Asia, earlier imperial authorities failed in this task and struggled for decades to wrest control of water management from local populations. In this paper, I examine this brief but significant initial period of conquest when the canals and the people of Turkestan resisted the imperial domination of the Russian Empire. Taking a turn toward new materialist perspectives, I explore how the precolonial canals themselves were important, subaltern agents of resistance that provided a basis around which humans could act to subvert authority. I consider the ways that these acts were imprinted on the material record of Central Asian landscapes, and explore how irrigation canals may be legible artifacts of resistance to imperial expansion.

[141] Collaborating on the Federal Level: Moving beyond Mandated Consultation in the Section 106 Process

Collaboration versus Consultation—while both terms involve working with stakeholders, consultation implies a formulaic, reactionary response or product and can produce negative connotations while collaboration suggests a voluntary, shared method and a mutual goal, invoking more positive connotations. Within archaeology, collaboration is not a new practice. Yet within this postcolonial approach to conducting archaeology there is little discussion around what this looks like within the public sector. The National Historic Preservation Act and the National Environmental Policy Act mandates a consultation procedure with a variety of stakeholders—from state and local agencies to tribal nations and community interest groups. Since consultation as mandate is based in a colonial process and has definitive legal and bureaucratic boundaries, the question arises: can we as archaeologists working in the public sector take a postcolonial approach to required consultation? If so, how, what? What institutional changes are needed to enable a collaborative practice rather than merely a consultation product? And with that, how does this processual change affect methodology and theory throughout the discipline and beyond? This paper looks at areas of constraint and potential spaces for moving beyond the mandate of consultation within a federal agency, specifically the Federal Emergency Management Agency (FEMA).

[390] Ceramic Production and Community Formation in the Middle Little Colorado River Valley, Northern Arizona

As is true today, migration throughout the past had a phenomenal impact on communities through the renegotiation of cultural practices, community and social identity. Using LA-ICP-MS I investigate community formation through shared ceramic production practices in Northern Arizona during the Pueblo III period (1125–1275 CE). This paper introduces the preliminary results of ceramic compositional analysis from contemporaneous sites in the middle Little Colorado River valley. During short-term environmental fluctuations throughout prehistory the reliability of the Little Colorado River would have served as an important draw to the region. The overall environment of the middle Little Colorado River valley, as well as variability in climatic conditions throughout prehistory has contributed to widespread movement into and out of the region over time. During the Pueblo III period in particular this region experienced an influx of migrants from a variety of cultural and geographic backgrounds, providing a unique opportunity to examine how groups negotiated the social environment during periods of widespread population movement and social reorganization.

[127] The Archaeology of Dogs at the Precontact Yup’ik site of Nunalleq, Western Alaska

Historically and ethnographically dogs have played a prominent role in the lifeways and lifeworlds of many Arctic and sub-Arctic peoples, and are considered to be a vital aspect of adaptation to living in these regions, providing protection, fur and meat, as well as aiding hunting and transportation. Excavations at the precontact site of Nunalleq in the Yukon-Kuskokwim Delta in coastal Western Alaska have uncovered a significant proportion of dog bones among the faunal assemblage. The presence of discontinuous permafrost at the site has resulted in the excellent preservation, not only of bone, but also of dog fur and even dog lice in deposits at the site, along with vast organic and inorganic material culture assemblages. Here we present a multi-stranded, cross-disciplinary study of the archaeology of dogs at Nunalleq. By incorporating the bioarchaeological analysis of dog remains (osteology, morphology, aDNA, isotopes) with the study of material culture, soils and other bodies of evidence, and the ethno-historic record, we go beyond domestication, providing insight into this vital component of precontact animal-human relationships in Western Alaska and the varied roles, and significance, of Arctic North America’s only precontact domesticate.

[237] Results of a New Method for Characterizing Casas Grandes Polychromes
Through time, the analyses of archaeological ceramics have produced a diverse number of characterization techniques. These various techniques have allowed us to create multiple understandings of style, production, and exchange patterns, building a formidable tool that is able to speak to many aspects of human behavior. However, though our standard set of techniques is imposing and productive, they may not automatically produce datasets that naturally lead to concrete patterns and natural interpretations. For example, typically-used techniques that have successfully characterized polychromes in the American Southwest, NAA and petrography, have not led my dissertation work with Chihuahuan polychromes to clear or concrete understandings of the production and exchange of these vessels in the Casas Grandes region. This is not to say that either technique has been not-useful in exploring potential patterns. Rather, a combination of cultural choice and natural environment has colluded in making these standard methods less-appropriate techniques for this area. In response to these conditions, I will discuss the results of a pilot study of 18 Ramos and Babicora polychromes, from across the region, using a relatively new mode of analysis, capitalizing on zircons, that could address regional issues in characterizing the ceramics of Northwest Mexico.

[330] Resolving Patterns in Radiocarbon Data
Radiocarbon is one of the most widely used chronological tools in archaeology but resolving patterns in large datasets is still difficult to achieve. This is partly due to the calibration process that itself generates patterns reflecting the changes in the radiocarbon levels within the environment. In addition, in many cases, the difficulty in obtaining sufficient numbers of measurements to draw definitive conclusions can be an issue and there is always the danger of over-interpretation. Bayesian analysis has been very powerfully used to resolve chronology in deeply stratified single sites but cannot be used in many types of archaeological research. Kernel density methods have the potential to explore less structured distributions of dates to reveal both temporal and geographical patterns. Critically they can also help to evaluate whether the datasets are large enough to answer specific questions. This paper will draw on a number of case studies with a particular focus on data on hunter-gatherers in the Baikal region.

[180] Is Mediterranean Island Colonization Still Interesting?
Island colonization took off as a field of comparative archaeological investigation during the 1970s and 1980s, with thought-provoking analyses of regional theatres (primarily Oceanic, Caribbean and Pacific), as well as pioneering efforts to explore wider commonalities and differences between these. In the Mediterranean, the research of John Cherry sought underlying patterns and processes among a mass of empirical data, within which new evidence might find meaning and place. Such evidence has indeed accumulated, much of it affirming existing patterns but some potentially questioning earlier interpretative frameworks. This paper considers to what degree island colonization analysis remains a challenging, innovative framework for Mediterranean archaeology today, versus the degree to which it is now essentially an intellectually mined-out field of study awaiting only the last infillings of data. The focus is on the questionable discreteness of insular colonization from wider processes in this fragmented environment, the disputed significance of putative Paleolithic activity, early-mid Holocene insights from Cyprus and the Balearics, and the relatively more dynamic results to be obtained from post-colonization studies. Some implications of these considerations for global island archaeology will be proposed.

[220] Cochasqui in Context: The Evolution of a Monumental Center
Recent investigations suggest that the history of the northern Ecuadorian mound group at Cochasqui was complex and that the perception of the site as a single, mostly unchanged monumental center is simplistic at best. Begun by AD 1000, the earliest constructions within the complex were modest rounded mounds, several containing burials. By AD 1250, much larger, ramped square mounds signaled a major shift in site function possibly associated with the eruption of Quilotoa volcano, 125 km to the southwest. Expanded soon after the devastating eruption and occupied during a subsequent widespread drought, the new, larger pyramids were topped by round temple buildings that might have included water-related rituals. Decades of excavations have failed to find evidence of a significant population near the site and Cochasqui may have been an extra-regional pilgrimage center, at least after AD 1250. The Inka, who arrived sometime around 1500, did not destroy the site as once thought, but refurbished several pyramids within the fully functioning center, as they did at Pachacamac and Tucumé on the coast of Perú. Modern myths surrounding Cochasqui have obscured the Inka presence and little is known of the site’s role in the Inka conquest and ultimate domination of northern Ecuador.

[221] Bronze Age Economy and Rituals at Krasnosamarskoe in the Russian Steppes
The final report of the Samara Valley Project (SVP), a U.S.-Russian archaeological investigation conducted between 1995 and 2002 in the Samara Oblast in central Russia, was published in June 2016. The SVP explored the changing organization and subsistence resources of pastoral steppe economies from the Eneolithic (4500 BC) through the Late Bronze Age (1900–1200 BC) across the steppe and river valley landscape in the middle
Volga region. Particular attention focuses on the role of agriculture during the unusual episode of sedentary, settled pastoralism that spread across the Eurasian steppes with the Srubnaya and Andronovo cultures (1900–1200 BC). Three astonishing discoveries were made by the SVP archaeologists: agriculture played no role in the LBA diet across the region, a surprise given the settled residential pattern; a unique winter ritual was practiced at Krasnosamarskoe involving dog and wolf sacrifices, probably related to male initiation ceremonies; and overlapping spheres of obligation, cooperation, and affiliation operated at different scales to integrate groups defined by politics, economics, and ritual behaviors.

[86] Radiocarbon Dating Versus Luminescence Dating in the Pacific Northwest
In the Pacific Northwest of North America, the radiocarbon dating of charcoal has become the standard for assigning age to archaeological contexts. Other dating techniques are seldom used. Underused techniques like luminescence dating can apply when organic materials for radiocarbon dating are absent, unreliable or not associated with events of interest. In the Pacific Northwest, luminescence dating is beginning to be used for dating features containing fire-modified rock. By dating the last exposure to sufficient heat, luminescence has potential of high accuracy, even if precision is less than radiocarbon. Here we compare paired radiocarbon dates on charcoal and luminescence dates on fire-modified rock from seven feature contexts in three archaeological sites. A strong association between these radiocarbon and luminescence dates could justify an increased use of luminescence dating. All samples were recovered from hearth or oven features. The results of this analysis indicate a close relationship of the match-pairs within 2-sigma date ranges, indicating luminescence is a viable alternative for chronometric dating in the Pacific Northwest. The ability to date fire-modified rock features is especially important for tracing the age and distribution of rock ovens along with the intensification of plant use between 5,000 and 2,000 years ago.

Brown, Kaitlin (University of California, Santa Barbara)
[142] Colonialism and Cuisine: Change and Continuity in Soapstone Consumption during the Contact Period in Alta, California
This paper investigates the processes of colonialism and identity politics in the Santa Barbara Channel region through the lens of consumption. The establishment of colonial institutions became entangled with preexisting indigenous industries, thus creating change and continuity in a variety of practices. Here, I focus on soapstone vessels as they were utilized for cooking and storing foods before, during, and after the mission period. A drastic shift in the morphological characteristics of these cooking pots inside the mission space indicates a shift in food processing activities and gendered specific tasks beginning in AD 1782. I argue that this change reflects the rise of a new citizen class, one in which Christianized Indians began producing and consuming goods that were influenced by Spanish/Early Hispanic practices. I also find that the use of traditional soapstone vessels indicates the persistence of deep-rooted practices that were maintained in the historic period. By situating soapstone consumption at the center of this study, a reassessment of foodways, identity, and gender is offered in the region during the colonial period.

Brown, Linda (George Washington University)
[80] Tz'utujil Maya Ritual Practitioners, Embodied Objects, and the Night
For contemporary Tz'utujil Maya ritual practitioners living in the highlands of Guatemala, the night is a particularly potent time and one to which they are inherently linked. Individuals often lease of their destiny to become ritual practitioners when they are first contacted by ancestral beings, known collectively as nawales, at night during dreams. Thereafter ancestral nawales and ritual practitioners enter into mutually beneficial social relationships that are mediated through sacred objects associated with the night. These objects—precolumbian figurine fragments, obsidian cores, greenstone celts, etc.—may look ordinary but they are far from it. Instead, they hold a unique ontological status as animate objects embodied by beings from a previous era, a dark world that existed prior to the creation of our present sun. Ritual practitioners understand that although sacred materials appear to be mundane inanimate objects by day, during this time they are resting. Reflecting their predawn origins, they become active at night when they go forth to wander the earth and conduct their sacred work. In this talk, I examine the night through the lens of contemporary Tz'utujil ritual practitioners who enter into reciprocal relationships with these embodied nawaal-objects.

[5] Pot Luck: Building Community and Feasting among the Middle Preclassic Maya
Ritual feasting as a practice by which sponsors create uneven social relations with other participants has been suggested to play an important role in establishing social hierarchies in many ancient societies including the ancient Maya. Feasting activities may have also been an important part of Preclassic communal building projects in the Maya lowlands. In this paper, we present data from Middle Preclassic special deposits associated with a series of early public platforms at the site of Blackman Eddy, Belize. Ceramic, faunal and botanical analyses support the interpretation that feasting activities occurred at these locations and appear to have been highly ritualized.

Brown, Mary
[175] Rock Art as Ritual Communicator: A Theoretical Evaluation
Archaeologists typically dissect rock art stylistically, symbolically, and chronologically. Symbols, in particular, lead to studies of representational imagery, entoptic phenomena, or religious icons. What remains underexplored is the concept of animism and its related behavioral activities. This paper applies a behavioral theory of communication to study the interactions between people and things. It uses performance characteristics analysis to determine the activities associated with attributes of rock art’s natural and cultural context, manufacture traces, use wear, and maintenance. The analysis is illustrated through a case study of rock art surrounding the fourteenth century Cottonwood Springs Pueblo (LA 175), in the Jornada Mogollon of southwest New Mexico. This pilot study evaluates the potential for using a communication model to interpret rock art and similar media, such as ceramic design elements, textile imagery, and wall murals.

[176] A Radiocarbon Test for Significant Demographic Events in Written and Oral History
We present the results of a simulation based test for the existence and significance of two known demographic event horizons. We extend the Shennan et al. (2013) summed probability distribution frequency method to provide a value of statistical significance for the period between two defined calendar dates. Case study one extrapolates population data from the Western historical record relating to the catastrophic European Black Death and finds a consistent statistically significant drop in population. Case study two uses a regionally scaled database of radiocarbon dates to test for a gap in settlement recorded in the oral historical traditions of descendant Tsimshian First Nation communities from the modern Prince Rupert Harbour region of Pacific Northwest British Columbia, Canada. Strong support for this “gap hypothesis” is found.
Brown, William (Department of Anthropology, University of Washington) [387]  
*Disentangling the Demographic Consequences of Subsistence Stress and Parasite Epidemiology among the Ancestral Alutiiq of the Kodiak Archipelago*

Ecological and biodemographic perspectives on human population history emphasize changes in health and disease as key drivers of macrodemographic change. However, the approaches that demographers and archaeologists have taken to modeling the epidemiologic and demographic sequelae of infectious disease differ in several noteworthy respects: Models addressing disease largely conform to a coarse-grained and globally generic typological account, focusing primarily on the demographic consequences of Neolithic and modern Epidemiologic Transitions. This paper presents an attempt to synthesize these perspectives, using a case study from the Kodiak Archipelago in the Gulf of Alaska. I present preliminary results of a time series analysis combining archaeological temporal frequency data with the GISP2-based paleotemperature record and time series data on regional salmon population dynamics and archaeofaunal abundances, as well as incoming archaeoparasitological data.

Brune Ribeiro, Anna (University of Louisville Kentucky) [45]  
*“Um Lugar dos Antigos”: A Tiered Approach to Community-Driven Survey in Cultural Palimpsests of the Brazilian Amazon.*

The Mouth of the Xingu River, on the Lower Amazon River, is a place of many histories. The edge of the Amazon Delta, it was the first Portuguese foothold in contemporary Northern Brazil, and later home to a “glorious” nineteenth-century rubber boomtown. Centered on the city of Gurupá, the region was a major hub in the traffic of Amerindians and also marked the Western extent of African slaving networks in Luso-Amazonia. Part of the Cabanagem, the history of the place itself is largely unknown. Survey conducted during ethnographic fieldwork among descendant Maroon communities in the municipality of Gurupá reveals that this complex history manifests in material and immaterial forms. I present results from guided tours through three territories, in which local teachers and community members presented known and unknown “places of the old ones” that structure their lives, memories and histories. Using a GPS, trowel, soil probe, and notebooks, I attempted to map the places and stories onto Cartesian coordinate grids. Gurupá emerges as a multidimensional place of historical, cultural, political, and social intersection.

Bruchac, Margaret (University of Pennsylvania) [138]  
*Digging for Shells: Recovering Indigenous Wampum Technologies in Museum Collections*

During the salvage anthropology era, more than 400 wampum belts (woven with whelk and quahog shell beads) were removed from the hands of Native North American keepers and accessioned into museum collections. Despite the existence of a complex system of wampum diplomacy and ritual, museums often represent these belts as almost indecipherable colonial relics. The “Wampum Trail” research team (with assistance from Native knowledge-bearers and ethnographic curators) seeks to reconnect these objects with Indigenous nations, using a range of restorative methods: archival research, object cartography, material analysis, and ethnographic interviews. Close visual studies of historic belts have revealed some heretofore unexamined physical details: anomalous beads (stone, bone, clay, glass, etc.); regional patterns of twining warp and weft; evidence of repair and reuse of components; and clear distinctions among historical and modern methods of bead manufacture and belt construction. In the past, antiquarians were so intent focused on the exotic, monetary and artistic value of wampum that they overlooked details that bespeak savvy Indigenous technologies. In the present, recovery of these details resolves questions of cultural continuity, in part, by providing evidence of discernable patterns of Indigenous curation in ritual contexts, re-purposing, and even reconstruction of wampum belts over time.

*Osage Cultural Continuity and Change in the Contact Era: Evidence from the Flaked Stone Assemblages at the Brown and Carrington Sites*

Many traditional anthropological studies used acculturation theory to understand Colonial era Native American cultural dynamics. Acculturation theory assumes a process of gradual culture change through the adoption of European culture. More recently, anthropologists have incorporated additional concepts including agency, scales of analysis, and historical silencing to more productively investigate not only indigenous culture change but also continuity during the historic period. The project reported here uses these ideas in a study of contact era continuity and change as reflected in Osage flaked stone technology. This is accomplished through analysis of flaked stone artifacts from house features and surrounding areas at two historic Osage sites—Brown and Carrington. These sites are located in western Missouri and were excavated by the University of Missouri under Carl Chapman from the 1941 through 1982. We present the research problems, methods, study sites, artifact samples, and the results of this study.

*Designer Antiquities: A Current Trend in the Not so Honest Antiquities Trade*

The fine art of creating new or composite styles of (supposed) antiquities has a long and ignoble history, beginning, as far as we know for the Americas, in the sixteenth century. It appeared again, full steam ahead, with “Tlatelolco Ware” in the late nineteenth century. Today, with increasing legal controls of antiquities importation and vending, this art has arisen again. Pieces claiming to be one thing while actually being entirely new stylistic creations, given the names of popular, but little known ancient cultures or even entirely made up, exotic names, are appearing regularly at European and North American galleries. Since so many art historians are determined to be ostriches as far as forgeries are concerned—indeed, their employment often depends on it—these utterly faux creations have begun to enter what passes as legitimate studies of precolumbian art to the detriment of everyone, save, of course, the dealers.

Brugere, Cecile (University of Louisville Kentucky)

But the history of the place itself is largely unknown. Survey conducted during ethnographic fieldwork among descendant Maroon communities in the municipality of Gurupá reveals that this complex history manifests in material and immaterial forms. I present results from guided tours through three territories, in which local teachers and community members presented known and unknown “places of the old ones” that structure their lives, memories and histories. Using a GPS, trowel, soil probe, and notebooks, I attempted to map the places and stories onto Cartesian coordinate grids. Gurupá emerges as a multidimensional place of historical, cultural, political, and social intersection.

Preliminary Faunal Analysis of Qijiaping, Gansu Province

Qijiaping in Guanghe County, Gansu Province is the type site for the Bronze Age Qijia Culture (ca. 2200–1600 BC). In July of 2016, the Tao River Archaeological Project began small-scale excavations at Qijiaping. We present a preliminary analysis of the faunal remains uncovered during these excavations. Pigs and sheep were the most commonly identified specimens. Additional identified taxa include large bovines (probably domestic cattle), dog, deer, small rodents, and an unidentified wild bovid. Other notable findings include a fairly complete corvid skeleton and two divinatory oracle bones. Our analysis makes an important contribution to the limited zooarchaeological data for this period.

Analysis of an Obsidian Source from the Cougar Pass Region of the Absaroka Mountain Range

Obsidian samples from a variety of sites across Northwest Wyoming have been sourced using X-ray fluorescence and analyzed in order to determine the importance of a relatively unheard of source from the Cougar Pass region of the Absaroka Mountain Range. Artifacts manufactured with obsidian nodules from Cougar Pass have been found in archaeological contexts across Northwest Wyoming, extending as far as a presently unknown kilometer range from their source. The wide range of specimens from a selection of sites within the Absaroka Mountain Range and surrounding areas demonstrate the varied use of the Cougar Pass obsidian source and highlight the rich archaeological importance of high elevation occupational areas. Further investigation into the use of the Cougar Pass obsidian source will help to determine the spatial-temporal significance of the region as a whole.

Investigating Seasonality of Fishing and Trade during the Maya Postclassic, with Otoliths Thin-Sections from the Inland Site of Mayapán

This paper will offer preliminary results of fish otolith thin-section growth ring analysis from the Postclassic archaeological site of Mayapán, Yucatán, Mexico. This study offers the first use of otoliths for investigating seasonality of the fish trade in the Yucatán, utilizing perhaps the largest collection of otoliths from an inland site in the Maya world. Data on seasonality, age, and size of several fish species are presented, and discussed in the context of trade ethnohistory, ecology, and fish trade sourcing.

From the Canyon to the Staircase: Expanding the Paleoindian Presence in the Arizona Strip

Evidence of Paleoindian and Paleo-Archaic occupation of the Arizona Strip, in northwest Arizona and southwest Utah, largely remains limited to isolated projectile points found lying on the modern ground surface, dispersed across large swaths of land. Building upon the few isolated finds, this presentation discusses the recent identification of multiple fluted and unfluted lanceolate and Great Basin Stemmed projectile points. In contrast to the few previously known finds, the various projectile points and types presented here were spatially concentrated within a narrow 23 km (17 miles) corridor near Kanab Creek Canyon in northwest Arizona. After a discussion of the newly documented points we incorporate Paleoindian projectile points from the North Rim of the Grand Canyon and southern Grand Staircase-Escalante National Monument in southwestern Utah to provide additional data and inferences into the Paleoindian and Paleo-Archaic occupation of the Arizona Strip.

Recent Excavations at Cerro de la Virgen, Oaxaca, Mexico

This paper presents the preliminary results of recent excavations carried out at Cerro de la Virgen, a 92-ha hilltop site located in the lower Río Verde Valley of coastal Oaxaca, Mexico. The lower Verde’s first complex polity emerged during the Terminal Formative period (150 BCE—CE 250), during which Cerro de la Virgen was one of several secondary political centers distributed around the region’s political seat, Río Viejo. Current research at Cerro de la Virgen is designed to study the negotiations that took place between secondary centers and polity leaders by examining the scale at which political, economic, and religious resources were controlled. Excavations carried out in the spring of 2016 targeted public and domestic architecture to examine resource control within communal and household settings. Preliminary evidence indicates that architectural patterns and ceremonial caching practices at Cerro de la Virgen differed significantly from those witnessed at other Terminal Formative sites in the lower Verde, including Río Viejo. These data suggest that the region’s first complex polity collapsed at ca. CE 250 because hinterland populations were not integrated into the political system managed by leaders at Río Viejo.

Castles and Their Landscapes: A Gravity Model Experiment

Castle studies in recent years has developed two major themes in developing technology: landscape studies and spatial analysis. Studies of castle landscapes have shown that external spaces were intensively used and a significant part of the space actively portrayed as noble environment. Spatial analysis has been key in identifying spaces of control, privacy, and household interaction within the castle structure. One of the limitations of spatial analysis in castle studies is the failure to include external spaces as an option for social interaction. Including external spaces raises questions about
how the physical layout of the entire castle property affected the ways people interacted with these external features and which features and external spaces might be more attractive than others. Therefore, a methodology that includes the assessment of external spaces is sorely needed. This paper discusses the gravity model as a new method for analyzing the landscape features of castles in Scotland. This study also strives to open up a dialogue about new methods and technologies for quantifying interaction with the medieval noble landscapes.

Sub-Pixel Detection of Obsidian and Pottery by NASA Satellite and Aircraft Data

We determine the detection limits of sub-pixel artifacts (site midden, obsidian artifacts, and pottery) using airborne and spaceborne image data. Research results are presented from the Glass Mountain Site in northern CA and the Boquillas site in southern Arizona. Multiple visits were made at different seasons over three years. Visible, SWIR, and TIR spectral characteristics of targets and background were measured in the field. A spectral library has been constructed from ~200 target and background samples. The average density of these artifacts (per m2) has been calculated for 25 8 × 8 m squares and for 4 × 4 m squares. Imagery data include: NASA’s MODIS/ASTER airborne simulator (MASTER) imaging system, the Airborne Visible/Infrared Imaging Spectrometer (AVIRIS), and the Advanced Spaceborne Thermal Emission and Reflection Radiometer (ASTER). We (1) determined the detection limits of obsidian and ceramic artifacts at the sub-pixel scale; (2) examined the influence of background, seasonal vegetation change and other on-site changes on the detectability of these artifact types; (3) established the instrumentation, spatial scale, and spectral bands needed to improve the detectability; and (4) tested predictions of new locations for obsidian artifacts at specific (spatial) densities in other image scenes and ground truthed these predictions.

Diet and In-Migration in the Tlajinga District of Teotihuacán: New Insights from Stable Isotope Analysis and AMS Radiocarbon Dating

Thirty years ago, the apartment compound known as Tlajinga 33 (33:S3W1) in the southern district of Teotihuacán was extensively excavated, resulting in the recovery of over 100 individuals. A paleodemographic analysis indicated that chronic morbidity was a serious health issue among residents. Additionally, previous geochemical analysis from 25 of these individuals suggested that at least 29% of residents grew up outside of Teotihuacán. Due to chronic health issues, the movement of high numbers of in-migrants from outside the district into Tlajinga would have been important in order to maintain population numbers. In this new study of the Tlajinga district, both hypotheses concerning diet and in-migration are directly tested using stable isotopic analysis. Here, 25 additional individuals from Tlajinga 17 (17:S3E1), 18 (18:S3E1), and 33 are analyzed for carbon (δ13C) and nitrogen (δ15N) stable isotopes to better understand dietary variation between individuals. Stable oxygen (δ18O) isotopes and radiogenic strontium (87Sr/86Sr) are measured in human tooth enamel to estimate the extent of in-migration at Tlajinga. Additionally, AMS radiocarbon dates from bone collagen are used to build a more precise chronology. Results shed new insights into the demographic profile of the Tlajinga district.

Zooarchaeology by Mass Spectrometry (ZooMS) and Rethinking a Definition of NISP

Biomolecular methods can vastly improve the confidence in species determination of animal bone in a manner that, unlike traditional morphology-based methods, is not subject to the skills of the analyst. Until recently these have largely focused on ancient DNA-based approaches, and so have been at costs too great to become widely used for most archaeofaunal assemblages despite being available for more than 30 years. However, within the last decade I have pioneered the development of a low-cost biomolecular method of species identification based on using soft-ionization mass spectrometry to fingerprint enzymatic digests of collagen—the most abundant protein in bone. Termed “ZooMS” (for Zooarchaeology by Mass Spectrometry), appropriate given the speed at which objective identifications can be made with this approach, this approach in recent years has been applied to thousands of bone fragments in some cases. However, it remains unclear to what extent we can utilize such large-scale approaches beyond improving our understanding of the presence or absence of particular taxa. This presentation considers the advantages of ZooMS, including its temporal ranges across the planet and taxonomic resolution but more importantly its limitations, particularly in light of how to accommodate such highly enhanced NISP counts in archaeofaunal analyses.

A Biodiversity Study of Shang Dynasty Human Sacrifice

Ongoing archaeological investigations at the Shang capital of Yin Xu in modern Anyang have contributed much to the understanding of the Shang Dynasty (~1600–1046 BCE) and Bronze Age China. Bioarchaeological investigations of the thousands of sacrificed individuals recovered from the royal cemetery at Yin Xu has historically been somewhat limited, but is becoming an important component of current research at the site. Earlier work focused mainly on collection of craniofacial data and the typology of collections. While bioarchaeology has moved away from typology and toward a more nuanced and contextualized understanding of population structure and history, the craniofacial data collected and published with these earlier studies remain a valuable resource. This project uses this data to explore the structure and history of a sample of the population of sacrificed individuals at the site of Yin Xu using a biodiversity approach. The structure and microevolutionary history of the sample are investigated in order to contribute to the understanding of the practice of human sacrifice by the Shang and the relationships between the Shang and those sacrificed.

Budden-Hoskins, Sandy (Archaeopots/UAISK)

Tracing Purpose: An Emic View of Pottery Making in Prehistory and Beyond

Archaeologists have, until recently, tended to study pots in what I view as an outside/in or etic manner. We have looked at size, form, decoration and touched on the manner of making only insofar as a pot being hand-built, wheel-thrown, or cast. However, by developing a profoundly emic
understanding of potting, as performance, we have a tool that can allow us to view the entirely social and shifting cultural nature of a particular genre of pots. In 2007 I developed a skill methodology that has been used successfully on a number of European prehistoric assemblages. In 2015 the methodology was applied to the indigenous pottery of Taiwan, including that of the Paiwan. I will discuss the results of this research and what I believe it reveals about the shifting social nature of this pottery genre and what this may mean for an understanding of prehistoric pottery in Taiwan.

Green Lake Burial Grounds: An Unprecedented Collaboration in Shuswap Territory

Located atop the shores of Green Lake, and on Shuswap First Nation traditional territory, a First Nations burial site was slumping into the water. Long bones began emerging 40 years ago, when the local landowner was just nine years old. In 1997, archaeologists relocated one burial; but up to 15 individuals remained in this sliding cemetery. Since 1997, provincial government Archaeology Branch has worked toward moving those individuals. In July of 2013, Crossroads Cultural Resource Management worked in collaboration with other industry agencies and four First Nations to relocate these individuals. This project is historic in British Columbia, as Archaeology Branch acted as the client for the first time. Moreover, in another industry first, two distinct cultural resource management firms collaborated on the overall management of the project—one focused on archaeological recovery, and the other on sociocultural aspects of past and present peoples. The Canim Lake Indian Band has since purchased the site. They plan to make it into a memorial. The success of this project is attributed to the emphasis on intangible cultural aspects surrounding archaeological recovery and First Nations protocols, which will be the focus of this presentation.

Excavation and Survey in the Argentine Andes: Preliminary Field Report of the First IFR Field School in Uspallata, Mendoza

The first field school in the Uspallata valley, Mendoza, took place in 2016 and was organized by the Institute for Field Research (IFR). Its goals were to clarify the use of the landscape over the last two thousand years by people with an economy that incorporated hunting, gathering, small-scale agriculture, and possibility llama herding. Research was near one of Mendoza’s best known archaeological sites, Cerro Tunduqueral. This site’s dense rock art has been known for decades, but little is known about the people who made the engravings. Excavations at the adjacent cave site Tunduqueral 1 revealed 1.6 m of cultural deposits dominated by lithic artifacts and a major hearth feature. Ceramics were absent and faunal remains were poorly preserved, with the exception of Rhea Americana eggshell. Typologically early tools hint that the initial occupation was as early as the Middle or Early Holocene. Systematic surface collections in the same area revealed extensive concentrations of ceramics, ground stone, and lithics, remnants of activities in seasonally active alluvial plains. People’s movements around the landscape probably included seasonal occupations of all three places: long occupations near streams, brief stays at the rockshelter, and making rock art at Cerro Tunduqueral.

Sourcing FGV Artifacts Recovered from Housepit 54, Bridge River Housepit Village, British Columbia

Geochemical analysis of trace elements in fine grained volcanic rocks (FGV) using HHpXRF technology allows elemental characterization that enables matching fine grained volcanic artifacts with their original toolstone sources. Excavations of Housepit 54 during 2013–2016 field seasons have yielded a large assemblage of FGV artifacts that we attempt to match with toolstone sources or outcrops in the region. Preliminary research on characterizing artifacts recovered during the 2013 field season through mineralogical and elemental analysis noted two dominant chemical groups, likely indicating two distinct sources. One of the distinct chemical groups of artifacts shares elemental similarity with the Arrowstone Hills volcanic deposits. During the summer of 2016, further field survey in the region identified several more possible local toolstone sources, including both young volcanic deposits and glacial deposits featuring fine grained volcanic cobbles. This paper further explores the use of FGV through the entire occupation of HP54, allowing an important understanding of shifting toolstone acquisition during the use life of the pithouse.

A Bayesian Model Sensitivity Study of Non-Static Diet-Collagen Isotope Fractionations Factors Used to Assess Breastfeeding and Weaning Practices among Fisher-Gatherers Populations, Western Cuba

Reconstructing pale diets from bone-collagen isotope values (carbon and nitrogen) requires proper knowledge of diet-collagen isotopic fractionations ($\Delta^{13}C_{diet-coll}$, $\Delta^{15}N_{diet-coll}$). While these isotopic fractionations vary considerably among previous human pale diet reconstructions, some more recent studies have successfully employed “non-static” dietary offsets. New research suggests that non-static diet-collagen isotope fractionations is best when attempting to reconstruct pale diets of cultures consuming varied diets, particularly when used in association with a variety of new Bayesian multisource stable isotope-mixing models now available. This particular study involves a sensitivity study of some non-static diet-collagen isotope fractionations employed in three Bayesian multisource stable isotope-mixing models to assess breastfeeding and weaning practices among fisher-gatherer populations from Western Cuba.

A Prism or a Mirror? Reflections of a Hopewell Man

Interred within a deep, mounded and relatively elaborate tomb nearly two millennia ago, our Hopewell man lived approximately as many years as we have studied his remains. While his tissues have remained unchanged since excavation, our analytical gaze has witnessed near tectonic shifts in...
Remnant fats from these activities preserve exceptionally well in many Alaskan sites and various sources can be identified using standard techniques of processing and combustion of animal products including bone, fat, and oil for food and fuel was critical for human occupation of far northern latitudes.

Combustion Features, and Ceramics

by increasingly sophisticated analytical methods? In this presentation we first consider fundamental mid-twentieth century distinctions between our Hopewell man and his Illinois River valley community. How has his/our viewpoint changed across so many theoretical approaches, informed as well the theoretical perspectives. The first interpretations, those of the senior author in zealous pursuit of her doctoral degree, were decidedly processual and lacked reflexivity. She spoke of status, for example, identifying our subject as one who had controlled disproportionate resources in life and after death. Today, having absorbed the post-processual critique and currently engaging the challenges inherent in interpreting intersecting identities, we return to our Hopewell man and his Illinois River valley community. How has his/her viewpoint changed across so many theoretical approaches, informed as well by increasingly sophisticated analytical methods? In this presentation we first consider fundamental mid-twentieth century distinctions between bioarchaeological and osteobiographical approaches. Then we turn to interpretations colored by postprocessual visions of worldview. Finally, we enter a new osteobiographical interpretative arena informed by agency, embodiment, personhood, and identity theories. Our assumption throughout is that osteobiography is a prism through which we view a community—or perhaps it is a mirror?

[221] Biological Diversity in Medieval Uzbekistan: Examining Community Expression under the Qarakhanid State

This paper examines the expression of community during the Qarakhanid period (ninth–twelfth century CE) through a study of patterns of phenotypic diversity at medieval sites across Uzbekistan. The Qarakhanid dynasty is argued to be an integral period in the shaping of population, linguistic, and religious frameworks that shaped the social and ethnic landscapes of Central Asia up through the modern day. Historical sources suggest that the Qarakhanid rise to power instigated an in-migration of Turkic populations, the spread of Islam across the region, and the cultivation of Turkic language and culture. Little archaeological work has been done, however, to investigate how community interaction and expression was affected by these activities. In this study, geometric morphometric analysis of cranial shape is used to understand levels of biological diversity and association between groups at a collection of sites that cover a range of environmental, geographic, and economic contexts. Results indicate that biological expressions of community are variable across the landscape and are likely dependent on complex social and environmental contexts. This suggests that despite Qarakhanid sponsored cultural and religious campaigns, community expression was still in part mitigated by a range of variables, spanning economic, ethnic, and other social spheres.

Processing and combustion of animal products including bone, fat, and oil for food and fuel was critical for human occupation of far northern latitudes. Remnant fats from these activities preserve exceptionally well in many Alaskan sites and various sources can be identified using standard techniques of lipid analysis. Combining lipid analysis with ethnographically informed experiments and high-resolution analysis of archaeological sediments, combustion features and ceramics, could help trace the use and processing of various animal products for food and fuel in Alaskan prehistory. Interpretive highlights of several recent studies will be discussed, as will directions for future analysis.

[22] Sustainable Research in Archaeological Science: Examples from High-and Low Resolution Biogeochemical Studies of Archaeological Shell

Advances in archaeological sciences demonstrated the (almost) unlimited potential to apply new methods and techniques to existing and underutilized archaeological collections. Developing programs of research using innovative and multidisciplinary approaches to the analysis of material cultural, hard tissues, sediments and organic remains are critical to move the discipline of archaeological sciences forward. More critical, is the balance between technical skills one learns to become an ‘archaeometrist’ while still being rooted in contemporary anthropological theory. This paper discusses the results shell biogeochemical data, specifically oxygen and carbon isotopes and micro-growth patterns from sites across Canada British Columbia, Ontario and Newfoundland, revealing patterns of trade, seasonality, and landscape use over the past 6,000 years. By combining low- and high-resolution studies on hard-tissues, such as shell, bone and teeth from existing collections, archaeologists can build sustainable archaeometric research programs to develop new environmental proxies and interpret past cultural, historical and natural environments.

[204] Ancient Urbanites: The Spatial and Social Organization of Outlying Temple Groups at Ceibal, Guatemala

Recent investigations of minor temple groups at Ceibal, Guatemala shed light on the social and spatial organization of ancient Maya cities. Many researchers suggest that minor temples were important integrative hubs in lowland Maya settlements. Because minor temples were constructed at regular intervals around the urban epicenter of Ceibal, it appears that they were integral to city planning, and likely the centers of localized communities.
Although they may have been discrete social units, the formation of these “intermediate” groups was crucial to shaping and sustaining the larger sociopolitical order. This research investigates community organization at Ceibal by: 1) assessing the existence of spatially-distinct residential zones organized in association with at least one temple; 2) evaluating variations in material culture across different residential zones; and 3) identifying local sources of water within each zone, which would have been important loci of routine interactions and crucial for supporting local populations. A diachronic assessment of multiple lines of evidence provides a basis for more clearly identifying and understanding how intermediate social groups at Ceibal formed and articulated with the larger society. More broadly, this paper provides methodological and theoretical approaches for studying different levels of community organization among the ancient Maya.

Burke, Adrian (Université de Montréal) [216] Traditional Knowledge and Lithic Sources in Northeastern North America
Northeastern North America contains numerous lithic sources that are found in a variety of geologic and geographic settings. These materials vary widely in their knapping quality, color, texture, translucency, and block/cobble size. Access to these sources can also vary greatly, from underwater to the top of mountains. Aboriginal traditional knowledge allowed people in the past to navigate and use these varied sources. I present data from ethnographic and ethnohistoric documents that provide an insight into this traditional knowledge in precontact times. Toponyms point to lithic sources in the physical landscape that were known for generations. Oral traditions indicate that several sources in the Northeast possessed important symbolic meaning as part of the cultural landscape. I also explore how this traditional knowledge can help the archaeologist to better understand the exploitation of these lithic sources and their importance, whether symbolic or economic, to Aboriginal societies in the Northeast.

Burke, Ariane (Université de Montréal), Colin D. Wren (University of Colorado) and Julien Riel-Salvatore (Universite de Montreal) [165] The Social Consequences of Climate-Driven Changes in the Spatial Distribution of Human Populations during the Last Glacial Maximum (LGM)
Risk-reducing strategies allow humans to manage ecological risk while minimizing disruptions. Unpredictable resource fluctuations, i.e., ecological risk, are driven by a combination of climate conditions and climate variability. Under extreme conditions reduction strategies may fail, however, forcing a reorganization of the social and economic structure of affected populations, as well as their technological systems. Risky conditions during the LGM, for example, affected the spatial distribution of populations in Western Europe as well as the ease and frequency of interregional mobility. This will have had an impact on human social networks and cultural exchange. Using predictive modeling, climate simulations and agent-based modeling, we explore how a risk-averse strategy created the spatial patterns observed in the archaeological record and consider their social consequences.

Burke, Chrissina C. (Northern Arizona University), Katie Tappan (Northern Arizona University), Gavin Wisner (Northern Arizona University) and Gregory Allen (Northern Arizona University) [321] Ritual Fauna Use in an Elite Ancient Maya Burial: Examination of an Animal Long-Bone Cache in the Recently Discovered Royal Tomb at Xunantunich, Belize
Animal use in elite burials can provide a more holistic perspective on the importance of specific fauna as prestige goods or as status and power markers in the Maya world. This presentation discusses a discrete cache of animal long-bones located at the feet of a human burial recovered from the newly discovered royal tomb at Xunantunich during the 2016 field season of the Belize Valley Archaeological Reconnaissance (BVAR) project. Maya zooarchaeologists have long held that the use of specific species or the identification of right or left sided elements in ritual contexts can indicate cultural ideas of masculinity, power, or social status. This presentation discusses the results of analysis, specifically skeletal elements recovered, species identification, and taphonomic signatures present to determine if these faunal remains can contribute to our greater understanding of the individual buried in the tomb and help us better understand fauna in Maya ritual.

Burkholder, Jo (University of Wisconsin–Whitewater) [273] Pisanay and the Endangered Rock Art Traditions of Arequipa, Peru
Drawing on the archaeological excavations at the site of Pisanay, located in the Sihuas Valley of Arequipa (southern) Peru, this paper will situate the rock art at the site within the broader contexts of multiple rock art traditions in the region. These traditions include both painted and pecked images on rock surfaces, a wide variety of geoglyphs, mobiliary art, and sacred offerings made to particular rocks and geographic landmarks that represent huacas (loosely ‘holy places’). Within the boundaries of the Pisanay site, both pecked designs (petroglyphs) and mobiliary art have been found, but Pisanay also appears to occupy a central location within the broader sacred geography of the valley and surrounding pampa, a geography defined by a variety of geoglyph styles. The need to document, and hopefully date, these sites has increased in recent decades as the economic development associated with the Majes Irrigation Project, one of the largest in the world, has begun to endanger not only individual sites, but whole sacred landscapes. To date preservation efforts have been minimal, challenged by both economic forces and a lack of awareness of the rich rock art traditions.

Burks, Jarrod (Ohio Valley Archaeology, Inc.) [283] Mapping Residential and Public Space in Cahokia’s Merrell Tract: Results of Recent Magnetic Surveys
The Merrell Tract is located west of Monk’s Mound and just outside downtown Cahokia. It is well-known for excavations of the famous Woodhenge at its west end and a large residential district at the east end. However, very little is known about what lies between. In 2012 and 2013, with logistical funding from the Cahokia Mounds Museum Society and the Illinois Association for Advancement of Archaeology, a large-area magnetic survey was undertaken to determine the density and extent of the area’s archaeological features. Though their magnetic signatures proved to be quite subtle, many dozens of pit features and houses from various time periods were detected. Also notable are large areas lacking features. In this presentation I review the results of the magnetic surveys and situate them alongside earlier excavation data. These recent geophysical surveys continue a long tradition of the use of remote sensing data at Cahokia for examining site structure, and they further show the utility of even larger-area surveys.

Burley, David [180] Small Island Adaptations in the Initial Colonization of Fiji and Tonga
Current research into the earliest Lapita occupation of Fiji and Tonga emphasizes the importance of small offshore island settlement choices for founder populations. Associated faunal data typically illustrate reliance on reef and marine resources that, in turn, have resurrected 1960s “strand looper” interpretations for Lapita economy, with little to no reliance on agricultural production. Recent studies at early Lapita sites at Kavewa (northern Fiji) and Nukuleka (southern Tonga) provide an alternative view, including use of freshwater wetlands and planting pits for reliable taro yields.

Burns, Gregory (University of California, Davis)

[381] Ancient Origins of Ethnographic Shell Bead Money in Central California
Far from providing a bounty that obviated agriculture, the California acorn economy presented risks of secular variation more extreme than experienced by other densely populated hunter-gatherers. Decentralized political organization and high ethno-linguistic diversity further complicated redistribution of spatio-temporally variant resources. In the ethnographic period, shell bead money played a key role in enabling exchange. We examine changing patterns in bead manufacture and distribution through time to identify when and how beads took on this role, and suggest how the development of money may be tied to broader social and demographic developments in ancient California.

The measurement of platform angles on lithic flakes by hand is notoriously difficult, and is plagued by intra- and inter-observer variability. The measurement method proposed in this poster uses 3D models of flakes loaded into Blender, a free open-source 3D design program. After identifying the platform, two points (a) and (b) are defined at the intersections of the left and right lateral margins and the platform. A line (a-b) is drawn between these two points, ignoring any platform roundedness or complex faceting. A line (d-e) is drawn that intersects the midpoint of line (a-b) at a 90 degree angle and that terminates in points (d) and (e) on the intersections of the ventral and dorsal faces with the platform. Next, a flat plane that bisects line (a-b) at a 90 degree angle is drawn through the flake. A point (f) can be chosen at any point where this plane intersects with the ventral and dorsal side of the flake, and the angle between line (d-e) and lines (d-f) and (e-f) can be accurately measured using built-in tools, giving a well-defined, replicable measurement of interior and exterior platform angles.

[371] Behind the Bear’s Ears: Climate and Culture in the Early Pueblo Era on Elk Ridge, Southeast Utah
The Pueblo I period was a time of tumultuous throughout the Four Corners region. Long regarded as an era of gradual transition, it is now recognized by most authors as a discrete and decisive turning point in North American prehistory. While this topic has been studied extensively in the central Mesa Verde area of southwestern Colorado, very little formal research has occurred for the early Pueblo era in southeast Utah. The high uplands area of Elk Ridge contains probably the greatest concentration of Pueblo I sites in this region. Cultural resource inventories on Elk Ridge itself, and an extensive published literature on nearby landforms like Cedar Mesa, comprise a useful dataset for investigating the early Pueblo archaeology of southeast Utah. This study presents a synthetic analysis of Pueblo I settlement patterning in the Elk Ridge area in terms of climatic and environmental factors.

[127] Hard Fare: Investigating Dog Teeth to Interpret the Value of a Dog among Northwestern Plains and Rocky Mountains
In this paper, Dental Microwear Texture Analysis is used to evaluate the teeth of dogs recovered from Late Prehistoric sites to investigate the idea that these animals had their natural diets modified by their human counterparts. This study compares microwear from wolves (Canis lupus) and coyotes (Canis latrans) to that of archaeological dogs recovered from various sites that represent human mobile groups of the Northwestern Plains and Rocky Mountains. Varied practices have been described in the ethnohistoric record, including Native groups intentionally provisioning their dogs as well as letting them subsist solely by scavenging. Understanding feeding programs as a proxy for the value of the dog among indigenous groups will contribute to continuing investigations on how dependent humans and dogs were on each other and the significance of dogs in general. Typical ecological models measure value as a compromise between what is given and what is received. This approach to understanding human behavior can be applied to the use of dogs and may inform fundamental anthropological questions about people and their environmental interactions in the past.

[73] The Long Life of the Transient: Investigating Painted plasters at Çatalhöyük
During the two decades of the Çatalhöyük Research Project, painted plasters have been investigated using a wide array of methodologies and theoretical perspectives, spanning from contextual to experimental approaches, and from iconographic classification to archaeological analyses. While the transient character of Çatalhöyük paintings has often been discussed, the longer life-cycles of entire plaster sequences have rarely been investigated. Using a mixed methodology that combines block sampling, excavation tests, photogrammetric techniques (3D modeling and Reflectance Transformation Imaging) and archival research, a new dissertation project has started to investigate how painted surfaces at Çatalhöyük changed over time. For instance, how often were walls painted and where are painted layers placed in the sequence of plasters? How do earlier painted layers relate to later ones? Were paintings always covered by successive plaster layers or were they preserved and repaired in some cases? Preliminary research shows a remarkable variability in plaster sequences across the site and suggests that some paintings were less “transient” than others, being retouched and repaired after the first painting event. This paper will discuss these preliminary results and their implications on previous interpretations and research practices at Çatalhöyük.

Busby, Ashley (Texas Tech University)

[126] From Viewer to Observer: Analyzing Spatial Complexity of Pictographs in the Lower Pecos
From Viewer to Observer will discuss the visual elements of the Pecos River style rock art, exploring the painting techniques and patterns that created these complex spaces. In addition, this paper will examine Lower Pecos pictographs through David Summers’s Real Spaces, as well as other texts, to create a context within current and traditional art historical methodologies. In using Summers’s idea of the spatially aware “observer” instead of the “viewer” I hope to expand the boundaries of the traditional composition to incorporate the physical space these works of art occupy, which enhance their spatial complexity as paintings. Analysis of the pictographs within their respective settings can deepen our understanding of the formal qualities of these paintings, and further, reveal interactions between image, surface, and surrounding space. By expanding our understanding of how meaning was communicated through the art and how it formed part of the culture within which it was produced, we gain insights into the cognitive behaviors which underlie Pecos River style imagery.

Shifting Practices: Materiality and Mortuary Ritual at Early Classic Charco Redondo

This paper explores the relationships between the people, objects and practices that engendered communal obligations and constrained strong social hierarchies in the Formative were being altered in ways that may have promoted individual and familial identities. The abundance of new materials used in mortuary ritual, such as the abundance of new materials used in mortuary ritual, such as bone artifacts, pottery, and stone tools, may have facilitated the spread of a Mississippian religion from Cahokia, the only Native American city north of Mexico. The establishment and spread of a Cahokia-Mississippian religious tradition can be seen as a religious movement differentially generated by many physical movements of persons, things, ideas, and substances. Archaeology is well suited to examine the fine-grained negotiation process of religious change. This paper focuses on one specific case study at the Collins site in East-Central Illinois and examines whether missionary practices were a catalyst for a religious movement.

Moving a Movement: Missions and Missionaries in Medieval North America

The relationship between cultural interaction and religion as a catalyst for long-term historical change is an underdeveloped line of inquiry in pre-columbian archaeology. Particularly in North American archaeology, Mississippian cultural expansions and intrusions have been considered primarily in political or economic terms. Missionizing—defined as the intent to convert someone or something to a new idea or religion—in cultural and religious change may have facilitated the spread of a Mississippian religion from Cahokia, the only Native American city north of Mexico. The establishment and spread of a Cahokia-Mississippian religious tradition can be seen as a religious movement differentially generated by many physical movements of persons, things, ideas, and substances. Archaeology is well suited to examine the fine-grained negotiation process of religious change. This paper focuses on one specific case study at the Collins site in East-Central Illinois and examines whether missionary practices were a catalyst for a religious movement.

Hopewellian Connections in the Midsouth: Tunacunnhee and Yearwood

In 1976 Richard Jefferies published on a Middle Woodland burial mound complex in northwestern Georgia called Tunacunnhee. The previous year, Brian Butler salvaged an unusual Middle Woodland burial mound complex in southern Middle Tennessee, called Yearwood, published in summary fashion in 1979. At the time, radiocarbon dating was too limited and primitive to get an accurate read on the age of these two sites, and the then available dates suggested a considerable difference in age despite many similar artifacts with Hopewellian connections. A reexamination of the Yearwood data along with new radiocarbon dates now permits a better appreciation of the correct age of Yearwood and the potential relationships of these and other sites.

Shifting Practices: Materiality and Mortuary Ritual at Early Classic Charco Redondo

This paper explores the relationships between the people, objects and practices that engendered communal mortuary practices at the site of Charco Redondo in the lower Río Verde Valley of Oaxaca. The Early Classic follows the collapse of the first Río Viejo polity, and significant differences in mortuary practices may signify a transformation in how power and authority were constituted. While communal internment continued, burials were undisturbed by later internments and individual offerings accompanied most burials as compared to communal caches and limited individual mortuary practices may signify a transformation in how power and authority were constituted. While communal internment continued, burials were generally undisturbed by later internments and individual offerings accompanied most burials as compared to communal caches and limited individual mortuary offerings in the Formative. Biodiversity analyses also indicate that decedents were clustered according to phenotypic similarities. Entanglements between people, places, objects, and practices that engaged communal obligations and constrained strong social hierarchies in the Formative were being altered in ways that may have promoted individual and familial identities. The abundance of new materials used in mortuary ritual, such as Pachuca obsidian, likely also participated in the renegotiation of power and authority as more visibly hierarchical. The focus on individuals and dynasties is firmly established in the region by the Late Classic, a period that is in part defined by a rejuvenation of the Río Viejo polity centered on elite rulership.

On the Ecodynamics of Fisheries at Tse-whit-zen

On the northern Pacific Coast of North America, fish play an extremely important role in conceptual models related to hunter-gatherer evolution and social dynamics of household production and resource control. Our ability to rigorously apply archaeo-fish remains to these models is limited by substantial data requirements including well-documented contexts, high-resolution chronology, control over complex site formation processes and taphonomy, as well as large sample sizes. The 2004 excavation and careful geoarchaeological documentation of micro-stratigraphic contexts from Tse-whit-zen provides an opportunity to study fine-grained patterns in the fishery in the context of abrupt environmental change. Over 112,000 fish remains were documented, including ~57,000 specimens identified to at least order, from seven chronostratigraphic zones and associated with two plankhouses and extramural activity areas. Herring represent over 50% of the identified specimens, with 20+ taxa also present. While some variation in fish use is...

Abalone in the Archaeological Record of Barkley Sound

This report focuses on the northern abalone (Haliotis kamtschatkana) recovered in the 2016 excavation of Hup'kisakuu7a (Site 93T) in Pacific Rim National Park. This study combines an analysis of the data recovered through archaeological excavation and column sampling at 93T, a review of neighboring archaeological site reports, and the collection and measurement of a modern assemblage of abalone shells. The aim was to answer three research questions: first, how ubiquitous is the presence of abalone in the archaeological record at 93T; second, how does the ubiquity of the abalone recovered at 93T compare to other sites in Barkley Sound; third, is it possible to estimate the size of archaeological abalone using a modern collection? It was determined that abalone is present in 5.6% of the levels examined at 93T, which represents the lowest ubiquity found among the six archaeological excavations reviewed. An assemblage of 22 modern abalone shells was used to create a regression model representing the relationship between hole measurements and total shell length. The strongest of these regressions can explain 59.45% of variability in shell length.

Buvit, Ian

A Source and an End: Hokkaido, Sakhalin, and the Peopling of Beringia

After nearly a century since confirming Pleistocene humans in North America, having taken a few misguided turns along the way, our discussions about First American origins remain focused on late glacial northeast Asia. While questions persist about exact timing and means, geographically, Beringia is central in terms of routes. Recent genetic literature describes a standstill or isolation when a series of distinct Native American lineages formed prior to movement south of the continental ice. While Beringia is a highly possible location for this event, we argue it was more likely the Paleo-Sakhalin-Hokkaido-Kuril (PSHK) Peninsula where geochronological evidence points to Last Glacial Maximum (LGM) refugia and where inhabitants produced a highly diverse suite of lithic tool kits. This was followed, however, by a period that coincides with the so-called standstill when nearly all PSHK sites recovered at 93T compare to other sites in Barkley Sound; third, is it possible to estimate the size of archaeological abalone using a modern collection? It was determined that abalone is present in 5.6% of the levels examined at 93T, which represents the lowest ubiquity found among the six archaeological excavations reviewed. An assemblage of 22 modern abalone shells was used to create a regression model representing the relationship between hole measurements and total shell length. The strongest of these regressions can explain 59.45% of variability in shell length.

Comparison of Nubian and Egyptian Patterns of Physical Activity at New Kingdom Tombos

Tombos, located at the Third Cataract of the Nile River in Sudan, was established as an Egyptian colonial site in Nubia during the New Kingdom period. Burials provide evidence for high level Egyptian administrators and support staff as well as local community members. Previous investigations of the Tombos remains have indicated that individuals buried at Tombos participated in relatively low levels of strenuous physical activities, indicative of roles such as administrators, scribes, and craftspeople. This study examines the differences in physical activities via entheseal remodeling and osteoarthritis in subgroups at Tombos. Strontium isotope analysis is used to differentiate locals from first generation immigrants, craniometric analyses are used to separate Egyptian and Nubian biological groups, and Egyptian/Nubian ethnic patterns are viewed via burial ritual. Though sample sizes are small, results indicate that Nubians may have been engaged in more strenuous manual labor than Egyptian individuals at Tombos. While most individuals in the overall Tombos population show few signs of hard labor, these results suggest that Egyptians may have participated is less physical roles, such as administrators, while Nubians had other tasks such as craft production.

Did Increased Landscape Management through Pyrodiversity Lead to a Rise in Deer Procurement in the San Francisco Bay Area?

Some of the earliest archaeological applications of human behavioral ecology were Central California studies of faunal resource depression by Jack Broughton including a detailed study of the massive Emeryville Shellmound, located on the east shore of San Francisco Bay. An intriguing pattern identified by Broughton was a significant increase in the relative abundance of deer in the later occupational strata at Emeryville. Broughton attributed this shift to the initiation of distant-patch hunting and supported this attribution with body part representation data. Recent research along the Central California coast at Quirouste Valley has highlighted the role of native Californians in maintaining a diverse and highly productive mélange of habitats through controlled burning. We seek to examine whether there is a faunal signature that provides evidence for similar burning in the San Francisco Bay Area and if so, whether this might provide a complementary explanation to Broughton’s distant-patch foraging. We hypothesize that controlled burning of
the hills adjacent to the Emeryville Shellmound would have enhanced habitat in a manner that increased deer populations and also made deer more regular targets for hunters from Emeryville. Finally, we discuss the broader implications of landscape management on prehistoric foraging in Central California.

Cabrero, Teresa (Shaft Tomb) [23] La piedra verde como motivo ce la colonización del Cañón De Bolaños en el Occidente de México

Uno de los factores más importantes para la colonización del cañón de Bolaños fue la necesidad de establecer contacto de tipo comercial con el área de Chapultepec donde se explotaba la codiciada piedra verde o malaquita. Lograron su objetivo a través del establecimiento y control de una ruta comercial que atravesaba la región de Bolaños; la adquisición y redistribución de la malaquita primero; y la turquesa después, por todo el occidente de México fue el eje rector de su economía. La turquesa cuyos yacimientos se encuentran en Nuevo México, la adquirían mediante el contacto con los integrantes de las caravanas de comerciantes provenientes del Centro de México a través de la ruta comercial del interior.

Cagnato, Clarissa (University Paris 1-Panthéon Sorbonne), Olivia Navarro-Farr (College of Wooster), Griselda Pérez Robles (Proyecto Regional Arqueológico El Perú-Waka'), Juan Carlos Pérez Calderón (Proyecto Regional Arqueológico El Perú-Waka') and Damaris Menéndez (Proyecto Regional Arqueológico El Perú-Waka') [174] Feeding the Mountain: Plant Remains from Ritual Contexts on and around Structure M13–1 at El Perú-Waka'

Structure M13–1, a major civic-ceremonial building at the center of the Classic Maya city El Perú-Waka' in northwestern Petén, Guatemala, held special significance to its citizenry. While it was likely ritually significant since the Early Classic period, evidence indicates it was the focus of sustained and repeated ceremonial acts of likely varying scales, accouterment, and practitioners throughout the Late and Terminal Classic periods (circa AD 600–900). In this paper, we explore data from recent paleoethnobotanical analyses pertaining to numerous archaeologically documented contexts revealing that plant remains were among the offerings in various of these ritualized contexts. The contexts in question date to the Late Classic period and include a subterranean chamber, a fire shrine, and the tomb of the Late Classic Queen Lady K'abel. Even after El Perú-Waka's royal court declined in the early ninth century AD, Wakeños continued to ritually engage Structure M13–1, blanketing the structure in a variety of offerings ranging from gurgantuan stelae fragments to now nearly imperceptible plant remains. Paleoethnobotanical evidence, in conjunction with other archaeological data, provides key information regarding ancient ritual practices in the Maya region, in this case shedding light on how the Maya metaphorically fed this particular structure.

Cai, Dawei (Research Center for Chinese Frontier Archaeology), Quanjia Chen (Research Center for Chinese Frontier Archaeology), Hui Zhou (Research Center for Chinese Frontier Archaeology) and Dongya Yang (JLU-SFU Joint Laboratory for Bioarchaeological Res) [116] Ancient DNA Analysis of Early Neolithic Cattle from Houtaomuga site, Northern China

The Houtaomuga site is located on the east bank of Xinhuangpao Lake, in Dā'an County, Jilin Province, Northeast China. According to the archaeological excavations, the Houtaomuga site can be divided into seven phases from the early Neolithic to the Late Bronze Age (8000–2050 BP). Although many Bos skeletal remains were found in the phases Houtaomuga III (6300–5500 cal. BP) and Houtaomuga IV (5000 cal. BP), it was very difficult to identify to the species level. In this study, ancient DNA analysis of Bos remains was utilized. Our results showed that most Bos specimens belong to mtDNA Haplogroup C of wild Bos primigenius which was never domesticated in China. Only one sample from phase IV belongs to Haplogroup T3 of domestic cattle that originated in the Near East. Our research provides new insight into the origin of Chinese cattle.

Cain, Tiffany (University of Pennsylvania) [280] Formative Experiences: Everyday Life and Political Violence in Yucatán, 1847–1866

How can we study political violence in the archaeological record? How does it impact civilian spaces and how can we rethink its consequences for everyday life? This paper argues for the interpretive value of civilian landscapes for the study of violent conflict. The tendency to treat political violence as an event (e.g., the Caste War of Yucatán) in archaeology, rather than a prolonged sociopolitical episode or process, impoverishes our archaeological theorization of violence: violence is forced to enter a sphere of exceptionalism, positioned outside of the “everyday.” Yet, such violence is not confined to the battlefield or other archetypal conflict spaces. It enters into the domestic sphere and assaults civilian population centers. Here, I present the preliminary findings of an archaeological study of the postconflict landscapes of Quintana Roo, Mexico. I focus specifically on evidence likely representative of the early years of the Caste War or Maya Social War (1847–1901). I show that when we reconsider the common material proxies of war—fortification and abandonment—in a way that centers ordinary people, we position ourselves to understand not only the mechanics of war but the transformative effect of political violence on people’s lives and the landscape.

Caldwell, Megan (University of Alberta), Dana Lepofsky (Simon Fraser University) and Robert Losey (University of Alberta) [380] Ecological, Archaeological, and Social Perspectives of Northern Coast Salish Marine Resource Management Systems
Coastal peoples around the world have complex systems of marine management that are situated within and influenced by a myriad of social and ecological actions and contexts. On the Northwest Coast of North America, as elsewhere, understanding the physical and non-tangible aspects of these systems requires using diverse kinds of knowledge and data. In this presentation, we bring together traditional ecological knowledge of Tla’amin First Nation elders with archaeological data to understand the marine resource management systems of the Northern Coast Salish of southern British Columbia. Our archaeological data include fish and shellfish remains from middens, and the spatial distribution and forms of associated intertidal stone and wood features. By analyzing the archaeological evidence though a series of nested spatial scales, and combining these analyses with Tla’amin knowledge of marine ecosystems, we show how ancient systems of management ensured equal access to and sustained use of a suite of marine resources throughout the late Holocene.

Callaghan, Michael (University of Central Florida), Daniel Pierce (University of Missouri) and William Gilstrap (University of Missouri) [9] Integrated Compositional Analysis of Lowland Maya Middle Preclassic Pottery at Holtun, Guatemala

The archaeological site of Holtun is an intermediate sized Maya civic-ceremonial center with documented occupation from the Middle Preclassic through Terminal Classic periods (800 BC–AD 900) featuring well-preserved cultural deposits in multiple contexts. Previously, NAA was conducted on an assemblage from the Middle Preclassic ceramics in which four discrete compositional groups were identified. One such group in particular was composed almost exclusively of Mars Orange Paste Ware, a product thought to be from Belize, while the other groups are assumed to be of local production. As a complement to the previous study, samples from each compositional group, representing both local and imported assemblages, were analyzed using ceramic thin section petrography. Resulting petrographic fabrics were then compared to locally sourced geological materials. This paper presents the interpretation of the combined petrographic and chemical composition studies in an attempt to better characterize local products and to further our understanding of the source and means of transportation of Mars Orange Paste Ware found in Middle Preclassic ceramics at Holtun. Finally, this study provides new insight into the production technologies of lowland Maya Middle Preclassic pottery, with a special emphasis on the use of volcanic ash temper.

Callaghan, Richard (University of Calgary) [180] The Strategic Location of the Maldives in Indian Ocean Maritime Trade and Colonization

The Maldives Islands, situated off the southwest coast of India, form a chain trending from north 6.930° to south 0.700° latitude, an extent of approximately 850 km. The chain divides the Indian into east and west as well as marking the divide between the seasonal monsoon weather patterns. Present evidence suggests that the island chain was occupied as early as the fifth or fourth century BC with close ties to India. The islands became approximately 850 km. The chain divides the Indian into east and west as well as marking the divide between the seasonal monsoon weather patterns. Present evidence suggests that the island chain was occupied as early as the fifth or fourth century BC with close ties to India. The islands became strongly culturally and commercially connected to both Asia and Africa after Islam was brought to the archipelago in the twelfth century. Beginning in the sixteenth century they became increasingly important to European colonial powers. Their location is strategic for maritime trade in the Indian Ocean. Here computer simulations using wind and current data and sailing vessel performance characteristics are used to evaluate the possible routes traders and colonists may have used that relied on the Maldives particularly in the earlier periods of occupation. The chain provides a convenient way station while waiting for favorable shifts in the monsoon winds. The Maldives may have been particularly important in the colonization of the Comoros Is. and Madagascar and the east African Indian Ocean trade.

H. B. Nicholson was considered the Tlamatini of Aztec studies. He was also known as a warm and generous professor who dedicated his life to the study of Mesoamerican cultures. His legacy is highlighted by his remarkable collection of articles, books, photographs, and slides acquired over more than five decades. After his death in 2007, Nicholson’s family donated his entire private collection of books, articles, slides, and photographs to the University of California, Los Angeles. Five years ago, when that university was deaccessioning much of his collection, part of it was given to California State University, Los Angeles (CSULA). The gift included Nicholson’s entire slide archive of more than 10,000 slides of published and unpublished images. For the past years, a group of CSULA students has worked to digitize these slides to organize and preserve the valuable and sometimes rare information that they contain. This paper will report on the content of the digitized archive and the importance of H. B. Nicholson’s legacy to Mesoamerican studies.

Camp, Anna (University of Nevada, Reno) [367] Mats, Trays, Bowls, and Patches: Results from the Analysis of over 9,000 Years of Catlow Twine Basketry in the Archaeological Record

Catlow Twine is a unique and diagnostic basketry type found in archaeological sites of the Great Basin and some parts of California. It has a relatively wide geographic distribution and is thought to have over ~9,000 calendar years before present (cal BP) of technological continuity. Through the reexamination and recording of specific attributes and the direct Accelerator Mass Spectrometry (AMS) dating of Catlow Twine basketry from sites in Nevada, California, and Oregon, I have observed these continuities and some discontinuities in this basketry type, and propose that Catlow Twine basketry had significant technological and personal significance to the people who manufactured it. The value of this type of basketry can be seen in the size and types of vessels that were made, the fineness of the weave, and the use and reuse of Catlow Twine baskets. These specific attributes observed through time and space demonstrate how basketry can be used as a cultural and technological marker in the archaeological record.

[154] Statistical Evidence for a New Method of Identifying Anthropogenic Fire in the Archaeological Record

Clarifying evidence for anthropogenic fire in the archaeological record has been subject to contention and vagueness. This uncertainty centers not on evidence for fire, rather what constitutes it being human-controlled. New research pursuing this question suggests that a peculiar angular fragment, termed thermal curved-fractures (TCF), are the byproduct of knapped materials (flakes, cores, bifaces) exposed at length to high heat. We present here results of experiments expanding our TCF database designed to test hypotheses: a) are TCFs significantly, statistically, distinct from unfired debitage, and b) are there potential TCFs residing in archaeological collections from sites purported to have evidence of (early) hominin-controlled fire? These results strongly indicate support for both hypotheses.

[340] 4,000 Years of Animal Translocations: Mocha Island and Its Zooraerchaeological Record

Islands are territories that allow us to assess phenomena and processes in a way that is impossible to do in the mainland. One of these concerns the human interaction with animals that are usually considered as wild. The case of Mocha Island (Chile; South Pacific, 38.36°S) is remarkable because of its small size (50 km²), proximity to the mainland (30 km), three different and independent human occupation events, and an endemic terrestrial fauna constituted only by small reptiles, amphibians, and rodents. Here our research has shown the distinctive presence of translocated medium-to-large native mainland mammals—nutria (Myoscastor coypus), pudu (Pudu pudu), camelds (Lama sp.), fox (Lycalopex sp.), grison (Galictis sp.), and wild cat (Oncifelis sp.)—in relation to the different populations that have occupied this island: aceramic hunter-gatherers (1950–1300 BC), ceramic food-producers (AD 100/1000–1687), and Chilean tenants (AD 1840–today). This evidence leads us then to question the simple idea of “wild animal,” and opens up a set of much more complex and rich issues, such as wild management and the use of “living reservoirs,” the re-creation of known landscapes, the modification of landscapes, local extinctions, pet keeping, taming, and even the consideration of animals as nonhuman persons.

[228] Habitat Change versus Human Impact: Size and Frequency Trends in Multiple Taxa of Marine Invertebrates at Tse-whit-zen Village

Tectonic activity along coastlines can subtly or radically alter the substrate and elevation of the intertidal zone, thus affecting benthic marine invertebrates; however, there is no single signature for impacts. Research following mega-earthquakes in the last decade shows that the nature of the effects varies widely across taxa and locations. Analysis of the Tse-whit-zen village invertebrate fauna shows that mean sizes of bivalves of the genera Macoma, Leukoma, Saxidomus, and Tresus, and also of the gastropod Nucella lamellosa and the chiton Katharina tunicata vary significantly, and independently across seven chronological zones spanning the last ~2,200 years. Taxonomic abundance of these and other frequently harvested bivalves such as Mytilus and Clinoacridium also vary significantly between these relatively short occupation periods that are bracketed by known tectonic events and global climatic warming and cooling events. To evaluate the relative influence of tectonic events and human harvesting, these empirical patterns are compared to expectations for which taxa should be impacted in parallel or inverse ways deduced from predator/prey relationships, habitat preferences, and constraints on colonization and growth. The effects of climate change on ocean temperatures are controlled for using a high-resolution shell isotope sequence developed from site-specific samples.

[22] Differrentiating Commingled Human Remains using EDXRF (Energy Dispersive X-ray Fluorescence)

The ability to differentiate commingled skeletal remains is critical in the analysis of mass burials, archaeological sites and mass fatality events in forensic cases. The potential application of EDXRF (Energy Dispersive X-ray fluorescence) to aid in differentiating commingled remains is being explored at the MAX Lab (McMaster Archaeological XRF Lab), expanding the lab’s research focus from solely obsidian sourcing to include bioarchaeological applications. There are numerous factors affecting bone’s chemical composition; consequently, an individual’s bones should have a unique elemental characterization which can be determined using EDXRF, a quick, nondestructive technique. Drawing upon Gonzalez-Rodriguez and Fowler’s (2013) research which utilized a portable XRF (pXRF), the hypothesis is that it is possible to differentiate individuals based on their unique chemical composition was tested using EDXRF on three archaeological skeletons from southern Italy. Applying multivariate statistical analysis, PCA (principal component analysis), to acquired data, it was possible to show distinct elemental variations and groupings among these skeletons. Trace elements, and ratios thereof, provided a greater distinction between the individuals than major elemental concentrations. Current research involves applying this method to a set of commingled remains expected to contain three individuals, in order to determine whether they can be differentiated.

[4] Metal Sensing and Indigenous Copper from Isle Royale National Park and Gila National Forest
Though much professional work utilizing metal sensing comes from within the historic period and battlefield archaeology, the application of metal sensing techniques to precontact sites has much to offer contemporary studies of copper use in the United States, particularly inter- and intrasite geospatial analyses of indigenous copper exploitation. Ongoing research in two U.S. regions is illustrative of the contributions metal sensing technology is making to studies of copper and copper technology. Recent work at relict shoreline sites on Isle Royale National Park in northern Michigan and Mimbres sites within Gila National Forest in New Mexico serve as case studies highlighting new insight into copper exploitation in the northern Lake Superior Basin and the American Southwest.

Campos, Cinthia M. (California State University, Los Angeles)  
[386] An Interpretation of the Rock Art in La Cueva de la Huachiza, Santa Clara del Cobre, Michoacán
The Cueva de la Huachiza is a tectonic cave formed within a basaltic flow in the municipio of Salvador Escalante just south of Lake Pátzcuaro, Michoacán. The cave was initially recorded in 2014 by Dr. Jose Luis Punzo-Díaz as part of Proyecto Arqueología y Paisaje del Área Centro Sur de Michoacán (PAPACSM). An investigation of the cave conducted this summer recorded pecked petroglyphs of a man facing an eagle, above a spiral motif. These motifs resemble those from contact period Codex de Carapan, explicitly. In front of the petroglyphs a feather and burnt wood were recovered that are described in La Relación de Michoacán as sacred items. This paper will combine archaeology, ethnography, ethnohistory, and epigraphy to interpret the cave. The inscriptions and artifacts found within offer insights into Tarascan customs, ceremonies, and beliefs. The evidence suggests La Cueva de la Huachiza was a perceived as landmark in the sacred landscape and as having connections with Cumichequaro, the underworld. It is evident that this cave was an important religious site for the Tarascans, and future explorations will produce a better understanding of the use of caves in this largely understudied region.

Camurri, Erica  
[132] Monte Bibe (Monterenzio, Italy): Analyzing Patterns of Cultural Interaction between Celts, Etruscans, and Other Italic Populations in Northern Italy from the Fourth to the Second Century BC
The site of Monte Bibe, located near Bologna (northern Italy), contains the remains of a settlement on Pianella di Monte Savino and a necropolis on Monte Tamburino, altogether dating from the fifth to the second century BC. According to historical sources, this region was inhabited by Etruscans and other Italic populations, before it witnessed the invasion of Celtic tribes from the fourth century BC onward. Following these sources, the main consequence of the invasions has to be seen either in the assimilation or in the expulsion of the local groups by the Celts, just prior to the Roman conquest of northern Italy. Recent studies of the epigraphic record and the archaeological documentation of the region indicate a reality that is more complex and dynamic than previously assumed. Based on the site of Monte Bibe, which has to be considered one of the best documented archaeological sites of the area, I will demonstrate that the different ethnic groups mentioned in ancient sources were in fact coexisting, reaching in some cases such a profound level of social and cultural interaction that it is difficult (if not impossible) to determine their ethnic identity: Were they Celts, Etruscans, Italics, Etrusco-Celts/Celtic-Etruscans, or something else entirely?

Canaday, Timothy (Salmon-Challis National Forest), Bryan Hanks (University of Pittsburgh) and Roger Doonan (University of Sheffield)  
[343] The Middle Fork Geophysics Project, Central Idaho
The Middle Fork Salmon River is a designated Wild and Scenic river located within the heart of the Frank Church—River of No Return Wilderness in central Idaho. Over the last three years the University of Pittsburgh, the Salmon-Challis National Forest, and the University of Sheffield have collaborated on a minimally invasive multi-method geophysical and geochemical approach for characterizing intact archaeological deposits at seven prehistoric sites impacted by recreational activities. The objective of this work is to develop long-term management strategies for the protection of at-risk sites using minimally invasive methods such as fluxgate gradiometry, earth resistance electrical resistivity, magnetic susceptibility, and handheld portable XRF for soil chemistry. Preliminary results from several of the sites are presented.

[22] A Culture of Innovation in Archaeological Science at McMaster University
Archaeological science has exploded globally in the past several decades, a pattern that is evident in the range and sophistication of scholarship at a variety of Canadian institutions. McMaster University, however, has played, and continues to play, a particularly important role in the development of archaeological science. In this introductory paper, we explore the genealogy and early impact of a number of pioneering scholars at McMaster. We highlight the pivotal role of the Canadian Foundation for Innovation (CFI) in enabling the development of groundbreaking laboratory facilities for archaeology. We outline what we describe as the “cultural transmission” of the practice of archaeological science. What began with early pioneering developments in methods and applications was refined through the construction of CFI funded facilities. These spaces have permitted the emergence of new research applications at McMaster and, through graduates who have extended this legacy of innovation, at other institutions in Canada and internationally. We also argue that the diversity of archaeological science research at McMaster has been maintained with a particular anthropological focus. As will be seen in the papers in this session, exploring social questions of the past requires both analytical skill and a sophisticated theoretical awareness.

[259] Provenance Analysis of Pottery Sherds from an Early Nineteenth-Century Milling Village in Northeast Pennsylvania
As a cost-effective and nondestructive method for multi-element analysis, portable X-ray fluorescence spectrometry (pXRF) has the potential for broad archaeological application. Here, we employ pXRF for the compositional analysis of pottery sherds collected from Stoddartsville, an early nineteenth-century milling village built along the upper Lehigh River in northeast Pennsylvania. Our analysis demonstrates that we can use compositional data to source pottery sherds to regional potteries, documenting the links developed between Stoddartsville and the surrounding region as the village grew into a short-lived center of trade and industry. At a more general level, our study demonstrates the potential for historical archaeologists to use compositional data, even in the absence of makers’ marks, to source historic artifacts and, in turn, develop insights into regional economies.

[131] Preliminary Lidar-Based Analyses of the La Corona–El Achiotal Corridor

Located in the northwestern Petén, Guatemala, the Maya sites of La Corona and El Achiotal have been investigated since 2008 by a multidisciplinary U.S. and Guatemalan research project. While a primary goal of this project has been to reconstruct the region’s political history, we are now beginning to investigate the management of local resources and general human impact on the landscape. In fact, the area between La Corona and El Achiotal is almost entirely unknown archaeologically, especially regarding settlement that is largely residential and dispersed due to the wetland environment. In 2016, a LIDAR survey, funded by the Pacunam Foundation and operated by NCALM, was undertaken in nearly 200 km² rectangular zone encompassing both La Corona and El Achiotal. This survey aims to record the full extent of ancient settlement around and between these two sites and cast light on land-use strategies in a region dominated by seasonal and perennial wetlands. In the following paper, we will present the preliminary results and interpretations of the LIDAR dataset focusing both on the methodological advantages of this technology and on the possibilities it creates for analysis and interpretation of ancient landscapes.

Cap, Bernadette (University of Texas-San Antonio)

[7] Implications for Spinning Thread in a Marketplace at the Classic Maya site of Xunantunich, Belize

The identification of marketplaces among the Classic Maya has contributed to more complex understandings of their economies, but scholars are still working to determine the fundamentals and variations of Maya marketplace exchange across time and space. Recent investigations at the Classic Maya site of Xunantunich, Belize recovered a small assemblage of spindle whorls from the site’s Lost Plaza, a posited marketplace. This the only example among the Classic Maya to directly connect the activity of spinning thread with a physical marketplace, from which I infer that thread was part of the marketplace exchange system. Classic Maya artwork provides examples of a variety of textiles, but due to tropical conditions few traces have been left of the production process. Spindle whorls represent one of the most durable lines of evidence for textile production. This poster presents details of the spindle whorl assemblage and associated features and soil chemical signatures to understand the activity of spinning thread within the Lost Plaza. Broad economic implications of thread as a marketplace good are also discussed. In Mesoamerica, spinning and weaving is depicted primarily as a female activity. The Lost Plaza assemblage provides an opportunity to discuss the role of gender in marketplace exchange.

[71] Investigating Ancient Foodways in the Copan Valley: Macrobotanicals from Late Classic, Terminal Classic, and Postclassic Middens in the Río Amarillo East Pocket

In this paper, the analysis of macrobotemal samples from household contexts in the Río Amarillo East Pocket will be discussed. The analysis of these samples is part of a larger project to define the use of the environment by ancient inhabitants of the valley. Following upon the efforts of earlier projects such as PAC I and PAC II, we plan to assess macrobotemals from a diversity of groups and time periods to illuminate ancient consumption patterns. Hopefully, this data will increase our understanding of the sustainable practices of the ancient Maya and allow us to assess possible evidence of environmental stress related to Terminal Classic demographic drops.

Capone, Patricia

[138] Museum Archaeology and Studying Technology

Increasing combinations of perspectives and epistemologies contribute knowledge and consciousness of practice to the study of technology. Museum archaeology is well situated to study and interpret technology through material culture, archives, and engaging partnerships. Partnerships through museum collections continue to build and contribute to a variety of interests. The interdisciplinary direction of technological studies continues to expand. Projects also increasingly relate to forward thinking topics such as sustainability, and consciousness of practice. Examples of partnerships with various collections including the Peabody Museum, Harvard University demonstrate the advancement of knowledge in this area.

[292] Nieve Nieve, a Local Rural Community under Spanish Rule

The archaeological site of Nieve Nieve is located in the middle Lurin Valley, Central Coast of Peru. The spatial configuration of this site differs drastically from other late prehispanic settlements in the valley. The presence of a colonial church as well as a series of architectonic compounds built along parallel and perpendicular streets not only indicate a well-planned construction but also the introduction of a new, and probably foreign, urban design. Yet, other aspects such as the construction techniques and internal distribution and use of spaces remain essentially local. We will present the results of our excavations at the site suggesting a strong permanence of local cultural elements during the first years of colonial times.

Geochemical Characterization and Archaeological Utilization of the Cerro Kaskio Obsidian Source in Southwestern Bolivia

Obsidian is not only an excellent raw material for the manufacture of stone tools but because of its compositional homogeneity, it can also be related to specific geographic sources. The geochemical characterization of obsidian sources can help to determine the geographic origin of different stone tools as well as to infer patterns of resource utilization and exchange. Although some of the most important obsidian sources in the Andes have been identified and adequately characterized, many remain unknown. Here we report for the first time, the location, description, geochemical characterization, and regional distribution of Cerro Kaskio, a new obsidian source from southwestern Bolivia. We show how artifacts made with Cerro Kaskio obsidian were initially utilized by some of the first explorers to enter the territory during the late Pleistocene but also by subsequent populations of pastoralists during the late Holocene. Given the singular composition, high-quality, and long-term use of this source, we anticipate that additional sites with stone tools made with Cerro Kaskio obsidian will be identified in the future.

The Ice-Age Landscape around Manot Cave (Israel) during the Upper and Middle Paleolithic: New Insights from the Anthropological Record and Carbon Isotopes Analyses

Since 2012, a series of investigations in Manot Cave recovered charcoal samples from archaeological layers in order to study the landscape around the site between the Upper and the Middle Paleolithic (UP/MP). Samples of soils and loose charcoal were collected in different areas of the cave, while particular attention was paid to the sampling of the hearths found in Area I and E. Anatomical features of the charcoal samples were analyzed using a metallographic microscope in order to identify tree species which grew in the site area at the time of its occupation. Amygdalus sp. was found to be the most common species, while Quercus spp. (type calliprinos and ihaburensis) are comparatively rare. The anthropological study reveals the presence of an open forest, during the UP/MP, which differs from the modern maquis. Over thirty specimens of Amygdalus sp. were radiocarbon dated at the D-REAMS laboratory and subject to stable carbon isotopic analysis (δ13C) to obtain information on the local rainfall regime between 50,000 and 30,000 years cal BP. These analyses indicate climatic conditions during the ice-age were unlike modern conditions.

Caramanica, Ari [382]  A History of Landscape Transformation and Environmental Change across the Ascope Irrigation System of the Chicama Valley

The sequence of landscape transformation across the area of the Ascope Canal System in the Chicama Valley involved both natural and anthropogenic events and processes that unfolded in nonlinear ways. We argue that early events were crucial in determining transformations later in the sequence. In the arid environment of the North Coast, water availability plays a key role in landscape histories. This paper highlights evidence for El Niño events, water management, and changing ecologies for the Paleindian period through the Colonial period in the area, drawing from sedimentary, archaeo-botanical, and ethno-historical data. Retracing both the human and natural histories of this landscape reveals both their interdependence and the potential impact that early modifications had on later outcomes.

Altaic Ceramics and Figurines: Stylistic and Chronological Analyses

Craft specialization and exchange feature prominently in explanations for the development of the first complex societies in Mesoamerica. It is clear from analyses of surface collections at Altica that during the Early and early Middle Formative periods (c. 1300–850 BC) its inhabitants exported obsidian tools and imported pottery from long distances, including the southern Gulf Coast. Altica is one of the few early agricultural settlements located in the northern Basin of Mexico from which we have excavated ceramics and figurines, and thus provides an important opportunity to investigate early craft specialization, including the interregional exchange of obsidian and ceramics. Employing a multi-scalar approach, we investigate differences in the uses and styles of newly excavated ceramic vessels and figurines from Altica, focusing particularly on objects decorated with symbols of ideological importance. We also compare these materials to pottery and figurines at contemporary sites. This study provides evidence of how the first sedentary communities of the Basin of Mexico participated in an extensive network of societies exchanging goods, ideas, and decorative motifs, during a significant period of increasing sociopolitical complexity.

Witches and Aliens: How an Archaeologist Inspired Two New Religious Movements

Egyptologist and Folklorist Margaret Murray was a major figure in the creation of professional archaeology in the United Kingdom, President of the Folklore Society, and advocate for women’s rights in higher education. However, another major part of her legacy was the mainstream acceptance of the concept of the “witch-cult,” a hidden ancient religion dating back to the Pleistocene but continuing until at least the seventeenth century when it was persecuted by witch-hunters. Historians have subsequently found this concept to be unsupported but it is still commonly found in the popular imagination. One obvious legacy was the role of the witch-cult in the formation of Wicca and other neopagan movements in the second half of the twentieth century. But another major product of Murray’s archaeologically informed witch-work was the Cthulhu Cult, created in fiction by science fiction and horror pioneer H. P. Lovecraft. Not only has Lovecraft’s Mythos inspired direct Lovecraftian magical practices, but it has been a huge influence on paranormal and conspiracy beliefs centered around ancient civilizations and hidden secrets. Through these influences, core elements of early anthropology have persisted and grown outside of the professional establishment.

Cardinal, J. Scott (New York State Museum) and Jennifer Loughmiller-Cardinal (State University of New York) [287] Through the Gates of Logic, into the Middle of . . . What?
For several decades, middle range theories in archaeology have generally been understood and applied as a set of rhetorical and analogical linkages between the archaeological record and interpretive hypotheses of behaviors. Epistemologically, however, “middle range” has broader implications than this relatively narrow archaeological application. As a relative positioning, middle range denotes establishment of logical linking arguments between evidence and inferred or hypothetical context irrespective of theoretical scale. Archaeologically, these typically relate to inverse trajectories of causality (i.e., from effect to cause), but have potential be much more than mere methodological steps or analogies between field data and conclusions. Properly conceived, middle ranged theories should link data, through explicit or inferred causal mechanisms and sets of observations, to broad or generalized theoretical abstractions. The latter step has traditionally been difficult to achieve with contemporary social theory as it is engaged and applied by archaeologists, leading to a broad disgruntlement with higher-level social theory and abstractions. We propose that this has been, in part, due to the overly narrow and insufficient applications of formal logic to middle-ranged linkages beyond the methodological scale, and present a suggested restructuring of archaeological middle range for identifying reasonable inferences at higher scales.

Cardona Machado, Hector (El Colegio de Michoacán, A.C.), Héctor Cardona (El Colegio de Michoacán, A.C.), Verenice Y. Heredia Espinoza (El Colegio de Michoacán, A.C.) and John K. Millhauser (North Carolina State University) [215] La Obsidiana en el Occidente de México: “Ausencias” en la opulencia
La región de Tequila es reconocida por la elaboración de una famosa bebida alcohólica, sello de la mexicanidad actual. Pero a partir de investigaciones arqueológicas realizadas en la zona desde hace más de un siglo, se ha reconocido la abundancia de fuentes y tipos de obsidiana que fueron utilizadas en época prehispánica para la fabricación de bienes tanto de lujo como para uso cotidiano. Esta actividad ha sido un componente importante de las narrativas académicas que procuran definir dinámicas que apuntan a la complejidad social desde el Formativo, siendo uno de los rasgos fundamentales de la propuesta de la Tradición Teuchitlán. Bajo este modelo, la obsidiana ha sido tratada como un “recurso raro,” que debió ser controlada por la élite y que originó una red de intercambio, tanto regional como a larga distancia, lo que caracterizaría un tipo particular de economía incrustada en una organización estatal. Sin embargo, la evidencia empírica referida no señala un control sobre este recurso ni sobre la manufactura de artefactos, como tampoco a la naturaleza de las relaciones de intercambio. En este trabajo se evalúa tanto los datos como sus interpretaciones, proponiendo enfoques alternativos a la luz de nuevas teorías arqueológicas.

Cardoso, Hugo (Simon Fraser University), Joana Abrantes (University of Porto), Laure Spake (Simon Fraser University) and Luis Rios [86] A Test of Juvenile Age Estimation Methods Based on the Diaphyseal Length of the Long Bones
Little work has been done on whether juvenile age estimation methods perform well beyond the population that was used as a reference. This study uses a sample of 81 known-age juvenile skeletons, aged between birth and 12 years, combining data from archaeological, anatomical and forensic reference collections in the United States, Canada, and South Africa. Ages were estimated from the diaphyseal lengths of the humerus, radius, femur and tibia, using Cardoso et al. (2014) and Stull et al. (2014) prediction models. Results show that methods based on size are only reliably applied across samples before the age of two years, after which population differences in growth become noticeable. Results also show that ancestry-specific bone size and limb proportions have little if any effect on the reliability of age predictions. The main factor to consider when selecting an age estimation method is population nutritional and health status, not ancestry. These findings have important implications for age estimation of juvenile skeletons in archaeological contexts, and suggest that bone size is not a reliable age predictor, particularly after the age of two years.

Carey, Mia (University of Florida) [122] I Don’t See Color, but I See Your Hijab: How Public Archaeology Can Confront Race, Racism, and Islamophobia in Social Science Education
Millennials are hailed as one of the most racially progressive generations in America’s history. African Americans and other people of color are becoming consciously aware of the challenges that they face in navigating America as a minority. White millennials, who describe themselves as being racially progressive, typically lack awareness or understanding of discrimination and racism and use colorblindness as a way of coping with fear and ignorance. Their colorblindness invalidates the identities and experiences of minorities, and equates color with something negative. This leaves white millennials ill-equipped to deal with changing classroom demographics and the knowledge and experiences that minorities bring to the classroom. By embracing a culturally relevant pedagogy aided by archaeology, young, white social science educators can begin to bridge the gap by confronting their own white privileges and inherent biases.

Carleton, William (Simon Fraser University), Mark Collard (Simon Fraser University) and Dave Campbell (Simon Fraser University) [77] Radiocarbon Dating Uncertainty Constrains Our Ability to Identify Cyclical Human-Environment Dynamics
Archaeologists have long been interested in cyclical human-environment dynamics. This interest is indicated by the dozens of published studies that refer to “adaptive cycles” and by the fact that one of the highest cited papers in the history of archaeology focuses on the impact of cyclical drought on the Classic Maya. Unfortunately, recent work suggests that identifying cycles in archaeological and paleoclimatological time series data can be challenging when the observations are dated with radiocarbon assays. The problem is that the highly irregular, temporal uncertainties that are characteristic of calibrated radiocarbon dates can lead to the identification of spurious cycles. In the present study, we sought to delineate the conditions under which cycles can be confidently recognized in radiocarbon-dated time series datasets. To do so, we conducted simulation experiments involving thousands of artificial time series with known cyclical patterns, varying the parameters of each experiment to determine when radiocarbon dating uncertainty became too great to allow for the reliable detection of the known cycle. We found that, at best, we could correctly identify cycles only 42% of
the time, indicating that the temporal uncertainty of calibrated radiocarbon dates makes it very difficult to identify cycles in archaeological and environmental records.

Modeling Age and Sedimentation Rates at the Page-Ladson Site

Stone tools and mastodon bones occur in an undisturbed geological context at the Page-Ladson site, Florida. Age models were created for excavation unit 50N/23E and core PLAD-AUC14–4A to estimate age ranges and sedimentation rates. The models were constructed using Bayesian models as implemented in OxCal to calibrate ages, combine equivalent age estimates, exclude outliers, and estimate deposition rates. The models were used to provide age estimates for artifacts recovered from the site, correlate deposition at the site with the Late Pleistocene transgression, and provide influx estimates for Sporomioeria spores as proxy evidence for the presence of megafauna. Taken with other evidence, the analysis demonstrated that about 14,550 years ago people butchered or scavenged a mastodon next to a pond in a bedrock sinkhole within the Aucilla River. This occupation surface was buried by approximately 4 m of sediment during the late Pleistocene marine transgression, which also left the site submerged. Peak concentrations of Sporomioeria occur around −13,700 cal y BP may indicate peak megafaunal abundance in the vicinity of the sinkhole. A rapid decline in spore concentrations by −12,600 cal y BP occurs after the onset of the Younger Dryas Stadial.

An Experimental and Archaeological Investigation of the Role of Edge Angle in Lithic Artifact Damage: Applications to the Koobi Fora Fm. Kenya

The analysis of damage patterning on lithic artifacts has the potential to distinguish between predepositional use of artifacts and postdepositional taphonomic processes, providing important evidence for particular hominin behaviors. Previous study has suggested that damage accrues in a non-random fashion in archaeological assemblages. Limited work has been done using the quantified variable of edge angle to account for patterns of edge damage. This study focuses on assemblage-level patterns of flake edge angle and their relationships to macroscopic damage. Experimentally produced lithics were subjected to different use and taphonomic treatments. This provided a means for investigating the relationship between edge angle and damage across a variety of different processes. Preliminary results suggest the pattern of damage across edge angles varies based on the processes of use or taphonomy to which an assemblage is subjected. These results were compared to damage patterns of surface collections from two Okote Member (1.6 –1.39 Ma) sites in the Koobi Fora Formation, Kenya exhibiting both ancient and modern instances of edge damage. We use this dataset to explore the extent to which experimental edge damage/angle relationships conform to archaeological data. An overview of potentially diagnostic angle/damage relationships is presented. Research sponsored by NSF-RES (OISE-1358178 and 1358200).

Raised Marine Predictive Model Advances Knowledge of Early Holocene Site Assemblages in Southern Southeast Alaska

In 2009, Carlson and Baichtal used the age and elevation of raised marine deposits left during the highest marine transgression to create a hypothetical early Holocene shoreline in the Alexander Archipelago of southern Southeast Alaska. Over the past seven years, archaeological surveys that employed this predictive model revealed over twenty new early Holocene sites. Our understanding of the Holocene island landscape has increased dramatically with the discovery of these sites in new geographical areas of the archipelago. The sites are directly upland of the ancient shoreline that dates from 14,550 years ago. Peak concentrations of burnt and calcined bones, worked sea mammal bones, marine shells, and fish and bird bones. These new sites expand on traditional characterizations of artifact assemblages and material types used for tool production during the early Holocene in Southeast Alaska.

Carolina’s Cattle: Eighteenth-Century Livestock Production at Drayton Hall

Utilizing faunal evidence from two assemblages from Drayton Hall, this paper explores the changing cattle husbandry strategies employed in the eighteenth-century South Carolina Lowcountry. Before colonists had perfected rice production in the region, they worked with the varied terrains and natural resources of the Lowcountry to create a very successful livestock industry in the early eighteenth century. Cattle remains from the Pre-Drayton assemblage (circa 1730s) reflect this thriving livestock industry, indicating that cattle were raised at the site for market in a largely free-range system. In contrast, cattle remains from the South Flanker Well assemblage (circa 1770s) suggest cattle being raised in a more hands-on manner, with some individuals likely serving as draught oxen. Through analyses of general species distributions, kill-off patterns in cattle, and pathologies present on the

Caroline, Carline, Kristin [231] see Buehlinman-Barbeau, Savanna
cattle cranial and lower limb elements at Drayton Hall, one can appreciate the changing relationships between humans and cattle in the eighteenth-century Carolina Lowcountry.

[213] Portable XRF Analysis of the Pigments of Majiayao Pottery from Dayatou, NW China

The site of Dayatou is located on a terrace bluff in the Tao River Valley in Gansu province, Northwest China. In 2015, the Tao River Archaeological Project team conducted systematic collection across the surface of the bluff and recovered thousands of Majiayao culture potsherds. To identify the technology and provenances of these potsherds, in the 2016 field season we used a portable XRF in a handheld configuration to analyze the chemical elements of the black paint decorated on 124 selected samples. For comparison, we also used the same method to analyze the paste composition of each sample. All the samples had enough clear painted and unpainted spots for analysis. These samples were selected from random bags of sherds collected from areas across the site. Different from previous studies, our case study provides a micro perspective on the technology and organization of pottery production at a single settlement. Portable XRF analysis proves to be an effective source for this research because of the efficient and accurate chemical identification. The data we have collected provide a general overview of the site, and will lend to future research on ceramics at the site of Dayatou, and for the Majiayao as a whole.

Carmichael, Patrick

[270] Really Ugly Nasca Pots of Ancient Peru, and Why They Are Important

Polychrome ceramics of the Nasca culture (south coast of Peru, c. 100 BC–AD 600) are world renowned as one of the most colorful and artistically complex creations of the ancient Americas. Up to ten distinct colors depicting fabulous supernatural creatures adorn unique vessel forms with eggshell thin walls fixed in perfect oxidizing firings. Such masterpieces fill art books and spawn enthusiastic but fanciful speculations about Nasca society and its artisans. This paper rounds out the view of Nasca pottery production and its place in society by focusing on what is not shown in art books—the remarkably ugly, poorly made, and badly fired products of neophytes and the ungifted. Such pieces provide valuable information on the construction, painting, and firing stages of production, but also lead us to consider the individual potter as agent, the family workshop, and the potting community. The role of polychromes in Nasca society was potent. An informed understanding of their production, circulation, use, and deposition must include not only the brilliant and spectacular but also the unsightly and hideous.

[173] Inhaling Prehistory: Exploring the Smoking Culture of the Eastern Woodlands

Pipes, pipe-smoked plants, and the tradition of smoking in the Eastern Woodlands of North America have long interested anthropologists and archaeologists because these artifacts and activities are viewed as material correlates of ritual, ceremonial, and religious activities. While pipes are regularly recovered from archaeological sites, the remains of plants materials that were smoked are far more difficult to recover. Traditionally, pipe-smoked plants, such as tobacco, have been identified through the analysis of macroremains recovered from archaeological sites. The earliest comes from Middle Woodland period contexts at the Smiling Dan site in Illinois. However, pipes themselves predate evidence of tobacco in the region, leaving many questions unanswered about the smoking culture. Over the past two decades’ chemical analysis of pipe residues have made substantial contributions in this area. A chemical signature for nicotine identified in a pipe from West Virginia demonstrated the efficacy of gas chromatography/mass spectrometry (GC/MS) and pushed the earliest dates for tobacco use back approximately 2,000 years. Here, we present the results of our recent GC/MS study on pipe residues from the region. We use these results to contribute to ongoing investigations into the timing, transmission, use, and customs surrounding tobacco and the smoking culture.

Carney, Molly

While the diabetes epidemic among indigenous Native American populations has been examined for more than 30 years, the nuances between environmental and genetic causes of this disease remain understudied. In this paper, I explore the idea that the diabetes epidemic among Native American populations may be partially attributed to the introduction of a diet suited for Westernized populations. I will specifically look at gene-culture coevolution and the salivary amylase gene (AMY1) copy numbers among different world populations, arguing that populations with higher AMY1 copy numbers are better adapted to digest starchy foods such as wheat, rye, millet, or rice. Conversely, many Native American populations used technological adaptations such as pit oven cooking to process the sugars found in native root foods, thereby bypassing the need for genetic adaptation. I examine two populations, in the American Southwest and in Mexico, to illustrate these differences in native and introduced diets and their subsequent health effects. By looking at gene-culture coevolution, the ethnohistoric record and archaeological evidence, we are better able to address some of the causes for the high prevalence of diabetes among Native Americans.

[84] El Corrido de Pablo y Suzy Pescado: Inspiring Archaeological Investigations in Northwest Mexico

We discuss Paul and Suzy Fish’s integral role in archaeological research in northwest Mexico, an important region that has been little studied by relatively few archaeologists to date. Over more than 25 years, along with our colleagues and many students, our archaeological investigations have included a reanalysis of the funerary mound at Guasave, Sinaloa and an evaluation of the relationship between Mesoamerica and Northwestern Mexico, the Pleistocene people of Sonora and Mexico, the Early Agricultural period at La Playa (SON F:10:3) and other sites, paleoethnobotanical studies and environmental reconstruction in several sites in Sonora, regional survey of the Río Fuerte Valley in Sinaloa, the long-distance exchange routes linking West Mexico with northwest Mexico and the American Southwest, research at the exceptional Fin del Mundo Clovis site and 12,000 years of human occupation and the climatic changes in the Sonoran Desert. Most recently, we have begun research in the Sahuaripa region of eastern Sonora in order to investigate both the long-distance and regional interaction spheres and socio-politico-economic organization of the Río Sonora and Serrana archaeological traditions. We believe that this research effectively expresses the depth and breadth of Paul and Suzy’s multifaceted archaeological perspectives.

Carpenter, Lacey (University of Michigan)
A household approach is applied to the ceramics to investigate household organization at the site. This study begins to explore some of these issues, through a feature-level stylistic analysis of ceramics, through the combined results of 1) formal technological and geochemical source analysis of obsidian recovered from recent archaeological excavations at Cerro Magoni, a hilltop Epiclassic site in Tula, Hidalgo. Archaeologists can use a variety of archaeometric techniques to better understand ancient interaction networks. Obsidian is a chemically homogeneous volcanic glass that was widely traded in Mesoamerica throughout the prehispanic era. This valuable resource was procured at geographically specific source areas, each of which has a unique chemical signature. Portable X-ray fluorescence (pXRF) permits archaeologists to detect the unique trace-element signature of obsidian artifacts with a high degree of certainty. With this information, the original source of each obsidian artifact can be determined. This paper presents a preliminary appreciation of patterns in local lithic production and regional exchange networks through the combined results of 1) formal technological analysis of the obsidian assemblage from Magoni, and 2) pXRF source analysis of a sample of the assemblage to provide additional insight into the social and economic networks that operated during the Epiclassic period in the Tula region and beyond.

Movement and Vision: Reconstruction and Analysis of a Multi-Occupation Fortified Site Complex in the Moche Valley

This poster reports the results of noninvasive field prospecting using aerial drone photogrammetry to map and reconstruct surface architecture at two multi-occupation archaeological sites in the Moche Valley of Peru. Sites MV-42 and MV-49 (Puente Serrano) make up a fortified and possibly ceremonial center complex located in the middle valley. The sites were occupied contiguous during the Salinar, Gallinazo, and Early Moche phases (EIP: 400 BC–AD 400), with a later reoccupation by the Chimú phase (LIP: AD 1000–1470). Aerial drone maps were imported into GIS software to allow for more robust analyses working toward interpreting and analyzing human movement while ascending to the summit. These data will help us to better assess the importance of vision in settlement location and protective architectural positioning using view sheds and inter-visibility analyses with the surrounding landscape.

Carr, Sean (Penn State University) and Alma Gabriela López Rivera (Tula Region Interaction and Migration Project [TRIMP])

Technological and Archaeometric Analysis of Obsidian from Cerro Magoni

This study addresses one of the fundamental goals of the TRIMP—to contextualize local processes with broader patterns on regional scales—by combining formal technological and geochemical source analysis of obsidian recovered from recent archaeological excavations at Cerro Magoni, a hilltop Epiclassic site in Tula, Hidalgo. Archaeologists can use a variety of archaeometric techniques to better understand ancient interaction networks. Obsidian is a chemically homogeneous volcanic glass that was widely traded in Mesoamerica throughout the prehispanic era. This valuable resource was procured at geographically specific source areas, each of which has a unique chemical signature. Portable X-ray fluorescence (pXRF) permits archaeologists to detect the unique trace-element signature of obsidian artifacts with a high degree of certainty. With this information, the original source of each obsidian artifact can be determined. This paper presents a preliminary appreciation of patterns in local lithic production and regional exchange networks through the combined results of 1) formal technological analysis of the obsidian assemblage from Magoni, and 2) pXRF source analysis of a sample of the assemblage to provide additional insight into the social and economic networks that operated during the Epiclassic period in the Tula region and beyond.

Using LIDAR to Locate and Classify Ancient Maya Water Storage Features at Yaxnohcah, Campeche, Mexico

Airborne lidar presents a valuable tool to investigate water management for water-scarce region of the Maya lowlands. We analyze 25 km² of lidar elevation data for the ancient Maya site of Yaxnohcah in Campeche, Mexico. Using the hydrologic tools in the GIS software ArcMap we identified hundreds of closed depressions (many extremely small). These features may have a natural origin (e.g., a sinkhole) or may be anthropogenic (e.g., from quarrying), or may be data artifacts. We used a series of filters to narrow the list of closed depressions to those which have the potential to be used for water storage. We examined many of these features on the ground and excavated several, with the archaeological data indicating their origins during the Middle Preclassic period (900–400 BC). As the lidar also shows residential and monumental structures, we examine the spatial relationships between structures and water storage features (including watershed area, drainage lines, and water storage capacity).

Representing and Intervening: Team-Based Learning in AN 442 Cultural Resource Management
Team-Based Learning (TBL), a powerful pedagogical tool, has several essential elements: forming permanent teams; flipping the classroom; following a specific sequence of individual work and teamwork; and providing immediate feedback. In combination, these elements create a motivational framework in which students increasingly hold each other accountable for coming to class prepared and contributing to solving meaningful problems in various manners. Creating in-class application activities as part of the flipped classroom strategy is an essential element and can be daunting for first-time adopters of TBL because of the upfront commitment to their creation. Employing the thought process “representing and intervening” from philosophy provides a strategy for constructing these activities by which students are provided the “textbook” view of a topic outside of class (representing) and are given the meaningful and “messy” real-world (intervening) activities in class. By working through the activity, students clarify and deepen their understanding of the textbook view and hone their experience with significant problems. TBL holds great promise for undergraduate students in the classroom acquiring a deep knowledge and an enduring understanding of archaeological method, theory, and practice.

Carrillo Bosch, Vania (Dirección de Registro Público de Monumentos y Zonas Arqueológicos e Históricos) [328] Protection of Cultural Heritage: The Case of Yaxcabá and Yaxunah, Yucatán
The objective of the paper is to present and compare the notions held by the contemporary residents of the town of Yaxcabá, the municipality’s head, and the village of Yaxunah in Central Yucatán, about the protection and conservation of the archaeological sites on their lands. Even though Yaxcabá and Yaxunah are less than 20 km apart, these two population centers display social, political, and economic differences and have been influenced by varying amounts of exposure to archaeological research projects and tourism. As a result the notions of cultural heritage vary among the inhabitants of Yaxcabá and Yaxunah. We will also provide recommendations for how to integrate local residents’ full participation in promoting the protection and conservation of cultural heritage. Archaeologists need to be fully aware of the different land tenure and management systems of the lands onto which archaeo logical sites are located, as these will affect the way communities relate and engage with the ruins. Close collaboration of archaeologists and local communities are essential for a successful cultural heritage conservation and management process.

Carroll, Jon (Oakland University) [350] Using Aerial Remote Sensing to Assess Error and Uncertainty in Archaeological Site Mapping
Archaeologists often find themselves excavating sites where previous investigations have been performed, and documentation relating to earlier work may be of varying quality. This discussion focuses on the use of a topographic mapping drone to assess error and uncertainty in archaeological site survey performed at Tel Lachish, Israel since the 1930s. Systematic assessments of historical map datasets were performed within a Geographic Information System (GIS) allowing for an enhanced understanding of site excavation over time. These assessments allow researchers to avoid previously disturbed areas with a much greater degree of confidence maximizing valuable field time.

Carson, Mike (Micronesian Area Research Center [MARC]) [208] Changing landscapes of the Paleolithic/Neolithic transition in Taiwan
Toward understanding the Paleolithic/Neolithic transition in Taiwan, a paleo-terrain approach allows reconstruction of the ancient landscapes and habitats of where people lived. Those ancient contexts help us to situate the activities of people using their landscapes in different ways at intervals of 7,000, 6,000, 5,000, and 4,000 years ago. This approach needs to account for significant change in tectonic movement of land masses, slope erosion and redeposition patterns, fluctuating sea level, and other factors coordinated with the geographic distribution of cultural sites at specific measured time periods. By building a stronger sense of the natural and cultural context during the time period of study, other questions can be explored more productively.

Carter, Alison K. (University of Illinois Urbana-Champaign) [333] Houses (and Gardens?) at Angkor
Household archaeology and a focus on residential spaces is an emerging field in Southeast Asia. At Angkor, this approach has great potential for exploring the resiliency of nonelite members of society through changes in environmental and sociopolitical processes. In this paper we present results from the ongoing analyses of a 2015 excavation of a house mound within the Angkor Wat enclosure. Using a variety of techniques including macro- and microbotanical analyses, geoarchaeology, soil chemistry, and spatial analyses of artifacts we aim to identify specific activity areas on top of the mound. Botanical analyses are especially informative for identifying the presence of household gardens and subsistence practices of the people on the mounds. Radiocarbon dates suggest a continuous occupation of the mound during the Angkorian period, with reoccupation or reuse during the post-Angkorian period. Although issues of preservation and the nature of Angkorian house construction (which built houses on stilts with their house floors above the ground) are challenging, we see great potential in this research.

Carter, Michael (Director, Industry Relations, Master in Digital Media), Jean Li (Department of History, Ryerson University) and Alex Ferworn (Department of Computer Science, Ryerson University)

This paper will examine a recent effort to develop an interdisciplinary graduate level digital media and physical computing course, framed as experiential archaeology for non-archaeologists. By combining theory and practice of digital media, archaeology and a computer science course in robotics as an introduction to the cultural heritage destruction of the el-Hibeh site in southern Egypt due to pervasive looting, graduate students in digital media worked alongside undergraduates students in computer science to design, develop and “deploy” functional prototypes that testing hypotheses used to examine the extent of looting holes and tunnels within a simulated archaeological landscape. Egyptian co-director of the el-Hibeh site, Dr. Jean Li framed the archaeological, historical and current best practices of Egyptian archaeology while Dr. Alex Ferworn, a specialist in disaster management robotics design, provided the practical technical knowledge to address design, functionality and applicability in the field. This interdisciplinary approach demonstrated how non-archaeological students from varied fields of expertise and skill, could negotiate archaeology, digital media and physical computing in the creation of new archaeological knowledge in methods and practice. In doing so, archaeology and the application of digital media became the basis of experiential learning.

Social Interaction at Distance over the Long Term: Obsidian Sourcing from the Southern Levant (Ninth–Fourth Millennia cal BC)

The McMaster Archaeological XRF Lab is dedicated to undertaking major regional obsidian sourcing studies, not least in the Eastern Mediterranean where we have the North American geological source collection. We take a holistic, integrated approach, melding chemical composition with the artifacts’ techno-typological characteristics, contextual information and other pertinent data to produce “thick description” narratives. In this case we consider obsidian circulation and consumption among Southern Levantine populations over five millennia, from Pre-Pottery Neolithic B to the Early Bronze Age (ninth–fourth cal millennia BC). Artifacts were analyzed using EDXRF spectrometry from Nahala Lavan 109, Beisamoun, Sha’ar Hagolan, Ein el Jarba, Tell Tsaf, Tell Ali and Marj Rabba. Sourcing data is then located within a broader Levantine, South-East Anatolian and Mesopotamian context using Social Network Analysis. The results show that while the relative quantities of these exotic products (closest sources >800 km distant) in circulation did not change significantly, the range of raw materials increased significantly through time, from an initial reliance on central Anatolian products, to the use of central, eastern and north-eastern Anatolian and Armenian obsidian. The expanded socioeconomic networks that underpinned these Southern Levantine communities’ access to obsidian are interrogated with regard to larger cultural dynamics of these periods.

Rethinking the Formative Stage: A Reconsideration from Two Archaeological Sites on the Colombian Caribbean Lowlands

The concept of formative in Colombia is traditionally framed as a transitional period within the unilinear cultural evolution in the Americas, characterized for several indicators such as sedentary life, diversity of socioeconomic forms and the emergence of new technologies such as pottery. In this paper, we revised two archaeological sites: Monsu and Puerto Hormiga, incorporating zooarchaeological analysis, technological and use-wear analyses to provide understanding into past human behavior including interaction with tropical environments, changes in subsistence, seasonality, mobility and adaptation. With this understanding, we discuss the scope around the formative stage for the comprehension of early human adaptations in the Caribbean Lowlands.

Carvalho, Milena (University of Louisville)

An Assessment of Small Game Exploitation at Gruta Nova da Columbeira in the Middle Paleolithic (Portugal)

This paper presents an analysis of small game faunal remains and stable isotope data from Gruta Nova da Columbeira. We present a discussion on the importance of small game as a protein source in Middle Paleolithic subsistence strategies. Our analysis of 226 identified taxa shows that small game was an important component of subsistence strategies during this time period. We use stable isotope data to test two subsistence models: 1. Anatomically modern humans gained a competitive advantage over Neanderthals by exploiting broad-spectrum diet type prey items such as the rabbit (as in Fa et al. 2013); and 2. Neanderthals practiced a broad-spectrum diet in local environments exemplified by sites such as Bolomor Cave (as in Blasco and Peris 2012). To conclude, I explore whether central Portugal displays the same shift in subsistence patterns from the Middle to Upper Paleolithic transition as elsewhere in Europe and if using the concept of a transition is an efficient way to track human adaptation to environmental change in the Pleistocene.

A Hot New Technology: Advancing Methodologies for Archaeological Aerial Thermography

Since the 1970s, archaeologists have known that a wide range of features, including subsurface architecture, pits and ditches, pathways, and surface artifacts should theoretically be visible in an aerial thermal image, but technological hurdles largely prevented thermography from being deployed in most field settings. Recent research has begun to take advantage of new lightweight, uncooled thermal cameras, increasingly reliable drones, and photogrammetric image processing software, revolutionizing archaeologists’ ability to collect and mosaic thermal imagery. Utilizing data from archaeological sites in North America and the Middle East, this paper presents new methods for acquisition and processing of aerial thermal imagery using a camera system that collects raw thermal imagery at very high spectral resolution. These data offer many possibilities for quantitative, raster-based methods to filter out noise, improve feature recognition, and perform archaeological feature discrimination. Results reveal a great deal regarding the varied archaeological sites investigated by this project, in many cases rivaling results of more conventional archaeo-geophysical data, and thereby offering researchers a powerful new method to explore the archaeological record in a way that is rapid, inexpensive, and nondestructive.

Houses of Colonial Chiefly Authority: Local Elites in the Social Order of Mawchu Llacta, a Colonial Reducción Town in the Southern Highlands of Peru

As a result of the Toledan Reforms in the Viceroyalty of Peru during the late fifteenth century, new settlements known as reducciones were established to centralize indigenous populations. Such is the case of Mawchu Llacta, a colonial town located in the Cusco Province, Peru. The introduction of these reducciones brought a series of major changes to the social order. External agents were established as the new bearers of power and local elites took on a secondary status. However, a dearth of archaeological data limits our understanding of the social and political character of local elites in reducciones. Excavations by the PATA project during the 2016 season inside three structures that are the likely dwellings of curacas allow us to learn more about the role played by these local authorities within their community. Initial evidence suggests that these houses served a semi-public role as gathering spaces for religious festivals and community events, though diversity in the lifeways of the three elite households is also clearly displayed. The comparative analysis of the architectural elements and cultural materials provides us with enough information to better define the principal activities of local elites and how they participated in a new colonial social order.

An Android-Based System for Archaeological Survey and On-Site Stone Tool Analysis

This study presents results from the photogrammetric documentation of rock art in western Mongolia. Unlike many traditional rock art documentation techniques practiced in Mongolia, photogrammetry presents unique advantages for the study and preservation of cultural heritage. These include the production of a digital 3D model, preservation of color and original lighting conditions, ease of documentation, and the inclusion of contextual information such as surrounding features, panel orientation, and geologic context. Using photogrammetric techniques, we documented 10 late Bronze Age standing stones and three separate rock art localities in the Khangai mountains of Bayankhongor province, western Mongolia. By taking images at different times of day, we were able to produce high-visibility images of “deer stone” stelae, obviating the need for chalk or other substances which can damage the stone surface. By integrating our data with aerial photography, we produced high-resolution digital maps of our study sites. Results suggest that 3D photogrammetry may be profitably integrated into future research of late Bronze Age monuments in Central Asia.

Case, Emily and Emma Britton (UC Santa Cruz)

Compositional and Lead Isotope Analyses of Carretas and Huércigos Polychrome from Northwestern Chihuahua

The northern Mexican state of Chihuahua contains many little-known archaeological sites. Established collections, such as E. B. Sayles’s 1933 survey collection, can provide new insights using analytic techniques not available when they were originally acquired. We analyzed a subset of Sayles’s collection, including Carretas and Huércigos polychrome ceramic types, for glaze compositional information and geographic sourcing of the lead flux. Analyzing the samples using laser ablation inductively coupled mass spectrometry (LA-ICP-MS) determined new compositional information. Isotopic analysis using acid dissolution ICP-MS and subsequent comparison with previously analyzed samples from lead ore mines in the Chihuahua area contributed to geographic sourcing of the lead component. Chemical characterization suggests that both Carretas and Huércigos polychromes used similar, consistent and effective glaze recipes in their creation. Lead isotope ratios suggest pottery creators likely procured ore for glaze-paint production from mines in northern Chihuahua. However, lack of comparative isotopic data from the immediate area around sampled sites means the comparisons and conclusions presented here are preliminary.

Caseldine, Christopher (Arizona State University)
The city of Axum in northern Ethiopia is well-known for its high quality, hand woven cloth. Sundays and festivals bring throngs of local people who, to the outside observer, appear to be uniformly dressed in beautiful white handspun clothing embellished with colorful woven borders and embroidery. This apparent uniformity belies a very complex set of activities that lead to the production, distribution and consumption of cloth in Axum. Each step in production is dominated by people of particular ages, genders, economic levels, religions and ethnicities, who work entirely independently in different parts of town and have complete autonomy over the products of their labor, but usually very little interest in the finished product. Consumption is a matter of taste, tradition and finances. In the town shops lure wealthy customers with new embroidery styles named for current events, while village women enhance inexpensive industrially produced cloths that develop a parallel conversation about feminine craft in rural households. The purpose of this paper is to chart the landscape of cloth in Axum through production, trade and consumption and to challenge the perception that the production of cloth resides in the moment of weaving and in the skills of the master weaver.

Cassedy, Daniel (AECOM)  
[260] Archaeology of British Military Logistics in the French and Indian War  
The Hudson River in upstate New York formed a strategic military corridor between the North American British and French colonies for centuries. In the 1750s, it was the setting for multiple British expeditions moving north to contest the French coming south out of Lake Champlain and Canada. Because the fighting was seasonal, as were the garrisons of the forts and storage depots, the facilities had to be frequently rebuilt, and the entire supply chain had to be renewed annually to move tons of food and weapons by bateaux and ox cart to the front lines. Primary historic documents combined with data from excavations at multiple sites along the river between Albany and Lake Champlain have provided evidence to help re-create and understand this complex logistical supply chain and better illuminate the daily lives and experiences of eighteenth-century soldiers.

[23] Spaces and Signs of Transfer of Jade and Callais in the Neolithic of Western Europe  
Two different groups of green stones with a distant origin are found together in the Neolithic tombs of the Carnac Region (Brittany, France): the Alpine jades (jadellite, omphacitite, eclogite) were used as raw material for polished axes and disc-rings, while the Iberian callais (varsicite, turquoise) for pendants and beads. The way in which these transfers took place will be the subject of this presentation, highlighting the specific features of each geographical area. With such aim in mind, the rows of steles and the iconographic programs inscribed in the standing stones of the study area will be analyzed in order to propose a comparison of the respective symbolic systems. If the land routes from the Alps begin to be better monitored during the fifth millennium, the sea routes to/from the Iberian Peninsula remain theoretical but very promising. We will offer several arguments in favor of the latter hypothesis.

[43] Developing Long-Term Public Archaeology in Slippery Rock, Pennsylvania  
Slippery Rock University (SRU) maintains the historic Old Stone House as a museum in Slippery Rock, Pennsylvania (Butler County). In addition to living history and educational events held on site, an active archaeological excavation is being conducted on an external structure, hypothesized to be a summer kitchen. Preliminary excavations have been a joint venture between SRU students and faculty and members of the local community—including amateur archaeologists. This presentation will discuss efforts to develop long-term integrated public archaeology using the Old Stone House and the new SRU Archaeology Lab to foster engaged community stewardship and interest in cultural heritage management among town and gown alike.

Castañeda, Amanda M. (Texas State University- San Marcos)  
[126] Characterizing Hunter-Gatherer Ground Stone Bedrock Features in the Northeastern Chihuahuan Desert  
Ground stone bedrock features are common at archaeological sites in the Lower Pecos Canyonlands of southwest Texas. These features are human-made depressions pecked, ground, or worn into bedrock or large boulders, and were used for a variety of processing activities by the indigenous peoples. Although archaeologists in the region have informally recognized different “types” of ground stone bedrock features (e.g., slicks, grinding facets, deep mortars), there have been no dedicated studies of bedrock features. Due to their widespread occurrence in the region, bedrock features represent an untapped research avenue regarding the lifeways of Lower Pecos hunter-gatherers. Therefore, to gain a better understanding of these features, 824 bedrock features were mapped, documented, and analyzed at ten sites across the Lower Pecos. Structure from Motion (SfM) photogrammetry was utilized to map the bedrock features and provide high resolution three-dimensional data to gather metric measurements. Statistical analyses were employed to characterize the range of bedrock feature variation. This paper discusses the potential implications of bedrock feature morphological variation and explores the role(s) these features played in Lower Pecos hunter-gatherer lifeways.
Cereals in Southeast Asian Prehistory

Rice is the most important crop in Southeast Asia today. The evidence is that rice was equally important in Southeast Asia’s past. From the Neolithic period to the Middle Ages, rice has been discussed as food, a ritual item, a farming system, a culinary tradition, a tradable commodity and the basis of power. However, was it always the staple crop in Southeast Asia? The archaeobotanical studies conducted in Central Thailand by Weber revealed that in some instances and places, millet was more important than rice. In this paper, we discuss cereals and their role in Southeast Asia. Sites belonging to different periods in Mainland Southeast Asia are presented with information derived from the study of plant remains, including cereals and weeds of cultivation.

Settlement Ecology in the Tula Region of Mesoamerica: A Local Landscape Perspective

Based on seminal contributions by Suzy and Paul Fish associated with full-coverage surveys and agave cultivation, this paper explores changes in regional settlement patterns in relation to land-surface morphology in the Tula region in Mesoamerica during the Classic to Postclassic periods (200 CE–1500 CE). Drawing on our field surveys, independent settlement data from the Tula Region, and landform segmentation and classification in Geographic Information Systems (GIS), this paper illustrates that place to place landscape variation provides a more complex picture of changes in regional settlement patterns over time. In addition, to interpret the landscape ecology of settlement patterns, geomorphometric analysis provides an additional tool for assessing potential taphonomic impact on archaeological remains. In this paper we provide preliminary results and discuss how integration of other spatial datasets can provide a more robust framework from interpretation of settlement changes in relation to Mesoamerican’s local landscape ecologies in central Mexico.

Drones, Photogrammetry and 3D Modeling in Peruvian Archaeology

Air photography, using Drones and 2D/3D Models produced with Photogrammetry, is changing the way we do field archaeology. This technology also can be a powerful tool in telling a story about the sites and the work that we, as archaeologists, do there. However, several technological adaptations have to be developed in order to take full advantage of these new technologies. In this paper, we will walk you through the process of combining air and ground based 3D modeling along the North Coast of Peru, which utilizes air photography technology to produce a new way to render our visions of the past.

Based on geo-archaeological studies on the Argentinian-Chilean border in the southern Andes, a method is proposed for ranking lithic sources based on the quality of the material, cost of accessibility, and location along travel corridors. In the upper Las Taguas river valley (northwestern San Juan Province, Argentina, 5500–3700 masl), 32,622 lithic artifacts from 30 sites were analyzed to study the variation in the use of seven lithic sources between 10,000 and 500 cal BP. We ranked the time required to travel from each site to all sources with anisotropic analysis based on a surface elevation model and Tobler’s cost for movement on slopes. Considering Andean topography the accessibility of each source is ranked in terms of its distance to travel corridors and movement based on least cost path calculations. Finally, based on detailed analyses of archaeological material and regional models, we propose distances that may help to estimate lithic sources as nonlocal or extra-regional.

[34] Relational Native Ontology and Tewa Ethnogenesis in the Pueblo of Pojoaque

This paper recognizes the collaborative potential between American Indian Studies and an emerging landscape archaeology in furthering interdisciplinary studies of the American Southwest. Here the authors call for the continued reinterpretation of ancestral and contemporary Tewa sites by employing Native ontological and decolonized historical approaches to archaeological and ethnographic contexts situated in the backdrop of a larger and active cultural landscape. Such methods offer nuanced insight into the functions and meanings relating to multiple interacting identity communities through time, population movements, and other types of migration. In particular, we discuss the effects of early Spanish colonialism and later American colonialism, mass migrations, indigenous language, and the potential relationship between archaeological inquiry and Pueblo people in what is now the modern day Pueblo of Pojoaque.

[302] Preliminary Investigations at Raiatea, Society Islands, French Polynesia

The Society Islands are of primary importance for understanding human impacts on island ecologies and the dispersal of precontact voyaging populations in East Polynesia. Raiatea, the largest island of the Leeward Group, is recognized through Polynesian oral traditions as a locus of regional interaction and a departure point for migrations that colonized the distant islands of Hawaii and Aotearoa (New Zealand) in the second millennium AD. Here we present results from our first season of fieldwork in the district of Tumaraa, western Raiatea. Subsurface testing has provided a stratigraphic profile for coastal flats and offshore islets (motu). Excavations at the megalithic Marae Tainuu revealed evidence of a substantial occupation history, with the exposure of early architecture, a dense deposit of subsistence remains, and evidence for the manufacture and use of lithic tools. Long-term project goals include a detailed analysis of the historical ecology of Tumaraa from which to situate this region in the broader context of East Polynesian settlement history and examine the impacts of human activity on coastal and offshore environments.

Cegielski, Wendy (Arizona State University)

[234] Chronology and Social Process in Bronze Age Spain

This research presents an evaluation of the use of morphometrics of ceramic vessels for organizing site chronologies and social interaction. The object of morphometric analysis is to study how changes in artifact shape covary with time and space. This particular method is tested against Bronze Age ceramics from the Valencian region in Spain along the Western Mediterranean. The characteristic stylistic homogeneity of these ceramics has proven especially resistant to chronological fine-tuning through stylistic analyses and absolute dating. This study uses simple metric indices produced from ceramic rim drawings commonly available in publication for archaeological assemblages to characterize patterns in rim morphology through time and space. The development of methods that easily and successfully improve the chronological resolution of these “resistant” assemblages is essential for projects tackling cause and process. This is the case as applied to the wider goals of this research project, using social network analysis to understand processes that maintain stability of social structures in the Valencian Bronze Age.

[35]  The Importance of Wild Animal Resources in Skagafjörður, North Iceland
In both past and present, pastoralism has been an integral part of life in Iceland. In fact, status is generally defined by how many cattle one can keep;
however, wild resources are abundant in Iceland and are also used to supplement the diet. For much of Iceland’s history, wild resource use and access
was heavily regulated through formal laws and social contracts that often favored elite landowners. Using case studies from Skagafjörður, North Iceland,
this paper will explore the use of wild resources compared to domesticates. Preliminary zooarchaeological analyses of sites in the Hegranes region
suggest that larger, wealthier farms used fewer and less varied wild resources than smaller, abandoned farms. This differential use of resources hints at
the complex relationship between wealth and access to resources and, further, to the ways people would have thought about their use of wild animals—
as a vital part of daily life or as something to be exploited occasionally. I argue that wild resources would have been vital to the smaller farms that could not support a large herd of domesticates, while larger farms likely had a very different relationship with the few wild resources they utilized.

Chamlin, Matthew (James Madison University) Katherine Spielmann's work in the Salinas Pueblo area of New Mexico has, among other things, emphasized how ritual and economic interconnectivity among late prehistoric pueblo villages articulates with internal social and cultural changes. One thread of this work, developed by several of her students, has been change in gender relations during the rise of the large towns of the Pueblo IV period (AD 1400–1600), especially involving women's roles in exchange, production, and ceremonial life. Transformations in gendered agency may have been crucial in the development of inter-pueblo management strategies reflecting their community's values in the face of developments taking place in Gitga'at ancestral territory.

Chan, Amy (UCLA) isotopic analyses to explain how year-round occupation of the highlands could be the most plausible strategy for surviving and taking advantage of most of the perennial resources available in the puna, such as obsidian for tool making and camels for hide, bone and meat consumption.

Challis, Sam (Rock Art Research Institute, South Africa) mobility among Hunter-Gatherers in the Central Andean Highlands during the Early-Middle Holocene: GIS Models from Sr and O isotopic Analyses Cuncaicha rockshelter (4,480 masl) is one of the highest hunter-gatherer occupation sites found so far in the Americas; it brings new insights about human adaptation to extreme living conditions and subsistence strategies within the Peruvian puna. This research intends to define the possible type of occupation and mobility patterns at the site during the Early and Middle Holocene through Sr and O isotopic analyses in dental enamel of the human individuals and faunal remains found buried in this site. The Pucuncho Basin, in which Cuncaicha is located, presents a particular 87Sr/86Sr ratio different from the lower-altitude ecological zones that surround it, allowing the assessment of mobility of the individuals, whereas the Sr isotopic provides clues for defining water sources as well as likely elevations where people could live. We conclude with a GIS-developed mobility model based on these isotopic analyses to explain how year-round occupation of the highlands could be the most plausible strategy for surviving and taking advantage of most of the perennial resources available in the puna, such as obsidian for tool making and camels for hide, bone and meat consumption.

Challis, Sam (Rock Art Research Institute, South Africa) Rock Art and Emergent Identity: the Creolization Process in Nineteenth-Century South African Borderlands Statements of authorship of rock art necessarily involve statements of identity. What happens, then, when identity is assumed or implied? This paper examines a well-known historical rock art panel in South Africa, supposed to portray a narrative of the demise of the San from their own perspective. To the contrary it finds that in fact the "colonists" sporting wide-brimmed hats and toting guns are, more likely, members of an emergent identity of creolized raiding bands drawn from markedly different precolonial indigenous groups, as well as "runaway slaves" and Europeans.

Chalmer, Nyra (Simon Fraser University), Spencer Greening (Gitga’at First Nation), Chris Picard (Gitga’at First Nation), Ginevra Toniello (Simon Fraser University; Hakai Institute) and Dana Lepofsky (Simon Fraser University; Hakai Institute) The Gitga’at—Simon Fraser University (GSAHP) Archaeology and Heritage Project: Developing Community-Based Heritage Management Strategies in Gitga’at’area Territory The Gitga’at First Nation, traditionally known as the Gitga’at, of the Tsimshian peoples on the Northwest Coast of British Columbia is facing major marine developments in their ancestral territory, most notably tanker traffic related to several crude oil and liquefied natural gas export projects. While the Gitga’at hold extensive oral knowledge about their history and past landscape use, until recently, little was known about the territory archaeologically. To address this knowledge gap, in 2013 the Gitga’at—Simon Fraser University Archaeology and Heritage Project (GSAHP) was initiated to collect baseline archaeological data to inform decision-making related to development and community-driven research initiatives. Over the last seven years, the GSAHP research team has investigated over 150 coastal archaeological sites, contributing significantly to our understanding of the Gitga’at eco-cultural landscape. Many of these culturally significant places are touchstones of Gitga’at identity, representing an unbroken connection between Gitga’at people and their ancestors and illustrating the inextricable link between community well-being and their eco-cultural landscape. Through connecting archaeology with community knowledge and oral history, the nation is taking a proactive approach and developing holistic, long-term heritage management strategies reflecting their community’s values in the face of developments taking place in Gitga’at ancestral territory.

Chamberlin, Matthew (James Madison University) Women’s Mobility and Inter-Pueblo Exchange in the Salinas Area, AD 1100–1300 Katherine Spielmann’s work in the Salinas Pueblo area of New Mexico has, among other things, emphasized how ritual and economic interconnectivity among late prehistoric pueblo villages articulates with internal social and cultural changes. One thread of this work, developed by several of her students, has been change in gender relations during the rise of the large towns of the Pueblo IV period (AD 1400–1600), especially involving women’s roles in exchange, production, and ceremonial life. Transformations in gendered agency may have been crucial in the development of inter-pueblo exchange in earlier periods in the Salinas area as well, as suggested by evidence of change in women's mobility and involvement in symbolic communication over the transition from dispersed settlements to aggregated plaza-pueblos from AD 1100–1300.

Chan, Annie (University of Pennsylvania) The Monumentality of Ancient Pastoral Landscapes in Western Tian Shan (Xinjiang, China) This paper examines the spatial configuration of stone structures built for ritual and funerary uses in the steppes of Western Tian Shan based on results of survey and excavation in the Bortala and Ili River Valleys in Xinjiang, China. Marked by clusters of structures attributed typologically to different epochs of human activity in the sites evince a process of ritual and funerary customs spanning upwards of centuries. The additive process by which some of these structures came into existence, as previous field research in contiguous regions has noted, highlights the temporality of these locales and the perpetuation of pastoral landscapes. In dissecting monumentality, this paper contends that the influence of these structures on routes of movement among early pastoral societies manifests on a diachronic scale.

Chan, Chang, Claudia (University of Pennsylvania) An Analysis of Funerary Food Offerings and Imagery in Theban Tombs from New Kingdom, Egypt Food played an important role in ancient Egyptian funerary practices, but there has not been an examination of the types of food offered. I examined food offerings and their corresponding imagery in Theban tombs from New Kingdom, Egypt (1550–1070 BCE) in order to analyze how food in funerary rituals changed over time. Through museum records, excavation reports, and examinations of artifacts in the British Museum, the Petrie Museum and the Museo Egizio in Turin, I determined the most common food types offered and depicted in imagery in the New Kingdom dynasties. There was more stylistic variation in physical bread molds than in the depiction of bread. Also, the overall amount of food left in tombs and the amount of food depicted in imagery declined during the late New Kingdom. From the stylistic differences between physical bread offerings and their depictions, I conclude that food production in ancient Egypt was open to the general population which allowed for personalized expression as opposed to the limited and controlled medium of illustration. I also argue that there was a shift away from the practice of offering an abundance of food toward simplistic burial customs in response to economic hardship and stylistic preferences.
Chang, Hualing [58] Resources, Technology, and Distribution: A Discussion on Models of Early Bronze Production in China

This presentation tries to provide several models to capture major shifts of the bronze production system in the China’s Bronze Age. The earliest evidence of bronze production was found in the Yellow River Valley dated to 2500 BC. But during 2500–1900 BC, most products were small bronzes cast by two-part molds. Copper or arsenic bronze products made by hammering also existed but no evidence proves tin bronze technique was yet invented. Around 2300 BC, political entities in the middle Yellow River valley procured the basic skills for bronze manufacturing, which eventually led to the section-molds technique employing tin bronze for casting vessels established about 2100 BC. After the Erlitou period, this technique became the mainstream tradition in Early China producing prestige vessels for elite class in the Central Plains between 1800–1200 BC. The pattern that resources and technology monopolized by the Central Plains dynasty was significantly transformed about 1000 BC due to the expansion of the Zhou Dynasty. The new political regime transferred not only techniques but also the authority to procure raw materials to regional political entities. This change opened the prologue of a new era of bronze production and the exploitation of new ore resources.

Chang, Melanie (Portland State University) and April Nowell (University of Victoria) [210] A Census of Women in the Upper Paleolithic

Binary models of gender are often uncritically applied in paleoanthropology, even if the biological sex or gender identity of a specimen or representation is ambiguous. In the Upper Paleolithic, indicators ranging from simple bifurcating lines to overt representations of secondary sex characteristics may be used to identify an illustration, engraving, or piece of portable art as “male” or “female.” These taxonomic rubrics are rarely stated explicitly. Still, the impression given by an overview of the relevant literature is that Paleolithic artists (usually assumed to be male) overwhelmingly objectified females in their works, with corresponding interpretations of the meanings of these representations and the artists’ intent that reflect modern biases. We present an empirical survey of human representations in Paleolithic art using an explicit classification scheme that relies on unambiguous markers of biological sex to identify representations as biologically male or female. We attempt to resolve the many ambiguous instances by comparison to less ambiguous representations and assess the likelihood of abstract representations (disembodied “vulvas” or “breasts”) to be intentional representations of females. Within this context, we discuss the difficulties inherent in recognizing sex (much less gender) in Paleolithic art and the consequences of unfounded assumptions in scientific and popular discourse.

Chapman, John and Bisserka Gaydarska (Durham University, UK) [20] Can Urban Agglomerations Be Seasonal, Low-Density and Egalitarian? New Interpretations of the Ukrainian Trypillia Megasites

Recent geophysical investigations of Trypillia megasites created a second methodological revolution, following the first revolution (1970s) defined by the discovery of the megasites and their dating to the fourth millennium BC. So far, this second revolution comprised primarily a methodological advance based upon detailed geophysical prospection; but its potential gains may be subverted without a fundamental re-interpretation of the very nature of megasites. The prevailing view of the megasites for over 40 years is that Paleolithic artists (usually assumed to be male) overwhelmingly objectified females in their works, with corresponding interpretations of the meanings of these representations and the artists’ intent that reflect modern biases. We present an empirical survey of human representations in Paleolithic art using an explicit classification scheme that relies on unambiguous markers of biological sex to identify representations as biologically male or female. We attempt to resolve the many ambiguous instances by comparison to less ambiguous representations and assess the likelihood of abstract representations (disembodied “vulvas” or “breasts”) to be intentional representations of females. Within this context, we discuss the difficulties inherent in recognizing sex (much less gender) in Paleolithic art and the consequences of unfounded assumptions in scientific and popular discourse.

Charles, Douglas (Wesleyan University) and Jane E. Buikstra (Arizona State University) [102] Constructing Archaeological Knowledge: Interpreting Hopewell in the Illinois Valley

Through several books and articles, Martin Byers has developed an interpretation of the Hopewell phenomenon in the American Midwest that radically departs from the general consensus. To date he has focused almost exclusively on Ohio Hopewell. Many of the important sites in that region were excavated almost a century ago and the reports and records are less detailed than we would wish. In his latest book, Reclaiming the Hopewell Ceremonial Sphere, Byers seeks to extend his vision beyond Ohio to the Mann Site in Indiana, the Kolomoki site in Georgia, and the Elizabeth and Mound House sites in the lower Illinois River valley. The complex theoretical framework Byers constructs drives his interpretation of Hopewell sites. Our familiarity with the Illinois valley as excavators and report authors/editors provides us the opportunity to empirically examine the sequence of construction and use postulated by Byers. We also critically evaluate our own assumptions and biases as they shaped our interpretations at the time. The objective of this paper is not to squabble with Byers, but to examine the role theory and assumption play in the construction of archaeological knowledge.

As the horse spread across the American Southwest on the heels of Spanish colonial project, Native American ways of moving were abruptly transformed. This was particularly the case for the many indigenous peoples from the Plains and Rocky Mountains who used equestrianism to build new regional economies based on wide-ranging nomadism. Along with these new ways of moving came a new emphasis on particular sorts of archaeological sites—namely, on the “way station” as a point on the landscape that was owned by none but visited by many different ethnic groups in the course of long-distance travels. In this poster we consider the distinct archaeological signature of colonial era way stations through an analysis of a large archaeological complex surrounding a spring in the Rio Grande del Norte National Monument.

Terminal Classic Chert Use at Nohmul, Belize

Stone tools and debitage were recovered from Late to Terminal Classic contexts of the site Nohmul in 1978 as part of a dissertation project. Since then, Nohmul has been heavily damaged by a road contractor who used structures from the site as road fill. Additionally, the chert production economy in lowland Mesoamerica has become an issue of great debate. Nohmul is situated roughly 30 km from the Northern Belize chert-bearing zone and 30 km north of Colha, the argued center of lithic production in the region during the Terminal Classic. Consequently, these understudied artifacts from Nohmul have the potential (1) to broaden our understanding of chert consumption and production in the region, and (2) to provide researchers additional datasets for comparison to other Terminal Classic assemblages within and outside the Northern Belize Chert Bearing Zone. Our analysis of the Nohmul assemblage has found evidence for local reduction of cobbles, and core maintenance, as well as production and maintenance of tools. We discuss these findings in relation to the broader chert economy in the region.

Neanderthal Artists? Exploring Misconceptions about Neanderthal Symbolic Capacities through Rock Art Studies

The question of whether Neanderthals created art is one that is currently under debate within the field of prehistoric art studies. Originally thought to be brutish and unintelligent, Neanderthals have recently come to be acknowledged as complex humans with symbolic capacities, through discoveries of Neanderthal-associated modern behaviors including burials, pigment use, and ornament creation. One of the last hold outs separating the symbolic and artistic abilities of Neanderthals from those of Modern Humans (Homo sapiens) has been the creation of rock art. This is now being challenged by recent discoveries of possible Neanderthal rock art in Spain and Gibraltar. This paper will discuss what the implications would be if Neanderthals did, in fact, create rock art, and how it would affect the way we study rock art and conceptualize the uniqueness of humans.

Materials Processing in the Production of Ceramic Bronze-Casting Molds from the Zhouyuan area, China, c. 1100–771 BCE

The extraordinary bronze ritual vessels of Shang- and Zhou-period China were cast in multipart ceramic molds, constructed from many individually formed mold sections. This piece-mold casting method was unique to ancient China, and an essential component of the technology appears to have been the use of a specialized type of ceramic paste to form the casting molds. This ceramic material was soft, porous, and rich in silica, making it quite unlike pottery clays in terms of composition, properties, and apparent techniques of production. This presentation outlines a reconstructed operational sequence for the selection and processing of materials used to make ceramic bronze-casting molds. Western Zhou-period casting molds from three foundry sites in the Zhouyuan area of Shaanxi province were analyzed using petrographic microscopy, scanning electron microscopy, and X-ray and infrared spectroscopy. Replication experiments were conducted using soils collected from nearby the foundry sites. By identifying several activities fundamental to the piece-mold casting process, this research demonstrates the potential for the laboratory analysis of ceramic foundry debris to further our understanding of early Chinese metal-making practices.

The Life of the Adolescent Paleoindian Female from Hoyo Negro, Quintana Roo, Mexico

Cave divers discovered remains of an adolescent human female in an immense, submerged chamber of the Sac Actun cave system in 2007. Until recently, her remains had only been studied from photographs, photo-based 3D models, and minimal sampling. Now her skeleton has been removed from the cave, conserved, and subjected to bioarchaeological, chemical, and histomorphological analysis. Her unusually complete and well-preserved skeleton, a rarity for late Pleistocene females in the Americas, provides striking insights into the lives of women among the earliest Americans. Naia, as she is known, had endured a healed spiral forearm fracture—a potential indicator of rough handling—and died between 15 and 17 years of age, having
suffered a period of intense metabolic stress in the last months of her life. Radiographs and macroscopic analysis reveal numerous, strongly patterned Harris lines in her long bones, carious lesions, moderate LEH, malocclusion, dental crowding, and delayed development of the mandible, demonstrating that she struggled to maintain a stable protein supply and providing strong hints about the nature of Paleoindian subsistence in Central America. Dated between 13,000 and 12,000 cal BP, Naia’s remains join the few other early females to suggest that America’s first women led short, difficult lives.

Representing the Underworld: Manipulation and Reuse of Animal Bones from Offering 126

Offering 126 was discovered during the Seventh Field Season of the Templo Mayor Project. This ritual deposit was buried in the West Plaza of the Sacred Precinct, during the reign of Ahuítzotl (AD 1486–1502). Mexico priests deposited inside a box made of stone slabs, more than 9,000 animal bones from 94 individuals, corresponding to wolves, pumas, jaguars, bobcats and birds of prey, among others. These animals were covered with a layer of marine organisms such as corals, shells, snails, starfish, and sand dollars. On top of these, the priest deposited flint knives and stone sculptures. This impressive offering was covered with the monolith of Tlaltecuhtli, goddess of Earth. In this paper we will present results on the analysis of animal bones, with emphasis on taphonomic processes. We can conclude that all the specimens were buried at the same time, but they were sacrificed on multiple occasions. Their pelts were used with ritual purposes or as garments, while their bones were preserved in storage. Manipulation of bones in different decomposition stages supports this idea. In addition we will talk about the symbolism of this ritual deposit, characterized by its biological richness.

Is the Anthropocene a Beastly Problem? Thoughts on Human-Animal Relationships and Contemporary Narratives of Change

Pizzly bears and coywolves have been making headlines over the past few years. Offspring of illicit pairings between species of charismatic and aggressive megafauna, these hybrid monsters are presented as signs and portents of a troubled future. This paper explores the relationship between contemporary discourses about unruly and uncanny hybrid species and academic efforts to define and engage with the Anthropocene. It questions the relationships between tacit understandings of the animal as a ‘determined’ entity (to which the human is or is not reducible) and narratives about the human past and the relationship between humans and nonhumans over various timescales. This paper argues that the concern engendered by new, boundary-transgressing hybrid species relies on certain ideas about human-animal relationships. These ideas are shaped by imaginaries of how humans and animals relate as either wild or domesticated—premised on a temporal narrative of increasing human intervention and mastery over the natural world. In contrast, my work on human-animal relationships in ancient pastoralist societies suggests a different way of considering these questions. Viewing the herd as a human-animal hybrid shifts how we tell the history of human-animal interactions, moving the emphasis away from domestication.

Determination of Use-Wear Evidence on Quartzite Tools: Experimental and Archaeological Studies

Use-wear analysis has become an essential method for functional study of archaeological lithic artifacts. Quartzite is one of the main raw materials for lithic tools during Paleolithic period in many sites in the world. However, use-wear studies on quartzite tools are poorly developed due to its poor quality and rough surface. In this paper, the objective is to provide some reference data of determination of use-wear evidence, including both of the experimental and archaeological studies. In order to identify the use wear and their basic pattern on quartzite artifacts, two groups of experiments were conducted in relation to the different working motions and contact materials. On the basis of experimental data and reference, some archaeological artifacts from the Wulanmulun site were selected for comparable use-wear analysis. The Wulanmulun site is a new important Paleolithic site in Ordos City of Inner Mongolia, with an age of 60–50ka. About 1500 lithic artifacts were excavated in 2010, which are mainly of quartzite. The analytic results suggest that many lithic artifacts display used wear, and several show hafting wear. Compared to the experiments, the main working motion is considered as slicing and cutting (sawing), and the contact material is dominated by animal substances.

A Comparative Study on Ceramic Production from Central Plain China and South China in Early Shang Dynasty

The site of Panlongcheng is located 450 km south of Zhengzhou in present-day Henan province serves as the join point between the Central Plain Culture and the Lower and the southern regions of Yangtze River. Unlike almost all of more than twenty bronzes vessel shapes are represented in the Panlongcheng finds, there are three different ceramic types discovered at Panlongcheng: Typical Central Plain style(Erligang style), local style and numerous stone ware/hardware(some glazed). In pursuit of studying of ceramic production system on both sites, this Paper presents a comparative petrographic study of full range of variation of ceramic samples from Zhengzhou and Panlongcheng. The results of this research suggest that, despite similarities in type, form and stylistic attributes, the ceramic vessels form Panlongcheng are significantly different from Zhengzhou in terms of temper composition and fire temperature. The significant difference between stone ware and other type of ceramics may suggest that stone ware were nonlocal production. The results of petrographic analyses of ceramic thin sections from both sites may make us rethink the relationships among function, style, pattern, technology and ethnicity in production of ceramic.
Stratification has wide-ranging consequences over most if not all aspects of lifeways and life history. Groups lived a lifestyle with more repetitive hard-work than their counterparts in the dominant culture. Bioarchaeological analyses suggest that social and cultural cognition is figurative, metaphorical, analogical, and participatory in nature. Spatial constructions, presented as figurative patterns, are regarded in this paper as the imagery conceptualization processes. These processes map or encode spatial cognition and relative cultural aspects dwelling in humans at the Haminmangha site.

Manufacturing process for them as well as the characteristics of the artifacts that deepen our understanding of the production and living conditions of ornaments, and other bone and antler materials. According to the analysis of these artifacts, we can deduce the retouching technology and possible to identify social groups and their cultural continuities and fluidities during historic processes and movements. Preliminary results from the trauma analysis suggests that the Hamoto-the Xiong minority population experienced a higher risk of violent injuries. In addition, it appears that most individuals in this marginal group lived a lifestyle with more repetitive hard-work than their counterparts in the dominant culture. Bioarchaeological analyses suggest that social stratification has wide-ranging consequences over most if not all aspects of lifeways and life history.

The production of ritual bronze vessels is an internationally recognized feature of Bronze Age China, contrasting strikingly with other early civilizations across the world. Their manufacture exploded in the Shang period (sixteenth to eleventh centuries BC), when bronze metallurgy spread across the whole territory of present-day China. However, while the production of ritual bronze vessels predominated in the Central Plains, recent research is showing how surrounding regions exhibited strong local characteristics in bronze production, reflecting idiosyncratic ideological, cultural, and technological choices. A “core-periphery” diffusion model to explain Bronze Age metallurgy, rooted in the traditional dynastic evolution, remains the paradigm in both Chinese and Western literature. This mainstream interpretation emphasizes the domination of the Central Plains but oversimplifies the complicated historical trajectories and interactions among many geographically different regions. This paper will present recent archaeometallurgical studies of different regions such as Hanzhong, Northern and central Shaanxi focusing on their material and manufacturing features. The “core-periphery” paradigm will then be reexamined and characteristics of regional metallurgies and their relationships will be discussed further.

This paper investigates the impact of social and environmental changes on the health of people living during the Warring States period (ca. fifth–thirteenth century BC) on the Shanbei Loess Slope, a marginal area that connects the Guanzhong Plain and the Shanbei Plateau. Two human skeletal assemblages representing different cultural settings, but with a long-standing history of conflict, were selected: 1) Zhaitoutou cemetery (n = 73) (Xiong Culture, the minority), and 2) Shiijahe cemetery (n = 33) (Qin Culture, the dominant majority). Bioarchaeological data including traumatic injuries, osteoarthrits, dental pathology, and other nonspecific stress indicators were examined to elucidate the experiences of violence and labor over the life course, and to infer the social and environmental challenges of living in each of these two groups. Preliminary results from the trauma analysis suggests that the Zhaitoutou-the Xiong minority population experienced a higher risk of violent injuries. In addition, it appears that most individuals in this marginal group lived a lifestyle with more repetitive hard-work than their counterparts in the dominant culture. Bioarchaeological analyses suggest that social stratification has wide-ranging consequences over most if not all aspects of lifeways and life history.

This paper analyzes iron objects and iron making remains from the eastern Silk Road area, such as Xinjiang, Qinghai, Gansu, Ningxia, and Shaanxi provinces, and found that there are several characteristics about the development of iron technology: 1) iron production not only related to geographical distribution of ore resources, but also to state pattern; 2) iron played a vital role in everyday life; 3) The development and transmission of iron metallurgy had some relation to the evolution of bronze metallurgy; and 4) The origin of iron using and making in ancient China was the results of the interaction between China and central Asia areas via the early Silk Road. It suggests to further carry out field survey of iron manufacturing sites in more different areas and to construct a whole sequence of installations and techniques.

have continuously been reconstructed and used by various succeeding regimes after the end of the Dutch rule in AD 1662. The excavation of the vicinity of the Fort’s foundation carried out by this study yields evidence of early human existence which extends the antiquity of the area around Fort Provintia further back in time. Based on the new findings, this study clearly demonstrates the prolonged duration of cultural changes from the prehistoric past to the historic present. In addition, the evidence sheds new light on our understanding of the successive occupation and the formation processes of the area through time.

[117]  
Farming vs. Herding: Subsistence Practice during the Late Neolithic Evidenced by Stable Carbon and Nitrogen Isotopes in Shengedaliang, North Shaanxi, China

In order to explore subsistence patterns in northern Shaanxi Province around 4000 BP, human and animal bones from the Shimao, Zhaomouliang, Shengedaliang, Huoshiliang, and Muzhuhzuliang sites were sampled for stable carbon and nitrogen isotope ratio analysis. The results show that most people primarily subsisted on C4 resources, e.g., millet and millet-related animal products, despite the fact that there was some intake of C3 plants by some individuals. Stable nitrogen isotope values indicate that there were differences in meat consumption between individuals at the site. Pigs were mainly fed with millet and millet byproducts, as well as some cattle, according to their high δ13N values. However, the sheep/goats consumed wild C3 plants at those sites. Our above findings indicates that patterns of northern Shaanxi around 4000 BP were characterized by millet farming, while the grassland animal husbandry (e.g., cattle and sheep/goats raising) displayed very little contribution to local economy. The intensive millet farming in northern Shaanxi provided enough food for population growth, ensured the accumulation of wealth, and consequently accelerated social differentiation and complexity.

[78]  
Archaeological Survey of Mound Sites in Southwestern Shandong, China: Plants and People

The surveyed area, Heze city of southwestern Shandong, China, is located at the lower reaches of the Yellow River. Most archaeological sites in this region were deeply buried, from 3 m to more than 10 m. Very few archaeological works especially excavations had been taken due to the depth. Our survey of 2012–2015 revealed that these sites had been continuously occupied for a long history. The occupation started from Beixin culture (c. 5000–4100 BC), continued to Dawenkou culture (c. 4150–2650 BC), Longshan culture (c. 2650–2050 BC), and to early Bronze Age of Yuesshi culture, Shang and western Zhou dynasties. Then they were used as graveyards during eastern Zhou and Han periods. Since Sui–Tang dynasties, there had been temples built on these mounds. About one hundred soil samples were collected and floated during the survey. The results indicated people had been engaged in the dry land agriculture, planting millets (Seteria italica and Panicum miliaceum), bread wheat (Triticum aestivum), soybean (Glycine max), as well as explored wet land for rice (Oryza sativa) cultivation. Rice remains were mainly from Longshan culture (c. 2650–2050 BC), and declined dramatically after that. This may indicate changes of environment.

[78]  
Mineralogical Makeup of Casting Molds and Its Archaeological Implications for Bronze Making Techniques in Ancient China

In order to understand how bronze vessels were produced and the knowledge involved we cannot limit our study to simply the bronze vessels themselves. Thus, the analysis on bronze mold production plays a key role to our understanding of bronze vessel production. The focus in this study will be on the 155 mold fragments currently housed at the Royal Ontario Museum, originally from Anyang dated to the Shang dynasty. Petrographic analysis was utilized for this research on raw materials and how the fabrics were processed to distinguish the texture and production method that may have applied to form these artifacts. Mineralogical analysis can shed new light between fabric types and previously distinguished mold forms as well as how distinct the various fabric types were within the different layers of the bronze mold itself. Thus giving us new insight on both the knowledge involved in the mold production and the technology available to the bronze craftsmen of the Shang dynasty.

Archaeobotanical Records of the Middle and Late Neolithic Plant Food Utilization from North Jiangsu Plain

As a transition zone between southern and northern China, the Huai River valley possesses distinct uniqueness in climate, environment, agriculture, archaeo-botanical culture, and other aspects. We have taken a series of archaeobotany case studies on the Neolithic sites of different period, such as Shunshanjie, Longquzhuang, Wanbei, in the lower Huai River valley. Combined with previous archaeobotany research in this area, we can summarize the plant food utilization in various periods. The clue of plant food utilization is not consistent in the lower Huai River. According to the existing archaeobotany evidence, this area stayed in a stage of low-level food production for a long time during 8500–6500 BP. Gathering was the uppermost way to obtain plant food; rice farming was a supplementary means of livelihood. As a lack of enough archaeobotany evidence, it is not clear how the plant food utilization developed during 6500–6000 BP. The rice farming tradition was in continuation. After 6000 BP, the mixed-farming of rice and millet came into being and developed rapidly in the lower Huai River valley. But it was different from the mode of the upper reaches; rice farming was of equal importance with millet farming.

[265]  
British Peasant Ideologies and Technological Approaches to Marginal Caribbean Landscapes

British colonial ideology originated, in part, from a view of the proper relationship between people, land, and government that was rooted in the ecology of Britain itself. This view was informed in the Caribbean by Barbadian and other large-scale sugar planting colonies, but the British Virgin Islands are ecologically and politically distinct. This paper employs high-resolution satellite imagery and GIS modeling to explore what happens when a British “peasant” ideology is laid onto a very different Caribbean landscape in an end-of-slavery experiment intended to place free Africans in their “proper” role. These data are combined with historic maps to analyze the different productive potentials of different parts of the site of Kingstown, British Virgin Islands, home to a group of free Africans settled there by the British Government in the 1830s. While the Kingstown people’s response was probably complex, this paper explores the limits under which they would have worked, had they employed the British model.

[347]  
Chirping Birds, Barking Dogs, and Singing Men: Ancient Ceramic Effigy Vessel Flutes from Tala, Jalisco, West Mexico

Duct flutes are an important class of aerophone instrument among the ancient and modern indigenous Americans. Duct flutes can be further classified into tubular and vessel types. While they are widely distributed, vessel flutes, unlike tubular flutes, are rarely depicted in regional iconographies. This is
perhaps because they are small in size and generally hidden by the player's hands and are thus difficult to portray in murals, vases and sculptures. However, this is not the case in West Mexico as data from our survey of online museum databases shows, they are third most commonly represented in ceramic sculptures. In this paper we describe, and examine, a collection of seven unpublished ceramic vessel flutes from Tala, Jalisco, Mexico.

“It comes from gathering”: Collaborative Archaeology and Future Directions
This session interrogates the practice, theoretical foundations, and outcomes of collaborative archaeology, and explores how collaborators are transforming our discipline today. Today’s papers demonstrate how collaborative archaeology offers epistemological resources that traditional, public and even community archaeology cannot provide, and how collaborative approaches force us to reexamine the disciplinary goals, practices, and outcomes of archaeological practice widely. We have divided the session papers into three broad themes: (1) Service: Working for Communities, Not on Them, (2) Conflict Resolution and Archaeological Engagement, and (3) Redefining the Discipline of Archaeology. As an example, I briefly present ethnoarchaeological research on homemaking on the islands of Inishark, Inishturk, and Inishbofin in western Ireland, highlighting how the documentation of delph, dressers, and shop ledgers serves these communities in preserving and celebrating island heritage today.

Historical Ecology of Tiv Migration and Conflicts in the Benue Valley of Nigeria: Implications for Food Security
When the Tiv, a Bantu language speaking group migrated into the Benue Valley of Nigeria from southwestern Cameroon over five hundred years ago, they faced hostilities from different groups in the valley. Hilltops readily served as important settlement locales to protect the Tiv from violence and conflict. As they migrated from one hilltop to another they eventually settled over much of the Middle Benue Valley. Archaeological research in the valley has investigated these ancient hilltop sites with emphasis on Tiv migrations and settlement history. But none of these investigations has considered the role of the biophysical environment regarding food resources and food production. This presentation reports on the ongoing archaeological research to investigate the relationship between conflict and food production by the hilltop communities, and resilience to food crises during such conflicts. Using archaeological, ethnographic, ecological, and historical data these findings will address issues of conflict and food security in the valley today.

A Comparison of Expedient Tools from Four Sites in Belize
Small lithic flakes have been recovered from most Maya sites in Belize. They are often viewed as byproducts of the lithic manufacturing process. A closer analysis of small flakes recovered from four sites (Cerros, Chau Hiix, Maax Na, and El Pilar) has found that while many of the flakes may have been removed during tool manufacture, the expedient tools themselves were used in a variety of household activities especially those associated with cutting or carving bone or wood. This poster compares flake samples from these four sites to determine if the flake tools reflect economic differences in the communities.

American Pompeii: Old Evidence on Late Classic Ties between the Pacific Coast and the Antigua Valley
An archaeological collection from finca Pompeya in the Antigua Guatemala valley provides significant information about Late Classic interaction with the adjacent Pacific coast. Excavated in 1893, the collection was eventually scattered to several museums in Germany, the United States, and Guatemala. However, it can be reconstructed from a photograph made not long after the discovery, and from newspaper reports that provide rough descriptions of the excavations. The objects themselves are still preserved, and provide important data for the study of highland-coastal interaction during the Late Classic period. This time period marked the height of the expansion of the Cotzumalhuapa polity in the coastal piedmont of Escuintla, which exerted a strong influence in elite culture at several sites in the Antigua Guatemala valley. The Pompeya collection also illustrates the history of early archaeological research and collecting in Guatemala.

This paper presents a technological and typological analysis of crucibles from the legacy collection spread across Zimbabwe and South Africa. The crucibles were most materials from the site are scattered in different archives where they are gathering dust with little or no research being performed. This contribution discusses a technological and typological analysis of crucibles from the legacy collection spread across Zimbabwe and South Africa. The crucibles were used for processing gold, bronze, brass, and copper at the site. Typological studies revealed the existence of specialized and non-specialized vessels, which were used for identical technical purposes. However, the non-specialized crucibles resembled quotidian pottery used for mundane activities. Quite interestingly, metallurgy and pottery-making are often portrayed as distinctly gendered pursuits, with minimal overlaps in symbolism and the participation of women.

Chiou, Katherine (University of California, Berkeley) and Luis Jaime Castillo (Pontificia Universidad Catolica del Peru)

The legacy collections from Great Zimbabwe (CE 1000–1700) emanated from uncontrolled treasure hunting expeditions of the late nineteenth and early twentieth century and the sporadic professional digs conducted at various points throughout the twentieth century. As a result of this colorful history, the majority of artifacts from the site are scattered in different archives where they are gathering dust with little or no research being performed. This contribution discusses a technological and typological analysis of crucibles from the legacy collection spread across Zimbabwe and South Africa. The crucibles were used for processing gold, bronze, brass, and copper at the site. Stressing Differences While Appearing to Be the Same: A Case Study from Lapita Pottery Motif Analysis

In previous research, employing a dataset composed of motifs recorded from 60 Lapita sites spread across the southwestern Pacific, we argued that a general trend of making highly similar, but not identical, motifs can be seen when motif repertoires of different island groups are compared. We thus proposed that the elements of surprise or amusement, generated from making something similar yet different from what the intended audience expected to see, was employed to stress shared traditions while also making a statement of being different, may be the underlying concept of making Lapita pottery decorations. In this paper we intend to examine the underlying motif construction rules employed by potters within these different island groups during the Lapita era, to identify whether they had specific preferences as to the rules used when applying motifs belonging to the ten most popular motif themes within our dataset.

Impressive Terraces and Ephemeral Houses: Domestic and Defensive Architecture at Cerro de Trincheras

Around AD 1200, Trinchereños (members of the Trincheras Tradition of the Sonoran Desert) covered the hillside of Cerro de Trincheras, Sonora, Mexico in over 900 terraces. After such extensive investment in shaping and laying out space within the site, they then proceeded to live in relatively ephemeral domestic structures on the hillside. This paper addresses the apparent contradiction of permanent houses on robust platforms by examining how Trinchereños built, maintained and managed space within the site. To do so, I present excavation data from Cerro de Trincheras, and surrounding sites. The construction of this site occurred during a period of population movement and upheaval, with large-scale migration, and site establishment in the middle Magdalena Valley. Placing domestic architecture at the center of my analysis provides a perspective for how the interrelated components of domestic, ritual and community architecture impacted the economic, social and religious behavior at the site.

Identifying Pre-Incineration State from Heat-Induced Fracture and Warping Patterns Found on Human Cremains in a Hungarian Bronze Age Cemetery

Attempts to determine the status of human remains prior to their final deposition are complicated in the analysis of cremains. Forensic and archaeological studies, however, have advocated for the interpretation of heat-induced fracture and warping patterns as indicators of the pre-incineration state of the body and of the characteristics of the funeral fire. The purpose of this research is to examine the possible internal social structures of a Bronze Age population in the Körös region of Eastern Hungary by testing whether or not trends in the distribution of macroscopic heat-induced features exist across the cemetery site of Békés 103. Fragments from fourteen cremation urns were assessed for the presence of diagnostic fracture and warping patterns according to their anatomical region. Their relative frequencies were then compared among human burials, among urn layers, and among individual bone fragments that exhibited colors possibly indicative of temperature exposure. Results reveal that statistically significant differences in the frequencies of a few features, such as postcranial warping and “thumbnail” fractures, exist and may suggest the presence of discrepancies in bone biomechanics and/or funerary preparations within the examined sample of Békés 103.

The Scientific Investigation and Cultural Implications for the Use of Prestigious Substances in the Ancient Mediterranean

The role of organic residue analysis in archaeological research has shifted from an intermittent side project of interested analytical specialists to becoming standard components of an archaeological research program with a growing number of archaeologists being trained in both excavation and analytical instrumentation. Such developments within the field of archaeology not only highlight the benefits of applying a range of scientific techniques, but also expand the scope of archaeological research questions. However, as organic residue analysis becomes an increasingly technical and specialized subdiscipline of archaeology, much explanatory time focuses on integrating scientific data with archaeological material correlates with perhaps less consideration of broader anthropological implications. This paper aims to examine the interpretative progression from archaeological site, through scientific analysis, and ending with broader cultural implications as they pertain specifically to the case of the use of psychoactive substances on the eastern Mediterranean island of Cyprus. The investigation of the history of intoxication in the Mediterranean Basin is fraught with interpretative problems, chief among which is the fact that the substances being investigated have long histories of use with wide geographic ranges. Further issues that will be addressed pertain to the documentation of organic substances in prehistoric settings.

Reconstructing Korean War Battlefields from Body Recovery Information

During the Chinese Spring Offensive of April and May 1951, Chinese People’s Volunteer Forces pushed United Nations troops back from their defensive lines in the Republic of Korea, with extensive casualties on both sides. Because UN forces were driven back, many of the dead were not recovered and identified until the battlefields were retaken. In some cases this occurred days after the battle, but for many it was weeks, months, or even years later. Individual Deceased Personnel Files (IDPFs) for each casualty provide information on where remains were recovered, the condition they were found in, and the identification process. The IDPFs from two different battles, the 7th Infantry Regiment’s defense of the Kansas Line on April 25, 1951, and the 2nd Infantry Division’s defense of the No-Name Line 24 days later, were examined to investigate the distribution of casualties across each battlefield, and in particular how the recovery locations fit with more traditional historical accounts. In general, files for individuals recovered immediately after the battles contain the least information about the condition and location of the remains, while those recovered later, by personnel not involved in the battles, provide artifactual, anthropological, and archaeological context, including inventories and sketch maps.

Archaeological Pedagogy, Gentrification and the City: Community-Engaged Scholarship in San Francisco

The Bay Area, and San Francisco in particular, is experiencing rapid gentrification due to the influx of highly paid workers employed by the tech economy centered in Silicon Valley. As the cost of living increases, long-time residents are being actively pushed out, and various community organizations have sprung up in response to highlight and address these issues of gentrification, displacement, and homelessness. In this paper, I explore the process and results of partnering with community groups including the Anti-Eviction Mapping Project during the fall of 2016 as part of teaching an introductory archaeology class for the UC Berkeley/UC Extension San Francisco Fall Program for Freshmen and the American Cultures Engaged Scholarship (ACES) program. While archaeological methods and interpretations can bring understanding to change over time, persistence, and historical context, how in particular can we contribute meaningful and useful information to community partners fighting contemporary displacement? How can an engaged pedagogy contribute to both student learning and social justice? While this is only the beginning of a longer-term research program, this paper appraises the benefits, pitfalls, and paths forward for engaging archaeological knowledge with teaching and learning and pressing local contemporary issues.

[179] Navajo Landscape Construction at Canyon de Chelly: A Quintessential Place

My paper will discuss how the Navajo construct Canyon de Chelly as a quintessential place on the reservation. The canyon has been occupied at least since Basketmaker times in the first centuries AD. Archaeological investigations have identified Ancestral Pueblo cliff dwellings from roughly AD 700 to 1300 followed by a brief Hopi presence. Navajo people began to settle Canyon de Chelly in the late 1700s. Unlike the Ancestral Pueblos, the Navajo lived on the canyon bottom and reused some of the facilities of their predecessors for storage. They also added their rock art to earlier panels. What makes Canyon de Chelly a quintessential place unlike other historical sites on the reservation are the rich oral narratives populated by the ancestral Holy People, which claim the canyon as Navajo intangible heritage. I will analyze these processes through White House ruins and Spider Rock where archaeological materials and ceremonial knowledge have been dynamically linked to construct a decidedly Navajo political history. The argument that the Navajo have been in the canyon as long as their spiritual ancestors, the Holy People, has been used in land claims cases. Canyon de Chelly is being reinvited as quintessential place in spiritual, political, and economic contexts.

[316] El Castillo and Its Regional Context in Huarmey Valley through GIS

Huarmey valley, at the southern fringe of Peruvian North Coast, was inhabited for millennia. It is a rich, multi-cultural area, where almost all types of archaeological sites are represented. The discovery of an imperial mausoleum at El Castillo in 2012/2013 is an example how little we know about this region. During the previous seasons modern state-of-art techniques of documentation were used on daily basis at the time of excavations. The successful attempts to implement new noninvasive, remote sensing techniques of archaeological prospection on precolumbian sites resulted in the development of highly accurate, rapid and relatively inexpensive methods of evaluation and inventorying of the Peruvian heritage. Spatial data collected at the time of excavations, especially of mausoleum and remains of architectural monuments around, as well as those gathered during archaeological survey of the valley rise a lot of questions about the site’s role in social and geographical landscapes of Wari Empire during the Middle Horizon period. Proper process of gathering, processing archival, field, and digital data allows to expand our knowledge about the past and reconstruct its forgotten landscapes.

Ciani, Michael  
[386] The Bear in the Footprint: Using Ethnography to Interpret Archaeological Evidence of Bear Hunting and Bear Veneration in the Northern Rockies

Archaeological evidence of prehistoric bear hunting and bear veneration in the northern Rocky Mountains and northwestern Plains is presented. Ethnographic documents and the writings of trappers, traders, and explorers are assessed in order to establish an interpretative framework to help decipher archaeological contexts in the region that include bear remains and rock art depicting bears. Examining prehistoric archaeological contexts in Montana and Wyoming within this framework suggests evidence of bear hunting and veneration similar to the regional ethnographic record. Data trends imply there may be a relationship between such sites and variables like location, seasonality, function, and age. Contexts with bear remains sometimes imply a winter occupation, and site constituents hint at the ritual treatment of bear skulls and paws. An apparent increase in bear hunting during the Late Prehistoric Period may have been influenced by the bears association with warfare and healing. Possible motivations for hunting are explored and include economic, social signaling, bear power attainment, and revenge incentives. Compatible theoretical approaches are briefly articulated in an effort to more clearly understand bear hunting and veneration in ecologic, symbolic, and utilitarian terms.

[389] Reworked Artifacts and Models of Raw Material Exploitation as Indicators for Settlement Duration on Middle Paleolithic Sites in the Highlands of Central Europe

Short-term settlement of Middle Paleolithic hunters leaves a specific tool kit on an archaeological site. In spite of this well-known fact, in some cases, concerning the duration of stay of groups of Neanderthals, mere techno-typological analysis of inventories seems insufficient. Analysis of raw materials exploitation, combined with information about long use, or reworking of certain artifacts appears to be helpful. On most sites from the Middle Paleolithic era, archaeological data, concerning the subject of raw materials extraction shows, that it generally had a local character. Although this is most typical, sometimes the situation is different. On a range of sites, known from uplands of Hungary, Slovakia, and Poland, artifacts prepared of raw material transported from long distance outcrops can be found (sometimes they were brought to the site from the distance of more than 300 km). Such artifacts are usually reworked, showing traces of their long use and value for prehistoric people. In some cases, they also appear in the context of first settlement on a particular site, suggesting a migration. It can also be assumed, that there exists a link between the settlement duration and the knowledge about explored area, which can be observed in some inventories.

Cifarelli, Megan (Manhattanville College, New York)  
[379] The Materiality of Life and Death: Dress Ornaments and Shifting Identities at Hasanlu, Iran

The site of Hasanlu, Iran, was destroyed thoroughly by a marauding army in approximately 800 BCE, leaving a hulk of smoking rubble that was a virtual tomb for the hundreds of residents and combatants who weren’t able to escape its citadel. The excavations of Hasanlu, led by Robert H. Dyson of the University of Pennsylvania Museum, took place between 1956 and 1977, and uncovered a remarkable range of contexts containing personal ornaments within the relatively narrow historical horizon of Hasanlu Period IVb (ca 800–1050 BCE). From the bodies of fallen victims, to temple treasuries and elite residences, to a cemetery with nearly 100 burials, the artifacts relating to dress and adornment played a critical role in the construction and perennial renegotiation of identity for the men and women at Hasanlu. This paper examines shifts to dress practices at Hasanlu during this period, arguing that transformations to the regulatory schema by which objects and individuals are gendered are manifestations of changes to the way this community conceived of gender as a social category.

Fortified Towns in a Nomadic Pastoral Landscape on the Mongolian Steppe: Bai Balik and the Northern Railways Archaeological Project

Mongolia is well-known for its history of nomadic pastoralism and Bronze and Early Iron Age burials and monuments. For a brief period in the eighth and ninth centuries, however, the Uyghur and Khitan Khanates built large towns and urban centers. One of these, Bai Balik was established about 758 CE during the northerward expansion of the Uyghur Empire, by the Uyghur khan, Bayanchur Khan as a ceremonial and trading center in the fertile and strategically located Selenge Valley. This well-known site, which was tested by a Japanese archaeological team, was recently recorded as part of a project conducted by the Mongolian International Heritage Team to provide recommendations on the routing of a proposed Northern Rail Link between Murun and Erdenet, in Northern Mongolia. Historical records, archaeological survey, and mapping are used to investigate the role centers such as Bai Balik may have played in the nomadic pastoral economy of the Mongolian Steppe. Specifically, we examine the size and layout of the town, the ethnic makeup and economic activities of the town’s population, and the possible role of agriculture.

Cipolla, Craig (Royal Ontario Museum)

Deep Impacts of Mohegan Archaeology: Indigenous Knowledge and Its Influence on the Past

There is no doubt that indigenous, collaborative, and community-based projects have made great strides in reshaping the ways in which archaeological research is conducted and carried out in North America. Comparatively speaking, however, reporting on collaborative projects often place less emphasis on the ways in which indigenous and hybridized versions of archaeology influence our interpretations of the past and penetrate archaeology at the level of theory. In this paper we attempt to fill this void, critically considering our collaborative work together in terms of deeper impacts that indigenous knowledge makes. We argue that our work together produces new and valuable perspectives on time and temporality, archaeological “data” in general, anthropocentrism, and colonial interaction and survivance. We discuss these insights in terms of several eighteenth- and nineteenth-century sites on the Mohican Reservation in Uncasville, Connecticut.

Mapping and 3D Modeling of Mayapán’s Monumental Center

During our 2016 field season, we mapped and created 3D models of Mayapán’s monumental center and several major architectural features. Located in the Northern Yucatán approximately 40 km south of Modern Mérida, Mexico, Mayapán was the largest ancient Maya political capital of the Postclassic Period and was one of the most densely nucleated of all Maya cities. It was a key center of political, religious, and economic activity. Mayapán’s monumental zone is relatively small, but contains a dense collection of temples, colonnaded halls, palaces, altars, and addition structures. We used unmanned aerial vehicles (UAVs/drones) to carry photographic equipment to collect both vertical and oblique photos and videos of the consolidated architecture. The resulting images were processed in photogrammetric software to generate an orthorectified photo mosaic and several 3D models major architectural features. These products were integrated into a geographical information system (GIS) to facilitate analysis. In this poster, we outline the technology and data processing workflow used and display the resulting products.

Healing through Heritage: Collaborative Archaeology as Process

Heritage is never static, rather it is a constantly evolving set of practices, beliefs, and tangible touchstones. Collaborative archaeology sits firmly in that thicket, whether through the data we uncover, the stakeholders we engage, or even the media attention we draw. The archaeology of Amache, the site of a World War II-era Japanese American incarceration camp, is an exemplary test case for how research intertwined in a contemporary community can recast our discipline’s relationship to heritage. This paper explores the potentially radical shift from a focus on the results of archaeology to that of the practice of archaeology. Framed by critical heritage studies, especially Laurajane Smith’s conceptualization of how heritage is a process, this presentation will highlight some ways archaeologists can enable or hinder engagement, especially at a site of civic injustice. At Amache, project success has been greatly enhanced through creating opportunities for intergenerational dialogue and exploration of suppressed histories. Also critical is embodied experience of a place sometimes only known through the silences around it.

Clark, Bonnie (University of Denver)

The archaeology of Amache, the site of a World War II-era Japanese American incarceration camp, is an exemplary test case for how research intertwined in a contemporary community can recast our discipline’s relationship to heritage. This paper explores the potentially radical shift from a focus on the results of archaeology to that of the practice of archaeology. Framed by critical heritage studies, especially Laurajane Smith’s conceptualization of how heritage is a process, this presentation will highlight some ways archaeologists can enable or hinder engagement, especially at a site of civic injustice. At Amache, project success has been greatly enhanced through creating opportunities for intergenerational dialogue and exploration of suppressed histories. Also critical is embodied experience of a place sometimes only known through the silences around it.

Sea Change: Maritime Maya Lifeways, Social Organization, and Dynamics at the Port of Isla Cerritos, Yucatán

Mesoamerican archaeology typically approaches social, cultural, political, and economic dynamics from a center-periphery perspective, tracing the historical pulses of integration and disintegration through the lens of the urban centers of the social and cosmological landscape. While the coastal Maya may seem peripheral geographically, maritime communities were actually central integrative forces throughout their dynamic histories. They facilitated and motivated movements and interactions of people, goods, and ideas within and beyond cultural regions and simultaneously stimulated sociocultural
In this paper, I shift the viewpoint from inland to the coast, focusing on recent household archaeology at the island port of Isla Cerroitos, on the Gulf coast of central Yucatán. The study addresses the question of social organization and change within the small resident population, as well as the sociocultural and political relationships with contemporaneous coastal and inland sites—especially Chichén Itzá. Moving between scales of archaeological data, from a single artifact assemblage and house mounds, to settlement patterns at the levels of site and region, I examine what we know about social life at this port from 300 BCE to 1500 CE and what a coastal Maya case study adds to our consideration of the social-historical dynamics of the northern Maya lowlands.

Clark, Jeffery (Archaeology Southwest)
[303] Not Quite Coalesced: Salado Settlements in the Upper Gila
Most fourteenth-century Salado settlements in the Upper Gila watershed are comprised of separate room blocks in both planned and ad hoc configurations. These spatial arrangements suggest that integration, and by extension coalescence, was never fully achieved despite occupation spans of more than a century. This poster examines ceramic and other material culture variability among room blocks within four settlements to identify social and cultural differences that persisted until depopulation in the early fifteenth century. Of particular interest is evidence for the co-residence of various immigrant and local groups who maintained deeply engrained traditions while closely interacting with each other on a daily basis.

Clark, Julia (American Center for Mongolian Studies)
[114] Mobility and Exchange Strategies in Neolithic and Bronze Age Mongolia
Mobility is a central part of the contemporary, traditional, historical and prehistorical economic strategies employed by hunters and pastoralists in Mongolia. While mobility is often contrasted with sedentism, there is much variation within the practice of “mobility” and how it is employed. Residential and logistical mobility are often used heuristics to discuss variations in mobility. In a critical application of these terms to the archaeological record of Northern Mongolia illustrates their utility, and tracks potential shifts in the mobility strategies of prehistoric and early historic populations who were undergoing great changes in their economic practices as hunting decreased and herding increased in the Neolithic and Bronze Ages.

Clark, Melissa (Ohio State University)
[235] Interpreting the Archaeology of Pregnancy Loss
The status of pregnancy loss as taboo in Western culture, as well as the poor preservation of fetal remains, contributes to the absence of pregnancy loss from the anthropological study of funerary practices. Furthermore, pregnancy loss is rarely viewed by society as a legitimate cause for bereavement and perhaps consequently, has been overlooked in the archaeological record. Additionally, grief associated with a miscarriage or stillbirth is often described as a novel phenomenon, while parental attitudes toward children in post-Medieval to modern Ireland historically have been characterized as detached and apathetic with little regard for the value of individual life. Moreover, it has been argued that pregnancy loss was regarded as insignificant. Archival, ethnographic, and biological evidence, however, suggest that Irish mothers likely mourned the loss of a fetus, and that grief for a lost pregnancy is not a modern phenomenon.

Clark, Terence (University of Saskatchewan)
[387] Beyond House Floors: The Logistics of Northwest Coast Plank-house Villages
Household architecture has a long and fruitful history in Northwest Coast archaeology. Excavation at numerous sites has provided detailed data on living surfaces and activity areas, but the greater dynamics of household and village organization remain elusive. This paper looks at important, but neglected functional constraints of plank-house villages, namely the need for firewood, potable water, and disposal of waste. These factors, which almost certainly informed on the construction and maintenance of villages while also acting as potential drains on their social cohesion, structured the archaeological record being studied.

Clark, Tiffany
[129] The Production and Exchange of Chupadero Black-on-white Pottery and Its Relationship to Social Identity
Produced between AD 1150 and 1550, Chupadero Black-on-white pottery is found throughout central and southern New Mexico, and adjacent parts of Texas, Arizona, and Chihuahua, Mexico. Despite its widespread distribution, chemical and mineralogical compositional data indicate that the pottery was manufactured in only two areas of central New Mexico—the Jumanos portion of the Salinas province and Sierra Blanca region. Distributional studies indicate that the Chupadero pottery produced in the two regions exhibits substantially different patterns of exchange. The majority of vessels produced in the Salinas province were used in the Jumanos pueblos, with smaller numbers going to their Manzanos neighbors. In contrast, compositional data indicate that pottery from Sierra Blanca production sources extensively circulated through interregional exchange networks. This paper explores the differing patterns of interregional exchange as they relate to the social identity of consuming populations. The findings of this study suggest that Jumanos and Sierra Blanca populations may have used this ceramic as a broad social marker to differentiate themselves from neighboring Pueblo groups to the north and west. The common usage of Chupadero pottery as a social referent suggests that populations in both regions endowed these vessels with similar cultural meanings and values.

[323] Inequality and Gender in Spaces of Craft Production
This paper explores questions of inequality and gender in the Classic Maya world by examining the spatial relationships between and within local sites of craft activity. Pulling from recent archaeological work at the Classic period site of Xultun, Guatemala, we present research on two contexts that were connected to the production and use of limestone and lime plaster. In presenting this work, we discuss the broader social implications of these spaces as they relate to class and gender through archaeological evidence discovered within and beyond zones of craft activity at Xultun. We draw on recent multi-scalar approaches to craft production implemented in other Mesoamerican contexts—spanning intrasite household workshops, distribution loci and final use contexts as well as broader macro-regional networks of trade and specialized production. We argue such analyses can foster a better understanding not only of operational sequences underpinning the production of limestone monuments and finished plaster objects at Xultun, but also of the social factors that contributed to the spatial arrangements of craft production and use in ancient Maya production contexts more broadly.

[391] **Handmade or Mass-Produced: Ritual Objects and the Making of Identity in the Teotihuacán Region**

A hallmark of the material culture of Teotihuacán, the largest city of its time in Mesoamerica (ca. 1–600 CE), is the wide circulation of a variety of mass-produced goods, including objects used in household ritual. Items made from molds included masks, figurines, ceramic vessels, and decorative attachments to large incense burners, which are often found in domestic refuse and in ritual contexts such as burials. Although such artifacts appear alike, they were not uniformly distributed across the population, and variation in the selection and use of mass-produced objects was socially as well as economically significant. Handmade objects, such as the small incense burners called candileiros, were also key components of the material culture of household ritual. In this paper I explore patterns in the distribution and use of handcrafted and mass-produced objects that are encountered archaeologically as buried offerings. I consider the cultural significance of contrasting patterns among the urban neighborhoods of Teotihuacán and settlements beyond the city and discuss data resulting from current research at the site of Chico Colloapan, in the southeastern Basin of Mexico.

[153] **Hearth Features at Krynysa Eastern Heads Cave 1, Southern Coast of South Africa**

The Agulhas Bank Paleoscapes (ABP), a broad coastal plain that is now a submerged continental shelf off the south coast of Africa, would have produced early modern humans with a variety of potential foraging options. A rich Middle Stone Age record documents the presence of early coastal foragers as well as terrestrial hunter-gatherers in the ABP. At Krynysa Eastern Heads Cave 1, both strategies are represented in a sequence spanning the end of the Middle Stone Age (about 40 ka) through to the end of the Last Glacial Maximum (about 19 ka), and through the technological transition to the Early Later Stone Age. Use of the cave throughout this period produced a dense sequence of well-preserved hearth features showing evidence of advance preparation of surfaces and frequent reuse. Here we report on the morphology, distribution, dating, and associated finds related to these features. Through an analysis of hearths, we investigate the issue of continuity of site use by groups with differing foraging strategies.

**Clem, Shimaine, Emily A. Schach (Arizona State University) and Jane E. Buikstra (Arizona State University)**

[233] **The Gendering of Children at Chiribaya Alta**

At the site of Chiribaya Alta (AD 900–1350), located in the Osmore Valley of southern Peru, certain Chiribaya grave goods are associated with either adult males or females. For example, females are often buried with weaving tools, and males with musical instruments. It is not possible to estimate the biological sex of children from their skeletal remains. Therefore, children are often excluded from studies addressing gender identities. Here, we use grave goods known to be associated with sexed adult remains to explore the process through which children learn their gender at Chiribaya Alta. Ethnohistoric and ethnographic data indicates that children begin to learn their gendered roles at a young age. The burial goods in the graves of the children at Chiribaya Alta help us to examine at what age and the process through which children begin to learn their expected adult gender roles and identities.

[395] **Indigenous Appropriations of Spanish Metal Goods in Southeastern North America**

Broadly speaking, iron and copper-alloy objects of Spanish origin in southeastern North America seem to fall into three categories that variably dominate from one site to another: 1) essentially unaltered, 2) trade goods modified by Europeans to conform to Native American demand; and 3) assemblages that consist of both categories 1 and 2, but were reworked by Native Americans. This diversity was a complex product of the convergence of structure, agency, and serendipity. The timing and nature of Spanish expeditions and settlements shaped the accessibility and even the value attached to objects, while Indigenous appropriations of those goods reflected local responses to novelty and opportunity.

[386] **Leaving Their Mark on the Wall: Determining Sex in Ancient Maya Rock Art**

Handprints and stencils are ubiquitous elements in rock art throughout the world. Numerous well preserved examples have been noted in Maya caves. These elements provide a clue as to the sex of the person whose hand is recorded on the cave wall. Recent studies have shown that sex may be estimated with a high degree of accuracy using anthropometric hand measurements. Sex is estimated by applying a variety of mathematical models based on sexual dimorphism in hand dimensions to direct measurement from rock art elements. Measurements have been collected from hand-prints in a number of caves in Yucatán to provide a large database for this project. Sex determination from rock art elements may improve the understanding of gender roles of ancient Maya within the context of cave use.

[160] **Selection-Driven Range Expansion Explains Lapita Colonization of Remote Oceania**

Archaeological explanations of colonization often focus on presumed human motivations. What drives humans when faced with the potentially risky and rewarding colonization of unoccupied island regions: curiosity, wanderlust, opportunity, escape? At best, human motivation is only a partial explanation for colonization and one that is difficult to evaluate with archaeological data. In contrast, archaeologically visible, population-scale patterns of human colonization are explicable by the natural and social environment, transmission and selection. This paper develops a range-expansion hypothesis from animal ecology and evolution to explain Lapita colonization of Remote Oceania. The hypothesis is tested with both archaeological data and simulation modeling.

[283] The Spatial Analysis of Debris from the Mound 34 Copper Workshop
During the 2007–2009 excavations at Mound 34, Washington University students and Museum Society volunteers piece plotted each individual artifact associated with the copper workshop at this mound. This information allowed for an in-depth macroscopic analysis of the debris associated with this activity area. This analysis focused on the spatial analysis of the copper and other debris within the workshop. Distribution maps of the debris were created to determine the relationships between the different types of debris (i.e., the copper in relation to bone) and the relationship between the debris and structure. The distribution patterns identified by this analysis, in addition to comparisons with experimental copper-working, have led to important spatial and temporal insights into how copper items were produced at this site and how the structure of the workshop itself was being utilized.

Coddington, Brian (University of Utah)
[383] Ecology, Territoriality, and the Emergence of Acorn and Maize Economies in Western North America
Ethnographic populations throughout Western North America sometimes relied on strategies and institutions to protect resources, patches, and territories for exclusive use. But explaining why and identifying when these exclusionary practices emerged (and dissolved) in the past remains difficult. Based on predictions from ecological and evolutionary theory, individuals should only engage in territorial behavior when the benefits of exclusive use, such as subsistence gains, are worth the costs of exclusionary tactics. We hypothesize this is likely to be the case when relatively dense populations shift toward intensified economies focused on abundant, storable, but relatively low profitability resources. If this is true, then demographic and economic shifts should occur coincident with changes in settlement patterns reflecting population infilling and stable clustering around key resources patches. Drawing on theoretical models from behavioral ecology and statistical models examining spatially explicit time series data, here we evaluate this hypothesis using two case studies: the emergence of acorn economies in central California, and the onset of maize agriculture in the eastern Great Basin and Colorado Plateau. If supported, this theoretical approach could help explain the origins of social institutions governing property rights, and this methodological approach could help identify such cases throughout prehistory.

Coe, Marion (Center for the Study of the First Americans, Texas A&M University)
Perishable artifact analysis in the Great Basin has often focused on whole or complete pieces to address questions regarding broad social groupings and environmental adaptation. In the Great Basin, past populations targeted distinct ecological zones to tend and gather wild plant species for the manufacture of perishable material culture, and by focusing on technological organization and the manufacturing process, there is great potential to better understand how these activities contributed to organizing smaller-scale social groupings, social interaction, and environmental interaction in fragmentary artifacts. This presentation will provide an analysis of early through late Holocene Bonneville Basin museum perishable assemblages, and the Bonneville Estates Rockshelter and Four Siblings Rockshelter collections at Texas A&M University, including basketry, cordage, netting, snares, manufacturing debris, and other miscellaneous artifacts. Focusing on the technological organization and the manufacturing process, from initial wild plant fiber processing to artifact construction of sites around the Bonneville Basin, this analysis yields unique interpretations of Great Basin social and environmental interaction.

Cohen, Anna (University of Washington)
[322] Advertising the Empire: Purépecha Strategies in the Imperial Heartland at Angamuco, Michoacán
Regime change is a social process that has occurred throughout human history and yet much is still unknown about how political developments shape local communities. This paper examines the impacts of the Late Postclassic (1350–1530 CE) Purépecha Empire on residents at Angamuco, an ancient city within the Lake Patzcuaro Basin imperial heartland in Michoacán, Mexico. Imperial narratives in ethnographic texts emphasize that authorities...
controlled craft production, tribute, and social practices. Archaeologists have investigated these narratives within a social evolutionary framework that underscores an expanding and highly centralized Purépecha state and empire. Drawing upon material from excavation and survey of domestic and public ritual contexts, I evaluate whether the dominant top-down model of political economic consolidation has more explanatory power than alternative bottom-up models. Changes in the production and use of the ceramic artifacts, as well as differences in stone architecture, suggest that the Purépecha exploited existing resource systems, and that imperial changes are most visible in elite areas of Angamuco. The results of this study provide a foundational chronological of occupation at Angamuco and add to our knowledge of complexity and urban forms in western Mexico.

Cojti-Ren, Iyaxel (Vanderbilt University) [216] The Emergence of the Kaqchikel Polity: Ethnogenesis in the Postclassic Guatemalan Highlands

In this paper, I will explore how the western Kaqchikel managed from being military auxiliaries to the K’iche’ kingdom to become independent and expansionist polity, and how this transition was reflected in the material culture of their two last settlements. I will use ethnohistorical documentation to inform how the western Kaqchikel conceived their auto determination, and how they achieved it after they abandoned their first capital Chi Awar after breaking their political alliances with the K’iche’ to start a new chapter of their sociopolitical life as an independent polity at Iximche. Archaeological data will be presented to corroborate ethnohistorical information regarding the Kaqchikel occupation of Chi Awar, the drastic abandonment of this site, and specially to discuss how the material culture let us know better about the lifestyle the Kaqchikel had at Chi Awar as an emerging polity but still under the dominance of the K’iche’. This research intends to be a diachronic study about the inception of a new political community in the highlands of Guatemala and to enrich the discussion about the Mesoamerica’s political geography in late Postclassic Mesoamerica.

Colclasure, Cayla (University of Tennessee, Knoxville), Martin Walker (University of Tennessee, Knoxville) and David Anderson (University of Tennessee, Knoxville) [241] Defining the Local Experience: A Distributional Analysis of Late Prehistoric Activities at the Topper Site (38AL23)

During the summers of 2015 and 2016, University of Tennessee, Knoxville field schools conducted excavations on the hillside at the Topper Site (38AL23), in Allendale, South Carolina. This work represents a shifting focus away from the Paleoindian period toward the dense Mississippian and Woodland assemblages present at the site. Maps constructed utilizing QGIS document the distribution of artifacts and the arrangement of identified features in the two excavation blocks and dispersed 1 × 1 m units. Evidence for habitation includes hearth features as well as linear and semicircular arrangements of postholes. The distributional analysis examines utilization of space within and without the structure and determines activity areas. These distributions were compared to similar datasets from other locations, including the Woodland occupation at the G.S. Lewis West site, located approximately 30 km north along the Savannah River. Site function and broader relationships to contemporary, local communities are considered. We discuss what aspects of daily life and household dynamics are reflected in our findings. This paper provides insights into intrasite activity patterning at Topper, local settlement variation in the Savannah River Valley, and contributes to our knowledge of the Woodland period on the Southeastern Atlantic Slope.

Cole, Kasey (Dept. of Anthropology, California State University) and Frank Bayham (Department of Anthropology, California State University) [251] Artiodactyl Exploitation in Northeastern California during the Terminal Prehistoric/Protohistoric Time Periods: Evidence of Environmental Rebound?

Artiodactyl representation in the archaeological record can be a particularly sensitive indicator of past human-environmental interactions due to their status as a high-ranking prey item. In this study we explore terminal prehistoric and protohistoric patterning of artiodactyl exploitation in the archaeological record in northeastern California. Specifically, this study examines previously published zooarchaeological data derived from residential sites situated along the Pit River in conjunction with new data derived from the faunal analysis of the Lorenzen site (CA-MOD-250), a residential village occupation located north of the Pit River drainage in Little Hot Springs Valley, California. The examination and comparison of artiodactyl exploitation during this time period and in these nearby localities provides some evidence for environmental rebound within the region. Additionally, this study explores factors that might influence both temporal and spatial variation in this phenomenon as a whole.

Collard, Mark (Simon Fraser University), Ben Raffield (Simon Fraser University) and Neil Price (Uppsala University) [15] Religious Belief and Cooperation in Viking Societies

It has become clear in recent years that it was not uncommon for Viking groups to be heterogeneous. Numerous studies carried out over the last 25 years indicate that, in the short term at least, sociocultural diversity has a negative impact on trust within communities, and that this leads to a reduction in the willingness of community members to support public projects. Thus, one issue raised by the discovery that many Viking groups were heterogeneous is how loyalty to the group was achieved. In the present paper, we seek to shed some light on this question. Recent work in the field known as the Cognitive Science of Religion suggests that certain religious beliefs can reduce selfishness and enhance within-group cooperation. Supernatural monitoring—wherein deities observe human thoughts and actions in order to identify and punish those who fail to act prosocially—is thought to be particularly important in this regard. With this in mind, we review archaeological data and written sources to address the question “did Norse gods engage in supernatural monitoring?” We show that there is reason to believe that the Norse gods were perceived to monitor human thoughts and actions and that this likely promoted a parochial form of prosociality.

Collins, Benjamin (University of Manitoba) and Christopher Ames (University of Victoria) [146] Preliminary Results from New Excavations of the Late Pleistocene Occupations at Grassridge Rockshelter, South Africa

Grassridge Rockshelter sits at the base of the Stormberg Mountains in the northern part of the Eastern Cape, South Africa. This region has only been the focus of two previous major archaeological projects, with research at Grassridge last conducted in 1979 and identifying Holocene Later Stone Age and Late Pleistocene Middle Stone Age occupations. The Grassridge Archaeological and Paleoenvironmental Project (GAPP) renewed research at Grassridge in 2014. In this presentation, we summarize the results of the new excavations, with a focus on the Late Pleistocene occupation. Major
findings include a rich lithic assemblage with abundant points and blades, frequent and overlapping burning features, ochre, fauna, and preserved plant remains. A radiocarbon date of 35,000 ± 2200 14C years BP places Grassridge’s upper Late Pleistocene occupation during a period of region-wide behavioral and technological diversity in southern Africa. GAP’s ongoing research of Grassridge’s rich Late Pleistocene archive looks to contribute to a better understanding of this diversity in relation to the paleoenvironmental, demographic, and social influences during this period.

Coltman, Jeremy (University of California, Riverside) [119] Climbing the Home of the Rain Gods: Mountain Cults in Ancient Central Mexico
According to Henry B. Nicholson, the rain deity Tlaloc enjoyed the most active and widespread cult in ancient Mexico. This assertion is surely correct, and is further evidenced from later ethnographic and ethnographic sources. Closely related to Tlaloc—and his earlier manifestations—were the Tepicoton, little directional mountain deities venerated during the veintenas of Tepeihuitl and Atemoztli. In this paper we review Nicholson’s original observations seen in the light of new discoveries and interpretations of the past 25 years. We will thus look at the significance and symbolism of mountain cults in ancient Central Mexico from the Classic period and onward, examining some of the regional and temporal variations of what was clearly a shared set of ideas and beliefs. Both Teothuacan and Mexico-Tenochtitlan sit in the shadow of important mountains that had ritual significance. Most likely, the very position of these mountains had something to do with the settlement of these centers as part of rituals of foundation.

Looking for Green Grass in the Desert: Methods for Land-Cover Classification in Drylands

In recent years, applications of Earth Observation for archaeology have been boosted by data acquisition and by the increased spatial and temporal resolution of new products (e.g., Sentinel-2, WorldView series, Pléiades mission). Nowadays, archaeologists are looking for ways to effectively merge multi-spatial and multi-temporal imagery, integrating spectral and contextual information as well. In arid lands, the lack of adequate data on long-term vegetation dynamics is hampering our capacity of understanding human-environment interactions. In this paper we present an ongoing research aimed at refine the land cover classification of the archaeological landscapes of Central Sahara and Gujarat (South Asia). Those areas where not subjected to major environmental changes throughout the late Holocene, and thus represent ideal case studies to apply remotely sensed based approaches. The understanding of the land cover dynamics in arid lands is key to refine our reconstruction of past cultural trajectories. In doing this, we are exploring a set of different approaches in land-cover classification (e.g., spectral ratios, LDA, image segmentation and OBIA) in open-source platforms (i.e., R, OTB) in order to get automatic and accurate results from multiple datasets.

Silk Road and Archaeology in Xinjiang: Insight from Adunqiaolu

The “Silk Road” describes the cultural communication routes established in the Han and Tang Dynasties. The term, coined by German scholar Richthofen (李希霍芬) in the historic literature, has since spread globally. The Xinjiang Uygur Autonomous Region in China, located in the line of communication between East and West, was part of the Western Region in Chinese historic literature. Because of the unique climate conditions of Xinjiang, preservation of ancient remains is excellent, providing a rich array of materials for exploring ancient cultures of the Western Region. This study examines human remains from the Bronze Age site of Adunqiaolu through aDNA, stable isotopic, and paleobotanic analyses. In addition, the bioarchaeological and archaeological data have been combined with extensive historic literature to investigate ancient human behavior, cultural exchanges, and lifeways that culminated in the formation of the “Silk Road.” This multidisciplinary approach applied to the complex history of Xinjiang from prehistoric to Bronze Age times facilitates a growing understanding of the Silk Road and the people of this vast trading and cultural exchange network.

Conkey, Margaret (UC-Berkeley)

Field Walking and Walking the Field

While we have gradually accepted that archaeological survey is as integral to our research as the overly-valued practice of excavation, the emotional dimensions of survey where one connects with the landscapes and with its occupants are hardly discussed, especially in the case of long-term surveys. What does a heart-centered survey project look like? How does the intimacy that comes from field walking inform the archaeology? As well, we are all participants in the field of archaeology, and everyone has a personal trajectory; we are walking the field over the years. Some of us have chosen to do this with as much collaboration as possible, as a way to bring more to the process, to recognize that walking (through the field) is a social, personal, emotional and intimate process that should be validated and endorsed. In this presentation, I will address both sides of “the field” from a heart-centered perspective drawing, on one hand, from my own field walking survey project in the French Midi-Pyrénées and, on the other hand, from the collaborative practices that have allowed me to walk through our disciplinary field.

From Hunting and Gathering to Farming in Northern Thailand

Southeast Asia’s prehistoric zooarchaeological record is peculiar: faunal assemblages are seemingly ‘diverse,’ and generally include a large number of mammalain/reptilian/avian/mollusk species, but often these assemblages lack telltale evidence for human consumption. Therefore, one of the primary challenges confronting zooarchaeologists in this region is identifying what taxa were actually exploited by prehistoric foragers and how these patterns changed over time. This paper investigates forager subsistence in northern Thailand over the past 12,000 years. Using new zooarchaeological evidence from Tham Phi Man (Spirit Cave), Tham Phaa Can (Steep Cliff Cave), Tham Sai (Banyan Valley Cave) and Non Nok Tha (Partridge Mound), I
argue that prehistoric hunter-gatherers only exploited some species present in these faunal assemblages and that this pattern of exploitation shifts in the early to mid-Holocene. These new datasets show that the transition from hunting and gathering to farming in mainland Southeast Asia was complex and requires an explanation of in situ foraging adaptations to understand why it was successful.

[37] Downscaling in Archaeology: From digital forest to probable trees

Integrating archaeological and paleoenvironmental data about the past is a long-standing archaeological goal. It is often central to basic archaeological interpretation, fundamental to addressing questions of human-environment interaction, and vital to realizing archaeology’s potential contributions to studies of vulnerability, resilience, and sustainability in the face of climate change. However, such integration faces challenges of scale, resolution, and mechanism. Increasingly abundant digital data open the possibility of adoption of statistical downscaling approaches used in ecology and paleoclimatology, which offers one means of addressing these challenges. In this paper I use a case study in Provence (France) as an example of the downscaling of paleoclimate data to explore the human consequences of Holocene climate change, particularly through its impacts on agricultural potential. The promises and pitfalls of downscaling in archaeology, I argue, exemplify the potentials of digital data: downscaling enables generation of interpretive possibilities, but also risks reifying one of them by producing seductive results. At the same time, downscaling is so explicit in its probabilistic foundations that it is a useful epistemological metaphor for digital archaeological data more generally.

[18] Teaching Digital Archaeology as Public Anthropology: Models for Using Social Media and Technology to Move Beyond the Classroom

Higher education pedagogy and university administration are pushing technologies as a way of increasing engagement and contact with students, rolling out digital learning environments and handheld devices aplenty. This shift has been critiqued as a fad but can it be harnessed to address the long-standing goals of public anthropology and calls to decolonize the classroom? Embracing multivocality, diversity, inclusivity and collaboration is complex, and opportunities to teach in a way that moves beyond simply lip service are rare. However, the tools to begin training students in public anthropology are often already at their fingertips—in fact, many of them are already doing it. By integrating technologies and social media thoughtfully and critically into curriculum, we can contribute to better understandings, approaches and skills for future generations of anthropologists. Digital literacy training as part of degree programs can also be harnessed in pursuit of increasing accountability, ethical practice, civic engagement, and global consciousness on the part of students and instructors alike to frame sustainable relationships outside of the classroom. Based on experiences teaching undergraduate and graduate students in North America and Europe, this presentation will share successes, failures, and lessons in digital public archaeology that our students have taught us.

Cook, Robert (Ohio State University) and Mark Schurr (University of Notre Dame)

Examining the formation histories of houses within prehistoric villages is difficult in cases with coarse resolution of radiocarbon dates and lack of stratigraphic relationships. Here we examine this problem by using two relative dating techniques, accumulation studies of artifacts and fluoride dating of animal bone, at the Guard site, an early (ca., AD 1000–1300) Fort Ancient village located in southeast Indiana. The sampling strategy involved excavating test units in all houses to assess the depositional history of the individual basins and to determine a relative sequence of house construction within the village. Results reveal much variation in artifact accumulation between houses, with houses containing more artifacts being hypothesized to be older structures that had been filled in with trash. Fluoride analysis was used to examine this hypothesis, producing generally consistent results. Vertical considerations revealed that stratigraphy was often reversed which is consistent with the interpretation that they were rapidly filled with trash. Horizontal considerations indicate that the initial construction age of houses with more trash were generally earlier than those with less trash.

[199] The Tempest: Geoarchaeological Investigations into the Effects of a Hurricane on a Submerged Prehistoric Archaeological Site, Apalachee Bay, Florida, USA

When Hurricane Hermine made landfall approximately 5 miles southeast of St. Mark’s, Florida, on September 1, 2016, it passed directly over several known submerged prehistoric archaeological sites in Apalachee Bay. This was less than one month after we had completed geoarchaeological investigations at one of them, the Econofina Channel Site, 8Ta139. The passage of the hurricane has allowed us a unique opportunity to assess what, if any, effects the storm had on the site. This study is particularly relevant because the nature of preservation at submerged prehistoric sites varies depending on multiple factors, many of which cannot be properly constrained. In this case, we have sedimentological datasets from prior to the storm. These will be compared to sedimentological datasets collected after, as well as any other observed changes in site features, artifacts, or overall geomorphological context.

Cooley, Delaney (University of Oklahoma) [343] A Comparison of the Lithic Assemblages from the Shavano Springs site (5MN40) and Christmas Rockshelter (5DT2), Western Colorado Archaeologists have long struggled to identify archaeological material diagnostic of prehistoric and protohistoric Ute occupation in the Rocky Mountains and surrounding areas. Despite continued efforts, researchers continue to rely principally on William Buckles’s (1971) seminal work examining Ute cultural continuity on the Uncomahgre Plateau of western Colorado. My research expands on Buckles’ 45-year-old dissertation by reexamining two excavated sites from his project: the open occupation Shavano Springs site (5MN40) and Christmas Rockshelter (5DT2). Together, the two sites chronologically encompass the Paleoindian period through historic times. I will compare the lithic procurement and production strategies through time and between the two sites, for levels of comparable antiquity, to characterize the degree of continuity or lack thereof. My results identify aspects of lithic technology unique to prehistoric and protohistoric Ute and provide researchers with new tools for evaluating the cultural affiliation of prospective Ute sites.

Cooney, Gabriel (UCD School of Archaeology), Jenny Murray (Shetland Museum and Archives) and Will Megarry (Queen’s University Belfast) [216] Powerful Objects: Traditional Beliefs about Neolithic Axes and Knives in Shetland At the Shetland islands off the north coast of Scotland there was major exploitation of a lithic source known as riebeckite felsite during the Neolithic period. This source provided the raw material for the majority of stone axes known from the archipelago and also for objects known as Shetland knives. At the source, North Roe, mainland Shetland intrusive dykes of felsite occur in granite. Integrated, multi-scalar survey and excavation by the North Roe Felsite Project has demonstrated that some of these were worked extensively. Objects from the quarry complex have been found right across the island group. Museum records and oral accounts indicate that traditionally felsite axes in particular were regarded as powerful objects, often deliberately incorporated into the walls of buildings and actively employed in practices to bring good luck to the family and farm. This paper will explore the basis for this active social role of felsite objects and raise the question of the extent of local knowledge of the quarry which was archaeologically identified within the last fifty years.

Cooper, Catherine G. (University of British Columbia), Angela Perri (Max Planck Institute for Evolutionary Anthropology), Jessica L. Burns (University of Utah), Jeremy M. Koster (University of Cincinnati) and Michael P. Richards (Simon Fraser University) [156] Dietary Variability through Isotopic Analysis of Modern Human Hair from Nicaragua: Exploring Significant Differences in Diet between and among Demographic Groups in a Single Population Carbon and nitrogen stable isotope analysis of modern human hair from Nicaragua was used to explore what constitutes significant differences in gross diet between and among demographic groups within the same population. Our results show that the absolute differences between isotopic central tendencies of demographic groups are small, but some are significant. Socioeconomic categories that were found to have significantly different isotopic signatures between or among groups included age groups (δ13C X2 = 76.99, df = 4, p = 0.000 and δ15N X2 = 86.85, df = 4, p = 0.000), locations (δ13C Mann Whitney U = 5992.000, p = 0.000 and δ15N Mann Whitney U = 8926.000, p = 0.021), and wealth (mean δ15N Mann Whitney U = 122.000, p = 0.003); there were no significant differences in isotopic signature between sexes.

Cooper, H. Kory (Purdue University), Robert J. Speakman (University of Georgia), Antonio Simonetti (Notre Dame), Matthew Pike (Purdue University) and Garett Hunt (Purdue University) [4] Native Copper Innovation in the North Native copper occurs in the Northwest Coast, western Subarctic, and Central Canadian Arctic and Subarctic. In all three regions there is archaeological evidence for its use by Hunter-Gatherers before the Contact Period. Since 2011, our project has been studying the innovation of native copper metallurgy in these three regions within a Behavioral Archaeology framework using data collected from: experimental archaeology, oral history, lead isotope analysis, research on museum collections using pXRF, government archaeological site databases, and gray literature. This project also has a community component, collaborating with the Native Alaskan and First Nations communities. Although the results of Pb isotope analysis of geological samples of copper from the Arctic and Subarctic are not encouraging, the large set of pXRF data suggests that this technique can be used to distinguish native copper from alloys such as brass and leaded materials and also relatively pure smelted copper. Additionally, this paper provides a brief overview of our results to date including a comparison of the use of copper by Hunter-Gatherers exhibiting differences in social complexity as well as thoughts on why and how copper innovation occurred in all three regions.

Cootsona, Melanie (Barnard College) and Madeleine Strait (Barnard College) [192] The Animals of Pueblo Ritual: Faunal Analysis of a Kiva from Pot Creek Pueblo, New Mexico This poster reports on the analysis of the faunal remains from a D-shaped kiva in use during the late 1200s or early 1300s at Pot Creek Pueblo in the northern Rio Grande region of New Mexico. The kiva was decommissioned in a highly ceremonial manner with both human and animal interments, as well as a variety of additional animal offerings on the floor. Additional animal deposits in the fill of the kiva suggest the continued use of the space as a receptacle for offerings. Close analysis of these zooarchaeological remains thus provides a key means of exploring the ritual practices of Ancestral Pueblo communities in the Rio Grande during a period of active village aggregation and social transformation.

Copeland, Lauren (California State University, Los Angeles) [11] The Iconography of a Late Classic Polychrome Maya Vessel from Petén, Guatemala While elite Maya polychrome ceramics often contain images and inscriptions related to political actors, motifs on the majority of polychrome ceramics relate to important elements of ancient Maya cosmology. This poster analyzes the iconography on a Classic Maya polychrome vessel from Petén, Guatemala, donated to the San Bernardino County Museum. The central figure on the interior of the bowl is a deer and a supernatural figure is painted on the inside wall. Terrestrial motifs are found on both the interior and exterior, emphasizing the centrality of the animate Earth.
The greatest climate change related threat to archaeological sites in the American Southwest is soil erosion brought on by hotter temperatures, increasingly intense wildfires, bark beetle infestations, and other subsequent changes in habitats. At Los Alamos National Laboratory in northern New Mexico, we manage 38 square miles of canyons and mesas that contain more than 1,700 archaeological sites, most of which are affiliated with Ancestral Pueblo cultures. In order to identify and protect the sites at highest risk for erosion, we created a soil erosion model using a geographic information system (GIS) and the revised universal soil loss equation (RUSLE). The model combines GIS layers that reflect climate, soil types, land cover, and LiDAR-based topography with a 2-m-square resolution. The model estimates tons of soil eroded per acre per year, but is best interpreted as a relative measure in this initial application. At Los Alamos National Laboratory, the model successfully identifies sites with threatening erosional issues, such as small gullies within the boundaries of mesa-top pueblo room blocks, and shows promise for use as a tool for comparing areas of greatest erosional concern across the Laboratory.

The Ballistic Performance of Prehistoric Weapons: First Results of a Comparative Study

Projectile points have recently taken a prominent position in debates on the complexity of Paleolithic human behavior. While the appearance of hunting weapons in the archaeological record was a central element in early discussions, the debate has shifted toward the appearance of specific projecting modes. Given that the organic propulsion tools (bow, spear-thrower) are only rarely preserved, energy has been invested in experiments to explore how the projecting mode can be identified based on the analysis of stone points. These experiments usually attempt to control selected parameters in projectile use (e.g., speed, target, angle of impact), but the ballistic parameters that are used are generally based on heterogeneous and not commonly reported studies. Little research has focused on the measurement of the complete ballistic performance of prehistoric weapons. We present the first results of a systematic ballistic study that quantifies and compares different modes of propulsion.

The Environmental Context of the Middle Pleistocene Occupation at the Shishan Marsh, Azraq, Jordan

With the current boom in the archaeology of the colonial period in the central Andes, we risk losing sight of the potential for archaeological investigation of the colonial aftermath. Following important work further afield in the Southern Cone, I argue for the particular relevance archaeology could have in exploring trade liberalization, emancipation, and the new commodity booms of the nineteenth century. Drawing on the recent investigation of a series of Middle Pleistocene hominin occupation dated approximately 250,000 BP. Archaeological and archaeozoological remains from this occupation have microfossil remains) research provide an environmental context to this occupation, which existed in association with a fan-delta on the northeast shores of paleo-lake Azraq. The lake-delta dynamics provided a rich wetland environment. A local fault influenced the flow of water from springs and stream small gullies within the boundaries of mesa-top pueblo room blocks, and shows promise for use as a tool for comparing areas of greatest erosional concern across the Laboratory.
El estudio de la organización política de la región de Tamtoc, tiene por objeto indagar en las relaciones que existieron entre los individuos, las formas en que ejercieron el poder político y la naturaleza y escala de su organización. Para realizar este propósito llevamos a cabo un programa de prospección arqueológica con el objeto de reconstruir los patrones de asentamientos y posible uso del antiguo paisaje. En esta ponencia presentamos los resultados de dos temporadas de trabajo en campo.

Settlement Patterns of Salado Period Occupations in the Duncan/York Valley on the Upper Gila River

The Salado period occupation sites have become the focus of substantial discussion in the Southwest as it relates to broader regional migrations, population fluctuations as well as sociocultural changes. Unfortunately many of these important sites have suffered from decades of destruction and continued looting. Comparing early site notes from the Gila Pueblo and other early researchers in the Duncan/York Valley to the University of Texas at San Antonio Southwest field project survey notes, this area has been a target of these destructive processes. However, documentation of the remnants of sites can still offer valuable information about the character of the Salado occupation and the circumstances under which the Salado horizon becomes visible. While many of the material traits used to define Salado occupation such as architecture, burial traits, and whole ceramic vessels are the first to be destroyed, information related to a site’s placement in space and material present can still provide important information.

Regional Diversity and Population Migration of the Classic Maya: Stable Isotope Analysis of Individuals from the Holmul Region, Guatemala

Stable isotope analysis is a productive tool for understanding the migratory histories of past populations in various regions of the world, including the ancient Maya. This paper presents the strontium and oxygen isotopic ratio values of dental enamel samples as compared to the geographical location of burial to address questions of regional identity, population migration, and social complexity of the Maya at the archaeological site of Holmul and the nearby centers of La Suficaya, K’o, Cival, Hamontun, Barton Ramie, and Uaxactun. The results of 68 individuals are reported here, selected from the osteological remains excavated by the current Holmul Archaeological Project and early twentieth century excavations by the Peabody Museum of Archaeology and Ethnology at Harvard University. The biological profiles of the individuals (burial treatment, estimated age, biological sex, perimortem trauma, cultural modification, pathology, and/or dental health) are combined with stable isotope analyses to understand the geographical diversity and mobility patterns of the Classic Maya. The application of this methodology can serve to encourage scholars throughout the Maya region and the world to analyze dental enamel as an alternative to bone collagen, especially in situations of poor preservation of human remains and difficult excavation locales.

Bonin Site: A Circular Village on Southern Brazilian Highlands?

Bonin site is one of many pit house villages located in Santa Catarina state, southern Brazilian highlands. It has been excavated since 2011. In this paper, we aim to present new data on pottery analysis, chronology, and spatial analysis which are suggesting a village plan organized in a circular shape. Dated from thirteenth to seventeenth centuries this village has 23 pit structures, many of them used as pit ovens, filled with basalt rocks and ceramic vessels. Microbotanical remains analysis reveals the consumption of manioc (Manihot esculenta Crantz), beans (Phaseolus sp.), and possibly yams (cf. Dioscorea sp.) in addition to maize (Zea mays L.) and squash (Cucurbita sp.). Macrobotanical and faunal remains recovered by flotation reveals the consumption of pinhão (Araucaria angustifolia nut), beans, Arecaceae nuts, as well fish, small mammals, and birds. The circular shape is easily identified in Jê villages located far north in Brazil, but it is a novel interpretation for ancient southern Jê settlements.

Cortes-Rincon, Marisol (Humboldt State University), Erik Marinkovich (University of Texas at San Antonio), Cady Rutherford (University of Texas at San Antonio), Spencer Mitchell (Texas Tech University) and Kyle Ports (Texas Tech University)
This study investigates the nature and intensity of ancient Maya household economies in northwestern Belize. The primary focus will be centered on investigative ways in which settlement pattern data offers insight to understanding production systems in hinterland communities. The preliminary patterned relationship that emerged among settlement features and land resources allowed for the interpretation of land management strategies and production systems implemented in different environment zones of the study area. Geospatial analysis of raw material procurement and distribution will be examined through the use of a Geographic Information System (GIS). Furthermore, spatial distribution of cultural materials should provide insight into the regional and localized circulation of goods. Results of this study will demonstrate how a hinterland community stratified land resources and built its local landscape into a complex diversified production area specialized in the production of marketable commodities.

Cossin, Zev [331] Community and the Contours of Empire: The Hacienda System in the Northern Highlands of Ecuador

Recent archaeological studies of Spanish colonialism have redirected scholarly attention both to the workings of imperialism and the multitude of ways in which marginalized populations navigated and remade the grids of power that constitute empire. A focus on the household and the materiality of everyday life has generated a rich body of evidence by which to trace between multiple scales of social life and foreground the material culture of daily life as constitutive elements in the making of social and political worlds. In Spanish America, the hacienda system was one means by which imperial logic took root. In this paper, I review preliminary archaeological investigations of the Hacienda Guachalá in the northern highlands of Ecuador, where excavations have begun to illuminate the domestic material realities of indigenous laborers and the lifeworlds they fashioned amid profound social and economic transformation over the long nineteenth century. Focusing not only on access to material goods but also to the ways in which such goods foreground collective obligations and identities suggests that the concept of “community” is key to understanding daily negotiations of empire by indigenous actors. Importantly, this approach emphasizes the enduring effects of imperial designs after the end of formal colonialism.

Crafting, Identity, and Power: A Comparative Analysis of Late Postclassic Facial Adornment Use in Central Mexico

In prehispanic Mesoamerica, individuals from diverse regions and social classes deployed facial adornments, such as ear spools and lip plugs, to materialize concepts of identity. Specifically, recent archaeological research at the Late Postclassic (AD 1250–1521) city of Tlaxcallan provides new insights into the role of facial adornments in a highly collective society. Tracing material sources reveals the inter-workings of regional and local economic interactions and local sociopolitical institutions impeding on distribution. Similarly, various styles of decoration can also reflect the sharing of cultural ideas between different settlements and regions and how Tlaxcaltecs identified within their own communities in relation to status, age, and gender. By looking at the distribution of raw materials, finished goods, and styles, we document the degree to which facial adornments were restricted to certain statuses/classes, genders, and age groups and, thereby, shed light on the social encoding of these items. Such information can then be used to evaluate the interplay between the degree of social embeddedness and degree of collectivity. Thus, facial adornments have the potential to provide information of great significance in revealing how economic and social institutions impeded on the production, distribution, and consumption of facial adornments among states during the Postclassic.

Costello, Eugene (University of Notre Dame)

Cows, Wolves, and Witches: The Question of Marginality within Transhumant Communities of Western Ireland

Small-scale transhumant movements were once quite common in Ireland, and continued in places like Conamara, Donegal and Achill Island up to the late nineteenth century and early twentieth century. Also known by the term “booleying,” these practices involved young people, usually girls, bringing dairy cows up to hill pastures for the summer so as to free up land at home for tillage and winter fodder. However, the seasonal landscapes and settlement patterns which they visited have until recently been neglected by archaeologists. Moreover, a significant amount of unexplored oral tradition exists in survey to interrogate the folk material and ask what it says about the social position of young female herders in nineteenth-century Ireland. It discusses their interactions, firstly, with one another and, secondly, with senior male figures in the home settlements. Is it justifiable to describe the young women as inhabiting marginal land when their economic role was absolutely central? To what extent were hill pastures considered to be liminal or dangerous places? Does the field archaeology support the idea that summer settlements were organized differently to home settlements?

Ceramic Differences at the Household/Neighborhood Level at Cerro Mejía: Evidence of a Possible Multiethnic “Mitmaqkuna” Community on the Southern Frontier of the Wari Empire

This poster will present the results of the analysis of household ceramic assemblages from the slopes of the secondary Wari center Cerro Mejía in the Moquegua Valley. The slopes of Cerro Mejía are divided into distinct domestic neighborhoods by fieldstone walls. Based on differences between these neighborhoods observed during excavations it has been hypothesized that this site was a multiethnic community similar to Inca mitmaqkuna with local inhabitants from throughout the region and possibly inhabitants from other locations in the Wari Empire. The analysis of ceramics from households in different neighborhoods appears to confirm the multiethnic nature of this community. Although there are some similarities across the site, the ceramic assemblages from each household suggest that ceramics were not centrally manufactured and distributed. Instead, the evidence suggests ceramics were manufactured at the household level. The assemblages were sufficiently different from each other to suggest that they were made not just by different individuals but by individuals who came from distinct ceramic manufacturing traditions. The goals of this poster are to clearly demonstrate the observed ceramic differences in detail and to discuss how these findings inform us about Wari imperial organization on the southern frontier of the empire.

"Can You Model My Valley? Particular People, Places, and Times in Archaeological Simulation"  
Every archaeological modeler, whether generalist or particularist, eventually gets asked whether “their model” can help reconstruct a particular past. Could a general archaeological simulation engine be built that can be customized to answer specific questions about specific archaeological contexts, or is simulation a tool that must remain largely general and heuristic? I will argue both that it is useful to work toward a general archaeological simulation engine, and that such an engine could help us understand what processes generated particular sets of archaeological remains, but that it won’t help us reconstruct particular pasts. I will also discuss the difference between these levels of understanding.

"Agrarian Landscapes of Coastal Croatia: A View from Nadin-Gradina"  
Generalized models of Mediterranean agroecosystems often elide the specific historical and political contexts in which food production necessarily takes place. This paper presents new historical-ecological research currently underway at the multi-period settlement site of Nadin-Gradina near the Adriatic coast of southern Croatia, a typically “Mediterranean” landscape that has hosted a dynamic social-political history of repeated invasion, migration, and colonization by a variety of human actors. The Nadin-Gradina Archaeological Project is endeavoring to elucidate the complex life history of this settlement and local environmental impacts of urbanization from late prehistory to the modern era. Attempting to think beyond basic questions of “subsistence” and “adaptation,” the research presented here asks how factors such as warfare and political destabilization were central in creating various configurations of land use and human-plant-animal relationships. A macrobotanical assemblage from our 2016 excavations is compared with various local datasets, including faunal remains, stable isotope data, and historical cartography, to develop hypotheses regarding historical continuity and variability in agropastoral practices. While broad historical continuities in the presence of economically important taxa are apparent at the regional level, our data begin to show marked diachronic variability the local level in usage of land and organization of urban-rural space.

"A History of Household Archaeology at Prince Rupert Harbour"  
The practice of household archaeology has a long history in the Prince Rupert area, owing in large part to the remarkable preservation of sites in the region including the existence of house depression features on the ground surface of many village sites. Approaches to investigating these house features have shifted over the years as new theoretical paradigms have arisen to replace older ones. Issues of chronology and culture history dominated early investigations, but more recently questions pertaining to social history have come to the fore. This paper reviews the use of household archaeology in the Prince Rupert area from its beginnings to the present and argues that the continued investigation of households is essential to understanding aboriginal social history in the region.

"People and Paleoclimates at the Diallowali Site Complex: Changing Patterns along the Middle Senegal Valley throughout the First Millennium BC"  
The first millennium BC was a time of considerable social, technological, and environmental change for the peoples of West Africa. Despite the growing number and distribution of archaeological projects throughout the region, very little is known about this critical period. Likewise, many of the climate models currently in use lack the sufficient temporal or spatial resolution needed to provide context for the variety of changes occurring at a localized level. Recent research at the Diallowali Site Complex along the Middle Senegal River Valley has provided a unique opportunity to investigate how first millennium BC social and environmental changes are linked. Combining stratigraphic excavations and large-scale, systematic survey, the Diallowali Archaeological Research Expedition (DARE) has compiled a detailed record of human habitation and climate change along the western margin of the Middle Senegal Valley. A multi-proxy approach to paleoclimate modeling and a detailed record of changing subsistence strategies and settlement patterns has provided a robust and localized dataset spanning the late second and first millenniums BC. This paper will utilize this new body of research to explore the dynamic relationship between the changing environment and the human communities that called it home.

[161]  
"The Roots of Global Trade in the Southern African Iron Age"  
During the African Iron Age from AD 800 to 1200, overseas trade began to expand out of southern Africa across the Indian Ocean, which caused an increase in the export of raw materials such as ivory. Archaeological evidence of ivory working has been found on sites across southern Africa dating to this period, including KwaGandaGanda and K2 in South Africa, Kaitshaa and Bosutswes in Botswana and Ingome Ilde in Zambia. It is unknown whether the raw ivory was obtained locally or traded in, whether certain sites were production centers, and which markets drove the demand for the manufacture of ivory bangles/bracelets. To this end, we explore the distribution and frequencies of ivory artifacts and working debris across these sites. We also report the results of carbon, nitrogen and strontium isotope analysis to understand the origins and procurement of the ivory alongside Zooarchaeology by Mass Spectrometry (ZooMS) analysis to identify the species of the ivory. Results indicate that the worked ivory derived from
elephants and that at some sites, ivory was derived from several catchment areas, implying a degree of landscape/resource partitioning. These sites therefore yield the earliest evidence for the trade of ivory in southern Africa.

Covert, Alexandra (Petrified Forest National Park) [304] Following the Shell Trail: Analysis of Prehistoric Shell at Petrified Forest National Park
Shell jewelry at Petrified Forest National Park has been found from Basketmaker II through Pueblo IV. Since there are no local sources of marine shell, it is important to understand how trade routes from the Gulf of California and the Gulf of Mexico directly affected how shell was traded to this region. Shell recovered from archaeological contexts curated in the Petrified Forest National Park collections were typed according to class, genus, and species and were sourced to the Gulf of California or the Gulf of Mexico. The shell was analyzed by temporal components to see if any discernible consumer patterns occurred. This analysis was conducted to determine if shell use was dependent on shell type or procurement location and to determine variability in shell use over time. A literature review was conducted to determine possible trade routes from both the Gulf of California and the Gulf of Mexico to Petrified Forest National Park. Ultimately this project will enhance the understandings of shell use, procurement, trade networks, and temporal consumer patterns on the Colorado Plateau.

Covey, R. Alan (University of Texas at Austin) and Miriam Aráoz Silva (Professional Archaeologist) [331] Empire in Ruins: Inca Urban Planning and the Colonial Occupation at Huánuco Pampa
Located in the Andean highlands of northern Peru, the Inca administrative center at Huánuco Pampa served as a provincial capital, drawing thousands of tributary households into scripted encounters with imperial officials on festive occasions. Inca site planning created spaces for performing diverse identities and reinforcing relationships between local people and Inca elites. After an unsuccessful Spanish attempt to establish a town within the central plaza of the site, Huánuco Pampa faded to a peripheral status, serving as a remote way-station on a Colonial highland route. The disembedded location of Huánuco Pampa contributed to the Spanish failure to maintain a central element of Inca provincial administration. Nevertheless, more attention needs to be given to how the long-term trajectory of the Colonial Period occupation was influenced by its dependence on, and departure from, principles of Inca urban planning. This paper will present the results of new architectural research from the eastern part of the site (Zone II), discussing how the distribution of Inca construction aesthetics and open spaces relates to the Colonial contexts that Craig Morris excavated in that part of the site during the 1960s and 1970s.

Cowan, Maya (University of Victoria) and Vanessa Tallarico (University of Victoria) [263] Cemetery Study at Emanu-El Jewish Cemetery in Victoria, British Columbia: A Look at the Potential Benefits of Simple, Shrouded Burials and the Use of Concrete Fills
The goal of our research was to analyze the correlation between decomposition, and damage to memorial structures around the Emanu-el Jewish Cemetery in Victoria, British Columbia. We hypothesized that some concrete fill damage was due to casket decay after the fill was placed, causing it to sink or crack. We used damaged double plots with a single fill as evidence, because the side of the older burial had time to settle before the fill was poured over both plots. We found that damage was almost always on the side of the most recent burial, where the ground had not settled beforehand. Jewish custom dictates that memorials be placed one year after burial, and that all materials used in burial be completely biodegradable. In some Jewish traditions, bodies are shrouded for burial, rather than placed in the pine caskets used by many communities. Since a human body decomposes much faster than a casket, concrete fills could be used for a shrouded burial with less possibility of damage. Prior to our research, we were informed that Victoria’s Jewish community has expressed interest in accessing more traditional burial customs. We offer our results to the community to consider in their future practice.

Cox, Kim and Carolyn Boyd (Shumla Archaeological Research and Education Center) [126] The White Shaman Mural: The Story Behind the Book
The prehistoric hunter-gatherers of the Lower Pecos Canyonlands created some of the most spectacular rock art of the ancient world. Perhaps the greatest of these masterpieces is the White Shaman mural. This presentation provides an introduction to our recently-published book The White Shaman Mural: An Enduring Creation Narrative, which is one of the most comprehensive analyses of a rock art mural ever attempted. Drawing on twenty-five years of archaeological research and analysis, as well as insights from ethnohistory and art history, we identified patterns in the imagery that equate in stunning detail to the mythologies of Uto-Aztecan-speaking peoples, including the ancient Nahua and present day Huichol. The identification of core Mesoamerican beliefs in Pecos River style rock art reveals that a shared ideological universe was already firmly established among foragers living in the Lower Pecos as long as 4,000 years ago. Crabtree, Stefani (Washington State University) and Tim Kohler (Washington State University) [38] Modeling Polity Growth among Ancestral Pueblo People in the Northern San Juan
In this paper we present research on the development of village-spanning polities in the central Mesa Verde region. First, we explore the dynamics of modeling not only households, but also groups of households, and how the interaction between them influences the development of social strategies. Second, we examine how territoriality shapes group development; we allow our agents to track lineage, and for lineages to own land, which, when populations increase, creates conflicts over the most productive lands. We apply models for the development of conflict and warfare on top of the “Village” agent-based model to examine how territoriality and conflict interact, allowing matrilineal groups to subsume competing groups in a chain of dominance and subordination to create large village-spanning polities. Finally, we demonstrate the dynamics of polity formation in the central Mesa Verde by showing the construction and dissolution of polities through time, comparing new data compiled from the archaeological record with output from our simulation.

Measuring Household Inequality in Hohokam Society: An Analysis of Domestic Architecture at Pueblo Grande

Recent archaeological efforts to explain the emergence and persistence of social inequality have been hampered by a lack of information about how wealth was transmitted across generations and how it may have accumulated or diminished over time. Building on studies that have shown domestic architecture to be an excellent material expression of household wealth, we provide a method for reconstructing the amount of labor invested in house construction at Pueblo Grande, taking into account different architectural styles from different time periods. Our analysis found variability in construction costs that was probably related to wealth and status differences among households, which persisted over time. High-status households were distinguished architecturally by larger and, in some instances, more elaborate houses. The proximity of these households to the village central precinct, a locus of ceremonial expression, further suggests that ritual played a key role in creating and maintaining inequality in Hohokam society.

Crawford, Kristina (University of Nevada, Reno)

Radiocarbon Age of Consolidants and Adhesives used in Archaeological Conservation

When radiocarbon dating archaeological material, it is paramount to understand how the object was conserved and which conservation products were used in order to determine: 1) the best location on the artifact to sample; 2) how to remove the consolidant physically and/or chemically, and; 3) whether or not the consolidant was successfully removed. The archaeologist usually knows the approximate age of the artifact given the context in which it was found so when the radiocarbon age is not as expected, it is possible the consolidant was not completely removed. However, without knowing the radiocarbon signature of the consolidant—this is purely speculation. Current, commonly used consolidants and adhesives cover both natural (animal and fish glues, tree resins, starches) and synthetic materials (acrylics, poly (vinyl acetates), poly (vinyl butyrals), polyethylene glycol, glycerol, cellulose ethers, cellulose esters, cyanoacrylates and soluble nylon). This paper will present data that indicate in which direction—young or old—the radiocarbon signature of the consolidant—this is purely speculation. Current, commonly used consolidants and adhesives cover both natural (animal and fish glues, tree resins, starches) and synthetic materials (acrylics, poly (vinyl acetates), poly (vinyl butyrals), polyethylene glycol, glycerol, cellulose ethers, cellulose esters, cyanoacrylates and soluble nylon). This paper will present data that indicate in which direction—young or old—conservation treatments may skew radiocarbon dating evidence for human remains obtained from a charnel chapel. It argues for the widespread and instrumental role of manipulated human remains in early Christian praxis in England and reflects on how this role has changed over the last 700 years.

Craig, Lorena (University of Montana)

Mapping Evolutionary Histories of Oceanic Mythology: Can Phylogenetic Methods Applied to Creation Myths Increase Our Understanding of Prehistoric Migrations?

This study seeks to understand the means of dissemination of oral cultural traditions of Oceania across time and geographic space. I hypothesize that the evidence from Oceania, will be analyzed using quantitative methods from the biological sciences. Results from evolutionary trees produced from analysis of creation myths provide a means to infer prehistoric migrations routes. Additionally, creation myths and cultural traditions can be intertwined. Moreover, by using data from other fields such as linguistic, genetics, archaeology, ethnology, and physical anthropology, the validity of using mythology as a proxy for migration can be measured. In a broader sense, phylogenetic studies, like this one, will provide new insights into evolutionary processes of sacred oral traditions and understanding of the evolutionary dynamics between multiple cultural traditions. Additionally, I propose this research will add to existing studies of prehistoric migration in Oceania, and provide a model for similar research in other regions.

Crawford,Kristina (University of Nevada, Reno)
When populations increase, more resources need to be extracted from the land to satisfy their needs. When cooking, one way to increase yields is to change techniques to include rock heating elements. To test this, twenty sites from the Late Archaic Period (3000 to 150 BP) in the northern Sacramento Valley of California were examined. The results of the study indicated that there is an increase in rock heating elements and thermally altered rock in archaeological deposits through time. It was noticed during the study that at the same time that rock heating elements increase in frequency in the archaeological record in the Sacramento Valley, substitutes for rock, specifically clay cooking stones were also introduced into the record. To test the validity of clay as a substitute for rock, a series of experiments have been conducted to determine heating ability, fracture rates, and fuel use. The results of rock versus clay cooking abilities are presented here.

Crawford, Gary (University of Toronto)

Hokkaido, Japan, is an island separate from the East Asian mainland and Honshu yet closely linked culturally to the rest of the Japanese archipelago. Hokkaido was never isolated entirely from the East Asian mainland either. This paper reviews several key events that relate Hokkaido as an island with a distinct cultural history. As the contemporary home of an indigenous population, the Ainu, Hokkaido has played, and can continue to play, an important role in our understanding of cultural trajectories in East Asia. Two cultures linked almost solely to Hokkaido as well as to Ainu development, the Epi–Jomon and Satsumon cultures, are examined from the perspective of how being situated on Hokkaido facilitated unique adaptations to and within the broader East Asian socioeconomic sphere. In particular, the cultural changes resulting from the incursion of a mainland form of agricultural society and economy to Japan beginning ca. 2800 BP resulted in a transformation of the cultural landscape throughout Japan except Hokkaido by ca. 2300–2000 BP. Hokkaido, being an island, participated in the transformation in a distinctive manner, first resisting change but ultimately participating in the transformation as evidenced by the formation of the Satsumon culture, the ancestors of the Ainu.

Crawford, Katherine (University of Southampton)

Visualization of the Invisible: How Can We Model Roman Religious Processions?

Religious processions colored the ancient world, filling a city’s streets with a multi-sensorial display of sounds and images. Although the presence of processional activity is acknowledged as a regular occurrence in the Roman world, our understanding of their movement patterns and their effect on the cityscape remains understudied. The record of processions was held primarily in the memories of those who experienced or took part in the festival, only manifesting within the archaeological record as a testament to their occurrence in the form of temples or monumental arches. The nuances of how a procession traversed a city’s streets and its urban impact are not easily revealed. Applying a computer-based approach to the study of processional activity allows new questions to be asked of a well-recognized Roman ritual. This paper considers the role that processions played within the city of Ostia, Rome’s ancient port. The application of a model-based methodology allows for critical analysis of a procession’s movement patterns by studying processions as a dynamic event that engaged both with a city’s inhabitants and the built environment. The use of computer models in combination with archaeological material offers new insight into ritual experiences within Ostia.

Detecting Spatially Local Deviations in Population Change Using Summed Probability Distribution of Radiocarbon Dates

The increasing availability of large radiocarbon databases encompassing continental geographic scales (e.g., CARD, EUROEVOL, AustArch, etc.) is now opening new possibilities for evaluating spatial variation in prehistoric population. We have, for the first time, the opportunity to determine whether and when different geographic regions experienced distinct demographic patterns using an absolute chronological framework. This line of research is however hindered by spatially uneven sample sizes reflecting differences in regional archaeological practices. Furthermore, given that spatial resolution is intertwined with the sample representativeness, the choice of appropriate scale of analysis becomes a non-trivial issue. Existing solutions have overcome some of these problems (e.g., by using correction surfaces) but no methods have been devised to assess the statistical significance of the observed differences in the inferred population trajectories. Current cross-regional comparisons of SPDs are thus limited to qualitative accounts, with a considerable risk of failing to distinguish genuine differences from spurious ones arising from sampling error. Here we propose a new method that overcomes many of these problems. We test the robustness and applicability of our solution through two case studies (a simulated dataset and the EUROEVOL database) showing the limits and the potentials of our approach.

[324] Materialization of Social Resistance: Trends on NW Iberia Late Prehistory and Protohistory and Beyond
This paper deals with a so-called negative approach to social complexity and social development. Instead of understanding the arising of complex societies as a result of positive ontology, it focuses on the resistances, negations and the invisible that tried to avoid or at least to minimize social inequality and exploitation. The arising of complex societies could, alternatively, be conceived as the trend to resist social division and its generalization. The paper will show as the material traces of archaeological record and the different dimensions of materialization processes could reflect in certain contexts communities’ strategies against the social division. The paper will focus on the development of monumentality and iron metallurgy. While primarily based on archaeological evidence from Galicia (NW of Iberia Peninsula), looking at late prehistory dynamics from IV to I millennia BC, it will also deal with case studies from other parts of the world as South America and Central Africa.

Crider, Destiny (Luther College)
[120] Examining Tula Region Ceramic Compositional Analysis
Chemical characterization of ceramics using Neutron Activation Analysis (NAA) in Central Mexico has proven to be an important analytical approach for assessing exchange, especially between subregions within the Basin of Mexico and neighboring areas. Recent efforts based upon Epiclassic and Early Postclassic Period decorated ceramics have extended the sampling to the ceremonial centers and settlements of Tula Chico and Tula Grande, the resulting chemical analysis defined a more robust compositional group for the Tula region. Building upon these findings, the Tula Region Interaction and Migration Project (TRIMP) targets additional ceramics from Epiclassic centers within the Tula region for NAA analysis. Sampling targets distinctive pottery pastes and decorative styles across multiple sites in an effort to further establish the regional signature for Tula production, but also to test and revise previously proposed compositional groups within the Tula region. Findings address the larger goal of the project to examine interactions and exchange within the Tula region.

[138] Reawakening a 2,000-Year-Old Salish Sea Basketry Tradition and Sharing It around the World: Master Salish Basketmaker and Wet Site Archaeologist Explore 100 Generations of Cultural Knowledge
Ed Carriere and I have been working with the U.W. Burke Museum to replicate 2,000-year-old waterlogged archaeological basketry found in the early 1960s from along the Snoqualmie River near Seattle. Ed learned old style split cedar limb/root clam basket making from his great-grandmother, Julia Jacobs, who raised him. Ed’s goal has always been to go back as many generations in his family to master their work. As a wet site archaeologist specializing in ancient basketry on the Northwest Coast, I work from the other direction, deep-time, statistically linking ancient basketry styles from throughout the region to the present. I had a brilliant idea while reassessing the 2,000-year-old basketry collection from the Snoqualmie River site, asking Ed to try replicating these baskets that statistically linked through 100 generations from this site through 1,200-, 750-, and 500-year-old Salish Sea wet site basketry to his great-grandmother’s old style in an approach we call generationally linked archaeology. Local Native weavers and anthropologists applaud this work and last summer we shared our work with the Indigenous Ainu on Hokkaido, Japan, and with archaeologists at the Wetland Archaeology Research Project (WARP) conference in Bradford, England, to a good response.

Cronin, Joseph (Harvard University), Anna Guengeric (Vanderbilt University) and Parker Van Valkenburgh (Brown University)
[230] Chacras in the Clouds: Documenting High-Altitude Agricultural Landscapes in the Tambillo Valley of Chachapoyas, Peru
Here we present preliminary results from targeted prospection and an Unmanned Aerial Vehicle (UAV) flight over the relic agricultural landscapes of the Tambillo Valley in northeastern Peru. This work was carried out as part of the first phase of Proyecto Arqueológico Tambillo (PATA), a project investigating the organization of political landscapes in the montane forest region of Chachapoyas. Specifically, PATA aims to determine whether the densely-clustered Late Intermediate Period settlements at the confluence of the Atum and Tambillo rivers were politically autonomous, independent settlements or a single socially integrated—if geographically fragmented—urban system. The first stages of prospection during the 2016 season documented at least four relic agricultural landscapes featuring several different modes of landscape modification. We discuss the diversity of these landscape modifications as well as their distribution throughout the Tambillo area relative to Late Intermediate Period settlement. As the spatial organization and technical requirements of these field systems can inform reconstructions of social organization in the Tambillo plain, we present a 3D model and high-resolution orthoimage of terraced sink-holes at La Boveda. This partial model of La Boveda demonstrates the promise of UAV work for studying well-preserved, high-altitude agricultural landscapes in the region.

Crothers, George (University of Kentucky)
Property rights require fundamental forms of cooperation. On a global scale, foragers maintained open-access property regimes, in which no one is excluded from using resources. In the most basic form, foragers cooperate simply by avoiding conflict—agreeing to share. These conditions will hold as long as the cost of excluding others from a resource exceeds the benefits derived from that resource and because cooperation increases reproductive success under conditions of low population density—in other words, when resources are plentiful or when foragers radiate into uninhabited...
environments. However, within variable environments and dynamic populations, common property regimes emerge when the benefit from exclusive access to resources exceeds the cost of defining, monitoring, and enforcing rights to those resources. On a local scale, foragers created qualitatively new property institutions that required collective responses to achieve common goals. Archaeologically, how do we identify changing property-rights regimes in prehistory? The Green River, Kentucky, archaeological record suggests several proxy measures that can be used to assess the timing, pace, and spread of exclusive, communal property rights, including anthropogenic land management, development of new technologies, and domestication of indigenous plants.

Living with the Dead: Plastered Skulls and ‘Continuing Bonds’

This paper proposes that the phenomenon of plastered skulls in the Neolithic of the Middle East, exploring a reinterpretation of evidence. Plastered skulls result from the burial and later retrieval of crania, onto which is sculpted a face using plaster. These were then used and displayed within household contexts. Rather than traditional interpretations which revolve around status and hierarchy or social cohesion, this paper suggests a reinterpretation based on the modern bereavement theory of “continuing bonds.” This paper suggests that grief and mourning may be a more appropriate explanation for the phenomenon, and examines the role that contemporary theories of grief might play in the interpretation of (some) ancient funerary remains.

From the Known to the Unknown: Exposing a Middle Preclassic Maya Power Structure at Pacbitun, Belize

The Middle Preclassic (900–300 BC) is known as a time for developing complexity in Maya society. The most perceptible evidence of this development is exhibited in the construction of the earliest forms of monumental architecture. However, for areas like the Belize River Valley, these structures are uncommon and poorly understood. Now, with the discovery of a large Middle Preclassic platform at the site of Pacbitun, we have the opportunity to increase our understanding of early monumental constructions that brought communities together and established power structures within Maya culture. Over the last few years, the Pacbitun Regional Archaeological Project (PRAP) has worked to uncover this large ceremonial structure dubbed El Quemado, which was found buried beneath Plaza A in the site core. Excavations of El Quemado continue to assess the structure’s dimensions and orientation and search for its earliest architectural form. Our investigations have also begun to explore the use of the area around the temple to identify potential adjacent sub-plaza structures. This paper will summarize our research to date and our latest excavations of El Quemado and Plaza A to provide a new understanding of public ceremonialism during a critical developmental period of political and social structures at Pacbitun.

Following the Shore: Refining Late Holocene Sea-Level Change through Settlement Histories on Northern Quadra Island, British Columbia

For people who rely on the ocean, changes in sea-level can have a profound effect on daily lives, connections to place, and identity. When we study sea-level from a broader or regional scale, we do not require the time and space specificity that is necessary to examine the effect of highly local sea-level change in a particular time and place. Thus, the regional sea-level curves that have been well-refined and developed, may not answer (or allow us) to understand and appreciate what this change had on lived lives, particularly in cases where sea-level changed up to several meters in an instant. Our research will detail how human settlement histories, intimately connected to sea-level, can provide a window into the effect sea-level change has on a finer scale that is not currently provided by broader models. Using an intensive coring and dating program in Waiatt and Kanish Bays, Quadra Island, we propose to evaluate how settlements expanded shoreward as sea-levels fell during the Late Holocene. This research will also serve as a test for coring methodology, and whether it can efficiently provide enough accurate data to be used elsewhere.

Crowley, Erin (University of Minnesota) [142]

Subsistence and Political Economy: Dairying and Change in Late Prehistoric Ireland

Cattle played a critical role in the economic and sociopolitical structure of the Iron Age in Ireland, yet the nature of this relationship is not yet clear. The Irish Iron Age (~500 BC–AD 500) is characterized by scant settlement evidence yet with several large, complex, ceremonial centers. It has been difficult, therefore, to contextualize the nature of social change leading into the Early Medieval Period. The Early Medieval Period (~ AD 500–1100) emerged with a fully-developed dairying economy, complex social structures, and social and political value placed on cattle and dairy products. Recently, however, increased archaeological work has uncovered more evidence of Iron Age settlement, agriculture, and industry. Therefore, we must ask, when did the dairying economy develop in Ireland and how did that shape the cultural landscape? This paper questions our traditional assumption that the dairying economy was a particular feature of the Early Medieval Period and poses alternative ways of understanding the economy of late prehistoric Ireland. Considering the connection between subsistence and political economy, this paper assesses the potential effects of a dairying economy on regional social and political identity.

Crow, Patricia (University of New Mexico) [130]

The Science and Performance of Ritual Drinking in Chaco Canyon

Consumption of caffeinated drinks made with cacao and perhaps holly is well documented for Chaco Canyon. Less understood is the context of consumption. Evidence for cylinder vessel production, use, and termination particularly reveals aspects of drinking ritual, including frothing. New compositional analysis demonstrates how Chaco potters decorated pots with post-firing pigments on stucco, permitting repeated decoration and cleansing of drinking vessels. Changes in the sizes, shapes, and contexts of Chacoan drinking vessels reveal rapid shifts in how Chacoans drank caffeinated concoctions and in the associated ritual practice between around AD 900 and 1125.

Assembling Conceptual Tools to Examine the Moral and Political Structures of the Past

As recent events demonstrate, power can manifest entirely outside the framework of state hierarchies and beyond their control. Beginning with the premise that tension between competition and cooperation exists in all human societies, we must explore the ways rules and norms permit or deny each, and how both interact with history and changing conditions to forge institutions. Today, new ways to stabilize societies and reduce conflict must be
found. One of the most important conditions for reducing conflict is to ensure inclusive and equitable conditions for everyone, particularly as regards food and water security, personal and group safety, and a satisfying quality of life. The form of governance of such communities and polities goes by many names: anarchist, collective, communitarian, pear-shaped, and many others and dates back thousands of years. These very forms are a perennial moral compass (family, neighborhood, community-based action). They are not left behind in human evolution; on the contrary, they remain the fabric of peaceable, supportive daily life and can still gift the future.

Tewa History and the Archaeology of the Peoples

According to tradition, soon after emergence into this world the Tewa were split into two peoples—the Summer and Winter—and were tasked with finding the “middle place,” or the location of their eventual historic villages. The Summer People traveled along the Jemez Mountains practicing agriculture, and the Winter People journeyed along the Sangre de Cristo Mountains eating wild game. On their travels southward the people stopped twelve times and these are represented as ancient villages. Eventually, the Peoples came together at large sites in the heart of the Tewa homeland. The Tewa view the creation of their society as the amalgamation of disparate people. In light of what we know about the late prehistory in the Southwest—as a time of dramatic reorganization, coalescence, and transformation—is it possible that the Tewa are remembering the coming together of people with different identities, memories, and histories? In this paper we examine the various Pueblo settlements on both the east and west sides of the northern Rio Grande before the coalescence of Tewa society, and seek, through the lens of Tewa cosmogony, to understand the identities of the various peoples who eventually negotiated the Tewa world.

Bone Calcination of Different Age Groups in Cremations from Bronze Age Hungary

Bronze Age Hungary saw the advancement of trade which may have been a cause of the movement from egalitarian societies to more complex societies with increasing social inequality. Social inequality between regions in Hungary may be reflected in variation among funeral customs. Excavations from Békés 103, a Bronze Age cemetery in southeastern Hungary, have uncovered 68 burials, most of which are cremations. This study focuses on color analysis (identified by Munsell Soil Color Charts) of the burned human bone from 11 cremation urns. Age may play a role in status differentiation, therefore subadults and adults were compared for level of calcination, indicating complete loss of the bone’s organic matrix due to the pyre’s high temperature. Preliminary results show a possible difference in calcination between subadult and adult cremations. Given that burials with greater calcination may indicate more energy being used in the maintenance of a funeral pyre; this suggests that age may play a role in mortuary behavior. These results may be helpful in understanding funerary customs of the Körös region when compared with the ceramic data associated with the burials.

The Church of Todos los Santos and Its Associated Cemetery in the Spanish Colony of San Salvador, Heping Dao, Taiwan (Seventeenth Century)

Archaeological excavations in the setting of the former Spanish colony of San Salvador, founded in 1626 in current Heping Dao, northern Taiwan, have uncovered remains of a European building that can be identified as the Convent or Church of Todos los Santos, founded while the Spanish colony was active and possibly preserved afterward under Dutch rule. Several burials have also been excavated, which constitutes a formal cemetery associated to the church. The human remains in the cemetery of Todos los Santos include both native and European individuals. This paper discusses the findings and their relevance in the context of the archaeology of early colonialism in Taiwan and the region, since this kind of remains have not often been discovered. This discussion will deal with the scope of European establishment in the region.

Social Differentiation and Hierarchy at a Central Place in the Eastern Andes of Ecuador

This paper focuses on the development of a central place in the Quijos Valley, Eastern Andes of Ecuador. Based on an intensive survey of the site complemented by small excavations, I offer a spatial, demographic, social, and economic characterization of this central place with the goal of discussing and contrasting views on the development of social differentiation, hierarchy, and centralized political authority in ancient chiefdoms. Contextualizing this in a body of regional settlement pattern information available for the Quijos Valley also permits the comparison of conclusions drawn from data corresponding to different scales of analysis for this case as well as for others in Northern South America.

La aplicación de esquemas de comunicación en las investigaciones de rutas terrestres: Un caso al Este de Los Tuxtlas

El estudio de las rutas de comunicación nos permite tener un mayor conocimiento de las sociedades prehispánicas, aspectos como dinámicas de transporte, comercio, conexión entre sitios arqueológicos, aprovechamiento del terreno o inclusive creencias compartidas. La aplicación de la teoría de la comunicación puede ser clave para plantear trabajos en los cuales se busca reconstruir las rutas en regiones donde no se cuente con evidencias visibles de éstas. La propuesta teórico-metodológica que aquí se presenta utiliza un esquema de las teorías de la comunicación y se aplica para crear un modelo de reconstrucción de posibles rutas prehispánicas junto con herramientas y técnicas como los son sistemas de información geográfica, modelos digitales de elevación, comparación de rutas y veredas contemporáneas y evidencia arqueotécnica prehispánica registrada durante las exploraciones hechas en campo por parte del Proyecto Arqueológico de Piedra Labrada Sierra de Santa Marta, Los Tuxtlas, Veracruz, (PiLaB).

Roman Glass Beads Found in Hulunbir, Inner Mongolia, China
In this study, we present some sandwich glass beads found in Hulunbir, Inner Mongolia, China. According to the chemical analysis, these beads are also soda-lime glass with very low Al, Mg and K contents. And the beads are transparent, which is due to the Mn2+ decourling technique used. Compared with the data published, the beads were much more likely to be from the area ruled by Roman Empire.

Culture Prosperity of Late Longshan on North Shaanxi and Its Environmental Background

The late Longshan culture of north Shaanxi was flourishing, while that of the southern Inner Mongolia was declined and migrated to the south. Meanwhile, in Guanzhong Basin, the culture was also declined to the bottom. In this paper, we aimed to know the possible climatic factors drove the occurrence of these culture phenomena. A compile of Holocene climate records related to these three regions were collected and analyzed. The following results can be drawn: after 4.4 Ka BP, the climate of Inner Mongolia was becoming colder and drier which could not support the agriculture subsistence again and the people therefore migrated to the north Shaanxi along the Yellow River. Second, a generally drier and cooler climate with intermittent warmer, wetter conditions developed in north Shaanxi during the mid-fourth millennium BC. This short warm and wet event (4.0–3.8/3.7Ka BP) attributed the prosperity of late longshan culture at this region. While the climate of the Guanzhong Basin and the North China Plain was warm-humid and extreme flooding events occurred frequently. The spatial distribution of culture was limited by the frequent floods and there was obvious decrease of the site numbers. In conclusion, people made diverse response strategies corresponding to different environmental background.

Cullen, Sara (University of Colorado Boulder) [345]

In Search of “False Alibates”: A Quagmire in Chert Sourcing from Northeastern New Mexico

Applications of elementally sensitive geochemical methods have made it possible for archaeologists to identify chert sources with more provenance accuracy than previously possible. Alibates dolomite from quarries in the Texas Panhandle is commonly identified in Southwest sites as evidence for trade with Southern Plains communities. However, regional archaeological research suggests the presence of an Alibates “look-alike” chert outcrop in northeastern New Mexico, near the Baldy Hill formation north of Folsom. This poster will examine the case study of Baldy Hill chert as it pertains to archaeological studies regarding lithic procurement and Plains-Pueblo interactions in far northeastern New Mexico and southeastern Colorado.

A Comparison of “Scenes” in Parietal and Non-Parietal Upper Paleolithic Imagery: Formal Differences and Ontological Implications

Upper Paleolithic cave art is well-known for its skilled execution, specifically the use of shading, relief, and perspective to render lifelike depictions of Pleistocene fauna. Cave art is equally well-known for a near absence of flora, humans, and scenes. In this regard, parietal imagery is distinct from “art mobilier,” where these are more common. However, defining “scenes” as a graphic phenomenon can be problematic, and identifying them among superimposed and fragmented images more so. Definitions based on how scenes are perceived offer some guidance and include more imagery than previously recognized; frequencies allow the comparison of scenes from different contexts. This paper evaluates differences in the nature of scenes as depicted on rock walls and on objects in France from ~40–11 kya. Differences in the frequency, in the types and range of constituent elements, in the degree of detailing or conceptual ambiguity, and in the type and extent of audience engagement with scenes are all considered. Emphasis is placed on the potential social consequences of scenes from different contexts. Consequently, while exploratory and qualitative in nature, the analysis points to avenues through which ontological differences in the production, use, and sociocultural role of Upper Paleolithic imagery can be specified.

Archaeological Fish Traps on the Coast of British Columbia

Fish traps are a ubiquitous fishing feature on the Northwest Coast, with thousands of features recorded at hundreds of sites. This fishing technology represents a use and modification of intertidal and riverine environments at an industrial scale, yet protocol and management practices ensured that fish populations flourished. As in other areas of the Northwest Coast, First Nations and archaeologists in British Columbia have documented fish traps, resulting in the registration of 822 fish “trap” or “weir” sites at the provincial Archaeology Branch. These represent more than 94% of all recorded fish traps sites in the province. Our review of this archaeological dataset is presented, revealing a wide distribution of fish traps, varying trap design, and differing modes of construction. Dating from as early as 4500 cal 14C years BP to the early twentieth century when they were banned, fish traps in British Columbia represent an innovation that was integral to those living on the Northwest Coast and they remain important to our understanding of late Holocene fish management practices.

Culquichicón-Venegas, María José and Alekia Alcaica (University of Toronto) [178]

Social Dynamics of the Past through the Body of the Camelid: Utilizing Evidence from Late Moche Peru

Assessing social dynamics in the past through archaeometry is more readily possible by constructing questions that more actively engage with issues beyond subsistence and technology. As archaeologists we are capable of reaching these higher-level interpretations of the past. In this paper, the use of camelid age profiles will bring insights into the kinds of value placed on the camelid body and the kinds of constrains and affordances that camelid herds would have placed on the Late Moche community of Huaca Colorada (AD 650–850). By considering the contribution of ethnographic accounts from herding communities of the Andean region, we are better equipped to interpret material correlates. Zooarchaeology and social archaeology can be better integrated through the goal of understanding how the actions and activities surrounding camelid herding were impacted by and influenced community organization and worldview. This paper will argue that the varied use of different aged camelds corresponds to specific value placed on the life stages of these animals. By considering camelds as active agents in the social dynamics of the past we are achieving a more complete picture of the exchanges that would have occurred within everyday and ceremonial contexts.

Cummins, Tom [391]

A Reconsideration of Mold-Made Ceramics in Coastal Ecuador: Chorrera and Jama Coaque
Based on an examination of ceramic Chorrera, Jama Coaque and La Tolita figurines from the coast of Ecuador, this talk discusses the central role of the mold as both a forming technique and as a means to create a stable visual tradition from generation to generation. It will also suggest the impact on later traditions on the coast, such as the Moche tradition.

Cunnar, Geoffrey (WCRM), Ed Stoner (WCRM) and Tom Bullard (Desert Research Institute)

[140] Searching for the “Paleoarchaic Individual” and Unique Paleoarchaic “Production Grammar” in the Great Basin

Archaeological investigations were conducted by Western Cultural Resource Management in the Fire Creek Archaeological District in the central Great Basin. We address the results of investigations at a Paleoarchaic site containing a buried soil with both an abundant stemmed point trajectory and a Levallois-like reduction method dating to the Younger Dryas. Employing agency theory and through an examination of depositional history, the chaîne opératoire and spatial analyses, we argue that the artifacts located both on the surface and in the buried soil are indicative of activities conducted in a moment in time and not a palimpsest accretion. Components of the chaîne opératoire are discussed and the identity of the Paleoarchaic occupants is examined within the broader regional context of the Great Basin. Further the identification of ancient soils on Great Basin alluvial fans and the ramifications for future archaeological work in such contexts is addressed.

This study examines the management of dogs as a resource and status symbol in ancient Mesoamerican society. One of the few New World domesticated animals, dogs provided communities with a steady source of meat. Artistic and ethnohistorical accounts suggest that dogs may also have been selectively bred to emphasize particular body shapes and hair types, including even absence of hair. These different breeds are described as playing different roles, as participants in specific ceremonies, as hunters, as companions (in life and death), as healers, and as favored foods. To date, however, archaeological evidence verifying the iconographic and historic record has been sparse. This study reviews chronological and spatial evidence of dog remains in different archaeological contexts, using morphometric and stable isotopic data to gain an understanding of the types, uses, and movements of dogs and dog breeds. An abundance of dog remains in Preclassic period contexts in comparison to Classic contexts, as well as evidence of higher than expected breed and dietary diversity throughout the Classic period suggests that the role dogs played in social and subsistence practices across the region varied over time, and that intensive dog breeding was much more specialized than previously assumed.

[300] The Impact of War Clubs: An Interdisciplinary Analysis of Conflict

This research focuses on the transformation of conflict from its earliest modes to more intensified forms seen in complex societies. Specifically, the focus is on the transition of combat in band level societies to its institutionalization in tribal social structures. One of the challenges in archaeology is in recognizing steps in the evolution of violence in formative and less stratified societies. To achieve this end, the transition of conflict needs to be operationalized. This investigation analyzes the impact of specialized weaponry (i.e., clubs) indicative of the earliest signs of escalating warfare in California. Working with forensic scientists and biomechanical engineers, experiments with traditional war clubs from a number of tribal societies are conducted to determine survivable data on lethality. The analysis focuses on the construction of weapons from historic accounts and museum specimens, tested using biomechanical engineering methods. The results of the test are related to the bioarchaeological record and specific case studies for blunt force trauma in California to connect the data to observations in the prehistoric past. This relation allows for the charting for the early development of conflict centered, social organizations.

[222] The Antiquity and Persistence of Traditional Health Beliefs and Practices in the Northern Andes

This paper presents findings of a new European Community funded research project: “Indigenous Concepts of Health and Healing in Andean Populations.” The study population is indigenous Quechua peoples in northern Andean Ecuador. The project examines ethnic Andeans’ understanding of their world and how health, illness, and healing are understood within it. Current practices of traditional medicine (TM) have evolved within complex historical contexts into new forms which can reveal the nature of precolonial and historical indigenous belief systems. They might demonstrate how beliefs and associated rituals and practices adapted and survived in social climates of persecution and repression. The project employs novel theoretical approaches and a multidisciplinary methodology to examine the relationship between traditional medicine and society in northern Andean Ecuador. The research focuses on the identification of traditional medical practitioners, the nature of their practice, and the role of traditional medicine in contemporary society. The findings suggest that traditional medicine continues to play an important role in the health and well-being of the population, while also highlighting the challenges faced by traditional medical practitioners in a rapidly changing society. The project also seeks to document the unique characteristics of traditional medical practice in the northern Andes and to contribute to a broader understanding of the role of traditional medicine in contemporary society.
and methodological approaches, using a time-depth perspective and a framework of interdisciplinary methods integrating archaeological-historical, ethnographic and modern health sciences approaches. It will model how peoples survive and adapt their traditional belief systems in a context of alien cultural impacts and determine what survives of pre-European Amerindian systems of knowledge and medicine in indigenous Andean cultures now, and the continuing role, relevance and use of TM in present-day communities. This approach highlights a culturally sensitive approach to the conservation of Andean "intangible cultural heritage."

Curtis, Matthew (UCLA Extension and UCLA Cotsen Institute of Archaeology) [309] Revisiting the Ancient Ona Culture of Eritrea: What Previous Research from the Asmara Plateau Might Offer for New Understandings of the First Millennium BCE in the Northern Horn of Africa

Sustained archaeological research on the Asmara Plateau of Eritrea occurred between 1998 and 2003, producing important initial efforts in ceramic and lithic artifact typologies, subsistence reconstruction, and regional perspectives in landscape use and settlement patterns dating to the first millennium BCE. Researchers identified a distinct regional cultural expression termed the Ancient Ona Culture. This paper reviews the key qualities of the Ancient Ona Culture and argues that, while distinct in a number of aspects, the Ancient Ona Culture may be seen as a localized expression of a wider regional cultural expression in the highlands of the northern Horn. Given the cessation of international research in the Asmara Plateau since 2003, it is crucial to revisit insights from previous research in Eritrea, relating these to new understandings of the archaeology of the first millennium BCE from research conducted over the last two decades in Tigray Ethiopia. This paper outlines ideas for accomplishing such an endeavor.

Cush, Patricia and Richard Callaghan (University of Calgary) [296] Continuity and Evolution in the Taiwanese Sailing Raft

The Taiwanese or Formosan sailing raft likely has considerable antiquity as well as geographic distribution on the coasts of China, Taiwan, Vietnam, and possibly as far south as the Coromandel Coast of India. The Taiwanese version is the most studied and may have the longest continuous evolution into the twentieth century. These seagoing craft were initially constructed from bamboo, equipped with lug sails, and steered using center boards in a very sophisticated manner. Analysis of their performance characteristics shows that they had considerable maneuverability, which along with the shallow draft allowed them to function well in seas with numerous sandbanks, reefs, and shoals. A great many of these vessels were registered for fishing in Taiwan in the mid-twentieth century. With the demise of the giant bamboos on Taiwan during the latter part of the twentieth century and the introduction of new technologies, the sailing rafts evolved but still retained some of their traditional elements. Along with a discussion of the history and performance of the sailing raft we present excerpts from an interview with the last of the craftsmen building the rafts at the beginning of the twenty-first century.

Cuthbertson, Cory (Centre for the Archaeology of Human Origins, University of Southampton) and Christian Hoggard (Centre for the Archaeology of Human Origins, University) [287] Stones, Shapes and Speech: Interpreting the Origins of Language from Lithic Variation with Geometric Morphometrics

Results from a recent experiment demonstrate that morphological standardization is an indicator of complex cultural transmission and cognition. A novel methodology integrating geometric morphometrics and Multiple Factor Analysis was employed to assess global shape variance in four experimental hand ax assemblages made by novice knappers trained under four different simulated social learning environments (emulation, imitation, silent teaching and verbal teaching). The higher the fidelity of their learning environment, the lower the morphological variability the assemblages exhibited. High fidelity social learning methods require theory of mind (the ability to think about thoughts), which is correlated with specific linguistic traits that scaffold its development. Therefore archaeological assemblages that exhibit high levels of standardization might only be possible when transmitted through high fidelity cultural transmission, in communities that operated with a theory of mind and linguistic skills. One hundred and four hand axes had 2D outline coordinate data taken for their planar, lateral, and superior view. A Multiple Factor Analysis then observed the three concatenated datasets. Hand axes in the low fidelity group (emulation) demonstrated the largest range of variation, while the high fidelity groups (teaching) demonstrated the lowest range of variation. The methods were also able to successfully discriminate between the four groups based on their shape variance.

Cvinar, Amanda (Los Alamos National Laboratory, Adams State University) [122] Using the NHL Framework to Advance the Development of Applied Archaeology

In 2016, the National Park Service celebrated its centennial anniversary thus reminding the public that places of historical significance matter to our national cognizance. Using the National Historic Landmark designation as a means for public education, this paper draws upon my master’s thesis project, which focuses on building a bridge among CRM, research, and public education at the national level. It serves as a model for how graduate-level, archaeological training contributes to traditional archaeological knowledge, public awareness of the past, and CRM compliance requirements. The Mortandad Cavate Complex and associated Sandia Pueblo compose a site complex located within the boundary of Los Alamos National Laboratory, a Department of Energy managed facility located in Northern New Mexico. This site complex exhibits an exceptional level of preservation and integrity. It is affiliated with the traditions of the Pueblo de San Ildefonso and represents a place of special cultural and traditional value. It is one of four Ancestral Pueblo cultural properties that the Department of Energy plans to nominate as National Historic Landmarks. The relationship among compliance regulations, public education, the traditions of Pueblo de San Ildefonso, and archaeological knowledge of the site serves as a model for the development of applied archaeology.

Dahlstedt, Allisen (Arizona State University) and Jane E. Buikstra (Arizona State University) [143] A Bioarchaeological Survey of Skeletal Tuberculosis in Prehistoric Southern Peru

Recent studies of precolombian Mycobacterium tuberculosis complex (MTC) genomes identify pinnipeds as a source of human tuberculosis in South America (Bos et al. 2014). These results raise questions regarding the timing of this zoonotic transfer and the subsequent human host adaptation and dissemination of Mycobacterium tuberculosis. Here we present a survey of skeletal tuberculosis throughout the Osmore Drainage of southern Peru, where the pinniped to human "jump" had occurred by ~AD 1000. This sample includes individuals interred within coastal and inland sites occupied between 385 BC and AD 1475. We explore patterning of disease across age at death and sex, as well as changes in skeletal expressions across time and space. We then address the hypothesis that M. tuberculosis manifested similar skeletal expressions in humans living in precolombian South America as it did in Europe prior to antibiotic treatment. The results of this study have implications within the fields of bioarchaeology and genomics for understanding the origin and spread of skeletal tuberculosis in the Americas.

Dai, Xiangming [99] Shimao: The Prehistoric Pioneer of Rising States in Northern China

In ancient China, a number of ethnic groups and polities rose and declined in northern China. The competition and wars between these frontier polities and Central-Plain dynasties occurred frequently in Chinese history. A series of new archaeological discoveries in recent years have revealed that Shimao was the first state-level society emerging in northern China. The Shimao social group was mainly distributed in the Ordos region, where the social complexity experienced a leaping development in late prehistory, and this social evolutionary trajectory is very different from the Central Plain. The rising of the Shimao state started a new model of social development for the following history in northern China. This paper will discuss the background and process of the rise of the Shimao state, and compare some similar phenomena in history.

Dakovic, Gligor (Belgrade University/University of Pittsburgh), Bonnie A. B. Blackwell (Williams College, Williamstown, MA), Dušan Mihailovic (Department of Archaeology, Belgrade University), Mirjana Roksandic (University of Winnipeg) and Anne R. Skinner (Williams College, Williamstown, MA) [181] ESR Dating Ungulate Tooth Enamel from the Mousterian Layers at Pešturina, Serbia

In southern Serbia, Pešturina contains three Mousterian layers, with late Pleistocene faunae. The site overlooks a tributary to the Nišava River southwest of Niš near the Sičeva Gorge. In all three sedimentological layers, the large mammalian faunae suggest a mixed environment with temperate forest, rocky cliffs, and steppe within walking distance from the cave. Fragmentation patterns and butchering marks plus the lithic tools indicate that some faunal remains were human kills. A depositional hiatus occurred between Layers 4 and 3. From 14 ungulate teeth from the Mousterian layers, 50 enamel subsamples were independently ESR dated. With < 0.1 ppm U in the enamel, and 1.0–3.5 ppm dentinal U, the ESR ages do not depend on the U uptake rates used for the calculations. Nor does any potential Rn loss introduce any uncertainty. To assess the external dose rates, bulk sediment samples and individual mineralogically distinct components were analyzed by NAA, then volumetrically averaged, while time-averaged cosmic dose rates were calculated using the ramped box method. At least two teeth had been reworked, likely associated with the erosion event that removed part of Layer 4 before the deposition of Layer 3. ESR ages correlated with Marine (Oxygen) Isotope Stages (MIS) 3–6.

d’Alpoim Guedes, Jade (Washington State University) and Kyle Bocinsky (Crow Canyon Archaeological Center) [27] Modeling the Spread of Crops across Eurasia

Understanding the routes and the timing of the spread of western Eurasia domesticates to Asia and of Asian domesticates to Europe and the Near East has become an increasing focus of research. To date, however, we have had little understanding of the types of constraints that farmers may have faced as they moved these domesticates into the challenging environments of Central Asia. The spread of many of these domesticates also took place during a time of marked climatic change. Although it has been hypothesized that these climatic changes may have impacted the nature and the manner of the spread in East Asia, a dynamic model of how crop niches changed throughout time has not yet been applied to Eurasia. This paper describes the creation of a multimillennial thermal model that compliments Naomi Miller’s pioneering work on outlining how patterns of rainfall limited the spread of millets.

Dalpra, Cody [304] Landscape Importance in Northern Arizona: An Application of Ethnographic Voices and Quantitative Viewshed Analysis

The importance of landscapes has long been discussed in archaeology, yet this is an often overlooked line of evidence. Landscapes often have a primary role in Native American oral histories and stories. Humans in general have a tendency to attach strong social meanings to visually prominent landforms. Such meanings are embedded within cultural landscapes as networks of natural and constructed places are perceived and made meaningful by communities. The Colorado Plateau of Northern Arizona features a vast landscape of mesa, canyons, and mountains that allows for an ideal test for incorporating these ideals into archaeological interpretation. Petrified Forest National Park (PEFO) near Holbrook, Arizona, allows for such comparisons with its extensive site database. This research focuses on applying the importance of these ethnographic meaningful landscapes from Puebloan groups to documented sites within PEFO. By examining sites of variable size representing both sides of the Pueblo III to Pueblo IV transition in relation to the
landscape, a clearer picture of how landscapes are vital to archaeological interpretation emerges. Three case studies demonstrate how viewed analysis allows for a qualitative and quantitative measure of connection to the landscape as described by Hopi, Zuni, and Navajo ethnography.

Dalton, Jordan and Nathaly Damián Dominguez (Licensed Peruvian Archaeologist) [232]

Inca Presence at Las Huacas, Chinchía Valley

When the Spanish arrived to the coast of Peru they heard stories of the wealthy Chinchía Kingdom and the privileged position that they enjoyed within the Inca Empire. Previous archaeological and ethnohistorical research has concluded that at the Chinchía Kingdom’s capital of La Centinela, the Inca rulers set up their authority alongside the local lord, and that they left him in charge of ruling the rest of the valley. This poster will present recent research conducted at the site of Las Huacas, a 60-hectare site located 10 km away from La Centinela in the prime agricultural fields of the valley. Based on architectural features and preliminary ceramic analysis this poster will argue that the Inca intervened in activities at Las Huacas. It will then explore what this new evidence on the Chinchía case adds to understanding the specific type of indirect rule that the Inca set-up in the Chinchía Valley. Furthermore, it will interpret the function of Las Huacas within the Chinchía Valley and the Inca Empire as a whole. Excavations this past summer encountered large quantities of botanics and artifacts from diverse types of craft production, leading to the interpretation that structure N1 at Las Huacas was a multifunctional structure.

Ancient Genomics of Neolithic to Bronze Age Baikal Hunter-Gatherers

Genome-wide data from hunter-gatherer populations of the Upper Paleolithic to Neolithic has provided unprecedented insight into the human evolutionary and demographic trajectory. However such datasets have hitherto been largely confined to Western Eurasia. The sole representative of Inner Asian past populations post-dating the split between paleolithic Europeans and Asians, as well as paleolithic Siberians and East Asians, are the Mal’ta and Afonotva Gora individuals, the Ancient North East Asian (ANE) branch, clouding the dating of the population split, and subsequent admixture events, between ANE and East Asian hunter-gatherers. Our genome data (~1X) reveal that Baikal Hunter-Gatherers (BHG) are an uncharacterized genetically homogeneous branch of Inner Asian hunter-gatherers, displaying highest shared genetic drift with present-day East Asians. Targeted sampling strategies coupled to excellent biomolecule preservation has permitted the generation of an advantageous sample size dataset (n = 31), rendering possible to estimate allele frequencies within these groups, thereby optimizing population tests. BHG model as an excellent proxy for an Inner Asian source population admixing into the late Bronze Age Andronovo groups, becoming Iron Age steppe nomads. With genomes allowing for kinship analyses, pathogen detection and strontium ratios, coupled to archaeological interpretative approaches we extend possible means to elucidate behavioral processes and cultural transformation.

Leaving the Blanks Unfilled: A Case Study in Productive Ambiguity from Early Bronze Age Lebanon

An oft-heard sentiment in prehistoric archaeology, particularly for contexts without traditionally visible indicators of gender (i.e., bodies or identifiable representations of bodies), is that “the evidence just isn’t there” to productively introduce intersectional gender research. This is partly due to the trend-sensitivity of archaeology, which often draws from other disciplines to supplement its own scope. Intersectionality is used in the same way, as archaeologists attempt to reframe their practice and interpretation with intersectional approaches derived from critical theory. Disrupting preconceived assumptions about identity categories is undoubtedly imperative and powerful; this paper, however, interrogates whether we might see archaeology as itself offering important tools for this process, and what opportunities those tools present for broadening intersectional thinking. Perhaps in cases where the “evidence” seems to be “missing,” we can rather see invitations to think otherwise about the constitution of evidentiary categories. What happens when, instead of seeking markers of what a body is, we instead interrogate the “absences” through which embodied identities are continuously in production? Rather than stressing its limitations, this paper investigates what is introduced by ambiguous and contradictory evidence, by examining the (sometimes “absent”) archaeological evidence for changing social differentiation in Early Bronze Age Lebanon.

Pipes and Smoking in Precontact Pacific Northwest North America

Smoking has been practiced by native peoples throughout the inland Pacific Northwest—and especially along the Columbia and Fraser River systems—for several millennia. This is evinced by the presence of stone pipes and pipe fragments in sites across the region. This poster presents the spatial and chronological distribution of archaeological smoking pipes throughout the inland Pacific Northwest based on literature and database searches, with a particular focus on those collections held or formerly held by the Washington State University Museum of Anthropology. In addition, the results of chemical residue analyses determining the material smoked in a number of pipes and pipe fragments from sites spanning the region will be reviewed, including the results of new testing by the authors. The research, developed in collaboration with indigenous communities in the USA and Canada, sheds light on the practice of smoking in the past and addresses questions relating to pipe form and distribution and the traditional use and management of smoke plants throughout the Pacific Northwest.

Damm, Jacob (UCLA—Cotsen Institute)

Consumption Preferences at the Collapse of Empire: The Case of New Kingdom Jaffa

The site of Tel Yafo (modern Jaffa, Israel) provides unique insight into the tenure of the Egyptian New Kingdom empire in the Levant (ca. sixteenth–eleventh centuries BCE). As attestd to in both ancient documents and by the presence of Egyptian monumental architecture, Jaffa functioned as an important imperial center. As the empire waned, Jaffa persisted as one of the last Egyptian holdings in the region. Recent excavations by the Jaffa Cultural Heritage Project (JCHP) have opened this final period to scrutiny by uncovering a series of narrowly dated occupation and destruction levels within the city’s gateway. Through close examination of the ceramic data generated by these excavations, it is possible to detect both gradual and punctuated shifts in the character of the assemblage wherein there is a diachronic decrease in the consumption of imported and locally produced Egyptian ceramics. When considered contextually, these shifts correlate with violent episodes at the site, culminating in the complete disappearance of Egyptian-style forms from the material record. Indeed, the C14-derived absolute chronology of each phase allows for the assessment of consumption preferences in both functional and symbolic ceramic categories at an almost generational level as individuals negotiated the end of Egyptian imperial control.

**Gendered Differences in the Consumption and Discard of Food in Arctic Alaska**

Recent archaeological survey, ethnoarchaeological and paleoenvironmental research conducted in northeastern Tigray by the Eastern Tigray Archaeological Project (ETAP) has produced new insights into the Pre-Aksumite and Aksumite periods (>800 BCE–CE 700). The principal ETAP excavations thus far include the Pre-Aksumite site of Mezber (1600 BCE–1CE) and Ona Adi (c. early first millennium CE) which was inhabited during the Pre-Aksumite to Aksumite transition. Both sites were occupied during times of widely ranging cultural developments. This paper will provide the archaeological and paleoenvironmental context for a new ETAP interdisciplinary partnership which is investigating what role, if any, environment and human-environmental interaction had in the 1) origins of social complexity during the Pre-Aksumite period; and 2) the Pre-Aksumite to Aksumite transition. Archaeological, paleoenvironmental and traditional knowledge studies are being integrated within a framework of historical ecology. By coupling environmental and archaeological records for more than one time period and polity with traditional agricultural knowledge, we are investigating alternate pathways of societal interactions with the environment.

Daniels, Annick J. E. (IIA-UNAM Mexico) [217]

**La Joya was the capital of a very small state during the first millennium AD in South Central Veracruz. This region is rarely associated with major political power, though obviously it was of high prestige in the Mesoamerican world in terms of the distribution of the paraphernalia associated with the ballgame ritual. Two contemporary monumental platforms at the site can be interpreted as palaces, with administrative, residential, ritual, and service areas, one possibly housing a political and the other a religious ruler. Besides architectural layout, evidence rests on the urban setting, the monumentality and quality of construction, the presence of a sumptuary burial in a commemorative pyramid, the recurrence of sacrificial deposits for building consecration, and a large termination sacrifice that may be interpreted as a lineage extermination act.**

**A Finer View of Regional Sociopolitical and Economic Change in the Southeast Aegean: Ceramic Production along the Datça Peninsula**

Situated along the dramatic Datça Peninsula in southwest Anatolia, the port-town of Burgaz provides a flourishing landscape of ceramic production and valuable case study for investigating the intersection of local dynamics and larger Mediterranean social, political, and economic shifts. During the Archaic and Classical periods Burgaz developed into a thriving commercial and cultural center by virtue of its proximity to fertile land and centrality within the Gulf of Hisarönü. From the mid-fourth century, while the focus of civic life shifted westward to the expanded urban center of (New) Knidos, Burgaz transformed into a local agricultural and industrial nucleus connected to Knidos and beyond into the increasingly cosmopolitan early Hellenistic world. This paper presents the results of comparative visual, chemical, and mineralogical analyses of ceramics from Burgaz and several smaller settlements and workshops around the peninsula, arguing for expanding and export-oriented production from the fourth century onward. Analyses of the transport jars and other pottery suggest that local settlements had now integrated into a regional economy and tied their fortunes to the larger export market at Knidos. Such abrupt and fundamental changes in livelihoods across Datça shed light on how local communities responded to new realities of the Mediterranean-wide network.

**Ilita before the Fall: Mitigation of a Unique Stratified Site in the High Arctic of Greenland**

Ilitâ (Etah), which sits on the north shore of Foulke Fjord in northwestern Greenland, in many ways could serve as a poster child for climate-change–driven destruction of coastal sites. Sitting on an alluvial fan at the base of a steep-sloped kame deposit, the site has rich historic and late prehistoric occupations visible on its surface. But more uniquely for the high Arctic, there are also 1,000 years of continuous human use locked in stratigraphically sequenced buried soils, starting with the Late Dorset, followed by the Thule and the Inughuit, and topped by debris from Euroamerican historic occupations. This paper provides the first detailed study of a men’s house using zooarchaeology as a proxy for gendered use of space.

**Genders Differences in the Consumption and Discard of Food in Arctic Alaska**

Cape Espenberg, Alaska, provides a unique opportunity to directly compare two Thule-period (ca. AD 1400–1450) houses built at virtually the same time on the same beach ridge only one m apart. The tunnels of these houses are identically built; however, their interior construction, use of space, and artifact types and manufacturing debris strongly suggest that one house was a traditional domestic structure and the other was a men’s house. Ringed seal, the dietary staple across the Arctic, dominates the domestic house (90%), but not the men’s house (50%). Rather the men’s house is comprised of 30% fish remains (primarily small, saffron cod), which make up less than 1% of the fauna recovered from the domestic house. In addition, there is a distinct pattern of discard in the men’s house, with all fish recovered from the tunnel. In Arctic cultures, women are responsible for the distribution of food, even in a men’s house. However, our understanding of this men’s sphere is poorly known outside the ethnographic record. This analysis provides the first detailed study of a men’s house using zooarchaeology as a proxy for gendered use of space.

**Scenes and Non-Scenes in Rock Art: Are There Things We Can Learn about Cognitive Evolution from the Differences**
Analysis of rock art in several regions shows great variability in the presence or absence of combinations of individual images that can be considered as scenes in our graphic traditions. This presentation will consider examples from Australia, Europe, and North America to show that the differences in the way people represented the world are significant about how they related to the world.

Davidson, Matthew (University of Kentucky)

**Terminal Prehistoric and Protophistoric Hide Processing in the Central Ohio Valley: Synthesizing Microwear and Metric Data to Evaluate Endscraper Function and Use Intensity**

As “beachheads of empire,” sixteenth- to seventeenth-century European colonies in eastern North America vigorously pursued trade relations with Natives to secure raw materials for export to an emerging global market. Exchanges of furs and hides, slaves, and other commodities stimulated economic activity throughout eastern North America. Production of hides for exchange was widespread among native groups located on colonial peripheries. To contrast, relatively little research has evaluated the degree to which production for exchange penetrated the continental interior. This paper combines endscraper microwear and metric data from the Fort Ancient Hardin Site in the central Ohio Valley. These data confirm that uniface endscrapers—widely employed in the protohistoric southeast—were used primarily for hide processing, while bifacial endscrapers—uncommon in the protohistoric southeast—were used to work hard materials. Comparison of Terminal Prehistoric (AD 1400–1500) and Protophistic (AD 1535–1635) tool assemblages does not strongly support the hypothesis that hide processing intensified over time. Several possible scenarios are proposed to examine this finding. This study also provides useful baseline information about endscraper function and use intensity that can be used to evaluate and compare hide processing at other sites in the Ohio Valley and beyond.

Davies, Benjamin (University of Auckland)

**Using the Archaeological Record to Better Understand Models: An Australian Case Study**

In Australia’s desert regions, different conceptual models are sometimes used to explain patterning in late Holocene surface deposits. Among these patterns are radio carbon determinations, which have been concurrently explained as generated by intermittent occupation by hypermobile foragers, or growing semi-resident populations of broad-spectrum hunter-gatherers. This paper shows how models connected to the language and logic of record formation can help resolve competing archaeological interpretations. We constructed an agent-based model to explore how cultural and sedimentary deposition and erosion can combine to form patterns in a record of heat-retainer hearths visible on the surface. Initial results suggest that explanations invoking population dynamics or geomorphic processes can produce qualitatively similar outcomes. A second chronometric proxy, optically-stimulated luminescence dates on hearth stones, was then used to assess expectations derived from the model based on how the process forms the pattern. These show patterning consistent with geomorphic model expectations to the exclusion of models invoking population dynamics. These findings have implications for interpreting Australian prehistory, contrasting with regional narratives of intensification, while also demonstrating how the formational approach applied here allows the archaeological record to inform back on model mechanics, presenting opportunities for models to be reassessed and reused.

Davies, Benjamin (University of Kentucky)

**Controlling the Flow: Interregional Interaction, Community Prosperity, and Politics at the Highland/Pacific Frontier of Lake Atitlan, Guatemala**

Lake Atitlan sits within the Sierra Madre mountain chain which represents the physical divide between the Guatemalan highlands and the Pacific lowlands. It was thus ideally situated to act as a hub for cultural and economic exchanges between these two contrasting ecological zones. The three imposing volcanoes that line its southern shore, however, severely limited options for travel between these areas and commerce and settlement thus concentrated around obvious natural corridors such as those near San Lucas Toliman and Santiago Atitlan. Archaeological and ethnohistorical evidence nevertheless indicates that communities in the western half of the basin made use of several alternative routes to the coast, some of which continued to appear on maps into the twentieth century. These lesser-known routes enabled the Preclassic and Classic communities of this area to establish independent ties to centers like Chocola and Palo Gordo, and to act as middlemen for exchanges originating to the north and east. During the Middle Classic (c. 400–600 AD), however, many of the centers connected to this network were abandoned and the elites of Chukmuk began to be buried with Teothuacán-style vessels, signaling dramatic changes in the political and economic organization of the lake.

Davies, Caitlin (Independent Researcher)

**Flower and Song: Exploring Literacy in Postclassical Mesoamerica**

The Postclassic codices of the Maya, Mixtec, and Nahua peoples have often been separated based on preconceived notions of literacy and language, with the Maya codices receiving an epigraphic approach while the Nahua and Mixtec receive an art historical approach. This division is largely arbitrary and based on Western assumptions of the nature of writing and its form, privileging scripts which lean toward the alphabetic as more advanced. Within these codices, the linguistic practice of difrasismo serves as a fundamental organizing principle. Difrasismo is a form of metaphorical speech which manipulates opposing elements in order to convey more abstract concepts. The codices feature extensive use of similar difrasismo represented in overlapping pictorial and phonetic means, demonstrating a continuity in the underlying principles governing metaphorical language and writing itself. This study challenges the division between pictorial and phonetic scripts which underscores much epigraphic research, and promotes a more holistic and cross-cultural view of Mesoamerican literacy.

**The Benefits of Short-Wave Infrared Imagery for Archaeological Landscape Analysis: A Case Study from Easter Island, Chile**

The use of multispectral imagery is particularly effective for studying the archaeological record of Rapa Nui (Easter Island, Chile) due to the lack of vegetation and the fact that rock features are composed of surface distributions of rock features. Flaws (2010) has demonstrated that WorldView-2 multispectral imagery that includes the NIR band can be used to identify “lithic mulch gardens,” a key component of prehistoric Rapa Nui subsistence strategies. Recently, the availability of WorldView-3 satellite imagery data offers researchers access to short-wave infrared (SWIR) bands, which provide significant additional information about moisture content and mineral composition. Unfortunately, this imagery is currently only available at a much lower spatial resolution than NIR images. Here, we evaluate whether or not this new source of SWIR imagery can be used for measuring “lithic mulch garden” features despite its significant resolution difference. Comparing the results of Flaws (2010) analysis of with the results obtained using maximum likelihood classification analysis of SWIR WorldView-3 imagery we found markedly similar classification accuracy, despite having a significantly lower
spatial resolution. This result suggests that SWIR may provide a new tool for researchers interested in questions of prehistoric land use that will become increasingly powerful as greater spatial resolutions become available.

[321] Artifactual Composition of Terminal Deposits from the Classic Maya site of Baking Pot, Belize
Throughout the Maya Lowlands, archaeologists have identified Terminal Classic deposits associated with the final activities in ceremonial spaces. These features include concentrations of cultural material deposited in the corners of plazas and courtyards. At the site of Baking Pot, Belize, the Belize Valley Archaeological Reconnaissance (BVAR) project has identified several of these terminal deposits. This presentation will shed light on the types of artifacts being deposited during these final events to answer questions related to the nature of abandonment activities. From this information, we aim to identify the cultural significance of ritual deposition of cultural materials, how distinct combinations of artifact classes can yield information on human behavior, and how the terminal deposits at Baking Pot offer additional information to learn about abandonment activity in the Maya Lowlands. We will present the preliminary artifact inventories associated with terminal deposits in the form of a proportional distributions of artifacts found in each deposit at the site of Baking Pot, Belize. These methods allow for direct comparisons between deposits at Baking Pot, with those at sites in the Belize River Valley, and with others in the Maya Lowlands.

Davis, Kaitlyn E. (University of Colorado, Boulder) and Scott G. Ortman (University of Colorado, Boulder)  
Initial applications of settlement scaling theory focused on measures derived from the built environment, such as house density and settled area. Although this is appropriate, the theory actually focuses on the role of social networks in socioeconomic rates, and thus connects to a variety of artifact-based measures of such rates. In this paper, we develop these connections using data from the Rio Grande Pueblos of New Mexico. We first compare pueblo room areas to show that socioeconomic outputs increased with settlement population. Then, we examine ratios of decorated pottery to cooking pottery to show that consumption rates of decorated vessels increased in the same manner. Finally, we use the ratio of chipped stone debris to cooking pottery to measure investment in production of stone tools, finding an increased efficiency in their production and use. We argue that this pattern derives from an expansion in the division of labor that accompanies group size. By extending the scaling framework to artifact-based measures like these, our results show that there is a connection between social networks and artifact accumulation rates in ancient societies. This suggests the scaling framework is useful for understanding a wide array of measures obtainable from the archaeological record.

[338] The Aurignacian Lithic Industry from Area E
Area E of Manot Cave, Western Galilee, is found at the top of the western talus, close to the apparent natural opening of the cave, which was blocked approximately 30 kya. The area appears to be the natural end of the living surfaces, with the main living area possibly being closer to the natural entrance. Area E is composed of two sedimentological Units; Unit 1, which is composed of topsoil and Unit 2, which contains the archaeological layers. Unit 2 in area E is divided into nine archaeological layers, I–IX, with possible additional subdivisions. These layers represent living surfaces. The living surfaces usually appear together with breccia, within which we find a large amount of faunal remains, flint, bone tools, decorated items and hearths. Layers I-III, appear to be composed of a post-Aurignacian tradition with small twisted bladelets, dofoIr bladelets, end scrapers and burins with very few faunal remains. The excavated Layers IV–IX are comparatively richer in faunal material and are characterized by Aurignacian tools flint tools including blades, carinated and nosed scrapers, flat scrapers, carinated burins and some dofoIr bladelets.

[226] Searching for the First Americans along Oregon’s Ancient Coast: New Methods and Upcoming Research
To date, efforts to search for and investigate Pleistocene-aged sites along the Northwest Coast have been largely limited to subaerial landforms and deposits. Beginning in 2017, the search for early coastal sites will extend onto Oregon’s outer continental shelf. These search efforts will be supported by the use of a GIS-based model that makes predictions about the foraging potential of reconstructed late Pleistocene-aged coastal landscapes. We review the modeling methodology and how reconstructed physical and human ecological aspects of Oregon’s coastal landscape may have changed from the LGM to 12,000 cal BP. We also discuss upcoming fieldwork activities and goals for the search, identification, and recovery of archaeological evidence from Oregon’s ancient submerged terrestrial landscapes.

[336] Documenting Archaeological Contexts with 3D Photography
Photography has long been one of the best tools archaeologists have for creating a visual record of excavations and contexts in the field. In recent years a variety of new techniques, from laser scanning to photogrammetry, have been developed and employed throughout the world that now allow archaeologists to create a three-dimensional photographic record. This paper explores one such technique—structure from motion—that has been used for mapping and to document excavated contexts at the late precontact Wall site in North Carolina. Structure from motion permits the construction of highly detailed, georeferenced, photo-realistic models using affordable software and field photographs taken with an ordinary digital camera common to all archaeological projects. Such models are much more than simply three-dimensional representations of the real world; they contain dense geospatial data that can be easily extracted and used in a variety of analytically useful ways.

[117] Starch Grain Analysis of Human Dental Calculus from Guanzhuang Site, Henan Province
This research aims to investigate the human foodstuffs and lifestyle during the Western and Eastern Zhou Dynasties in the core area of the Central Plains using starch grain analysis of human dental calculus. Plant microfossils, starch grains and phytoliths, which were found in most of calculus samples from Guanzhuang site, were from millets, bread wheat, rice, adzuki, tubers, and acorns. Diversity of starch grains and phytoliths in morphological characteristics extracted from dental calculus indicates that a variety of starchy plants, including crops and gathered plants were
consumed by the Guanzhuang inhabitants. Millets were dominant in the human diet of the Guanzhuang site; and bread wheat was of secondary importance. Combined with the macrobotanical evidences from Guanzhuang and other neighboring sites, the traditional millet agricultural system still existed in the core area of the Central Plains while the multiple cropping system had emerged in this region. In the meantime, the importance of bread wheat increased in the agricultural system and the change in the cropping system from millet-dominant to bread-wheat-dominant come up during the Western and Eastern Zhou Dynasties.

[261] Daily Life in a Classical Port City: Archaeobotanical Evidence from Northern Greece

Recent excavations at Molyvoti, a large fourth-century BC settlement on the northern Aegean coast, have uncovered a residential neighborhood of homes and roadways laid out on a Hippodamian grid system. Thousands of carbonized plant remains have been identified from excavated domestic contexts including house floors, hearths, and abandoned wells. Macrobotanical results indicate that residents' diets relied heavily on cereals such as barley and free-threshing wheat. Cereal processing activities at the site are evidenced by specimens of ground grain and bread fragments from a stone-and-plaster hearth feature. Along with grapes, hazelnut, and fig, the well-preserved contents of an abandoned well contained hundreds of charred conglomeration identified as probable food residues. The macrobotanical record at the site is complicated by the presence of sheep dung associated with courtyard floors, raising important questions about potential fuel sources and the multiple uses of courtyard-kitchen spaces. These results contribute to a growing picture of local and regional economies in Classical northern Greece through the lens of residents' food choices and routine food preparation activities.

[224] Community Action at Sites Threatened by Natural Processes

Around the world, thousands of archaeological sites are threatened by coastal processes. Although many countries have successfully implemented schemes to address threats from development, this is not the case for sites at risk from natural processes. Without developers to fund mitigation projects, the scale of the problem appears enormous, and it is difficult for individual agencies to commit to preserving, or even recording, everything at risk. Systems are needed to update information and prioritize action to channel resources toward the most vulnerable areas. In Scotland, a program of national coastal survey was followed by a desk-based prioritization project. However, the dynamic nature of the coast means that networks are needed to monitor change and report new discoveries. A citizen-science approach was adopted that recognized the wealth of knowledge and interest in heritage within local communities. The Scotland’s Coastal Heritage at Risk Project (SCHARP) works with a volunteer network to update records of prioritized sites. The information contributed by citizen archaeologists allows reevaluation of priority sites and provides a more accurate picture of the scale of the threat to heritage. This paper examines SCHARP and lessons learned through running a project that channels community archaeology into solving a national problem.

[225] Representations of Fauna in Mural Paintings of Tenochtitlan

The accelerated process of deterioration of the murals from the religious buildings of Tenochtitlan has threatened their long-term conservation. This has impulsed different activities including the creation of the project for the graphic documentation of the polychromy in the Mexica capital. It was specifically developed to recover and store, as an accurate witness, all the motives of the paintings, as well as its architectural context. Over the course of 20 years, the development of this methodology has combined different registering process, including direct copies over the decorated facades, the chromatic practice and identity in which the ‘foreign’ becomes incorporated and, in some cases, becomes the paradigm of tradition.

De Alba, Jennifer [231] see Buehlman-Barbeau, Savanna

Day, Peter (University of Sheffield)

Lesvos (Mytilini) in the Eastern Aegean has been prominent on our TV screens during the human migration toward Europe. The last major population movement in the area, around 100 years ago, comprised the Greek-speaking Christian Orthodox, including several potters, forced out of Asia Minor. Some of these craftspeople came from Canakkale, in present day Turkey, working in the tradition of sometimes bizarre glazed wares. They settled on an island with a large number of active workshops producing utilitarian pottery, notably water jars, but including cooking vessels. Several generations later, the present study of individual potters, their products, practices and motivations builds on rich ethnographic study on the island by a variety of scholars. It examines different narratives, involving individual potters in relation to the modern Greek state, placing value on “tradition” and “authenticity.” The idea promoted by heritage organizations of “tradition” as static and something to be preserved contrasts with the economic reality of life as a potter. The tensions highlighted by terminologies of inclusion or exclusion, whether that be potters versus ceramists, craft versus art, reveal a fluidity of materials, practice and identity in which the ‘foreign’ becomes incorporated and, in some cases, becomes the paradigm of tradition.

[161] Using Ethnoarchaeology to Interpret Archaeological Blacksmithing Sites in Togo, West Africa

A 2013 study of the ethnoarchaeology of the blacksmithing village of Upper Bidjomambe in the ironworking region of Bassar in northern Togo provided invaluable data to help archaeologists interpret archaeological smelting sites. Oral traditions document the village’s occupation from ca. 1870 to 1970 when it was abandoned leaving it virtually intact with little disturbance or tool recycling. An 80-plus-year-old informant formerly from Upper Bidjomambe, who was a stone hammerman for a traditional three-man smithing team, provided invaluable ethnoarchaeological data linked to a GPS-based site map that documents partially standing house ruins; forging locations based on in situ anvils and stone hammers; stone outcrops used to process iron blooms (likumanjool); and slag trash deposits near residences or in larger smithing dumps. These data points and their spatial interrelationships were used to interpret two eighteenth–nineteenth century archaeological smithing sites associated with the present-day, former smithing villages of Bitchabe and Bidjojebé. These archaeological sites have been impacted by hoe agriculture, tool recycling, and school and/or road construction. The partial reconstruction and interpretation of these sites using the Bidjomambe data is evaluated as to its degree of success.
Sharing Wares and Waging Wars: The Politics of Ceramic Exchange at the Classic Maya Site of El Zotz, Guatemala

The Classic Maya city of El Zotz, relatively small compared to its neighbors, is situated geographically, and at times politically, between El Perú-Waka’ to the west and Tikal to the east. The archaeological site occupies an elevated position within the Buenavista Valley, a southwest to northeast corridor running for some 32 km to the north of the Lake Petén Itza region. The valley connects the northeast and northwest Petén, from Chetumal Bay to the Bay of Campeche, placing the site in a strategic position along major trade routes in the region. Research by the El Zotz Archaeological Project (2006–present) demonstrates that the city’s fortunes and misfortunes were heavily influenced by political developments (both collaborative and antagonistic) in the surrounding region. Yet, even as the geopolitical landscape became increasingly fractured during the course of the Classic period, ceramic evidence suggests that El Zotz maintained connections with its neighbors in the Western Petén. This paper will evaluate the ceramics of El Zotz from a regional perspective, bringing to light the politics of ceramic exchange for this Classic Maya city.

Un complejo arqueológico en las márgenes del río Tehuantepec en la Sierra Sur de Oaxaca: El caso de Ladchixila

El presente estudio se basa en trabajos realizados en la Sierra Sur de Oaxaca, localizado en los márgenes del río Tehuantepec, región en donde se establecieron grupos humanos dedicados a la caza, pesca, recolección de frutos y agricultura, con recursos naturales que fueron explotados, haciendo posible su establecimiento permanente, dejando plasmada su historia a través de elementos arquitectónicos, que para el año de 2015 fueron explorados arqueológicamente. El desarrollo de esta investigación se enfoca de manera específica sobre la Zona Arqueológica en el paraje el “Llano,” correspondiente a la jurisdicción de Ladchixila y donde se tratarán temas sobre la distribución espacial de los edificios, la función de elementos arqueológicos y arquitectónicos que se localizaron alrededor de la acrópolis, así como terrazas localizadas en laderas y conjuntos habitacionales que fueron excavados, detectándose contextos funerarios con ofrendas asociadas. Las labores de exploración durante varios meses de trabajo en esta Zona Arqueológica, arrojaron información importante sobre los estilos arquitectónicos identificados, así como la temporalidad relativa (a través de la cerámica y lítica), y posible filiación cultural con los Valles Centrales de Oaxaca.

Switching Perspectives: Ethnographic Analysis of Community Viewpoints Regarding In Situ Preservation of Archaeological Sites

The varied definitions of cultural heritage imply that archaeological sites and their landscapes are important for the shaping of local cultural identities. Nonetheless, many of these definitions are unclear about the relationship that communities can have with archaeological sites. Using place attachment theory and a knowledge-centered approach, I explore the cultural and historical knowledge that people have regarding their cultural heritage, their general perception of archaeology, their attachment to archaeological sites, and their opinion regarding “in situ” preservation of heritage. The community of Los Indios in Santa Isabel, Puerto Rico, presents an ideal case study to evaluate these issues given that it has a very long history of occupation and is located on top of a large archaeological site. In this presentation I show how, through the use of ethnographic data, it is possible to evaluate and understand the motivations and interests of residents regarding the definitions, and preservation of cultural heritage. Knowing which elements limit or facilitate participation of residents toward the preservation of archaeological sites is an undervalued variable that affects local knowledge shaping local identities, cultural knowledge, and understanding of what it is cultural heritage; and should be incorporated into long-term site management plans and regulations.

Style, Memory, and the Production of History: Aztec Black-on-Orange Pottery in Xaltocan, Mexico

This paper will explore shifting patterns in ceramic consumption and stylistic design during the Postclassic period (AD 900–1350) at the site of Xaltocan in the Basin of Mexico. Xaltocan is the only site in the northern Basin of Mexico associated with a large percentage of early Black-on-Orange pottery. This same pottery is rare at contemporaneous sites located a few kilometers away. Because Black-on-Orange ceramics were used by elites and commoners alike, and also cross-cut various ethnic and linguistic groups, there would have been multiple potentialities and entanglements associated with stylistic shifts in pottery. I argue that rather than self-driven or inevitable processes, shifts in the style and consumption of Black on Orange pottery represented explicit ideological statements about the creation of difference and identity. Similarly, I argue that periods of stasis in stylistic design, as well as boundaries in pottery use, were actively maintained rather than a consequence of non-interaction. Although this paper focuses primarily on stylistic traditions within the Basin of Mexico, it may help us to understand styles more broadly as active processes linked to ritual and identity, while also involved in the construction of power and the production of history.

Ephemeral Features and Evolving Landscapes: Understanding Mankind’s (in-)Visibility in the Archaeo-Geophysical Record

Geophysical prospecting methods are coming of age as a standard part of the archaeological tool kit. Archaeologists, especially in Europe, are increasingly reliant on geophysical data in both developer-led and research archaeology. More recently, archaeological geophysics is bridging the gap between site and subsurface through motored survey strategies. This upscaling particularly highlights a number of methodological difficulties inherent to geophysical prospecting. A first follows its noninvasive character as, by approaching the subsurface from top to bottom, any geophysical result reflects a palimpsest stacking the most recent to the most ancient land-use traces within one dataset. Secondly, while the range of geophysical methods is diverse, each method’s potential correlates strongly to the targeted geological context. Lastly, the ephemeral nature of specific types of archaeology warrants caution in implementing these methods. Settlement traces of hunter-gatherer societies, for instance, often remain invisible to geophysical prospecting and, in general, prehistoric archaeology is the most evasive in geophysical datasets. Here, archaeological ‘invisibility’ in geophysical datasets will be addressed, while discussing the influence of recent land use and geology on the interpretive potential of such data. Additionally, a basic framework relevant to archaeologists working with geophysical prospecting data will be set out, illustrated through different case studies.
La presente ponencia trata de analizar las prácticas funerarias que se llevaban a cabo en distintos conjuntos domésticos excavados en el territorio dominado por la ciudad de Copán durante el Clásico Tardío. En la sociedad maya, las relaciones consanguíneas con los antepasados cobraban mucha importancia para el mantenimiento del poder. Las unidades sociales que se fundan en los lazos de parentesco implican desigualdad en la participación en el poder, definida con base en la proximidad al ancestro común. Las evidencias arqueológicas procedentes de casas de distintas partes del área maya demuestran la existencia de este culto en ámbito doméstico y que este jugaba un papel importante en la construcción y el mantenimiento de la unidad doméstica. Por ejemplo, en los distintos patios que formaban el conjunto doméstico 9N-8, en Copán, convivía gente de distintos niveles sociales, etnias, sexo y edades. Las distintas maneras en que se llevaban a cabo las prácticas funerarias estaban influenciadas por la heterogeneidad que caracterizaba el conjunto doméstico. La pregunta que esta investigación pretende contribuir a contestar es cómo funcionaba este mecanismo en un conjunto doméstico heterogéneo, en donde convivían distintas familias que con mucha probabilidad no compartían un antepasado común.

Integration of Multiple Geophysical Datasets to Classify Archaeological Responses
North American archaeologists are increasing using multiple near-surface geophysical techniques at archaeological sites to locate features of interest. Examining different physical properties in the subsurface has greatly improved archaeological interpretations; however, these data are often examined in a subjective site specific fashion (notable exceptions are the pioneering work of Kvmme and Ernenwein). This research seeks to quantitatively integrate magnetic gradiometry, frequency-domain electromagnetic-induction (magnetic susceptibility and apparent conductivity), and ground-penetrating radar data from the Magnolia Valley site, Rutherford County, Tennessee. Moreover, this research examines the effects of novel processing techniques (including reduction-to-the-pole, attribute analysis, and Hilbert transform) on the correlation structure of the data in order to improve subsequent classification via supervised and unsupervised learning. A short term goal of these data, or information, fusion techniques is the ability to statistically predict archaeological geophysical responses based upon geophysics and limited archaeological testing. The long-term goal of this research program is the stewardship and preservation of the archaeological record, where archaeogeophysics can be used as a standalone method to answer fundamental anthropological research questions about human behavior, social organization, and cultural change through time—without costly and destructive excavation.

A New Approach to Precontact Archaeological Research on the Annapolis River System, Nova Scotia, Canada

Boswell (BfDf-08) is the first archaeological site to be excavated along the Annapolis River, in north-central Nova Scotia. Previously, less than 50 sites had been recorded in the 2,130 km² watershed, and only a few of these were tested. Therefore, Boswell is the baseline for our understanding of precontact occupation for this entire drainage system. Thus far, the site has revealed a cultural sequence beginning with the Transitional Archaic (ca. 4100–2700 BP), followed by Middle and Late Woodland (ca. 2500–1500 BP) occupations. Work at the site since 2011 has included paleoethnobotanical and zooarchaeological analyses and a paleoenvironmental reconstruction. Subistence activities at the site included fishing, hunting of beaver and birds, and the collection of edible berries and nuts. The deeply stratified sediments at the site give an indication as to why so few sites and private collections have been recorded. Based on the Boswell excavations, the authors recommend a new approach for future archaeological work in this understudied part of the province.

DeCorse, Christopher (Syracuse University)

Imperfect Beeswax Production in the Land of Honey—Yucatán, Mexico

Spanish encomenderos and friars demanded beeswax from their subjects in Yucatán, Mexico, during the early Colonial period. This wax was harvested from beehives infrequently used for wax production in prehispanic times—insteed the focus throughout the long history of beekeeping in the region was on honey. In fact, indigenous honeybees, from the genus Melipona, make an impure wax in low quantities, which would have made candle production difficult. These candles were important for Catholic ceremonies and the process of conversion. This paper considered evidence of beeive production from a Colonial house situated within one small community in Yucatán, Mexico, and connect the local histories of honey and wax production to the complicated trajectory of Spanish conquest in the region. It is considered that the nature of local wax ecology and production as well as the quantities of...
wax demanded from communities based on historical tax records, comparing this information to tribute records from other regions in which people experienced early Spanish colonialism.

[238] The Political Ecology of Camelid Pastoralism by Wari and Tiwanaku Colonists in the Moquegua Valley, Peru

The Moquegua Valley in southern Peru was the locale where the rival early imperial states of Wari and Tiwanaku established provincial colonial centers. Both Wari and Tiwanaku colonists concentrated their settlements in the low to mid-sierra elevations of the valley, elevations that are not modern zones of camelid husbandry. The political ecology of imperial settlement at this elevation fostered the development of local systems of camelid pastoralism that were significant economic components for both groups of colonists. Camelids were used for dietary and ritual uses as well as for transport and trade. The osteological, morphological, pathological, and isotopic evidence from camelids remains from a range of sites associated with both Wari and Tiwanaku settlements indicate that local production and breeding of camelids were significant components of the livelihoods of colonists regardless of cultural affiliation. This ability to rear camelids in this setting and to create economic ties with communities at higher elevations attests to the significant political ability of these early empires to alter their local settings in order to sustain these animals and to create viable economic and cultural systems.

[99] Characterization of Neolithic Jade Objects from Shimao and Xinhua, Shaanxi Province, China, Using Handheld Portable Techniques

Fifty jade objects from the Late Longshan period, excavated from the Shimao (25) and Xinhua (25) Neolithic sites, were characterized mineral groups using handheld X-ray fluorescence (hhXRF) and handheld specular reflectance Fourier transform infrared spectroscopy (hhFTIR). The objects were found to belong to three types of minerals. Twenty-two objects found in Shimao (88%) are nephrite (19 tremolites and 3 actinolites), two are calcite and one antigorite. From Xinhua, 9 objects (36%) are nephrite (tremolites), 14 are antigorites, one is calcite, and one chlorite. The higher percentage of nephrite jades found in Shimao confirms its high status and affluence. The minerals were classified into subgroups using HHXRF. All Shimao nephrites, and all but one from Xinhua, are D-type nephrites. Only one Xinhua nephrite is an S-type nephrite. Based on R* values, the D-type nephrites were divided into four groups. The largest group (R*: 0.980 to 0.995) includes 8 nephrites from Xinhua and 14 nephrites from Shimao, indicating possible common geological origins. The Xinhua antigorites were classified into three groupings based on Ni, Cr and Al content. These results can be used to build a database of jade objects from the Late Longshan culture to help establish the origin of undocumented jades.

[279] Analysis of Ancient Chinese Pottery Utilizing X-ray Fluorescence and Diffuse Reflectance Infrared Fourier Transform Spectroscopy

Field studies were performed at the Yangguanzhai Neolithic site near Xi’an, China, using an Olympus Delta Premium portable XRF spectrometer and an Agilent ExoScan FTIR spectrometer. 932 ceramic sherd collected from nine locations across the site were broken, so that the analysis could be performed on a clean edge to minimize surface contamination. Although ceramics have much more complex matrices than most lithic samples, distinct patterns could be observed in several preliminary PCA (Principal Components Analysis) tests. In the main moat (G8–1), an apparent change in clay composition was observed from earlier layers to later layers. Three main clay composition groupings were found in many locations. Differences in clay compositions were also observed in sherd fired at different temperatures (FTIR-assigned firing temperature). One location (402) was clearly different in clay composition from all the others. Additionally, these data seem consistent with a more homogeneous clay composition in the Banpo IV period than in the earlier Miaodigou period.

[75] Mortuary Analysis of Juvenile Burials in the Sacristy of a Spanish Colonial Reducción in the Southern Highlands of Peru

Mortuary practices at Spanish colonial sites in Latin America varied in terms of burial location, style of burial, and associated grave goods. Understanding burial practices is one way to investigate shifting identities, conversion to Catholicism, and the degree of control over and involvement of priests in daily life at colonial sites. The mortuary practices at the reducción (planned colonial town) of Santa Cruz de Tuti (today known as Mawchu Llacta, Colca Valley, Peru) reveal nuanced insights into colonial life for the living through their treatment of the dead. Focusing on body orientation, associated grave items, and the demographic profile of this burial population, we present mortuary data from 21 child burials in the sacristy at Mawchu Llacta. The exclusively juvenile demographic profile of the burial population in the sacristy likely reflects its liminal status just outside the sacred space of the church nave, but in nearest proximity to it (and the main altar). We also make comparisons between the mortuary practices seen here, the mortuary
practices in nearby prehispanic mortuary complexes, and direct historical antecedents, such as at Malata, an early colonial Franciscan doctrinal settlement that was resettled to Mawchu Llacta.

The Complexity of Trash: Reframing Construction Fill

Mesoamerican archaeologists have traditionally, although not exclusively, viewed artifacts found in the context of construction fill as trash and devoid of primary contextual information, a view that has limited the questions that archaeologists are able to ask of these materials. This paper posits an alternative interpretation to the meaning of material culture used in construction fill, utilizing evidence from Formative period construction fill found at the site of Cahal Pech, Cayo, Belize. Specifically, this presentation illustrates the possibility of the deliberate and agentic placement of specific types of material culture into the context of construction fill as a deeply meaningful act of community building that places both kin groups and individuals at the center of construction episodes.

Mining and Interpreting Archaeo-Geophysical Data through Excavation: A Case from Prehistoric Knowlton (Dorset, UK).

Identified by aerial photography, the presence of a presumed prehistoric long-barrow and ring ditch called for detailed investigation by targeted excavation. Located in Dorset (UK), the features are presumed part of a larger ritual environment of which the ‘Knowlton Circles,’ a complex of Neolithic and Bronze Age monuments, are best known. To aid in planning excavations and add to subsequent interpretation, detailed geophysical prospecting, in the form of multi-receiver electromagnetic induction survey, preceded invasive fieldwork. Alongside fine-tuning the excavation layout, the geophysical data were calibrated through recording physical soil properties of the excavated surfaces, and validated archaeologically by comparison to the excavation results. Alongside evaluating of the survey methodology, the geophysical and excavation data were combined into an iterative interpretation procedure. This entitled joining both datasets on a physical and archaeological level to create a reference point which would not only allow improving future surveys, but enable better understanding of the 3D morphology of detected features, their level of preservation and geological context prior to excavation. While exemplified through a single case study, this presentation aims to show how considering geophysical prospection an inherent part of the excavation process, can help construct a more robust framework for subsequent archaeological interpretation.

Analytical Challenges Posed by the Early Holocene/Late Paleoindian Activity Areas at the Water Canyon Site, West-Central New Mexico: How Do We Know What We Think We Know?

Accuracy in the identification of Late Pleistocene-Early Holocene open activity areas and the subsequent inference of human behavior requires that non-behavioral causes for differential spatial patterning be considered before approaching the question of how patterning reflects human activities. Such challenges in the interpretation of behavioral patterning are exemplified at the Water Canyon Paleoindian site. In this paper, we initially describe the lithic and bone assemblages recovered from the Late Paleoindian component (ca. 9600 cal BP) at Locus 1, a suspected Bison antiquus processing area. We then map out any apparent spatial patterns in the assemblages and examine how post depositional geomorphic and taphonomic processes may have biased these patterns and the chronology of the deposits. Once potential biases are identified, we then move on to more securely infer various activities. Thus, not only is the recognition of these biases critical to the subsequent functional interpretations at Locus 1, it is instrumental in helping us design future investigations there and at other activity areas across the site.

The Columbian Exchange in Mesoamerica: Early Colonial Documents and Zooarchaeology in Guatemala

At the end of the fifteenth and the beginning of the sixteenth century, the massive introduction of new animal species in the Americas put an unprecedented stress on both the environment and Native American societies. Although archaeological animal remains are often used to inform discussions on American-European transculturation in other areas, few such studies have been done in southern Mesoamerica. This talk will use historical sources and published zooarchaeological data to provide a first overview of the human-animal relationship during the first century of Spanish
colonization in the Maya world. Primary data will be drawn from historical accounts from the former capital of the Audiencia, Santiago de Guatemala, and comparative zooarchaeological data from the period across Mesoamerica. During the early colonization, the trade of cattle hides and other animal products that can be traced archaeologically, was a significant source of riches for the European colonists. Santiago was also an important regional center and meeting place for the exchange of ideas between many ethnic groups including Spaniards, Mexican auxiliaries, Mayans and eventually, African slaves. The aim of this talk is to emphasize the relevance of further zooarchaeological research for informing us about this period of rapid cultural and environmental change.

[182] Investigations at San Andres Semetabaj and the Problematics of Middle to Late Preclassic Highland Archaeology

The site of San Andres Semetabaj, Guatemala, located on the northern edge of Lake Atitlan, is central, geographically and chronologically, to major theoretical and culture-historical controversies and problems of Preclassic highland archaeology. The size, nature, and importance of the site have been underestimated, in part due to limited available information based only on smaller preliminary seasons and a looted tomb and also due to the assumption by many that the very large structures there were Late Preclassic and/or Late Classic. Now a larger long term project there has begun and is completing its first season. Preliminary results confirm that the epicenter structures, including temples of 8 to 11 m in height, were Middle Preclassic with only a few mounds, one large, dating to the Early Classic, but after a clear hiatus. The investigation also reveals the large scale of the site and has identified related small centers. The nature, dating, and location of Semetabaj make it central to interpretation of Middle Preclassic highland and coastal exchange systems. It also falls fortuitously directly into the ongoing controversy on Middle Preclassic chronology. The Semetabaj Regional Archaeological Project will provide evidence and analyses that address these current issues of Preclassic highland archaeology.

Demarte, Pete (Trent University), Samantha Walker (Trent University), Dan Savage (Trent University) and Melissa Coria (Trent University)

The settlement sub-project of the Socio-Ecological Entanglement in Tropical Societies (SETS) investigations was executed by engaging a variety of data collection methods in order to assess the development and overall organization of settlements of support populations in a sample of preindustrial tropical societies from South and Southeast Asia, and Mesoamerica. This presentation explores the diverse types, character, and quality of the data employed in the study, and underscores how, when combined within a broader comparative study, the strengths and weaknesses of the various regional datasets can be productively evened out to provide a general understanding of settlement patterns in the preindustrial tropics. Specific attention is paid to the methods utilized in the examination of the dispersed urban settlements characteristic of tropical environments, while also providing a comparison of the utility of each method of archaeological data collection. Data proximity and ground-truthing are argued to be crucial tools that should be used in conjunction with extensive literature reviews, ground surveys, and extant GIS datasets (including lidar) in efforts to examine the complex socio-ecological relationships, human-thing entanglements, resiliency of support populations, individual settlement nodes, and larger political formations.

[103] The Luxury Of Cold: The Natural Ice Industry In Boca, California: 1868–1927

Before the invention of refrigeration and electrically produced ice, naturally harvested ice was an important seasonal commodity for food storage and heat regulation. In 1852, Boston ice was shipped to San Francisco and sold as a luxury. High demand soon led entrepreneurs to look for closer sources of ice, first in Russian controlled Alaska, and then in the Californian Sierra Nevada Mountains along the newly-completed transcontinental railroad line. The railroad transported ice to customers, utilizing it to ship perishable food items over long distances in refrigerated cars. The town of Boca, in the eastern Sierra, dominated the Californian ice market from the late 1860s–late 1920s, due to its extremely cold and dry conditions, purity of water, and proximity to the railroad. This presentation will discuss the archaeology taking place at Boca, as well as attempting to situate the Sierra ice industry in the broader context of economic and industrial development of the late nineteenth- to early twentieth-century West.

[18] Digital Archaeological Data in All the Classrooms: Case Studies Using the Digital Index of North American Archaeology (DINAA) for Teaching Digital Methods in Graduate and Undergraduate Curricula

This paper presents case studies in developing information literacy about archaeological methods and heritage resources, involving use of the Digital Index of North American Archaeology (DINAA) in graduate and undergraduate programs at Adams State University and Indiana University. DINAA is a linked online database which can be used by archaeologists as a core foundation from which to explore further a corpus of data, including excavation and collections data, scholarly publications, and related information from other scientific databases. These examples highlight DINAA’s potential for teaching digital archaeological methods, including critical thinking skills about information design, data representation, and reuse strategies. Courses discussed involved heritage management practice and theory, definitions of culture areas and history, and introduction to archaeological science. Perennially critical issues in teaching digital archaeological methods are (1) providing students with primary data or large volumes of data for hands on learning and (2) providing them with affordable software solutions; addressing these issues provides graduating students with important skills for contemporary workplaces that require navigation of diverse datasets and software, often with limited financial resources. DINAA’s open data and open-source commitments democratize the educational process for students, and simultaneously provide an avenue for educators to introduce real world data into the classroom. [156] Materializing Ritual: Sorcery, Transformation, and Divination in Greater Nicoya

Themes involving spiritual transformation have long been noted in the material culture of precolombian Greater Nicoya, with standardized ritual imagery appearing in local Sapoá period (AD 800–1250) ceramic type-classes such as Papagayo and Pataky Polychromes. A recent iconographic reevaluation suggests that at least some varieties from these “independent types” were designed to work together, to complement one another in both ritual messaging and formal function. Here we focus explicitly on the relationship between Pataky Polychrome, Pataky variety, effigy head vessels and Papagayo Polychrome, Alfredo variety, bowls. Together, this unique “set” appears to portray a sorcerer in the act of spiritual—and arguably entheogen-
The infamous seated goddess, flanked by two leopards, is perhaps the most sensationalized figurine to have been unearthed at Çatalhöyük, prompting a key role in understanding ancient canine lifeways and the interactions between humans and domestic dogs. Mortuary analysis can also bolster interpretations of life histories and dogs’ roles within human society. This paper describes the mortuary contexts and paleopathology for nearly 50 archaeological dog skeletons from two sections of the Tennessee River Valley—the Western Valley and the Ridge and Valley physiographic provinces. Dogs from the Western Valley date between 7000 and ca. 3500 years BP, and are associated with foraging cultural groups, while dogs from the Ridge and Valley are much later, dating between 900 AD, and 1500 AD and are associated with subsistence systems centered on maize agriculture. The social relationship between dogs and people manifests skeletally in traumatic fractures and/or metabolic diseases, as well as in the way dogs are treated in death. Differences in burial treatment and paleopathology between these two cultural groups indicate that dog lifeways changed within the context of anthropogenic cultural change.

Denton, David (Cree Nation Government)

Waapushukamikw: Sacred Site and Lithic Quarry in Subarctic Quebec

Traditionally, Waapushukamikw (“house of the hare”) was a sacred site for Cree and closely related Northern Algonquian people in subarctic Quebec. Its use as a place of prayer was noted in the early eighteenth century by Jesuit missionaries, and some elements of this tradition have continued to modern times. Waapushukamikw, known by archaeologists as the Colline Blanche, was also an important lithic source in subarctic Quebec, used for some 6,000 years. Artifacts of Mistassini quartzite from this source have been found in sites throughout a wide area of subarctic Quebec and well beyond, into the St. Lawrence River Valley and parts of New England. In areas furthest removed from the source, it is often found as offerings in burials. This paper brings together information concerning Waapushukamikw as part of the Cree/Northern Algonquian cultural landscape and suggests a close relationship between the spiritual power of the site and the typically white stone from the quarry, known to Crees as wiinwaapsk (“fat stone”).

Diet and Dentition on the Black Sea: An Examination of Dental Health and Dietary Reconstruction at Medieval Mesambria

Dental health and dietary habits from the Bulgarian town of Mesambria have never been investigated for the medieval period. The town has its roots in Mediterranean culture, however, in the Early Byzantine and Medieval periods in Bulgaria, the Slavic Bulgars were vying for power and territory, and Mesambria became caught between the dying Byzantine Empire and the new Bulgarian state. The Bulgars brought with them a different diet, with a preference for millet, meat, and cheeses over the Mediterranean staples of wheat, oil, and wine. Human remains from the Mesambrian Old Town and Necropolis were compared to investigate the dental health of individuals living in medieval Mesambria. Supplementary isotopic analyses from twelve individuals from the Old Town were used in dietary reconstruction, and to support the dental health findings. Possible differences in age, sex, time period, and class between the Necropolis and the Old Town populations were investigated. Numerous significant differences were noted in the frequency of affected teeth between sexes, age groups and between the two populations. Isotopic data suggests that there were slight dietary differences between males and females, and δ15N values indicated that individuals buried in the Old Town had elevated marine consumption.

Deppen, Jacob (University of Washington)

Connected through Things: Connectivity in Iron Age Mallorca

This presentation examines connectivity in the Late Iron Age on the island of Mallorca. While most case studies of connectivity in the western Mediterranean involve the movement of people and/or the construction of new settlements by nonlocal people, there is little evidence that this occurred in Mallorca. However, there is still abundant evidence that indigenous Iron Age Mallorcan sites were increasingly connected to the broader Mediterranean and that nonlocal goods were being consumed throughout the island. Mallorca, then, seems to have been a place where connectivity and consumption of nonlocal goods were negotiated on decidedly local terms. This presentation will outline what we know about the consumption of nonlocal goods in Mallorca during the Iron Age while also examining how the absence of nonlocal individuals impacts how we think about studies of connectivity and contact between groups.

God’s Empire: Ritual, Repression, and Resistance on the Rio Grande, 1300–1848

This interdisciplinary project evaluates the relationship between Spanish and indigenous religious practices and their respective political objectives in prehistoric and colonial New Mexico. Beginning with a discussion of the emergence of a new religious idiom in the Pueblo world during the fourteenth century CE, I investigate the entanglement of political and economic forces with religion up to the conquest of the region by Anglo-Americans in the mid-1840s. In doing so, I highlight the myriad connections between what contemporary society, in the interests of sublimating the violence of ideological struggle, has sought to separate: the sacred and the secular. I demonstrate that in New Mexico, religion never operated in a vacuum, nor was this desired; rather, it was intentionally mobilized as a tool of political and economic action. To that end, I employ archival/ethnohistoric, archaeological, and ethnographic sources to deconstruct the categories of “religion,” “politics,” “economics,” and “society” themselves.

Der, Lindsay (Stanford University)

From Goddesses to Zoomorphs: Figuring Out Figurines at Çatalhöyük

The infamous seated goddess, flanked by two leopards, is perhaps the most sensationalized figurine to have been unearthed at Çatalhöyük, prompting narratives of prehistoric cults and religion. Yet research conducted since its discovery by James Mellaart has shown that zoomorphic, rather than anthropomorphic, types are predominant in the figurine assemblage. In this paper, I trace the history of changing recording systems, analytical methodologies, and interpretations of figurines at Çatalhöyük. These new approaches have not only reconfigured our understanding of ritual and symbolism, but also revealed spatial and temporal continuity and variation across the settlement. In particular, research carried out on the figurines in the last five years, has illuminated the emphatic role of animals in the everyday lives and experiences of the Neolithic residents of the site. The figurines,
along with other animal materializations, can thus reveal new insights into the complexion of human-animal relations and ontological geographies at Çatalhöyük. Furthermore, these studies help to contextualize the site within broader patterns of phenomena related to symbolism, ritual, and social change at the origins of agriculture in the Middle East.

Changing Ecologies and Altered Landscapes: A 13,500-Year Paleoeological Record from Galiano Island, British Columbia

A high-resolution lake sediment core recovered from Shaw’s Bog on Galiano Island provides a window into the paleoecology of the island and region back to the Late Pleistocene. The extensive time depth represented offers an opportunity to evaluate ecology and climate prior to the known arrival of people in the southern Gulf Islands. It also provides a mechanism to measure impacts on the local ecology following the establishment of major, long-term village locations such as Dionisio Point and Montague Harbor in the later Holocene. Using fossil pollen, charcoal, and phytoliths identified in the core, we compare natural and potentially anthropogenic changes in the local and regional ecology and fire regimes of Galiano Island. Changes in charcoal frequency and morphology demonstrate shifts in fire frequency and fire regimes during the Holocene, and these are evaluated with respect to variability in the pollen and phytolith record. These paleoecological data, coupled with archaeological evidence for long-term landscape construction in nearby village sites, suggest that Salish peoples engaged a complex and dynamic landscape that both sustained and reflected increasingly place-based lifeways in the southern Gulf Islands.

[154] Ongoing Excavations at FxJj20Main-Extension-0, Koobi Fora, Kenya

Original excavation of FxJj20 sites in Koobi Fora, Kenya revealed nine oxidized patches described as combustion features associated with artifacts. Here we describe new excavations at a nearby new locality described as FxJj20Main-Ext-0. This excavation extends previous work in order to explore potential combustion features with newer techniques. Three squares adjacent to a reddened feature yielded 18 bones and 33 stone artifacts. All bone was fragmented. Most stone artifacts were basalt. Nearest neighbor analysis showed nonrandom clustering on both the horizontal and vertical planes with minimal evidence of postdepositional disturbance.

Des Lauriers, Matthew (California State University, Northridge)

[393] Inheritance, Innovation, and Interaction: The Motivations for and Consequences of Social Interaction in the Context of Initial Settlement

While providing a general outline of several initial settlement strategies pursued across the Americas, I argue that social networks between the small-scale communities involved would be established rapidly upon arrival. Certainly, the events of initial contact and process of network formation would have occurred within a sub-generational time frame. The flow of material goods, genes, and information between members of the small-scale pioneering communities is essential to the survival of initial populations and their continued expansion. As they moved into a new landscape, the establishment of these conduits would have been high on the priority lists of the early colonists leading us to ask several questions. Do the varied Terminal Pleistocene technological assemblages of the Americas indicate the existence of widespread and distinct cultural traditions? Are the expansive geographic areas of North and South America encompassed by some of these traditions commensurate with interaction systems? Finally, does the increasingly regionalized material culture in the millennia after ~8000 BP indicate a reduction in the geographic scope of networks or a more complex change in the role of interaction among Archaic populations?

[392] Lead and Zinc Pigmented Mural Paints: Lowry Pueblo Great House, Southwest Colorado

We used numerous techniques to study the white step pattern murals of Lowry Pueblo Villas A and B: visual analysis, portable X-ray fluorescence, scanning electron microscopy with an energy dispersive X-ray spectrometer, and powder X-ray diffraction. Elemental analyses identified lead and zinc in the shiny bright white paint layer and calcium in the dull white paint layer. X-ray diffraction confirmed zinc oxide and lead sulfate pigment minerals in the shiny, bright white paint layer, whereas calcium carbonate was identified as the pigment for the dull white paint layers. Radiocarbon dating places mural production at 1020–1185 cal AD, consistent with occupation at Lowry Pueblo Great House. Because this underlying shiny, white paint layer is from an earlier painting event than the dull white, the lead paint layer could not be due to a modern addition. Selection of this lead and zinc pigment by kiva decorators produced a desirable paint finish; however, lead ore processing and paint manufacture likely had negative health implications.

[173] Interpreting Maya Economic Activity Using Paleoethnobotany

Paleoethnobotany is a subfield of archaeology that requires an extensive knowledge of archaeology and botany. Because highly specialized skills are required, presenting data can be difficult. Botanical data must be conveyed in a way that is understood by fellow archaeologists while adhering to standards of botanists. Conveying this information becomes even more difficult when we begin to combine micro and macro botanical methods. Botanical datasets can contribute to a wide range of topics that enhance our understanding of pre columbian societies. This paper focuses on the contribution that paleoethnobotany can make to our understanding of ancient economies. I focus not only on the subsistence economy, but the contributions to our understanding of economic production, distribution, and consumption on a broader scale. I present a case study from the site of Xunantunich in Belize. Thousands of small unifacial bladelets associated with Late Classic Maya households were discovered at the site and were initially interpreted as crafting tools. A sample of 38 previously washed bladelets and 62 unwashed artifacts yielded starch from several plant species. The results suggest that at least one household at Xunantunich engaged in plant processing activities that exceed that of normal household production activities.

Devlin, Joanne

[79] Beyond the Basin: Forensic Archaeology in Tennessee

As professors at Hamilton College, G. Tom Jones and Charlotte Beck taught their students how to engage in research and how to be effective instructors in the classroom. I have used these lessons to build a career in forensic anthropology. My long-term research at the Forensic Anthropology
Center at the University of Tennessee has centered on establishing techniques to best examine burned bones and also on the application of geophysical methods to locate clandestine graves. This research has led to improved means for handling, identifying, and recovering burned bone while the geophysical work on experimental graves has demonstrated the utility and reliability of ground-penetrating radar in forensic investigations. Importantly, this work has significantly contributed to the development of training programs for students and Law enforcement personnel. The success of my forensic work is directly attributable to the influence of Tom and Charlotte and their dedication to students and anthropological science.

Dewan, Eve (Brown University) [247] Repatriation in Rhode Island: NAGPRA in Practice at a New England Museum
Located within a city park in Providence, Rhode Island, the Roger Williams Park Museum of Natural History has been a popular scientific and cultural institution since it was founded in the late nineteenth century. Only about 1% of the Museum’s quarter million pieces are currently on display. Included in this vast collection are approximately 25,000 archaeological and ethnographic objects from around the world, a number that was higher prior to the passage of NAGPRA in 1990. Since this pivotal legislation was introduced over two decades ago, the Museum has worked on numerous claims for the repatriation of cultural property and ancestral remains, with varying degrees of success. Using the Roger Williams Park Museum as an institutional case study leads to a more concrete understanding of how NAGPRA affects museum realities, as well as what ethical and practical challenges arise from it. Three cases in particular highlight the law’s impact and the inner workings of the Museum’s changing relationships with Indigenous peoples and their material culture in southern New England, throughout the United States, and across the globe.

DeWitte, Sharon (University of South Carolina) [235] Sex Differences in Pre- vs. Post-Black Death Trends in Developmental Stress Markers
Previous research revealed trends in periosteal new bone formation in medieval London that are consistent with improvements in health following the Black Death (c. 1347–1351). However, periosteal lesions can occur in response to a wide variety of factors at any age, so it remains unclear how the epidemic affected patterns of physiological stress specifically among subadults. To further our understanding of changes in physiological stress before and after the Black Death, this study examines sex-based variation in temporal trends in two developmental stress markers: linear enamel hypoplasia (LEH) and short tibia length (a proxy for stature). The samples (n = 879) are from medieval London cemeteries and dated to an Early Pre-Black Death (AD 1000–1200), Late Pre-Black Death (AD 1200–1250), or Post-Black Death (AD 1350–1540) period. The results of Chi-square and t-tests indicate that before the Black Death, males experienced an increase in LEH frequency and a decline in stature, but these did not change among females. The results also indicate declines in LEH and increases in stature for males but decreases in stature for females after the epidemic. These patterns might reflect sex differences in physiological buffering during childhood or unequal access to resources after the Black Death.

Diaz, Alejandra (University of British Columbia), Anna Marie Prentiss (University of Montana), Rebecca Macdonald (University of British Columbia), Olaf Nehlich (University of British Columbia) and Michael P. Richards (Simon Fraser University) [50] Diet and Mobility on the Canadian Plateau: Isotopic Analysis of Domestic Dogs and Other Fauna from the Bridge River Site
This study reports on carbon, nitrogen, and sulfur isotope analyses of dog remains and other fauna from the Bridge River site in the Mid-Fraser region of the Canadian Plateau. We discuss these results in relation to dietary variability and resource mobility through time and in the relationships between dogs and humans. While dogs are not a direct proxy for humans in dietary isotope studies, their diets are influenced by human dietary practices, and therefore indicative of human subsistence strategies and activities. Similarly, evidence of dog mobility reflects the spatial interactions between human groups and resources. Dietary results demonstrate that while salmon played an important part of dog diet at Bridge River, variability occurs across age groups and culture periods. Mobility of dogs and potential differences in origin through time is also indicated.

Diaz, Diana (California State University, Northridge) [98] Engaging the History of the San Fernando Valley: Collections and “Synergy” at CSUN
Perceptions of southern California’s San Fernando Valley have long pertained to its relationship to adjacent Los Angeles, with the region over time characterized as either agricultural hinterland or faceless suburbia. Such stereotypes overlook the numerous historical associations and resources of the region, in the process subverting the identities and “communitas” of valley residents. In 2016 courses taught in the Department of Anthropology at California State University-Northridge (CSUN) have been collaboratively designed to create “synergy” associated with the San Fernando Valley in regard to history, space, and place. A particular focus has been archaeological resources from numerous valley localities curated at CSUN, including artifacts from Mission San Fernando, Rey de Hispana, and numerous nineteenth-century “adobes.” These collections have never been synthesized, so evaluation in classroom laboratory settings offers the opportunity to engage local history and to involve students in the process. The results have expanded perceptions of the value of archaeological resources, the importance of local history, and the critical need for community engagement.

Toward an Interpretive Framework for Burnt Ostrich Eggshell: An Experimental Study

Ostrich eggs have been a valuable resource for Sub-Saharan populations for thousands of years, offering a rich nutritional source as well as a means of transporting water. While burned ostrich eggshell (OES) fragments are common at sites, it is difficult to determine whether they were subsistence refuse or the disposed remnants of canteens. Current tools for analyzing OES burning conditions involve expensive and time consuming isotopic analysis or scanning electron microscopy. This research aims to develop an interpretive framework for differentiating cooked OES from that burned through disposal or natural circumstances based on easily observed and measured criteria. This will be achieved through burning experiments with the intention of distinguishing shells heated while the egg was whole or in fragments as well as surface or subsurface burnings. This poster will present data regarding patterns of coloration, surface morphologies, and physical properties. This research will have implications for site interpretation in terms of seasonality, subsistence strategies, mobility, and paleoenvironmental reconstruction.

A Frontier in Bloom: Social Implications of Architectural Diversity and Conformity during the Colonization of the San Juan Region of the Northern Southwest

Behavioral conformity and, its inverse, behavioral diversity are social adaptations wielded by small scale agricultural societies faced with change. By the sixth and seventh centuries AD, the Basketmaker III period, long standing conflicts in the San Juan region of the northern Southwest had abated and new territories opened to agricultural colonization. Frontier colonization is by nature a contentious process that usually results in violence, displacement, and the reinforcement of factions. In contrast, the San Juan Region saw an unprecedented period of peace and integration during colonization. This study demonstrates how Basketmaker III populations mitigated conflict by signaling solidarity and common identity in the Frontier through architectural conformity at community centers while allowing for architectural variation and expression at single family farmsteads. These practices, in turn, may have set the stage for the development of kinship and non-kinship based institutions in the Ancestral Pueblo world.

Where the Land Meets the Sea: Preceramic Complexities on the North Coast of Peru

Interdisciplinary investigation of the large coastal mounds of Huaca Prieta and Paredones and their associated domestic settlements represent Preceramic human occupation as far back as ~14,000 cal BP. Research at these sites has documented a long Preceramic sequence from the activities of the first maritime/terrestrial foragers from the late Pleistocene to early Holocene to the construction of the mounds and the introduction and development of agriculture and monumentality from the middle to late Holocene. The community of sites in the study area emerges as innovative, complex and ritualized, with long distance contacts in several areas of the Central Andes. As yet this early community has no known antecedents in the wider Andean region. The social and ontological complexity of the sites is discussed and related to later societies.

The discourse surrounding loss, embracing it as an integral part of culture rather than avoiding it. This paper will demonstrate how such threats impact heritage preservation field that our work necessitates freezing the past in perpetuity at a given point, or only allows for sanctioned changes. This fear of disintegration.

Why does the threat of loss strike fear into our hearts as heritage professionals and archaeologists? Why do we not understand the loss of cultural practices as part and parcel of being human, and accept that loss is not the opposite of heritage, but in fact and integral part of it? We need to transform the discourse surrounding loss, embracing it as an integral part of culture rather than avoiding it. This paper will demonstrate how such threats impact the decision making processes surrounding historic structures and ruins in Tihosuco, Quintana Roo. It seeks to challenge the prevailing notion in the heritage preservation field that our work necessitates freezing the past in perpetuity at a given point, only for sanctioned changes. This fear of loss and failure to allow for adaptation can create a cycle of "living dead" within heritage assets: aging architectural and archaeological resources that are not being used to their full potential, or are left to deteriorate with no thought to their present or future value. In order to break this cycle, we need a people-centered heritage preservation one that adapts our methods to engage with the past and plan for the future.

Dillon, Katherine (Binghamton University)

A Depositional Analysis of Pit Features at the Pocumtuck Fort

Subsurface features are a basic unit of archaeological analysis, yet there is surprising little standardization in their identification, classification and analysis. In the northeastern region of the United States most archaeologists rely on simplistic pit feature typologies. I argue that studying features by deposit rather than as whole units allows for a clearer understanding of separate cultural depositions as indexes of specific past practices. The pit feature assemblage at Area D (19FR415), a mid-seventeenth-century Pocumtuck site in Deerfield, Massachusetts, demonstrates the potential for depositional analyses of pit features. I identify the range of past human practices manifested in these features through a systematic sorting of deposits based on 24 recorded attributes, which measure and describe deposit morphology, soils, and content.

DiNapoli, Robert J. (University of Oregon)

Reevaluating the Precolumbian Colonization of the Caribbean Using Chronometric Hygiene and Bayesian Modeling

The timing and pattern of initial human arrival to the Caribbean islands is discontinuous and anomalous, especially considering their proximity to both mainland areas and adjacent islands. With the exception of Trinidad, which was probably colonized ca. 8000 BP—but was connected to mainland South America during the late Pleistocene/early Holocene (and remains close to Venezuela)—some of the Antilles appear to have been colonized quite early ca. 7000–6000 BP, while others were settled centuries or even millennia after nearby landmasses. In addition, some islands have no documented precolombian settlements, which is curious given the generally small area and intervisibility of most islands. To better examine the pattern of prehistoric settlement in the Caribbean, we have compiled the largest database of radiocarbon dates currently available that consists of almost 2,000 dates. Using a strict chronometric hygiene protocol and a series of Bayesian models, we compare refined colonization estimates for more than 20 islands with several hypotheses that address prehistoric population dispersals in the region. In addition, our results highlight the need for improved radiocarbon dating protocols to help refine chronologies and provide more robust interpretations of island colonization.

Dilores, Kurt (Louisiana State University) and Heather McKillop (Louisiana State University)

Analysis of Marine Sediment to Explain Sea Level Rise in Paynes Creek National Park, Belize

Archaeological research in Paynes Creek National Park, Belize provides insight into environmental changes over time. Sea level rise has affected coastal Maya settlements during both the Classic and Postclassic Periods. Marine sediment samples from five submerged Classic Period Maya sites were exported under permit to the Archaeology lab at Louisiana State University where the samples were analyzed using loss-on-ignition and microscopic sorting. The results from loss-on-ignition as well as microscopic sorting of these marine sediment samples will be presented. Loss-on ignition was used to determine the percent organic matter in each of the marine sediment samples. Microscopic sorting showed the composition of the marine sediment. A high percent of organic matter in conjunction with red mangrove (R. mangle) roots is indicative of mangrove peat. Mangrove peat is an indicator of actual sea level rise because R. mangle has been shown to keep pace with the rise of sea level. The research presented in addition to material cultural remains contributes to our understanding of the Maya as well as the effect of global climate change on coastal Maya communities.

Famine Foods and Food Security in Ancient and Modern Yaxuna

Food as an object of study can reveal relationships between biological necessity, culture, and oppression. The 1996 World Summit on Food Security declared that "food should not be used as an instrument for political and economic pressure," yet archaeology shows myriad ways in which food access was manipulated in the past, and the ramifications of those manipulations. In the Maya area, prestige foods have tended to be the focus of analysis. In this paper, we emphasize the importance of the archaeological study of foods of low social status, including those referred to as famine foods. Through a survey of rejolladas and house gardens in the modern village of Yaxunah, and a review of the literature on Maya agriculture in times of hardship, we present a working list of the most efficient "famine foods" in Maya history, an analysis of the potential stigmas tied to those foods, and a portrait of the changing nature of food security insurance. We tie these observations to modern attitudes toward low status or poverty foods held by Yucatec Maya speakers in Yaxunah. We aim to illuminate the history of Maya food-insecure households and local efforts to integrate new foods during times of social disintegration.

The Cycle of the Living Dead: Ruins, Loss, and Preservation in Tihosuco, Quintana Roo

Why does the threat of loss strike fear into our hearts as heritage professionals and archaeologists? Why do we not understand the loss of cultural practices as part and parcel of being human, and accept that loss is not the opposite of heritage, but in fact and integral part of it? We need to transform the discourse surrounding loss, embracing it as an integral part of culture rather than avoiding it. This paper will demonstrate how such threats impact the decision making processes surrounding historic structures and ruins in Tihosuco, Quintana Roo. It seeks to challenge the prevailing notion in the heritage preservation field that our work necessitates freezing the past in perpetuity at a given point, only for sanctioned changes. This fear of loss and failure to allow for adaptation can create a cycle of "living dead" within heritage assets: aging architectural and archaeological resources that are not being used to their full potential, or are left to deteriorate with no thought to their present or future value. In order to break this cycle, we need a people-centered heritage preservation-one that adapts our methods to engage with the past and plan for the future.

[280] Chair
Over the past ten years I have sought to elaborate a new categorization for rock art images and one based on analysis of visual perception bolstered by cognitive psychology experiments and current knowledge of visual system neurophysiology. The result has been a suggestion for three classes of symbolic patterns of a given group that can be used to evaluate intracultural variation among the Ancestral Pueblo people. Landscape analysis of the Sand Canyon Pueblo community, Cajon Mesa communities, and the Ten Acres Community has revealed distinct differences in site location and orientation; masonry style; and public architecture. This study focused on large Pueblo III period community centers in the Four Corners region to assess the presence of intracultural variation; a presence that may further be used to identify possible ethnic differences between said communities. Ethnicity is not the same as culture, but rather allows for an individual to identify with a collective group. This paper will present the results of the study, showing that architecture serves as a medium of communication; a piece of material culture imbued with the symbolic patterns of a given group that can be used to evaluate intracultural variation among the Ancestral Pueblo people.

Ditchfield, Kane [302] see Manne, Tiina

Dobrez, Livio (Australian National University, retired) [210] Rock Art Categorization

Over the past ten years I have sought to elaborate a new categorization for rock art images and one based on analysis of visual perception bolstered by cognitive psychology experiments and current knowledge of visual system neurophysiology. The result has been a suggestion for three classes of image, viz the Canonical (mostly profile), Narrative (scene), and Performative (frontal). At the same time Patricia Dobrez has added two possible classes represented by hand traces and by tracks. In this paper I will give an account of this categorization, focusing on the idea of a scene. I would also like to present the results of the study, showing that architecture serves as a medium of communication; a piece of material culture imbued with the symbolic patterns of a given group that can be used to evaluate intracultural variation among the Ancestral Pueblo people.

Dobrez, Jared (Indiana University of PA) [191] Testing the Use and Reliability of 3D Scanning Technology in the construction of a Digital Comparative Faunal Bone Collection

This poster presents methodologies for testing the use of 3D scanning in its ability to capture quality 3D images of faunal bones for comparative purposes. An investigation of prior studies confirms that 3D scanning has successfully been used in aspects of archaeological research. Yet, the full potential for the use of 3D scanning in zooarchaeology is still unclear. At present, zooarchaeologists often have to resort to loaning physical bone specimens from other institutions when comparative examples are not available in their local collections. The process of needing to borrow physical comparative collections can be timely and costly to the researcher. This research utilizes a MakerBot 3D Digitizer to test its accuracy for creating 3D representations of faunal bones. In particular, this project focuses on scanning various waterfowl and fish species. The long-term goal for testing the use and reliability of 3D scanning is to further aid in the development of digital faunal bone comparative collections. A digital repository of faunal bone comparative collections could drastically increase the availability of zooarchaeological collections to researchers across the global. Consequently, this will bolster the potential for collaborative research efforts across the archaeological community since digital faunal collections could easily be shared among institutions.

Dixon, Christine C. (Green River College), Rachel Egan (University of Colorado, Boulder) and Nan Gonlin (Bellevue College, WA) [293] Natural Springs: A Critical Life Force in Ancient Costa Rica

Water is a life sustaining substance, sought after, fought over, and revered in both the past and present. The relationship between humans and water resources is an essential component of our human history that warrants archaeological focus. Natural springs have been identified as key locations of archaeological remains throughout the Americas—places inherently intermixed with practices of drinking, bathing, cooking, and worship of the divine. In Costa Rica, the documentation of Silencio Phase (750 CE–1020 CE) footpaths has led to a critical discovery of the significance of springs in this ancient landscape. This paper contextualizes recent discoveries in the Arenal area of Costa Rica by utilizing case studies of the meanings and uses of springs throughout the Intermediate and Mesoamerican regions. Findings suggest that the spring as a focus of investigation is an understudied component of Costa Rican archaeology and a vital component of ancient life.

Dobereiner, Jeffrey (Dartmouth College) and Rebecca B. Gonzalez Lauck (Proyecto Arqueológico La Venta) [3] Voted Off the Olmec Island: Remote Sensing and Regional Reconnaissance Surrounding La Venta, Tabasco, Mexico

This paper reports on the first stage of a regional settlement study initiated in 2016 by the Proyecto Arqueológico La Venta (PALV). Previous work beyond the primary site core of La Venta, Tabasco, Mexico, has primarily focused on a limited subset of regional features. PALV’s inaugural season of field reconnaissance, alongside analysis of 5-m resolution lidar and historic aerial photos, demonstrates that Formative and Post-Classic period occupations beyond the main La Venta “island” were likely more extensive than previously documented. This work is improving chronological and spatial resolution on the cultural trajectory of the Gulf Coast, enabling improved comparative analyses of emergent social complexity in Mesoamerica more broadly. Going forward, this multiyear project will draw upon a broader range of techniques, including geological coring and ground-based remote sensing, to produce a comprehensive model of settlement in La Venta’s poorly understood hinterland. The expanded catalogue of archaeological sites in this region will also serve to help protect heritage from ongoing oil prospection and pipeline production by PEMEX.

Dobney, Keith [85] see Ameen, Carly
ask whether any of the above classes might claim historical priority, whether any might have some sort of originatory claim, and whether any might offer specific insights into human cognitive or aesthetic development.

Dodd, Lynn (USC), Kevin Mercy (USC), Nolan Leuvano (CSU, Dominguez Hills) and Su Jin Lee (USC) [300] Analysis of Spatial Characteristics and Traditional Knowledge of Freshwater Springs as a Foundation for Predictive Settlement Modeling and Identification of Submarine Groundwater Discharge
Modeling of late Pleistocene and early Holocene coastal regions in the northern Channel Islands and globally has provided important foundations for understanding impacts of sea level rise on the archaeological record, near coastal communities and environments during the past 20,000 years. A complex, effective model of suitable coastal locations for human settlement and habitation takes into account myriad variables, including resources such as water and land-qualifiable, cultural causes. The research reported here details initial research into forms of local and traditional knowledge about freshwater, and reports on geospatial analysis of freshwater on Santa Catalina Island, one of the southern Channel Islands off the coast of southern California. With Stage Three water rationing being instituted, freshwater sources play an ever more important role in sustaining Catalina Island. Spring locations, terrain parameters, geology, and landscape parameters, including elevation, slope, aspect, land cover, and geology were analyzed. These data comprise a foundation for our surveys to define and document submarine groundwater discharge around Catalina Island; support a fuller understanding of the water balance and hydrological systems; and are valuable in modeling human settlement, past, present, and future, on this island.

Dodd, Walter (California State University, Fresno) [105] How Were Hohokam Palettes Used? Testing a Novel Hypothesis
Palette means "little shovel" in French. The name derives from a commonly held belief that these curious objects were shallow, hollowed-out containers in which paint pigments were prepared. Another suggestion is that they were used as snuff trays, i.e., surfaces for grinding up hallucinogens prior to chewing or inhalation. This paper advances a new hypothesis with testable implications. It is argued that palettes were employed as mirrors, possibly in ritual contexts. Test results from a series of simple experiments are presented that enable tentative acceptance or outright rejection of the hypothesis. Relevant facts from archaeology, ethnography, geology, and physics are interwoven to build and try a case for specular reflection.

Dodd, Robyn (University of Texas at Austin), David M. Hyde (Western State Colorado University) and Estella Weiss-Krejci (Institute for Oriental and European Archaeology, A) [83] La Milpa East, Hun Tun, and Medicinal Trail Communities: Ancient Maya Hinterland Settlements East of La Milpa, Belize
The hinterland east of La Milpa is distinctive of an upland landscape with bajos on its edges, a few formal courtyard groups, monuments, and numerous informal clusters of mounds. Multiple landscape modifications such as terraces, depressions, chultuns, and linear features are present in these eastern hinterland settlements as well. This paper will provide an overview of the excavations into three specific hinterland communities: La Milpa East, Hun Tun, and the Medicinal Trail Community, as well as associated aguada, or seasonal water holes, and dry depressions to document variable strategies of ancient Maya economy and water management. Archaeological evidence will be discussed as it relates to the function and interpretation of these hinterland settlements and the role they played in contributing to the larger, regional influence of the La Milpa polity.

Dodrill, Taylor, Nicholas P. Jew (University of Oregon), Scott M. Fitzpatrick (University of Oregon), Connor Thorud (University of Oregon) and Martin Nelson-Harrington (University of Oregon) [46] New Archaeological Site Recording and Assessment along the Southern Oregon Coast
As part of a newly established University of Oregon field school along the southern Oregon coast in cooperation with the Coquille Tribe and Oregon State Parks, we conducted a pedestrian survey of Bullard's Beach State Park. During systematic survey across the southern portion of the park, we relocated known prehistoric sites, identified and mapped several new ones, and assessed site condition for each. Because the last major survey had taken place more than 20 years ago, this was an opportunity to examine how these sites may have changed over time as a result of various natural processes and human activities. Our results, garnered from a combination of ground survey, site record comparisons, and satellite imagery dating back to 1994, revealed that many of these coastal sites are actively succumbing to erosion from wind, rain, and tidal action. In addition, we identified cases of looting that have caused damage to subsurface deposits. Future research will focus on investigating a number of sites in the park to determine the time frame of native occupation, maritime and subsistence adaptations through time, the degree to which these sites are under threat, and how adverse effects might be mitigated to ensure their long-term protection.

[342] **Colorful Material Connections: Noninvasive Analyses of Mesoamerican Pictorial Manuscripts and Their Cultural-Historical Implications**

Noninvasive scientific analyses recently performed by the "MOLAB" mobile laboratory on a number of prehispanic and early colonial pictorial manuscripts provided a host of new data that deepen our knowledge of Mesoamerican coloring materials and painting practices. The huge corpus of available analytical data—obtained from codices Madrid, Cospi, Borgia, Vatican B, Laud, Fejérváry-Mayer, Nuttall, Bodley, Selden, Selden Roll, Tudela, Vatican A, and Mendoza—allows the first cultural-historical interpretative effort aimed at identifying different technological traditions and at evaluating how they match with established stylistic and thematic classifications, as well as their relations with other coloring traditions such as mural painting or textile dyeing. The comparison of manuscripts from different regions and epochs also provides interesting hints on topics such as cross-cultural interactions among prehispanic Mesoamerican painters/scribes, the emic perception of the materiality of color, and the technological changes introduced in early colonial times.

Los instrumentos musicales de la Estructura II y III de Calakmul, Campeche: Caracterización fisicoquímica e interpretación cultural

Estudios recientes derivados de la caracterización de instrumentos musicales de Calakmul, Campeche, México, procedentes de las Estructuras II y III, han revelado importante información respecto a la relación que mantuvo Calakmul con ciertas tradiciones, más que alfareras desde el punto de vista estilístico con otras entidades políticas mayas. Es visible la presencia, en algunos instrumentos musicales, de rasgos y atributos procedentes de otras regiones mayas que nos hacen pensar en el indudable vínculo que Calakmul mantuvo con diversos sitios a través de relaciones políticas y diplomáticas, principalmente para el Clásico Tardío y Terminal. Un mapeo de estas tradiciones de los instrumentos musicales solo es posible a través de la caracterización fisicoquímica de los mismos, mediante diferentes técnicas analíticas como la difracción de rayos X, fluorescencia de rayos X y FITR.

Domínguez, Nancy (Dirección de Registro Público de Monumentos y Zonas Arqueológicos e Históricos)

The Importance of Updating Information: The “Proyecto de Actualización y Digitalización de las Cédulas del Registro Público”

In 2010 the “Sistema Único de Registro de Monumentos y Zonas Arqueológicos e Históricos” was developed to face the need of having a modern and strong technological support capable to cover the legal, academic and institutional aspects that the Public Registry required as a fundamental area of the Institution. It has the duty to guarantee information for query and monitoring activities about federal and particular monuments involved in the system. Due to the vast universe of information which have been gathered by INAH from its foundation in 1939, to our days, and after the Federal Supreme Audit, the government seeks to incorporate the accumulated data of movable goods to “Sistema Único de Registro Público de Monumentos y Zonas Arqueológicos e Históricos” before its creation with the purpose of standardizing all records, updating the information, safekeeping and location, as well the verification of the collections. In this paper, I’ll present the guidelines, procedures and preliminary results of “Proyecto de Actualización y Digitalización de las Cédulas del Registro Público,” stressing the importance of this contribution in our workplace.

Integrating Lithic Microwear and Sourcing to Improve Understanding of Socioeconomic Behavior in the British Mesolithic

We present the results of an integrated study of lithic microwear analysis and lithic sourcing at the large Mesolithic site of Stainton West. Microwear analysis helped to understand why the site was so large and how the occupants supported themselves while at the site. Microwear analysis of 700 artifacts led to 49% identification of use. There is much diversity in tool use: hide working, butchery (meat/fish), impact, antler/bone working, wood working, and plant working. Various patterns were detected between tool use and tool technology. Many of the numerous microliths, showed impact damage, but are attributed to fishing rather than hunting. This conforms to the riverside location of the site on the River Eden. Hide working was primarily limited to dry hide, which supports the hypothesis that hunting was not the primary procurement activity and is also suggestive of a residential site, which is further supported by the diverse set of tools and wide range of activities represented. The sourcing study shows that raw material was procured from long distances in all directions. We conclude that the site was likely an aggregation site where many bands came together to exploit an abundant but temporary fish resource.

New Research and Understandings at the Royal City of the Liao Supreme Capital Site

The Liao Supreme Capital site is located in Lindong, Balinzuoqi, Inner Mongolia. It contains the Royal City in its north and the “Han” City in its south, with a total area of five squared km. To preserve and better understand the Supreme Capital’s layout and evolution, Team Two of the Chinese Academy of Social Sciences Institute of Archaeological Research joined with the Inner Mongolia Institute of Archaeological Research to form the Liao Supreme
Capital Archaeological Team, which conducted full coverage surveying, augering, and systematic excavations at the site from 2011–2015. The Team surveyed and augered a three square km area of the Royal City. Excavations were conducted on the Royal City’s wall and its east and west gates, on the Buddhist temple site on the Royal City’s western edge, on roads and their adjacent architecture in the southern part of the Royal City, on the Palace City’s wall and east and west gates, and on the Palace City Hall Number 1. These investigations at the Supreme Capital resulted in foundational information on Liao Dynasty capital city archaeology, raised the level of research on the Supreme Capital’s layout and evolution, and greatly promoted archaeological and historical research on Liao Dynasty capital cities.

[179] What Do We Talk About When We Talk About Precolonial Sites in Chontales, Central Nicaragua?  
The Proyecto Arqueológico Centro de Nicaragua (PACEN), directed by Alexander Geurds, has recently conducted archaeological research in Chontales, Central Nicaragua. The main focuses of the study include the identification of the different types of settlements, understanding site and mound morphologies, as well as redefining the regional pottery sequence. Therefore, the authors of this paper carried out a systematic full-coverage high intensity survey of a 52 km² area, a complete mapping of the 46 mounded sites found, as well as stratigraphic excavations to diachronically and synchronically interrelate the different settlements. In this paper, we discuss the various distinctive traits that conform precolonial sites in Central Nicaragua, looking at archaeological remains, environment, and geomorphology as inherently interconnected analytical elements. Settlements are discussed as an intertwined combination of specific soil types, hydrology and landscape features, as well as particular architectural features and material culture. The analysis of the different sets of combinations of all these characteristics, which conform the quintessential ontology of the sites, will shed light on how we can define prehispanic settlements in the research area.

[348] Pills and Potions at the Niagara Apothecary  
In 1964, pharmacist E. W. Field, closed his practice in Niagara-on-the-Lake due to ill health. This pharmacy had been in operation for a total of 156 years by 6 pharmacists, 5 of whom had been apprenticed to their predecessors. Reopened in 1971 as an authentic restoration of an 1866 pharmacy, the building is owned by the Ontario Heritage Trust and curated by the Ontario College of Pharmacists. Several archaeological investigations have taken place in the rear yard of the apothecary, most recently in 2016 with further work planned in 2017. The excavation of a large pit feature recovered hundreds of pharmaceutical bottles dating from the late 1800s to the early 1900s. This assemblage allows for discussion on the role of the pharmacist in a small community as well as allowing observations to be made regarding the community’s behavior and social needs with this service over time particularly in response to disease. The local apothecary was part of an old tradition, that of being a medical advisor and this site has a wealth of historical records and archaeological data to review developments in the context of broader topics of health, disease and medicine in small town Ontario.

[250] Remote Sensing at 45PO435, the South Flying Goose Site  
In the summer of 2014, during the course of National Register evaluation of 45PO435, a site on the Kalispel Indian Reservation along the Pend Oreille River in the mountains of eastern Washington, an isolated small burned structure was located by means of magnetometry and ground-penetrating radar. Its existence was confirmed by means of soil augering. Its dimensions were delineated by a combination of augering, excavation and electrical resistance. This paper discusses the contributions made by each of these techniques to create a stronger picture of the whole. Functionality, ethnobotany and geoarchaeology of the structure were explored by Molly Carney.
Dowkes, Shalcey (University of Calgary) and Margaret Patton (University of Calgary)

Do you have cultural properties? These themes are addressed from the standpoint of an anthropology of technology and a landscape archaeology approach.

The date of Madagascar's initial settlement has long been the subject of academic inquiry and debate. Archaeologists, historians, geneticists, linguists and paleoecologists interested in the history of Malagasy and Indian Ocean peoples, regional exchange, and environmental change have contributed diverse datasets and perspectives to this debate over Madagascar's colonization, but consensus on the timing of human arrival remains elusive. Despite its relative proximity to the African mainland, Madagascar was thought to have been settled around 1500 BP by iron-using agriculturalists from SE Asia. Recent excavations at one site in eastern Connecticut. Recent excavations at the several other sites in eastern Connecticut and southeastern Massachusetts by PAL yielded large assemblages of Narrow-stemmed points, some in association with radiocarbon dated features, permitting an opportunity to compare and reassess the artifact typologies, cultural chronologies, and models of social organization southeastern New England.

Marking the (Under) Ground: Civil War Soldier Graffiti in the Mammoth Cave Region of Kentucky

During the American Civil War, numerous Union and Confederate soldiers visited dozens of caves in the major karst areas of the border and Confederate states, often marking the subterraneous walls with graffiti. In the most important karst area of all, the Mammoth Cave region of Kentucky, caves were significant (and famous) features of the landscape, possession of which was bitterly contested, especially in the military campaigns of 1862. A preliminary study of extant historic graffiti at several Kentucky cave sites, including Dendro Cave, Mammoth Cave, and others shows that men in the Union and Confederate armies did not just visit caves throughout the region, but they also claimed the underground spaces with their graffiti as part of the struggle for physical and political control of Kentucky. Rival soldiers also had much in common; their cultural conceptions of caves were mostly the same, and many of them had been transformed as they left behind their civilian lives and embraced new identities as soldiers.

The Anthropocene of Madagascar: Reviewing Chronological Evidence for Madagascar's Colonization

The date of Madagascar's initial settlement has long been the subject of academic inquiry and debate. Archaeologists, historians, geneticists, linguists and paleoecologists interested in the history of Malagasy and Indian Ocean peoples, regional exchange, and environmental change have contributed diverse datasets and perspectives to this debate over Madagascar's colonization, but consensus on the timing of human arrival remains elusive. Despite its relative proximity to the African mainland, Madagascar was thought to have been settled around 1500 BP by iron-using agriculturalists from SE Asia. Recent archaeological findings, however, suggest that foraging groups reached the island by as early as ca. 4000 BP, if not earlier. Such early dates for Madagascar force us to reconsider models of the island's colonization, particularly in terms of the nature and rate of anthropogenic impact on its biotic communities. In this paper we review chronological evidence for the settlement of Madagascar, applying standards of chronometric hygiene that have been used to refine the settlement histories of islands in the Caribbean and Pacific. This review allows us to more productively compare the colonization of Madagascar to other island colonization scenarios around the world.

Traditional Native American Raw Material Sources in the Yellowstone Region

Obsidian and other lithic sources in the Yellowstone region of Wyoming and nearby Montana or Idaho were used up until contact with Euroamericans and information from oral traditions, ethnohistory, ethnarchaeology, and toponymy provide data on the significance of certain raw material choices made by Native Americans such as the local Shoshone. Why did chipped stone weapons and tools persist even after new metal technologies were introduced? How did the choices of raw materials signal Native resistance to colonizing and settlement challenges posed by newcomers to the region? In what ways did the lithic raw material sources contribute to the formation of a set of quarry landscapes with symbolic associations meaningful within a broader cosmological worldview or social milieu? Were extraction locales perceived to have their own sacred power, potentially becoming traditional cultural properties? These themes are addressed from the standpoint of an anthropology of technology and a landscape archaeology approach.

Microwear on Shell Beads at Cluny Fortified Village (EePf-1)

Beads in many forms have been used as decorative items on the Great Plains during the historic and prehistoric periods. Cluny Fortified Village (EePf-1), dating just prior to European contact, is an intrusive village unique on the Northwestern Plains. The unique artifact assemblage at the site offers information on the understudied topic of prehistoric shell bead production on the Northern Plains using local bivalves. During the past ten years, a number of shell beads, shell bead blanks, and waste materials have been recovered during excavation. Research elsewhere on bead production has suggested the use of drills to form the hole of the bead. However, at EePf-1 there are relatively few lithic drills despite the amount of shell beads uncovered. As shell is a relatively soft material, several materials are considered for use as drills including bone, wood, and lithic tools. Analysis of shell beads from the site indicates a variety of bead types and provides evidence connecting potential drill materials to bead production. Microwear analysis of
Downeys, Jane (University of the Highlands and Islands) and Ingrid Mainland (University of the Highlands and Islands) [124] *Coastal Erosion as an Arena for Change*

The decreasing archaeological heritage through loss and damage caused by rising sea levels and increased storminess requires responses that are multifaceted and creative. Sufficient resources to deal with exposed archaeological sites and deposits through established ‘preservation by record’ methodologies are not available anywhere. In the Scottish archipelago of Orkney the combination of sand and low lying shores and extremely rich archaeological heritage make the problems of coastal erosion particularly acute. Multi-period sites are cut through by erosion, revealing sections through buildings and middens representing “deep time,” as frequently 5,000 years of occupation are visible. This paper describes a multidisciplinary and participatory approach to developing an understanding of the coastal erosion of archaeological heritage within wider contexts of debate around climate change and sustainability. The potential of creative and educative “uses” of the eroding coastal archaeological resource, are seen as complementary to the sites’ value as “distributed observing networks of the past.” The application of this approach is discussed using case studies from Orkney, and from Rapa Nui.

Downey, Jordan, Oliver Hegge, Kari Lentz and Steven A. Wernke (Vanderbilt University) [75] *Photogrammetry All the Way Down: Multi-Scalar and Multiplatform Photogrammetry as Primary Spatial Registry in a Large Excavation Project*

In 2016, a large excavation project was carried out at the site of Mawuchu Llacta in the Colca Valley of southern Peru. A colonial reducción (planned town), Mawuchu Llacta is a large site with plazas, chapels, a parish, and domestic compounds. These spaces all consist of complex standing architecture in varying degrees of preservation. Eleven excavation blocks were opened to better understand ritual and everyday life in the town. The extent and distribution of the excavations, however, presented the significant challenge of how to document large-scale, multi-team excavations dispersed around the site. We present a photogrammetry-centered solution, focusing on an integrated workflow for multi-scalar and multi-platform photogrammetry, from UAS-based documentation of the whole site, to detailed recording of excavations. All excavation blocks were serially documented using photogrammetry to create high-precision 3D models of the entire process, starting from the surface and continuing all the way down through the end of excavations. These models were integrated with an RTK GNSS mapping system for plotting ground control points, individual contexts, and individual artifacts. In this paper we demonstrate our workflow with specific examples at each scale and distinct contexts. Finally, we offer suggestions for other archaeologists interested in implementing these methods.

Downey, Caitlin (Washington State University), Sydney Hanson (Washington State University), Molly Carney (Washington State University) and Jade d’Alpoim Guedes (Washington State University) [260] *Paleoethnobotany in Undergraduate Research*

I have spent the last year gaining laboratory experience in the Paleoethnobotany laboratory at Washington State University. My purpose in the lab was to aid two graduate students with their master’s thesis research. Thus far, I have learned the basics of paleoethnobotanical analysis through examining material from both the Old World (Thailand) and the New World (the Pacific Northwest). These basics include how to identify different types of seed and wood charcoal, how to properly organize and label samples, and how to properly enter data for later quantification. Here, I propose how I will apply these skills to my future research. Additionally, I will discuss the importance of undergraduate research and laboratory experience in archaeology.

Downey, Nathan (University of Chicago), Alan Farahani (Cotsen Institute of Archaeology, UCLA) and Stephen Acabado (Department of Anthropology, UCLA) [229] *An Examination of Anthropogenic Burning in Old Kiyyangan Village, Ifugao*

The rapid expansion of the Old Kiyyangan Village (OKV) in Ifugao, Philippines was accompanied by population increase and a shift in crop production—from taro to wet-rice. Archaeological excavations at OKV have also uncovered larger-than-expected quantities of wood charcoal that likely represent burning episodes associated with this shift. Preliminary analysis of the distribution of wood charcoal indicates that specific locations within the OKV were for anthropogenic burning practices. Moreover, initial taxonomic identification of the charcoal includes one member of the Cordillera Pine species (Pinus kesiya Royle ex Gordon), possibly used as kindling. Currently, the forests surrounding the OKV do not sustain large populations of P. kesiya. Through the careful integration of ethnohistoric evidence of tree cutting and burning practices in Ifugao alongside the examination of charcoal recovered from OKV, this paper investigates the historical anthropogenic burning practices of the Ifugao and provides preliminary results from the paleoethnobotanical investigation of the OKV. Finally, the paper also illustrates how seemingly “inaccessible” or “remote” kinds of archaeological data such as wood charcoal can be used to illustrate cultural practices that have meaning both in the past and present.

Downey, Sean and Randy Haas (University of Wyoming) [227] *Early Warning Signals of Demographic Collapse Detected in a Meta-Database of European Neolithic Radiocarbon Dates*

This study uses statistical tests known as “early warning signals” (EWS) to determine whether declining socio-ecological resilience presaged a pattern of collapse during the Early Neolithic Period in Europe. Our earlier research has shown with a high degree of certainty that radiocarbon-inferred human societies began to recover from perturbation more slowly as resilience declined. We use simulation to validate our methods and show that sampling biases, atmospheric effects, radiocarbon calibration error, and taphonomic processes are unlikely to explain the observed EWS patterns. While EWS have been detected in biology and ecology, to our knowledge, this study is the first to find early warning signals of demographic regime shift among human populations.

Downs, Lauren (AECOM), Sandra Pentney (Atkins), Marla Mealey (California State Parks), Nicole Turner (California State Parks) and Natalie Brodie (LSA Associates) [300] *Climate Change Risk Assessment of Coastal Archaeological Resources in San Diego County*

Climate change poses threats to both inland and coastal archaeological resources alike. Sites along the coast of San Diego County are under various threats such as inundation and erosion due to sea level rise. For over two years, the Society for California Archaeology (SCA) and the San Diego County Archaeological Society (SDCAS) have been directing the Climate Change Project to assess the effects of climate change on San Diego County resources. This study utilizes GIS analysis to examine coastal sites recorded by the Climate Change Project and compares those data with elevation and erosion models to create a risk map of the San Diego coastline. This map can then be used by agencies such as California State Parks when deciding where to concentrate preservation efforts.

Vision and Action: Suzanne Fish and Paul Fish and the Hohokam World

Throughout their careers, Paul Fish and Suzanne Fish cast a wide net in their studies of the American Southwest, and the Hohokam region of southern Arizona in particular. This powerhouse duo vigorously applied their intellectual breadth and energy throughout their long productive careers to ferret out the complexities of the ancient past. Their team approach and complementary skill sets include regional archaeology; method and theory; settlement structure and social organization; field survey and excavation; ethnography; analysis; synthesis; and more, coupled with an enviable publication record. Then there are their lifetimes of teaching, directing field schools, and their many students. They had great vision and problem solving skills, and they knew how to translate their vision into action. Their work has left a permanent mark on how we study the Hohokam. And, of course, they aren't done yet. This paper provides an overview of their productive careers with a focus on the Hohokam region of the Southwest.

Chemostatigraphic Analysis of Alluvial Sediments in Chaco Canyon, New Mexico

Complex societies are generally dependent on agrarian economies whose success is contingent on water and nutrient availability. For Chaco Canyon, an Ancestral Pueblo cultural center in northwestern New Mexico with monumental construction dating from the ninth to twelfth centuries AD, the role of local agriculture has been of particular interest. Here, data are presented from three summers of fieldwork using X-ray fluorescence to identify the geochemical composition of sediments, with a focus on those elements relevant to agriculture (Potassium, Phosphorous, and Sulfur), indicators that can indicate evaporation as a proxy for hydrology (Calcium/Strontium ratio), and indicators of changing sedimentation sources (Titanium, Rubidium). Data was collected nondestructively along multiple exposed sections of the arroyo in 2–5 cm increments, allowing for a time series analysis to show changing patterns in all of the aforementioned elements during sediment deposition in the canyon.

Scarred Ponderosas, Rock Art, and Other Traces of Ute History: New Evidence from the Rio Grande Del Norte National Monument

This poster reports on an archaeological survey in the Rio Grande Del Norte National Monument that has revealed important new evidence of the Ute and other hunter-gatherers dating to the late precolonial and early colonial periods. Of particular interest are a series of culturally modified Ponderosa pine trees, which are likely linked to Ute foodways employed during period of starvation or want. I examine these culturally modified trees as artifacts on the landscape within the context of the wider archaeological evidence in the survey. This evidence includes an especially notable concentration of rock art that contributes to the understanding of Ute iconography in the region, as well as other traces of hunter-gatherer life.

Ceramic Production for Castillo de Huarmey, Peru: Multiple Productions and Buzzing Potters

The paste analysis of the ceramics found in the Castillo de Huarmey, a Middle Horizon Wari political center on the north coast of Peru brought forth the existence of a variety of production areas and a panorama of multiple producers with different agendas or practices. Much of the ceramics appear to have been made with material available in the Huarmey lower valley, coastal area, and probably the adjacent Culebras Valley. The fine painted Wari ceramics and fine reduced impressed wares present a degree of manufacture denoting care in material selection, granulometry control and firing, with homogeneity in paste composition and technology. Mold impressed wares were more rapidly made, with variability in material provenance, composition and sorting. Communities of potters sharing the same technological tradition (and types of molds) must have been working close to the coast and in the lower to mid-valley. Upper valley producers probably contributed much less if at all to the distribution network feeding the Huarmey community.

Dudgeon, John (Idaho State University—CAMAS) [123] Molecular Taphonomy of Biominerals in the Western Pacific
Molecular and microarchaeological artifacts of human subsistence are recorded in the bones, tissues and residues of the skeleton. These artifacts provide substantial correlative evidence for macroscopic and sedimentary data of dietary plant and animal use in the archaeological record. Within the depositional context however, many factors in the local environment disturb or degrade these signatures, reducing or eliminating their usefulness in diet reconstruction. The islands of the tropical Western Pacific produce local environmental conditions that can be particularly disruptive to biogenic signatures, and methods to assess diagenetic alteration are prudent, given the destructive and costly nature of these analyses. Here, we present data collected using ATR-FTIR on Western Pacific specimens submitted for dietary and molecular analysis, and compare our indices of preservation with local environments, chronologies, and dietary and molecular data survival. This is used to create a fine-scale inferential model for assessing the likelihood of extracting dietary data in these environments.

Dudley, Meghan (University of Oklahoma) [394] “Come Together, Right Now”: The Oklahoma Public Archaeology Network and Its Role in Oklahoma Public Archaeology
Like many other states, Oklahoma has a long history of productive public archaeology, with citizen and professional stakeholders working side-by-side to further archaeological research and preservation. However, the changing nature of archaeology (most particularly the shift to a heavy emphasis on compliance work) has led to miscommunication and misunderstanding among the many stakeholders in Oklahoma's archaeological community and to less-productive working relationship among them than existed several decades ago. Yet opportunities for citizen-archaeologist collaboration still abound, and with this in mind we founded the Oklahoma Public Archaeology Network (OKPAN). OKPAN facilitates dialogue among stakeholders and creates new opportunities for Oklahoma citizens, including members of the state’s many indigenous nations and avocational archaeologists to engage together in the study and stewardship of the past. In its first year, OKPAN sponsored several major statewide initiatives, the goals and results of which we discuss in our presentation.

Duelks, Jonathan (University of British Columbia), Jacob Jones (University of British Columbia), Steve Mozarowski (University of Toronto), John Maxwell (Ethos Archaeology) and Bryn Letham (University of British Columbia) [49] A Post-Glacial Relative Sea Level Curve and Paleoshoreline Archaeological Survey for the Prince Rupert Harbour, BC, Canada
We present a relative sea level (RSL) curve for the Prince Rupert Harbour area for the last 15,000 years that is based on nearly 150 radiocarbon-dated data points. RSL dropped from at least 50 masl to several m below current sea level immediately after deglaciation, before rising again to 4–6 m asl during the early Holocene. By 6,000 years ago RSL had approached its current position, though there have been some late Holocene fluctuations. We used this RSL history in conjunction with lidar-derived bare earth models to design and conduct an archaeological survey that targeted ideal landforms on paleoshorelines associated with the early Holocene high stand. We report on several archaeological sites that we found during this survey that date between 6500 and 9500 cal. BP, the oldest archaeological material currently recorded in the Prince Rupert Harbour. In addition, we highlight some other aspects of paleoenvironmental reconstruction for the region based on analyses of diatoms, charcoal, and other sediment characteristics in lake cores. Our research demonstrates the utility of a detailed understanding of RSL history and high resolution lidar digital elevation models for designing predictive models for surveying for early Holocene archaeological sites on coastal landscapes.

Dueppen, Stephen (University of Oregon) and Daphne Gallagher (University of Oregon) [161] Remodel, Rebuild, or Abandon? Changing Uses of Space in an Early West African Village
Ancient villages in western Burkina Faso were long-lived communities, temporally rooted in deep social histories experienced in the built environment and local geography. The site of Kirikongo, continuously inhabited from ca. 100 CE to 1700 CE, and composed of 13 separate tells (mounds), exemplifies these spatio-temporal dynamics, as over time the economic and social characters of tells, and their spatial positioning and characteristics changed dramatically despite maintenance of certain spatial and temporal referents. In this paper, we discuss how historical dialogues with space, place and materials shaped different phases in the site’s occupation. These relations and referents are at the core of changing identities from individuals to house and community. We explore how events and processes were significantly shaped by prior spatial and material choices as certain spaces maintained significant continuity for social roles, while others reflect the rejection of certain histories, through either abandonment and decay or through an active construction atop and physical alteration of the former space.

Duff, Andrew (Washington State University), Judith Habicht-Mauche (University of California, Santa Cruz) and Rob Franks (University of California, Santa Cruz) [155] Glaze-Paint Pigmenting Strategies in the Upper Little Colorado and Western Zuni Regions of the American Southwest
LA-ICP-MS is used to examine glaze-paint pigmenting strategies during the Pueblo IV period in the Upper Little Colorado and Western Zuni Regions of the American Southwest. These data are integrated with INAA sourcing information and compared to glaze-paint strategies from other areas of the late precontact Southwest to define cross-cutting technological communities of practice and to trace the circulation of ideas, production techniques, raw materials and finished objects through networks of social interaction and shared practices at village, intraregional and interregional scales. These results contribute to the increasingly macro-regional exploration of how social networks facilitated the exchange of technical information, fostered migration, and served as arenas of social reproduction that transformed late precontact period social groups in the American Southwest.

Duffield, Seonaid (University of Victoria), Duncan McLaren (University of Victoria) and Iain McKechnie (University of Victoria) [49] Archaeological and Architectural Considerations of Intertidal Shellfish Use and Deposition on Hecate Island, Central Coast of British Columbia
Detailed tracking of the chronology and spatial extent of shell middens on the Northwest Coast is a challenging and often expensive proposition given the size and time depth often represented at these sites. The Hakai Ancient Landscapes Archaeology Project (HALAP) used vibracore technology to efficiently sample intact 7 cm diameter stratigraphic profiles from multiple 4–6 m deep shell midden deposits at site EjTa-13 on Hecate Island. A series of radiocarbon dates from the initial core documents a continuum of site occupation ranging from 5000 to 1200 years cal BP. Faunal remains and artifacts from subsequent samples provide highly resolved records of coastal resource use, including the use of shell for personal adornment. Significantly, the purposeful terrafoming of massive amounts of shell likely harvested from the broad intertidal zone fronting the site provides an engineered and well-drained foundation for the site. A major feature of this site is that the shoreward portion appears to have been eroded considerably from its former extent indicating that when occupied, the site physically expanded the terrestrial shoreline above high tide mark.

Duffy, Paul R. (University of Toronto) [196]  
*Gone to Pot: Stylistic Breaks in a Radiocarbon-Based Ceramic Chronology for the Eastern Hungarian Bronze Age*  
The Great Hungarian Plain is densely populated with fortified tell sites dating to the second millennium BC. At the end of the Middle Bronze Age (c. 1400 BC), however, these settlements were abandoned. Traditionally, archaeologists argued that locals were run off by invading Tumulus culture groups or suffered an environmental disaster. The lack of non-tell contexts and radiocarbon dates bridging this transition precluded an understanding of what changed after the tells were abandoned, and what marked the beginning of the Late Bronze Age. We address this discontinuity with a recently well-dated cremation urn cemetery in the eastern Great Hungarian Plain bridging the three traditional sub-phases of the Bronze Age (Early, Middle and Late). We use changes and continuities in ceramic form and style to measure points of continuity and discontinuity in the material culture during the use life of the cemetery. We provide evidence that although ceramic style changes do occur during the Bronze Age, the overall pattern is one of continuity rather than regional abandonment, with use of the cemetery continuing after 1400 BC when the tell sites go into disuse.

*Geographic Origin of Sacrificed Camelds at Huanchaquito (Chimú Period, Northern Coast of Peru): Insight from Stable Isotopic Analysis*  
Excavations at the Chimú site of Huanchaquito located in the Moche Valley (northern coast of Peru) led to the discovery of an exceptional sacrificial deposit of more than 200 domestic camelid skeletons. This finding adds to the many testimonies of the presence of camelds on the Peruvian coast during the prehispanic era. The abundant presence of animals suggests—but does not bring definitive evidence—that breeding took place locally in an unfavorable arid environment. Measurements of stable isotopes of carbon, nitrogen and oxygen and radiogenic isotopes of strontium in archaeological remains are a primary source of information on the life history of past humans and animals. Isotopic analysis was used to address the question of the geographic origin and movements of Huanchaquito animals among the different ecological zones of the Andes. Both organic tissues (bone collagen and hair) and hard tissues (bone apatite and enamel) are well preserved at Huanchaquito. The combined isotopic analysis of these tissues allow for the reconstruction of a diachronic life history of camelds. Comparison with isotopic data for other cultures and valleys supports the existence herding practices specific to prehispanic times in northern Peru.

*Exploring the Limits of the Island Anthropocene: the Norse Colonization of Greenland in an Atlantic Context*  
The medieval Norse colonization of Greenland was unique, but we can use this completed experiment to explore key drivers of, and limits to, the “island Anthropocene.” The indigenous biota of Greenland while sensitive, lacks the fragility of small, isolated low latitude oceanic islands rich in endemic species. The timing of Norse settlement was determined by the patterns and process of island colonization to the east combined with a suitable environmental and economic window of opportunity. The timing and scale of settlement was contingent- and the consequences were different to previous Norse island colonizations to the east. In Greenland Norse settlement was limited to pockets of the west coast where the settlers either lacked the numbers or the means to impose rapid or lasting environmental transformations—or they were inhibited by their approach to environmental management. Much of the Norse impact on Greenland was transitory as species they introduced were dependent on people and disappeared with them. Key drivers of exploration, colonization and settlement were honor and prestige, and the ways of achieving this through control of land or trade items; environment and distance strongly mediated the process, with transitions to alternate states strongly determined by the numbers of people.

*Economic Intensification and Social Differentiation: A View from the Late Woodland Southeast*  
Intensification has long been equated with the rise of tightly-controlled economies, often in association with incipient social inequality. Previous research has sometimes suggested that centralization control is necessary both for the development of intensification as a viable economic strategy, and for the management of its repercussions. Here, we present evidence from Kolomoki, Crystal River, and Roberts Island, three prominent Late Woodland (ca. AD 500–1000) mound centers of the American Southeast, to demonstrate that economic intensification existed on a broad scale, and grew out of the social practices of communities lacking apparent social hierarchy. Specifically, we evaluate these phenomena by comparing trends between inland domestic economies and coastal subsistence economies. Our evidence suggests that different social groups within some Late Woodland communities were associated with intensification of particular resources. In our view, these trends highlight striking similarities in the development of economic and social differentiation during this period across a broad swath of the Southeast.

Pearsall (University of Missouri-Columbia) [180] Causes and Consequences of Colonization in the Caribbean: What Is Known and What Is Unknowable

One of the defining characteristics of humans is our propensity to migrate. However, the push or pull factors resulting in human migrations may be impossible to know in some cases. Furthermore, our sole reliance on the archaeological record may mislead our understanding of the timing and impact of migrations. Recognizing migrations in the archaeological past is made especially difficult in cases where migrating groups were small, leaving ephemeral traces of their occupations. Paleoenvironmental indicators provide clues to human activities that may predate known archaeological material remains. This paper will explore the interplay of cultural, social, and environmental causes for migrations into the Caribbean beginning at least 8,000 years ago and the environmental consequences of human occupation in the region.

Dungan, Katherine (Archaeology Southwest), Sylviane Déderix (School of Anthropology, University of Arizona), Barbara Mills (School of Anthropology, University of Arizona), Kristin Safi (Oak Ridge National Laboratory) and Devin White (Oak Ridge National Laboratory) [130] Local Visibility and Monumentality in the Chaco World: A Total Viewshed Approach

Chacoan great houses are considered “monumental,” in the sense both of scale and of conveying meaning. Throughout the Chaco World, great houses and other large-scale buildings would have been associated to some degree with a larger, regional Chacoan ideology. At the same time, these structures vary and should be understood in the context of diverse local and regional histories. Visibility can be a key component of monumentality, and it has been suggested that great houses were frequently placed to be highly visible. We use “total viewsheds”—cumulative viewsheds generated using regularly spaced points across a complete study area—to examine the degree to which Chacoan buildings were positioned to maximize these structures’ visibility within their local landscapes, which required leveraging advanced GIScience algorithms and techniques, as well as substantial supercomputing resources normally unavailable to archaeologists. The data aggregated by the Chaco Social Networks Project facilitate temporal and regional comparisons of visibility between AD 800 and 1200 across a sample of approximately 300 Chacoan buildings. The results of previous social network analyses allow us to consider the visibility choices made by the builders of Chacoan structures in light of the dynamics of intra- and intercommunity spatial and social organization.

Dunn, Stacy (Edinboro University Department of Criminal Justice, Anthropology, & Forensic Studies) [359] Adolf Bandelier’s 1892–1894 Expedition to the Central Coast of Peru

Adolf Francis Alphonse Bandelier (1840–1914) was an ethnologist and archaeologist best known for his work in the American Southwest. What is less well-known is Bandelier’s later years studying the ancient Andes, such as his 1892–1894 expedition on the central coast of Peru. Due to an unstable political environment, he moved his expedition to the Bolivian highlands and instead wrote about highland myths. Shortly thereafter, he passed away while pursuing historical sources in Seville, Spain to supplement his South America research. As part of the late nineteenth century shift toward an emphasis on material culture as a more truthful witness to the human past than the written word, Bandelier emphasized combining geographical, ethnological, and archaeological data to provide a more comprehensive portrayal of ancient societies. Unfortunately, Bandelier never had the opportunity to fully analyze or publish his work in central coast Peru. However, approximately 90 cases of items, including journals, watercolor maps, and photos, from his 1892–1894 expedition reside in the collections of the American Museum of Natural History in New York. This paper presents the details of Bandelier’s life and work from this period based on these archival materials, along with some preliminary examination of the materials he recovered.

Dunnivant, Justin (University of Florida) [203] In Search of King Tona’s Palace: The Politics of Archaeology and Memory in Southern Ethiopia

In 1896 Emperor Menelik II of Abyssinia engaged in one of the bloodiest battles of his military campaigns, attempting to unseat King Tona of Wolaita. After two weeks of fighting, King Tona was captured and the royal court devastated. The last palace of the Wolaita Kingdom stood in Dalbo just 10 km northeast of the current city of Soddo. While the general location of King Tona’s palace is known, contesting narratives situate the exact location at different sites. This paper reports on findings from a 2016 survey and excavations at Dalbo in search of the palace of King Tona. Although the excavations revealed evidence of a stone foundation and wooden structure, the materials are unlikely associated with the famed palace of the Wolaita King. Instead, analyses of the ceramic and lithic material allude to a long occupation history at the site that may stretch back as far as the Middle Stone Age. These findings provide insight into the development of complex societies in southern Ethiopia and, interestingly, unearth key contentions of memory and forgetting within contemporary Wolaita social politics.

Dunning, Nicholas (University of Cincinnati), Armando Anaya Hernández (Universidad Autónoma de Campeche), Christopher Carr (University of Cincinnati), Deborah Walker (Florida Museum of Natural History) and Helga Geovannini Acuaña (Universidad Autónoma de Campeche) [337] Preclassic Reservoirs and Urbanism at Yaxnohcah, Campeche, Mexico

The need to collect and store rain water has been proposed as an important urbanizing force during the development of Maya civilization in the Elevated Interior Region on the Maya Lowlands, where surface water is naturally scarce and the dry season lengthy. We present data from Yaxnohcah, Campeche, Mexico indicating that the construction of large reservoirs was an integral part of the development of this urban center in the Middle and Late Preclassic periods. Data collected to date indicate that the water management system at Yaxnohcah became more sophisticated over time. Investigations are ongoing and seek to further document this early, complex water management system.

Dupuy, Paula (Nazarbayev University)

This presentation focuses on analytical techniques for evaluating cloth and fiber characteristics imprinted on ceramic vessels, and how reconstructing textile industries contribute a social reading of Eurasian prehistory. Inner Asian Bronze Age pastoralists of the third—first millennium BC employed textiles to mold clay vessels as shown through woven fiber impressions coating the insides of containers. Although this production technique has preserved an otherwise marginally documented industry of early pastoralists, it has been methodologically challenging to accurately measure the morphological and structural features of cloth examples. The challenge not only stems from the lack of preserved textiles for comparative purposes but also from the rough surface texture of coarsewares that mask diagnostic features of fibers and weaves when viewed at close range. This paper outlines positive results from trials using high-resolution digital technology to examine textile features preserved in Bronze Age pottery from pastoral campsites of southeastern Kazakhstan. Findings suggest weaves and fiber processing were non-uniform across campsites and ecological micro-regions. Most significantly, the cross-use of textiles and clay in craft production demonstrate complex institutional ties and spheres of interaction among prehistoric pastoralists of central Eurasia that yield a new pattern for social exchange in this region.

[303] Research Analysis of Toolstone Procurement Patterns in the Gila Forks Region and Beyond

Lithic data from Twin Pines Pueblo in the Gila Forks region of New Mexico can shed new light on toolstone procurement strategies in the American Southwest. The goal of this research is to track the economic strategies among the Mimbres people by investigating stone-tool raw material distributions and procurement strategies. I begin by defining local, semi-local, and nonlocal lithic materials in the Gila Forks region. Then, I investigate how groups in this region procured and used different raw materials using both mass and metric analyses. These analyses allow us to understand general and particular patterns of raw material distributions and lithic reduction processes. For local and semi-local materials, I address the following points: 1) what types of tools were manufactured using particular raw materials, and 2) did residents at Twin Pines manufacture stone tools at the site or areas away from the habitation area? For nonlocal materials, I use X-ray fluorescence (XRF) analysis for obsidian tools and their debris. This analysis addresses issues of procurement from local obsidian quarries. My analysis ends with a discussion of local and regional interaction within the landscape, possible settlement patterns associated with procurement strategies, and toolstone variables between local and regional raw material sources.

Dussol, Lydie (University Paris 1 Panthéon-Sorbonne)

[174] Ritual Fires and Ancient Maya Termination Deposits at Naachtun (Guatemala): An Archaeobotanical Perspective

Termination rituals have been a well-documented practice among ancient Maya societies. Generally including the spread of broken artifacts on floors, the manipulation of ancestor bones, and the intentional destruction of architectural structures, termination deposits are believed to have served to symbolically “kill” a building at the time of its abandonment. Regardless of the nature or function of these different deposits, their frequent association with ashes, charcoal and burn marks clearly attests that fire was a central element in the ritual practices they originate from. Fire must have been necessary to burn incense, as it is the case in modern societies. But the complexity and the variability observed in the composition termination deposits encourage to consider that fires associated with them were also intentionally composed, implying a more complex relation to the vegetal world as materialized by wood and plants. This paper presents an archaeobotanical study of termination deposits dated from the Terminal Classic period (AD 830–1000) at Naachtun (Northern Petén, Guatemala), which aimed to better characterize their formation process and sociocultural significance.

Dussubieux, Laure (Field Museum of Natural History), Mark Hill (Ball State University) and Gregory Lattanzi (New Jersey State Museum)

Ideally, data produced by different laboratories performing the same type of analysis should be comparable. Comparability is important for exchanging data and the building of large databases in particular areas of research. Recently, the sourcing of North American copper using laser ablation—inductively coupled plasma—mass spectrometry (LA-ICP-MS) has developed significantly, prompting questions about the compatibility of the different published datasets. Several parameters affect the compositions obtained with LA-ICP-MS. The selection of external standards is used with LA-ICP-MS to convert the raw counts for each element in concentrations expressed in ppm or w%. Ideally external standards have a composition as close as possible to that of the analyzed object. Available standard reference materials are purer than archaeological artifacts and a combination of several of them is often selected to be able to quantify all the elements of interest. LA-ICP-MS laboratories use different sets of standard reference materials based on their experience, budget, and availability. This paper will compare three sets of copper standard reference materials that are used routinely to measure the composition of North American copper artifacts. It will assess how they affect the concentration measurements in those samples.

[34] An Archaeology of Becoming
From the emergence into this world to the settling of the modern villages, the Pueblos view their own history as a dynamic, living process. While key elements of Pueblo identity and worldview have always been with the people, migration experiences and the amalgamation of people with diverse backgrounds and beliefs were essential in shaping the culture and cosmology of each Pueblo group. This process—called “becoming” by Pueblo scholars—is never complete and represents the malleability of the Pueblo people and their ideas, as well as cultural continuity and resilience of their beliefs, in the past, present, and future. In this paper we propose developing an archaeology of becoming that captures the fluid and ever-moving character of Pueblo history as a nexus of identity, memory, and values, and use examples from the Keres and Tewa worlds to frame our discussion.

Dye, Thomas (T. S. Dye & Colleagues) and Timothy Rieth (International Archaeological Research Institute, I) [81]  
Archaeologists sometimes claim that the refined chronological models generated by Bayesian calibration make it possible to distinguish between prehistoric and historic periods. Historians of Hawai‘i leave little doubt that Hawai‘i was a “hot” society in the early historic period. A review and comparison of chronologies for the tempo of change in precontact Hawai‘i distinguishes the “cold” society reconstituted by ad hoc methods from the “hot” society reconstituted by the Bayesian method. We make two claims: 1) the ad-hoc chronologies from Hawai‘i are incongruous with the historical record, and 2) Bayesian chronologies provide context and time-depth for the “hot” Hawaiian society described by historians.

Dye, David (University of Memphis), Keith Jacobi (University of Alabama) and William DeVore (University of Alabama) [185]  
Violence in the daily lives of individuals in late prehistoric eastern North America took many forms. Exposure to violence was pervasive and persistent. A vast array of tools and weapons exist that can produce blunt force injury, complicating identification of individual weapons associated with archaeological cranial injuries. This paper presents a new application of an experimental skin-skull-brain model, which facilitates the testing of prehistoric weapons and inform current understanding of the context of violence and social interactions in small-scale societies. Determining the direct mechanism of cranial blunt force trauma in prehistoric cultures is currently a complex issue. This methodology is low cost, meets ethical standards and has improved accuracy over current animal analogues. The test results form a catalogue of fracture patterns that can aid identification of the mechanism of prehistoric trauma and facilitate the analysis of social implications of violence in small-scale societies.

Dyer, Meaghan (University of Edinburgh) [92]  
Experimental bioarchaeology can aid identification of prehistoric weapons and inform current understanding of the context of violence and social interactions in small-scale societies. Determining the direct mechanism of cranial blunt force trauma in prehistoric cultures is currently a complex issue. This methodology is low cost, meets ethical standards and has improved accuracy over current animal analogues. The test results form a catalogue of fracture patterns that can aid identification of the mechanism of prehistoric trauma and facilitate the analysis of social implications of violence in small-scale societies.

Captive Bodies, Captive Power: Reexamining the Role of the Captive in Ancient Maya Art
Stripped, humiliated, and often sacrificed, the captive in ancient Maya art acted as a potent symbol of defeat. Captives are a central theme of Maya art, appearing on media from painted vases to carved stone monuments. However, discussions of ancient Maya captives often focus on their captors: rulers, usually depicted as conquering warriors. “Captive Bodies, Captive Power” investigates, instead, the captives themselves. Treating the captive body as a
cultural project that both modeled and reflected the embodied experiences of ancient people, I argue that depictions of captives performed ideas about
world order and constructed specific social identities. Combining fieldwork in Chiapas, Mexico, with archaeological data and a broad survey of captive
imagery across multiple media, the paper begins by reexamining the identification of captives in Maya art. Focusing on the carved stone captives of
Tonina, the paper then explores the experience of captives, both actual and implied; and the role of the captive in establishing rhetorical relationships
between the powerful and the disempowered. Moving beyond traditional studies of kings and nobles, this paper clarifies the identification and
significance of captives in Maya art, revealing the power of the captive body to shape the ancient Maya world.

Earley-Spadoni, Tiffany (University of Central Florida)

Digital History and Digital Storytelling: The Future of Geospatial Technologies in the Study of the Past

Geospatial technologies are revolutionizing the practice of the Digital Humanities, and these developments have direct relevance to the practice of
archaeology. The most recent “spatial turn” among digital humanists can be attributed to the emergence of tools like ArcGIS that facilitate such
investigations as well as an interdisciplinary convergence upon theoretical models that conceive of socially-constructed space. This paper will briefly
review the current state-of-the-art in the sub-field of Spatial History as well as discuss a number of its emerging trends such as Deep Mapping, Digital
Storytelling and Data Visualization, utilizing examples from the Vayots Dzor field project in Armenia. This paper will argue that archaeologists have much
to gain from interdisciplinary engagement with the digital humanities.

Earnshaw, Jacob

Cultural Forests in Cross Section: The Exposure and Destruction of CMT Chronologies on Vancouver Island's West Coast Culturally Modified Trees (CMTs) are ubiquitous in British Columbia's old-growth forests, yet remain one of the most endangered archaeological site types due to industrial logging. The majority of CMTs are bark strip features with precise spatial, temporal, and harvesting pattern data that, when viewed on a landscape level, have great informative value related to forest use. However, CMT use in archaeological studies has been infrequent, small scale and largely confined to gray literature. Studies that do include CMTs have not accounted for the presence of invisible or "embedded" scars, which have fully healed over and cause unknown bias to samples. My research in Nuu-chah-nulth territory on Vancouver Island compares gray literature on CMTs taken from standing forests with data collected during surveys of stumps within expansive old-growth clearcuts. Logging activity has exposed the actual spatial extent and temporal reach of CMT archives in the landscape to be considerably different from what is recorded in Archaeological Impact Assessments. The wealth of data in cross-sectioned cultural forests may lead to greater insights regarding indigenous forest management and conservation strategies, local histories prior to and during the contact period, and greater old-growth protections.

Connestee and Pisgah Contexts in the Tuckaseegee Valley of Western North Carolina

This paper considers the stratigraphic evidence for Connestee series and Pisgah series components in the Tuckaseegee Valley of Western North
Carolina.

Easy, Samantha (University of Toronto)

Archaeology as Storytelling

The rise of open-source publications has increasingly made archaeological research available to wider audiences and yet the knowledge we as
archaeologists produce is not always freely accessible or available. It is fully understood within our discipline that archaeological sites have strong
connections to the past; that they are embodies spaces and irreparable sources of knowledge. However, this view of sites does not always extend to
the broader public or to communities with ties to those places. In the course of my research on the Mid to Late Stone Age, I have often encountered
disparities between the way I value sites or artifacts and the ways in which they are seen by community members or developers. The potential for
archaeology to be active in shaping social order lies in the way we imagine the connection between ourselves and the past, and in how reconstructions
of the past influence everyday action. I argue that storytelling is a form of transformative pedagogy which has the potential to foster engagement with
sites and artifacts, and to extend archaeological knowledge beyond academic institutions by establishing connections between sites and living
communities and providing the space for people to engage with the past.

Landscape Modification and Social Change as Resistance among the Ifugao on the Borderlands of Spanish Philippines

Dominant historical narratives suggest that groups located on the periphery of colonial empires and states received minimal influence from the latter.
However, recent studies that focused on borderlands indicate substantial culture change and ecological manipulation that contributed to successful
resistance against conquest. The Ifugao Archaeological Project (IAP) investigated the colonial borderland of Spanish Philippines, focusing on the role of
the adoption of wet-rice cultivation and landscape manipulation as a means to resist conquest in Ifugao, northern Philippines. Our paper presents the
findings from the IAP as they illustrate how the Ifugao intensely remodeled their environment and social structure for both subsistence and deliberate resistance against the Spanish.

*On the Verge: A Pottery Analysis of the Northern Periphery of the Northern San Juan Region*

Beef Basin is a geographic area located roughly 30 miles northwest of the Abajo Mountains in southeastern Utah. Archaeologically, Beef Basin is within the Northern San Juan Region, which has seen much less research. This study. Most of this research has focused on the area south of the Abajo Mountains, however, leaving the northern areas, including Beef Basin, only marginally studied. I discuss the results of pottery analyses from the area and discuss recent reconnaissance survey conducted by the Bureau of Land Management. I also present a chronology for the area based on ceramic dating. From previous research we know that Pueblo I occupations in the study area were scant to nonexistent, but population increased dramatically in the subsequent Pueblo II and Pueblo III periods. I discuss the later occupations in the context of a hypothesized widespread northwestern migration in response to late Pueblo II period Chacoan system proliferation.

*Exploring the Keresan Bridge: Acoma Glaze Ware Pottery Production and Exchange in an Interregional Context*

In recent years, patterns of decorated pottery production and exchange, as revealed through mineralogical, chemical and isotopic characterization analyses, have been central to modeling the interregional dynamics of late precontact social networks in the American Southwest. However, the role of the Acoma region within these networks remains poorly studied and largely unknown. In particular, questions remain about the significance of the Acoma or Western Keres region as a potential "bridge" facilitating the transfer of people, materials, ideas and practices between the Western and Eastern Pueblos during the thirteenth and fourteenth centuries. By presenting results from petrographic, INAA, and lead isotope analyses from a small sample of Acoma glaze ware pottery, we begin to fill this critical gap. By comparing these data with comparable INAA and lead isotope datasets from both the Zuni and Albuquerque areas we attempt to develop a clearer picture of social interactions across this east-west corridor.

*Supply and Demand in the Neolithic Quarry Production of Northwest Europe*

What factors influenced non-agricultural production in prehistoric times? This has long been a topic of debate in prehistoric archaeology, because it relates the question of whether people in prehistoric societies had 'economic' motivations and what those might have been. The paper presents the first results of the NEOMINE project, which is analyzing the evidence for stone quarrying and flint-mining and the factors affecting consumption of their products by Neolithic early farming communities in Britain and North West Europe (c. 5300–2000 BC). The project's aim is to evaluate what economic factors, if any, had an influence on their scale and intensity, and in particular the extent to which the amount of material they produced varied over time in response to external demand. Using newly collected and newly updated radiocarbon data on the dating of Neolithic mines and quarries in the region we will test whether their periods of use correlate with periods of high population and therefore high demand in the area surrounding the mine, using summed radiocarbon probabilities as a population proxy, taking into account sampling variation and fluctuations in the calibration curve. We go on to explore how the results compare with the patterns evidenced ethnographically in New Guinea.

*Life History from Human Teeth Microstructure: Methods for the Analysis of Hydroxyapatite from Tooth Cementum*

Life-history events such as pregnancies, skeletal trauma, and renal disease can be estimated from growth layers of tooth cementum. Cementum is a mineralized tissue surrounding root of each human tooth consist of an inorganic calcium phosphate mineral approximated by hydroxyapatite (HA) and collagen. Several parameters have an influence on the calcium metabolism and result in a lack of available calcium at the mineralization front of tooth cementum. The year of occurrence of certain life-history events can be precisely dated by hypo-mineralized cementum growth layers. On the basis of comparative study of HA from teeth derived from living humans (clinical patients) and Mesolithic-Neolithic inhabitants of the Danube Gorges (Serbia) this paper demonstrates the archaeological potential of HA research. We applied three methods for HA composition analysis: 1) fluorescence microscopy in order to detect presence of HA in the samples; 2) SEM-EDX analyses for elemental mapping; and 3) TOF-SIMS technique which enables localization of HA and identification of different CaP phases. We argue that the minimum number of possible pregnancies in females and other life history events as well as the accurate age of those events may have been revealed for the first time by this study.

*Oneota Risk Management Strategies and Agricultural Practices*

By its nature, agriculture is a risky endeavor. Unsatisfactory conditions for innumerable environmental or social factors can shift harvests from a bumper crop to famine (e.g., drought, poorly timed frost, enemy raids). All agricultural societies develop practices to mitigate this risk; however, the methods
employed are dependent on the environmental contexts, social settings, and historical trajectories of a given group. This study examines paleoethnobotanical and landscape data to determine the types of risk management strategies used by Oneota groups in the Koshkonong Locality of southeastern Wisconsin. It also investigates how these buffering strategies were integrated with other cultural practices of the Late Prehistoric in the Great Lakes region.

Eerkens, Jelmer (University of California, Davis) [286] Stable Isotope Perspectives on Intra-Community Sharing
Stable isotope analyses of human skeletal tissues provide estimates of paleodiet at the scale of the individual. This paper explores intra- and intercommunity variation in stable nitrogen, carbon, and sulfur isotopes in human bone and teeth as insight into the prevalence of food sharing in several ancient hunter-gatherer burial populations in California. The goal, in particular, is to trace intra-community variation over time to examine how cooperative foraging and food-sharing strategies evolved over several thousand years as regional population levels gradually grew.

Efford, Meaghan (University of Victoria), Nicole Smirl (University of Victoria) and Brittany Walker (University of Victoria) [263] Marble Monument Conservation in the Emanu-el Cemetery
The Emanu-el Jewish Cemetery in Victoria, BC, Canada contains a wide array of plot sizes and monument styles. This project focuses on the marble monuments dating from 1860 to 1910, many of which are now lying flat and cemented in place because they are too fragile to stand on their own. Marble monuments were popular because of their beauty and the malleability of this type of stone. The elliptical shaped pores allows for more water and acids to enter and move into the stone, and the calcium carbonate within marble is very susceptible to acids, making marble a delicate choice. This poster discusses a selection of monuments and the environmental threats they face. The intention of this research is to offer suggestions on how to protect these delicate monuments, as well bring attention to the design styles that have been the most durable. Included in this project are examples of marble monuments that have undergone attempted preservation through laying them flat and grouting them in place, further exposing the inscription to rain, acids, and debris. We conclude that current restoration attempts in the Emanu-El Cemetery need to be revisited and further effort in preserving the monuments should be considered.

Egan, Rachel (University of Colorado at Boulder) and Christine C. Dixon [80] Extending the Notion of Night: Volcanic Eruptions in Mesoamerica
The recent research on archaeological evidence for nightly practices has profoundly shaped interpretations of the past. As scholars begin to investigate this unexamined portion of ancient life, it is essential to include associations of night beyond the time of day. Volcanic events strongly influenced life throughout ancient Mesoamerica and provide an alternative avenue of investigation into ancient experiences of a form of night created by ash. Volcanic eruptions, particularly those of significant size such as mega-eruptions, are known for ejecting ash into the atmosphere, creating a darkness even in the height of daylight and in some cases initiating what are sometimes termed dark ages of history. This paper explores the relationship between night, darkness, and volcanoes in Mesoamerica.

Egeland, Charles P. (UNC-Greensboro, Department of Anthropology), Christopher Nicholson (University of Wyoming, Department of Anthropology), Kevin Covell (UNC-Greensboro, Department of Anthropology), Robert Sanderford (UNC-Greensboro, Department of Anthropology) and Kristen Welch (Colorado State University, Department of Anthropology) [169] Cutmark Orientation and the Identification of Skill in Experimental and Middle Paleolithic Contexts
The process of skill accumulation can reveal a great deal about learning, cultural transmission, and the value ascribed by societies to particular tasks or behaviors. Such information is of great interest to Paleolithic archaeologists who are charged with reconstructing these behaviors over vast expanses of space and time. Zooarchaeological remains, and the butchery marks that appear on them, are a potentially rich source of information on skill. Here, we present experimental data on cutmark orientations produced by novice, skilled, and expert butchers with a variety of lithic raw materials and tool types. The results of these experiments are applied to a sample of ancient faunal assemblages in an attempt to track skill level in the Middle Paleolithic.

Eguez, Natalia (Kiel University [Germany]), Carolina Mallol (AMBI-Lab Instituto Universitario de Bio-Orgánica) and Cheryl Makarewicz (Institute for Prehistoric and Protohistoric Archae) [275] Microstratigraphic Investigation of Nomadic Pastoral Campsites in Eastern Mongolia
Since the origins of domestication, pastoral societies have been an exceptional example of adaptation and resilience. In recent years, studies focusing on herbivore fecal remains have shown the importance of these remains and their implication for identifying socioeconomic activities. Here we present a multi-proxy examination of these deposits for an accurate identification of herds penning. We use micromorphology of soil sediments and stable isotopes analysis combined with archaeology and ethnography to provide us new insights into past activity areas, land use, site formation processes, domestic use of fuel, manuring and stabilating or foddering strategies. Mongolian mobile herders offer an exceptional ethnographical proof-of-concept to investigate the seasonal usage and occupation of pastoral camps, which is an important temporal variable in mobile societies, difficult to detect in the archaeological record. The application of this multidisciplinary approach will provide a robust framework to understand the complex interplay between human behavior and biology in a long-term perspective, and to contribute to spread knowledge about pastoral mobile societies and their value for archaeological, ethnographical and ecological research.

Ehrhardt, Kathleen (Illinois State Museum) [4] Current Approaches to the Study of Late Prehistoric North American Copper Materials: Contributions from the Hoxie Farm Site, Cook County, Illinois
In North America, contemporary archaeometallurgical approaches to the interpretation of native and copper-base metals go far beyond simply recording the artifacts to probing long-standing and emerging questions related to the multiple and complex role(s) metal working and metals play in the social lives of ancient peoples. Research on the appropriate application of scientific or laboratory-based methodologies whose results augment descriptions
and provide robustness to inferences is developing rapidly. This paper evaluates and interprets the results of an analysis of a 273 copper-base metal dataset from three late prehistoric components (Late Fisher, Huber, and generic Upper Mississippian) at the Hoxie Farm site, southwest Cook County, Illinois. The analysis is structured within a “technological systems” framework. Formal, technological, and laboratory-derived observations (metallography, PXRF) are employed to characterize the working techniques and the metals in the industries. Distributional, contextual, and comparative information are then drawn into a discussion that places the utilitarian, ornamental, and symbolic forms found in the industries within historical, technological, and social use contexts of Upper Mississippian peoples in the mid-continent. Middle Mississippian and Early Historic metal use are also important points of comparison.

Ehrlich, Richard (UCLA Cotsen Institute of Archaeology) [279] Microscopic Analysis of Sherds from Pit H85

H85 is the largest pit discovered in the north-central area of Yangguanzhai. In 2014 the archaeological team took sherd samples from the 12 layers excavated up to that point. Where possible, the team took one sherd from each of the colors gray, red, and beige as well as both fine, levigated texture and coarse, tempered texture from each layer. Thin sections of these sherds were produced and examined under the microscope to determine the choice of temper and other steps in the preparation of the clay. The results contribute to our understanding of pottery production methods during the Miaodigou Phase.

Ehrlich, Daniel E. [234] see Tremblay, Anna

Eichner, Katrina (UC Berkeley) [74] Entangled Identities on the American Frontier: Army Laundresses as Cultural Brokers at Nineteenth-Century Fort Davis, Texas

This paper focuses on the cultural slippage that occurs in frontier zones where competing worldviews create conditions for alternative, innovative, and layered performances of intersecting identities. As spaces of translation, frontiers are the ideal location to study entangled identities. Inhabitants of these queer landscapes constantly negotiate the multiple lived realities of often conflicting ideologies. I propose the use of third-space as a framework for understanding the fragmentation and fluidity of experience in the American frontier during the nineteenth century. This study considers materials utilized in the daily lives of black and Latina laundresses who worked at the multi-ethnoracial, military fort of Fort Davis, Texas. With their identity as Americans, women, care-takers, military employees, and racialized individuals constantly in flux, these women balanced their relationship with one another, the civilian community, and their military colleagues as a way of redefining and creating new personhoods and identities in the context of living on a geographic and cultural boundary. Moreover, the study considers the women’s roles as cultural brokers who navigate contentious social and physical landscapes by simultaneous asserting, contesting, and reasserting their intersecting personhoods in their daily interactions and performances.

Eiselt, B. Sunday (Southern Methodist University) [339] The Canine Question: The Role of Dog Husbandry in Athapaskan Migration and Plains-Pueblo Exchange

Plains-Pueblo Exchange is the study of interregional interactions during the Protohistoric Period (ca. AD 1450 to 1700) between the people and cultures of the Southern Plains and the eastern, frontier pueblo communities associated with the Rio Grande Valley and its tributaries. Plains-Pueblo research has focused generally on issues of culture contact, culture history, and social evolutionary trajectories leading up to European Colonization, but has skirted the increasingly obvious fact that Plains participants were Athapaskan. Ambiguities in the testimonies of early Spanish chroniclers concerning the identities of named groups on the Plains detract from these occasionally, detailed accounts, which consistently emphasize the Athapaskan practice of long-distance trade and communal hunting aided by pack dogs. The maintenance of large packs, on the order of several hundred head or more, implies a significant commitment to sustained and intensive bison hunting in order to supply for the needs of so many animals. This paper considers the implications of Protohistoric Plains Apache dog husbandry for the Athapaskan migration, the transformation of Southern Plains economies, and ethnic interactions in the American Southwest.

El-Behadi, Raghda (University of North Carolina Wilmington), Douglas Gamble (University of North Carolina Wilmington), Eman Ghoneim (University of North Carolina Wilmington) and Eleonora Reber (University of North Carolina Wilmington) [154] Using Remote Sensing to Monitor and Predict the Inundation of the Abu Simbel Temples, Egypt

The Abu Simbel temples, commissioned by Ramesses II in Upper Egypt, are vulnerable to inundation due to the ancient structure’s proximity to the Nile River. Because of the rapid rise of water in the Lake Nasser reservoir, large swaths of land are becoming submerged. In order to monitor the recession of the peninsula in which the structure is located, remote sensing techniques were employed. Using Landsat 5, 7, and 8 multispectral images coupled with SRTM data, change detection and risk maps were created in order to inspect the changes in the reservoir water line from the years 1985 to 2016. Due to the strong absorption of water in the mid-infrared spectral channel of the satellite images, land-water segregation was possible. In addition, two different scenarios of reservoir rise, 1 m and 3 m, were tested to forecast possible effects. A series of statistical calculations were conducted to predict the amount of future inundation in the years 2020 and 2030 using the R software. Results showed that there was a 60 m retreat of the shoreline over the last 30 years for some segments of the peninsula and its surrounding areas, and an annual shoreline retreat rate of up to ~2 m.

Eldridge, Morley ( Millennia Research Ltd) [176] Tsimshian Households and Trade: The View from Casey Point

Large-scale excavations at GbTo-13 and GbTo-54 near Casey Point, Prince Rupert Harbour, revealed house remains whose differential contents of exotic features, goods, and wealth or status-signaling artifacts strongly suggest that one household ranked above others. All labrets and all mountain goat horn cores were associated with a single house. Even the households lacking these prestige goods have more wealth items than at almost any regional assemblage. The extraordinary amount of bracelets argues for a specialized production center. The faunal remains are markedly different from all previously described assemblages in the area. The amount of mountain goat was far greater than for any assemblage in the culture area or indeed likely on the continent. Grizzly bear and sea lion remains are also extraordinarily high. Trade with the Haida is indicated from amber. Trade, or perhaps direct acquisition with the interior, is indicated by interior mammals including fisher, lynx, caribou, and mule deer. The material at the site argues for it
The results of the analysis suggest that it is very likely that the animals were kept under captivity. Furthermore, the study of animal captivity has allowed us to make offerings we analyzed. In this presentation we will discuss the pathological bone alterations produced by the interaction between humans and animals. These animals were sacrificed during Ahuitzotl's reign (AD 1486–1502) and deposited into the anomalies produced by different diseases and trauma in several specimens, such as golden eagles (Aquila chrysaetos), roseate spoonbills (Platalea ajaja), jaguars (Panthera onca) and wolves (Canis lupus). These animals were sacrificed during Ahuitzotl's reign (AD 1486–1502) and deposited into the offerings we analyzed. In this presentation we will discuss the pathological bone alterations produced by the interaction between humans and animals. The results of the analysis suggest that it is very likely that the animals were kept under captivity. Furthermore, the study of animal captivity has allowed us to deepen our understanding of the Mexica society, making it possible to reach new interpretations concerning the origin of the ritual goods and the power of the Mexica Empire at the end of the fifteenth century.

Elliot, Michelle (Université Paris 1, Panthéon-Sorbonne) [174] Flames, Ash, and Charcoal: Paleoethnobotanical Approaches to Understanding the Role of Fire in Postclassic Tarascan Ritual Practices Although ethnohistoric sources provide many interesting clues regarding the importance of fire in Postclassic Tarascan rituals, these practices are still not well characterized by archaeologists. We know that fire was omnipresent in Tarascan society, not just for ordinary, daily needs (heating, cooking, light, etc.), but also in a seemingly diverse variety of ritual practice that ranged from the public cremation ceremonies of deceased rulers to more humble household rituals carried out on a frequent basis. Paleoethnobotanical methods seem to provide an essential approach for reconstructing these acts that cross-cut the social hierarchy, as well as the spheres of private and public space. This paper presents an ongoing project that focuses on charcoal remains, hearths, and other loci of combustion in a variety of contexts at the site of Malpais Prieto, in the Zacapu Basin of northernMichoacán. Our objectives are to characterize systematically the range of fire-related ritual practices that occurred at the site and to determine how these varied among the different social strata, and in public vs. private contexts. We also investigate what types of wood resources were necessary for these practices, and the system(s) that were developed to obtain and manage them.

Elliot, Michelle [251] see Fisher, Christopher T.

Elliot, Sarah (University of Aberdeen, UK) and Wendy Matthews (University of Reading, UK) [275] A New Multi-Scalar, Multi-Methodology for the Detection, Identification, and Analysis of Ancient Animal Dung Animal domestication has traditionally been investigated through archaeozoological approaches which can be problematic and may not detect the earliest stages in this important transformation (Zeder 2006). The study of dung provides an alternative line of evidence for the investigation of: animal presence and proximity, increased animal management, domestication and sedentism, potential secondary product use, animal diet and environment. To identify and analyze fecal material there is still the need for development of an integrated and systematic field and laboratory approach (Shillito et al. 2011; Shahack-Gross 2011). The standardization and integration of analytical methods for fecal material identification and analysis is the primary step required in future dung research. This research develops a multidisciplinary approach that integrates field and laboratory analyses of archaeological dung from the Neolithic with comparative reference to modern ethnoarchaeological samples as control data. The aim in this research was to develop a methodology that enables detection and examination fecal deposits in the field as well as in specialist laboratories. Once dung remains have been successfully located using field methods, interdisciplinary analyses in the laboratory can inform on their type, content and context and provide direct evidence on interactions and relations between animals and plants, humans and environments.

Digital Archiving for Archaeological Projects
Despite a growing awareness of the need to properly care for digital information generated through past and current archaeological research, many archaeologists remain uncertain of “best practices” in digital curation. As a result, it is not uncommon to leave consideration for the long-term care of digital information to the very last step in a project. At that point, proper care can seem overwhelming. In this poster we outline simple steps for preparing (and budgeting) for digital archiving before research begins, tracking digital files while research is ongoing, making decisions about what types of information to archive, and identifying characteristics of a good digital repository. We will also use real world examples from tDAR (the Digital Archaeological Record) to illustrate how researchers are preserving their digital materials for access and future use.

Forensic Materials Science Applications in Archaeology
Forensic science and archaeology share many similarities in laboratory and field methods that are deeply rooted in geology, chemistry and biology. Questions addressed in forensic science contexts often include item/material identification and provenance, rarity (probative value), comparative examination for sourcing purposes, and accurate scene reconstruction. This paper will examine actual forensic cases and their archaeological analogs in order to demonstrate how current forensic analyses may be applied within an archaeological context.

Ellyson, Laura (Washington State University), William Lipe (Washington State University) and R.G. Matson (University of British Columbia) [368]
Changes in Turkey and Artiodactyl Abundance in Central Mesa Verde and Northern Rio Grande Archaeological Assemblages
Previous zooarchaeological studies in the Southwest indicate that over time, larger animal resources such as deer are replaced by smaller ones such as lagomorphs (cottontails and jackrabbits) and domesticated turkey in Ancestral Pueblo sites. These trends are identified on the basis of various faunal indices that measure the proportional abundance of one animal resource against another. In this study, we utilize an index that measures the proportion of domesticated turkey relative to artiodactyl (primarily deer) remains to explore temporal changes in the dietary importance of domesticated turkey. We use this index to make regional and temporal comparisons between the central Mesa Verde (CMV) and northern Rio Grande regions (NRG). Our results indicate that in the CMV, turkey became an important source of animal protein in later periods as artiodactyls decreased in abundance on the landscape. For the NRG, where artiodactyls evidently remained more accessible through time, people in this region did not rely as heavily upon turkeys.

Carrying On the Tradition: University of Arizona Field School Excavations at University Indian Ruin
Recent field school excavations at University Indian Ruin, under the direction of Drs. Paul and Suzanne Fish, have uncovered a wealth of new data. University Indian Ruin is a large Classic period Hohokam village situated in the eastern Tucson Basin. The site likely contains hundreds of adobe rooms and at least two platform mounds, a form of monumental architecture built by or for elites. In the late 1930s, such archaeological luminaries as Byron Cummings and Emil Haury investigated the site and trained archaeology students. The most intensive investigations occurred in 1940, when Julian Hayden and a crew of CCC workers excavated a room-block and the primary platform mound. After a hiatus of 70 years, the Fishes, joined by field school students and members of the local CRM community, reinvestigated the site for four field seasons between 2010 and 2013. This work resulted in intensive mapping and surface collection of the site, the testing of a second platform mound and a large borrow pit, and the excavation of several rooms, two of which were in the platform mound precinct and contained evidence for ritual closure. This paper summarizes our work and presents new data on the occupation of this highly important site.

Emery, Kitty (FL Museum of Natural History, UF), Antonia Foias (Williams College) and Erin Thornton (Washington State University) [5]
Exchanging and Sharing Food in the Classic Maya polity of Motul de San José
Anthropologists often describe food as the cement that holds people together both by symbolizing shared values and by the practice of sharing food. But in Maya archaeology, “food” is also often assumed to have been acquired locally and consumed primarily at the family level, therefore having a limited role in creating and maintaining alliances except in special circumstances. In contrast, our recent interdisciplinary research at the Classic period Motul de San José polity, Guatemala, argues against this model and shows that basic foodstuffs like meat and corn were exchanged among sites and also among members of different status groups and occupations within those sites. In this case study we use data from Maya archaeological animal remains and food-related artifacts to explore how basic foodstuffs, not just special feast foods, were used as a social cement to identify and bind social and political entities.

Emslie, Steven
[177] Steven A. Weber and the Birth of the Society of Ethnobiology
In June 1978, two young graduate students met while working for the U.S. Forest Service in Flagstaff, Arizona. At the time, I was organizing the 2nd Ethnobiology Conference to be held at the Museum of Northern Arizona in honor of two founding fathers of ethnobiology, Alfred Whiting and Lyndon L. Hargrave. Steve and I soon became friends and colleagues, spending many evenings over beers, and our conversations often centered on our mutual interests in interdisciplinary studies for which ethnobiology was a core component. We came up with the idea to initiate a Journal of Ethnobiology with papers from the 2nd conference as the first issue. Further, we believed this journal should be the basis for a new nonprofit society, the Society of Ethnobiology, and both were launched in 1981. This early history of the Society is presented here with Steve Weber’s critical role. His foresight in developing this Society indicates how, early in his career, he was already having a huge influence on the field of ethnobiology. Now, over 35 years later, the Society and Journal remain strong and are a testament to Steve’s lifelong contributions and dedication to ethnobiology.

[115] Late Bronze Age Women of the Steppe Frontier: A Bioarchaeological Analysis of Multiple Sites in Northern China
The late Bronze Age in the Inner Asian steppe was a transitional period, with the adoption of mobile herding, as well as increasing sociopolitical interaction and complexity among groups in this region. Although archaeological studies have indicated that many steppe groups engaged in a variety of subsistence practices, pastoralism in general has been characterized as a rather uniform lifestyle; and nomadic pastoralism in particular has been associated more often with the role of males, i.e., as mounted warriors. The bioarchaeological study of ancient female “pastoralists” and their lived experiences, however, offer a broader perspective on life among these steppe communities, including potential variations in health, stress, and activity markers. This study focuses on the remains of adult females from four sites in northern China (from east to west): Jinggouzi (n = 35, 1000–600 BC) in Inner Mongolia; Xiaohandi (n = 33, 1500–1000 BC) in Qinghai; and Tianshan Beilu (n = 33, 1800–1200 BC) and Yanghai (n = 24, 1000–600 BC) in Xinjiang. The geographic diversity of these sites contributes to our understanding of how environmental variation, as well as temporal and culturally contingent factors may have led to differential frequencies of dental disease, stress in childhood and adulthood, and markers of activity among the women of these samples.

[299] The Tale of a Rock: Backdirt, Backfill, and Intrusive Historic Occupations of Woodpecker Cave
Prehistoric occupations in rockshelter deposits are frequently of interest to archaeologists because of potentially good preservation of material culture and the possibility of multiple occupations in stratigraphic succession. Those sought-after phenomena are frequently occluded by subsequent accretional or intrusive historic occupations. This is particularly complicating when modern investigations are carried out in the context of poorly documented earlier archaeological excavations. Determining the sequence and causes of such intrusive disturbance is necessary for defining the extent and stratigraphic position of intact prehistoric occupations. Treating the historic materials in the same manner as prehistoric finds may help clarify the interpretation of the prehistoric components, as well as helping modern investigators understand how such locations have been used in both older and more recent occupations. Woodpecker Cave is a rockshelter purportedly entirely excavated in 1956; recent investigations have yielded areas of undisturbed prehistoric occupations. The lack of existing datum markers from the earlier excavation complicated spatial and stratigraphic correlation with the modern excavation. Historic and modern photographs in conjunction with meticulous mapping of modern artifacts have been essential in establishing horizontal and stratigraphic relationships between early and later excavations and in discovering evidence of more recent occupations with spatial and behavioral implications.

[125] 1,300 years of a Classic Maya Ceramic Tradition at El Perú-Waka’, Guatemala
In the course of 13 field seasons, archaeologists have carried out 23 operations across the ruined city of El Perú-Waka’. During these investigations, excavators recovered upwards of a million ceramic sherds from a wide variety of contexts; palaces, pyramids, residences, sheet middens, construction fill, ritual deposits, spoil piles, termination deposits, votive deposits, surface collections, burials, caches, and tombs. The excavation contexts are good enough, the quality of preservation generally high enough, and the quantity of sherds easily high enough to being to reconstruct the ceramic tradition of this ancient city. The Maya of El Perú-Waka’ crafted a multitude of ceramic artifacts, from artistic polychromatic masterworks to low-end unslipped water jars and chamberpots. This includes all the ceramic vessels required for everyday life in the tropical rainforest of the Classic Maya. From this material, one can examine both the internal society of the city-state as well as the external connection to neighbors near and far. What emerges from this analysis is the distribution of quotidian ceramics and the exchange of high-end serving-wares. This exchange is not just between social units within the El Perú-Waka’, or between this city and neighboring cities, but interaction between social units in different cities.

**Space and Scale in Reconstructions of the Social Organization of Craft Production**

Archaeologists often speak of production in spatial terms, contrasting nucleated and dispersed forms of crafting. However, the importance of the scale of spatial patterning in production activities (as opposed to “scale” in reference to quantitative output) has yet to be fully explored. It is impossible to relate the spatial distribution of crafting activities to a particular social organization of production without considering spatial scale. An examination of spatial distributions at multiple scales highlights significant variability beyond a nucleated/dispersed binary. For instance, a distribution that appears clustered at one scale may appear dispersed at another. A focus on spatial scale highlights complexities in the relationship between space and social organization. Dispersed, small production sites are often taken to indicate a lack of central administration, yet spatial centralization is not a strict requirement for social centralization. To build a robust production model, spatial ordering must be considered with reference to constraints on the distribution and management of resources and labor. Moreover, spatial data must be well-integrated with information on the techniques and practices of production. These arguments are illustrated using examples of metal production in Western Asia, focusing on my recent fieldwork in the South Caucasus.

Erdman, Katherine (University of Minnesota—Twin Cities)

**“Are You There Gods?” Offerings and Communication between Worlds in Protohistoric France**

Ritual offerings are inherently communicative; they are created or selected for the meanings they convey to the giver, other viewers, and the intended recipient(s). With this concept in mind, objects deposited in the Source of the Douix, a freshwater spring in eastern France, were recently examined to understand how people use offerings for communication in ritual practices. During exploration of the spring’s subterranean karst system, cave divers observed human-made objects in the water. Through the collaborative effort of several local agencies in the mid-1990s, the spring water was diverted, the area explored, and artifacts dating from over two thousand years recovered. This paper presents the results of multiple levels of statistical and spatial analyses focused on the diverse objects from the Iron Age and Gallo-Roman periods. These results suggest the objects were given as offerings to a god or supernatural entity perceived to inhabit the spring, and provide insights as to why objects were selected to become offerings. The most significant conclusion reveals how people used offerings to communicate with their gods during rituals at the spring, but also, a more universal model for interpreting offerings from other geographic and temporal contexts.

**Assessment of Lateral Edge Grinding on Hafting Performance Using Experimental Clovis Points**

In the 1930s, F. H. H. Roberts proposed that lateral basal grinding was executed on Paleoindian projectile points to limit damage to the lashings that attached them to their shafts. This assumption is logical and widely accepted, but remains empirically untested. Here, we present an experiment that examines the role of lateral basal grinding in replica Clovis projectile points made of Texas chert. We compare via controlled ballistics experiments large samples of points with lateral edge grinding versus those with sharp lateral edges, but otherwise similar in every other morphometric aspect. The two point types are further divided by lashing type: animal derived silk fiber (similar to sinew) and flax cellulose fiber (both sealed with hide-glue). By analyzing and comparing the hafting performance of all four groups (ground, animal-fiber; sharp, animal-fiber; ground, flax-fiber; sharp, flax-fiber), we hope to better understand the function of lateral basal grinding, as well as any differences in use wear between animal-based and plant-based lashings.

**A History of Service: The Civilian Conservation Corps at Petrified Forest**

Part of Roosevelt’s New Deal Program, the Civilian Conservation Corps (CCC) was established in 1934 as a work relief program for unmarried men between the ages of 18 and 25. Designed to assist families during the Great Depression, the Corp members were paid $30 per month, $25 of which was sent back to help support their families. Up until its disbandment in 1942, multiple companies of these young men were stationed at Petrified Forest National Park (PEFO). Throughout their time at PEFO these CCC groups contributed to the construction and improvement of the park’s existing infrastructure. The presence of these individuals in the park is represented today by limited historic documents, isolated artifacts, and historic sites including: sandstone quarries, park trails, culverts, trash scatters, the remnants of three CCC camps, and the park’s existing waterline. Through archaeological surveys and research at Petrified Forest, we are better able to understand the extent of the impact these groups of young men had on the National Park Service.

Erickson, Renée (University of Oklahoma)

**Gauging Style: A Stylistic Analysis of Arkansas and Red River Valley Earspools**

Archaeologists have theorized that earspools functioned as symbolic adornments of high social status. However, earspools may also indicate the localized cultural practices of smaller communities within a larger region and highlight the role of specific individuals. By focusing on the sizes, material types, and decorative elements, I discuss the stylistic variations found within the temporal and spatial distribution of earspools in the Arkansas and Red River Valleys. These variations may indicate differences in social, ritual, or political practices within a broader cultural area.

**Defining the Anthropocene on California’s Northern Channel Islands**

California’s Northern Channel Islands provide some of the most detailed and well-preserved records of human occupation of dynamic island landscapes in the world. Here, archaeological and historical ecological research over the past 20 years has produced a variety of data about human eco-dynamics in both terrestrial and marine ecosystems, spanning nearly 13,000 years. We summarize current knowledge of cultural and ecological changes from Paleoindian to historic times, focusing on what archaeological and paleoecological records tell us about when the Anthropocene might have begun on this archipelago. Contrary to current recommendations that the onset of the Anthropocene be defined as occurring during the past century or so, humans have actively transformed Channel Island ecosystems for millennia. Such transformations—the result of landscape burning, animal and plant...
translocations, hunting, fishing, ranching, and other activities—have accelerated through time, but their effects can be traced back 7,000 to 8,000 years (or more) in terrestrial and marine ecosystems of the islands. Globally, ignoring such ancient human transformations will result in defining an Anthropocene devoid of anthropological data.

[395] **Breaking and Making Identities: Transformations of Ceramic Repertoires in Early Colonial Hispaniola**

Placed within the context of the ERC-NEXUS1492 research, this paper focuses on transformations in indigenous social and material worlds in Early Colonial Hispaniola. The initial intercultural encounters in the New World have led to the creation of entirely new social identities and changing material culture repertoires in the first decennia after colonization. The incorporation of European earthenwares in the indigenous sites of El Cabo and Playa Grande will be contrasted with the presence of indigenous ceramics and new manufacturing traditions in the early Spanish colonial sites of Cotul and Concepción de la Vega. The transformation processes in ceramic repertoires will be assessed through a multipronged approach using theories of gift giving, appropriation and imitation combined with archaeological and ethnoarchaeological studies of the operational sequence (chaîne opératoire) of ceramic manufacture. The paper presents new insights into the dynamics of Amerindian-European-African interactions, mutual influences and resilience at the onset of colonial encounters in the Americas.

[277] **Settlement Scaling and the Emergence of the Greek Polis**

The collapse of the Mycenaean palatial centers at the end of the Late Bronze Age (circa 1190 BCE) and the nature of society in the ensuing “Dark Age” or Early Iron Age have long been important topics in the study of prehistoric Greece. The centuries after the collapse were characterized by a seeming decrease in population, changing patterns of settlement, less political centralization, a decline in trans-Mediterranean trade and the production of luxury goods, and the disappearance of the Linear B script used for keeping Mycenaean palatial records. Complex society did not reemerge on the Greek mainland until the rise of the Archaic Greek polis in the middle of the eighth century BCE. While both Mycenaean palaces and Archaic poleis can be classified as city-states, it is their political, cultural, and economic differences that are most often stressed. This paper will use settlement scaling theory to investigate continuity and change over the course of the Early Iron Age. Scaling relationships will be derived for Mycenaean settlements, Early Iron Age settlements, and several early poleis. Comparing the values of the pre-factors in these relationships will allow for a more nuanced understanding of the conditions necessary for the development of the polis.

[168] **Recognizing Ritual in the Elaboration of Earthwork Construction at Jaketown**

Elaborately constructed earthworks indicate monumental behavior requiring unique social processes to produce. This paper presents new subsurface data on the Late Archaic Poverty Point earthworks at the Jaketown site in the Mississippi Yazoo Basin. Unit excavations and soil coring demonstrate detailed and complicated internal architecture standing in contrast to earlier mounded landscapes in the eastern United States. Challenging traditional agrocentric models for socially complex societies, this research provides a new perspective on the emergence of ritual complexity in the Lower Mississippi Valley, and more broadly urges a reform of the civilization narrative in archaeology with the elaboration of landscapes built by hunter-gatherers.

[128] **Law, Private Property, and the Construction of the Family in the Archaeological Record of Colonial Moquegua**

In 1884, Friedrich Engels attributed the development of the nuclear family unit to the rise of the capitalist state and the subsequent emergence of private property in sixteenth-century Europe. In The Origin of the Family, Private Property, and the State, he posited that private property resulted in the restructuring of kinship practices where women gradually lost authority over their own activities, spaces, and their lives, and where the division of labor became gendered and spatialized. In this paper, I draw from political economic theories of property and anthropological studies of the family to shed light on the daily lived realities of indigenous social actors in colonial Peru. I explore private property and family materially by considering the adoption or rejection of nuclear households at two indigenous settlements of Sabaya and Torata Alta in the southern highlands in the department of Moquegua. I ask: to what extent did “Indios” at Sabaya and Torata Alta conceptually and materially embrace the concept of private property and how might archaeologists contribute to studies of private property?

[42] **Recognizing Artifact Transport from Debitage Assemblages: Examples from Middle Holocene Sites in Alaska**

When studying the technology of mobile foraging groups, tools and cores that pass through a site can be even more informative than those that end up deposited there. This is especially true in regions like interior Alaska, where cultural historical frameworks rely on the presence or absence of specific technologies or tool forms. A flake-attribute based debitage analysis combined with a minimum analytical nodule analysis can be integral for recognizing artifact transport. Examples from Archaic sites in Alaska demonstrate how identification of artifacts transported off site can influence cultural historical reconstructions, address co-occurrences of unrelated technologies, and contribute to theories concerning patterns of logistical organization.

While extensive research has been conducted in and around well-known sociopolitical centers located in valley and coastal regions of southern Mexico, relatively little work has been done in the rural regions outside these core areas. Specifically, one of the understudied regions of southern Mexico is the mountainous area in the municipality of San Pedro Mártir Quiechapa located in the mountains southeast of the Valley of Oaxaca. This paper will examine the methods and preliminary results of PAQuie’s 2016 field season. To better understand the occupation history of the region, project members documented prehispanic land use and settlement patterns using GPS equipment, and created a geodatabase of all visible features. Additionally, samples of diagnostic ceramics were collected and compared to existing typologies from neighboring regions, demonstrating changes in settlement patterns over time. Together, the Quiechapa time series maps and ceramic chronology provided valuable information regarding prehispanic occupation, settlement distribution, and how the people of the area might be connected to larger economic and sociopolitical networks.

Shifting Use of Mammals at Tse-whit-zen: Response to Gradual or Catastrophic Change?

The mammalian component of the Tse-whit-zen village (WA) midden samples is typical of Northwest Coast archaeological sites. However, overall identification rates are quite low, with only 8% to 11% of the overall number of mammal specimens (NSP) identified beyond Class. This pattern is driven by the increase in resolution and accessibility of this technology, but not so in the forested Maya lowlands where multi-canopy forest can obscure even the largest of urban centers built by the Maya. Lidar mapping has begun to alleviate many of these problems. Moreover, thanks to handheld devices, social media and virtualizations, our finds can now reach large audiences with incredible speed and with greater richness of content than ever before.

Accelerating the “Maddeningly Slow Work of Archaeology” in the Forested Maya Lowlands

Investigations in the thickly forested Petén region is complicated by lack of roads, water, communications, visibility and other things we often take for granted even in archaeology. In most cases the time it takes for results of such field work to reach a general audience can be measured in years. Many of us have turned to technology to alleviate this situation but the gains can be less than what is expected. The advent of GPS handheld devices have been useful to locate sites (and ourselves) much more efficiently in those vast uncharted regions, but the kind of automated GPS mapping that is common in most developed countries remains unattainable to some. Satellite imagery has also provided a bonanza of opportunities for archaeologists thanks to the increase in resolution and accessibility of this technology, but not so in the forested Maya lowlands where multi-canopy forest forest can obscure even the largest of urban centers built by the Maya. Lidar mapping has begun to alleviate many of these problems. Moreover, thanks to handheld devices, social media and virtualizations, our finds can now reach large audiences with incredible speed and with greater richness of content than ever before.
by fragmentation and burning, with burned bone making up 18% to 44% of NSP. Burning rates peak in Chronozone 5 (CZ5, 525–1000 BP), while identification rates decrease steadily through time. Artiodactyls (deer and elk—3% to 7% of NSP) are the most abundant taxon, followed by dog (1% to 4% of NSP) and pinnipeds (seals, fur seals, and sea lions—1% to 2% of NSP). Pinniped use through time is stable. Artiodactyls peak in CZ3 (1550–1300 BP) at 7% of mammal NSP, but they were also increasing in the final stages of occupation of the site (CZ6 and CZ7, 525–50 BP). The initial increase in Artiodactyl use does not correspond to any of the seismic events documented at Tse-Whitzen. However, the peak of burned bone, and associated decrease in overall identification rates in CZ5 may reflect increased processing of bone for tool production and grease extraction following Event W, a seismic event dated to 420–570 BP.

Eusebio, Michelle (University of Florida)

“Call Any Vegetable”: Culinary Practices in Neolithic and Metal Age Mekong River Delta

Almost nothing is known about the early development and diversity of Vietnamese cuisine, which potentially has its origin more than 2,000 years ago. This research investigates the culinary practices in southern Vietnam during the Neolithic and Metal Age (3000 BC–AD 500) by analysis of food residues recovered from earthenware pottery. To identify former food contents, organic residue analysis was conducted on sampled pottery vessels recovered from two Neolithic sites (Rạch Núi and An Sơn) and two Metal Age sites (Lò Gạch and Gò Ô Chùa). Data assayed include lipid biomarker compound distributions, compound-specific carbon isotopes of palmitic and stearic acids, as well as bulk carbon and nitrogen isotope ratios of adhered residues. Results indicate that the people who inhabited these sites had broadly similar culinary practices, but differed possibly due to local ecology and differential access. Continuity of culinary practices involving the use of earthenware pottery vessels to prepare and serve plant and aquatic food sources is observed from Neolithic to Metal Age. It is also demonstrated by the evidence for a common plant food source available within the vicinities of three inland sites. Results of this study contribute to the construction of long-term culinary heritage of Mekong River Delta.

Woodland Systematics and Monumentality: A Preliminary Discussion of the Rediscovery of the Caldwell Mound

The Caldwell Mound was a prehistoric conical mound located in the central Scioto River Valley, in modern-day Ross County, Ohio. Excavated by prominent amateur archaeologist, Donald McBeth in 1942, the Caldwell mound revealed a unique, if detailed funerary complex. Yet, these results remained largely unpublished. Exhibiting characteristics historically considered “Adena” and “Hopewell,” the Caldwell mound presents either a call to update local cultural systematics or adds data speaking to a period of transitioning ceremonialism during the first half of the Woodland Period. A preliminary reanalysis of remaining artifacts and archival materials reveals interesting implications for a more holistic understanding of Woodland monumentality and the necessity of a recursive process in developing regional cultural systematics. This research also demonstrates the utility of research of incomplete archival materials and museum collections generated from the late nineteenth and early twentieth century excavations.

Sinew Thread Production and Properties in Western Alaska

The production and functional properties of sinew thread are integral to the creation of Arctic Clothing. I focus on the creation of sinew thread from tendons and how production techniques affect thread usability in clothing production. Specifically, the strength and pliability of sinew thread. My reproduction of sinew threads is modeled upon the sinew used in extant Western Arctic garments in the collection of the Smithsonian Museum of Natural History. The strength of sinew thread is compared to that of modern commercially available threads to evaluate the durability of sinew in relation to readily available modern alternatives.

Ewonus, Paul (Vancouver Island University)

The Social Implications of Elk Hunting for Ancestral Coast Salish Communities

Field, laboratory and archival archaeological research has helped to reconstruct important parts of the ancestral seasonal landscape in the southern Strait of Georgia. Contextual understanding of place provides a baseline for questions of sociality during the last c. 5,000 years prior to the colonial era. Evidence illustrates several of the historical processes through which community identities were brought into focus in the Coast Salish world. As an
example, I explore what is known about one of these narratives: the practice of hunting elk (Cervus elaphus). At most Northwest Coast sites deer (Odocoileus) is more common than elk (by NISP), and in the Salish Sea it can be strikingly so. While it is possible to consider both deer and elk together as simply cervids, I believe there are also reasons why their relationships with people in the past were not necessarily as similar as their taxonomy might suggest. Bound up with ritual life, I argue, a practical tradition focused on the elk hunt and consumption of the animal itself was emphasized among Coast Salish Peoples in the Fraser River delta and lower Fraser Valley. Over the millennia, ancestral communities identifying in part with this practice were formed through routine social engagement.

Fadem, Cynthia M. (Earlham College) [305]  
**Paleoecological Assessment of the Douglas Korongo East and Bell’s Korongo East Sites, Olduvai Gorge, Tanzania**  
Current work in DKE and BKE in conjunction with the Olduvai Paleoanthropology and Paleoecology Project (TOPP) has excavated Bed I and Bed II deposits, respectively. At DKE a series of tuffs and siltstones, including paleosols, indicates DKE hosted a series of productive landscapes through time. Paleosols have well-developed blocky structure and host large concentrations of fossils. At BKE sandy fluvial deposits adjacent to siliceous siltstones confirm previous descriptions of site materials. Cultural materials occur primarily in these fluvial sands, which are complex on a fine scale, featuring cross-bedding, density sorting, and carbonate rip-up class, indicating relatively high velocity water flow that would have attracted animals. Sediment mineralogy and chemistry, including stable isotopic analysis reveal the nature and formation conditions of deposits at both sites. Following assessment of site formation processes and artifact matrices, investigation of the continuity of tuffs and paleosols at DKE, and of channel-fill deposits at BKE will enable mapping of paleolandscape surfaces that would have been available to hominin populations. Additionally, dating and correlation of unnamed tuffs will allow calculation of sediment flux and provide more narrow age ranges for cultural deposits and paleolandslapes at DKE and BKE.

**The Promise and Pitfalls of Quantitative Paleoenvironmental Reconstruction in Zoarchaeology: Evaluation of Late Quaternary Micromammal Assemblages from Southern Africa**  
Over the last several decades, Quaternary scientists have developed numerous techniques to generate quantitative paleoenvironmental reconstructions based on the taxonomic composition of fossil assemblages. The appeal of these methods is that, rather than providing reconstructions in qualitative terms (e.g., cooler versus warmer), they offer potential to generate numerical assessments. While these methods have been applied to a variety of fossil organisms, including pollen, diatoms, foraminifera, and chironomids, they are rarely applied to mammals. Our aim in this study is to explore the promise and pitfalls of quantitative paleoenvironmental reconstruction through the analysis of modern and fossil micromammal assemblages (rodents and shrews) from southern Africa. In a training set of ~150 modern assemblages collected from barn owl (Tyto alba) roosts throughout southern Africa, multivariate analyses demonstrate strong correlations between assemblage composition and several climate variables, especially those relating to precipitation seasonality. Transfer functions derived from these relationships are used to generate quantitative paleoclimate reconstructions for late Quaternary micromammal sequences from southern Africa’s Cape Floristic Region, a region that features prominently in modern human origins research. We show that the methods of quantitative paleoenvironmental reconstruction offer untapped potential in zooarchaeology, but that there are also limitations that must be considered.

Fallu, Daniel (Boston University) and W. Flint Dibble (University of Cincinnati) [354]  
**Answers in the Dirt: Taphonomy, Preservation Bias, and Pastoralism at Iron Age Nichoria, Greece**  
The assumed increase of cattle in Dark Age Nichoria has been a key piece of evidence for the “cattle-ranching” model of Dark Age Greek economy. New zooarchaeological analysis, however, demonstrates a distribution of more robust skeletal specimens which are likely the result of preservation bias, rather than economic reliance on cattle. Geoaarchaeological analysis of “archival” soils retrieved from uncleaned bones provides some confirmation and additional detail: the abundance of cattle bones at Nichoria is likely the result of taphonomic, rather than economic, processes. Initial micromorphology revealed that the Dark Age assemblages were likely affected by soil formation, while calcium carbonate concentrations in Bronze Age layers protected bones from dissolution. Infrared analysis confirms that calcite is largely absent in the Dark Age soils. Further comparison of spectra shows that apatite, likely resulting from the degradation of bone, is present within the soil matrix. This matrix apatite is present in similar proportions in both the Bronze Age and Dark Age soils, suggesting some uniformity in process. While yet inconclusive, these results call into question the validity of a long-held economic model for the so-called Greek Dark Ages, and show the potential for geoaarchaeological research even on sediments from earlier excavations.

Fan, Rong [33]  
**Physiological Stress, Activity Patterns, and the Emergence of Social Complexity in Early China**  
Because of a lack of artifacts or archaeological features which can indicate social status, the Early and Middle Neolithic periods ca.7000–4000 BC in China are considered to be relatively egalitarian periods. Differences within and among settlements became pronounced in the third millennium BC. The adaptation of agricultural lifeways might be a cause of social complexity. However, it requires further investigation into how and why this happened. In the case when there are not enough artifacts to represent status, one way to investigate the emergence of social complexity is to look at whether differentiation exists beyond gender and age using human skeletal remains. During research, multiple lines of evidence from contextualized human remains were utilized. By comparing different degrees of enthesal changes, different dental wear patterns, duration of physiological stress which reflected on enamel hypoplasia, and trauma, combining the known data of stable isotopic analysis and other subsistence and mortuary practice information, the workload and nutritional distribution within communities was determined. In this presentation, data from two Middle Neolithic sites in northern China, the Xinglonggou site and the Beiqian site will be presented.
Farahani, Alan (University of California, Los Angeles) 

Big Changes in Little Places: An Examination of the Political Strategies of Leaders at Late Postclassic Xaltocan, Mexico

During the Late Postclassic the Basin of Mexico underwent dramatic political and cultural shifts, chiefly due to the formation and rapid expansion of the Aztec Triple Alliance. Xaltocan was among the many regional centers to be conquered and incorporated into the Aztec state. Historical documents indicate that prolonged conflict ultimately resulted in Xaltocan’s conquest and partial abandonment, thus local leaders were not integrated into the new political framework and were replaced by Mexica leaders. This fundamental shift impacted the community as a whole, and several authors have effectively outlined the impacts of the transition to empire on commoner practices (Brumfiel 1991; Morehart 2010; Overholtzer 2012). This paper builds on these previous studies, but shifts the focus to Xaltocan’s leaders and their social relationships with both the community and the state. Archaeological data collected from the successive residences of Xaltocan’s leaders throughout the Postclassic demonstrate how both private domestic practices and public displays changed for Xaltocan’s leaders over this transition. This paper will also address wider theoretical themes, particularly social memory and identity.

Farahani, Alan (University of California, Los Angeles) 

Imperial Context and Agricultural Content: Dimensions of Space and Practice in Agricultural Lifeways in Dhiban, Jordan, 500–1400 CE

In this paper the results of an archaeological case study are presented to argue that considerations of space, taken here to be a physical location in Cartesian terms, are essential to identifying changes in agricultural practices in premodern imperial contexts. The recording of the location of samples intended for paleoethnobotanical analysis, whether through digital or other means, allows for more nuanced reconstructions of the depositional routes of archaeological plant remains. In turn, these depositional routes can highlight the ways in which imperial interventions may un/intentionally restructure daily (agricultural) practice. Such techniques were utilized at the archaeological site of Dhiban, Jordan during excavations from 2009 to 2013. The tell of Dhiban was inhabited from at least 1000 BCE to 1500 CE, but it was transformed during two moments of imperial intervention, the Byzantine (300–640 CE) and Mamluk (1250–1450 CE) periods. The spatial visualization of over 200 analyzed and point-provenienced flotation samples reveals that communities at Dhiban responded to each of these moments of imperial intervention through changes in on-site depositional practices of daily waste as well as plant processing detritus.

Farager, Lane F. [215] see Pérez Alcántara, Ivonne

Peasants, Agricultural Intensification, and Collective Action in Premodern States

Historically, anthropological archaeologists assumed that intensification, in complex societies, involved a combination of population pressure and state direction, which culminated in the rise of powerful, centralized states. However, intensive research over the last 30 years has considerably altered our concepts of intensification and the state. Drawing on landscape archaeology and alternative pathways theory, we consider how diverse political-economic and landscape strategies interact to create complex socio-bio-physical environments. Specifically, we focus on the ways that rural populations (peasants) solved (or failed to solve) cooperation problems involving landscape intensification strategies that require large-scale quasi-voluntary participation in the context of varying political environments. Data from a wide sample of premodern states indicate that peasants pursued a wide array of strategies that varied in degree of collectivity. In states low in collectivity, some peasants were able to overcome cooperation problems and invest in large-scale agricultural facilities; whereas in others, they failed to do so and agricultural strategies were limited to the household scale. In some highly collective states where food security was a concern, principals relied on preexisting intermediate-scale cooperative units to increase agricultural production; and, in others the state had to penetrate deep into society to build these cooperative units.

Farager, Lane (CINVESTAV del IPN)

Peasants, Agricultural Intensification, and Collective Action in Premodern States

In recent years there has been a growing interest in understanding the dynamics of agricultural intensification in premodern states. This interest is evident in the growing body of archaeological research that focuses on the ways that rural populations (peasants) solved (or failed to solve) cooperation problems involving landscape intensification strategies that require large-scale quasi-voluntary participation in the context of varying political environments. Data from a wide sample of premodern states indicate that peasants pursued a wide array of strategies that varied in degree of collectivity. In states low in collectivity, some peasants were able to overcome cooperation problems and invest in large-scale agricultural facilities; whereas in others, they failed to do so and agricultural strategies were limited to the household scale. In some highly collective states where food security was a concern, principals relied on preexisting intermediate-scale cooperative units to increase agricultural production; and, in others the state had to penetrate deep into society to build these cooperative units.

Farquhar, Jennifer (University of Pittsburgh), Joan Schneider (California State Parks, Colorado Desert District), Arlene Rosen (University of Texas at Austin), Yadmaa Tserendagva (Mongolian Academy of Sciences) and Michael Heilen (Statistical Research, Inc.)

The Cultural Heritage Program at Ikh Nart Nature Reserve is an ongoing project sponsored by the Mongolian Academy of Sciences and Anza-Borrego Desert State Park (California State Parks). Over the past seven years, the project has focused on developing methods, strategies, and protocols for the management of the rich archaeological landscapes within the reserve. During this period, the project has recorded and assessed over 140 archaeological sites documenting more than 9,000 years of cultural history. A random sample pedestrian survey of about 1% of the 66,670 hectare reserve predicts that nearly 5,000 cultural heritage sites are present. This paper presents detailed survey findings including an evaluation of a predictive model focused on spatial and temporal relationships between cultural sites, land forms, and environmental features. These data are invaluable to ongoing efforts to characterize local socioeconomic patterns over time including subsistence, land use, settlement organization, and technological investment. Data will ultimately contribute to broader research concerning the development of pastoralism and the evolution of social and political complexity. The study is especially pertinent to research by the current authors focused on understanding the nature of human-environment interactions and the role of hunter-gatherers and low level food production in the development of pastoralism.

[39] Leverage Power: Stonecarvers and Architectural Sculpture Production in the Copan Region

The abundance and diversity of monumental art, architecture, and hieroglyphic texts at sites outside the Principal Group in the Copan Valley, and into the hinterlands, illuminate the timing and intent of regal investiture of authority in elites considered important to the stability of the kingdom. The consistent use of two imagery programs in architecture, and the linking of one of those programs with textual confirmation of membership in the royal court, reveal two strategies for leveraging the production and distribution of political power and its display. Recent research highlights the emphasis on foreign inspirations of ideology at the valley site of Group 6N-1, Rastrojon, Copan.

Fash, William (Harvard University)

[39] Piecing Together the Life History of K'ahk' Ul'witz K'awil

Copan's longest-lived ruler dramatically expanded his realm, reach, and resources. The valley population nearly doubled, and the historical record indicates he was active in the ritual and political lives of other centers both near to home and farther afield. Ruler 12 contextualized his defensive perimeter within the sacred geography of the valley by erecting six stelae in 652 CE. His successor enshrined that achievement and his memory in the most elaborately decorated temple outside the royal precinct, at the site of Rastrojon (6N-1), which formed part of that circuit. The first version of the Hieroglyphic Stairway was built above his elaborate tomb, securing his legacy in the royal center as well. Yet despite his 67 year reign, Ruler 12’s constructions in the Acropolis are relatively modest in scale and elaboration. This focus on external affairs and the eschewing of grandiose public works in the royal precinct suggest a leader who was comfortable both in his own skin, and in the façades and facilities constructed by his predecessors. While
Ruler 12’s earliest stelae are rather austere, in old age and after death he was depicted in Central Mexican garb, a possible clue about his political philosophy.

R ritual and/or Transformation: The Anadara granosa—Dominated Shell Mounds of the Australian Tropics

Mounded shell deposits dominated by the mudflat bivalve Anadara granosa are highly visible features on the north Australian coast. Because of their distinctive, often monumental, features they have been a focal point for research into hunter-gatherer groups in these coastal environments. Interpretations of these mounded deposits have oscillated between those concerned with the functioning of prehistoric economic systems and those invoking ceremonial and ritual behaviors. In this paper we review these debates to make several points. First, the behavioral mechanisms involved in building Anadara mounds are still relatively poorly understood, and the details of construction dynamics need to be incorporated into models of both economy and social life. Second, models of all flavors must articulate with understandings of the degree of social and cultural change that has occurred in northern Australia over the last few centuries. We employ information from these projects to evaluate the nature of ritualized behaviors involved in mound building and use. We advance the idea that these archaeological structures were a product of cultural systems with distinct economic and ideological components, and which subsequently underwent substantial transformations. We argue that the character of those transformations is the key to historicizing ritual behaviors.

Faulset, Ronald (Field Museum) and Jeremias Pink (Oregon State University)

R Ritual and/or Transformation: The Anadara granosa—Dominated Shell Mounds of the Australian Tropics

Dainzú, located in the Oaxaca Valley of Mexico, has a long history of religious-ceremonial significance. In the Classic Period (AD 200—900), the site expanded significantly from its once small core into an urban settlement covering around 4 km². Our mapping project reveals that the new site construction was carefully planned out to represent a “cosmogram,” or spatial representation of the ancient Zapotec ritual calendar. After the decline of Monte Albán, Dainzú was slowly abandoned as people moved to smaller, regionally dispersed settlements. In that time, the relationship between the landscape, elites, and ritual activities in the region transformed as a new political order emerged. In this paper, I will present findings from recent excavations at the site, which help detail this slow transformation. Additionally, we will discuss patterns of ritual that also indicate cultural resilience in the wake of this political transition.

Fauvelle, Mikael (University of California, San Diego)

R Ritual and/or Transformation: The Anadara granosa—Dominated Shell Mounds of the Australian Tropics

No society exists in isolation. In order to understand the history of North America it is therefore critical to see the continent as a landscape of mutually known and interacting places and peoples. One of the goals of this panel is to bring together specialists from different corners of the continent to share narratives of regional interaction in their areas. This paper will introduce the thematic and theoretical groundings for the session, suggesting that both systemic and historical models for understanding the past can be usefully combined in an approach that sees the continent as a shared history. We will use case studies from California’s Northern Channel Islands to argue for the importance of integrating regional histories and events into our models past processes and social changes.

R Ritual and/or Transformation: The Anadara granosa—Dominated Shell Mounds of the Australian Tropics

We report for the first time, the presence of a species of dung beetle recovered from an offering found at the foot of the staircase of the Great Temple of Tenochtitlan. The dung beetle specimen was found on a copal (aromatic resin) ball and was identified as female of Canthon cyanellus, a copro-necrophagous scarab (Coleoptera: Scarabaeinae) by the presence of four cleft teeth (exclusive characteristic of this species) and because its last abdominal sternite is continuous (characteristic of females). This species lives in tropical forests in the coastal plains of Mexico. A previous phylogeographic study of this species using nuclear and mitochondrial DNA molecular markers give us the possibility to explore the geographic precedence of the archaeological beetle. We extracted DNA of the femur of the right posterior leg of the beetle. Only the sequences of the nuclear gene Internal Transcribed Spacer Region 2 (ITS2) were successfully sequenced. Mapping the nDNA sequence of the archaeological beetle in the genealogical reconstruction of Canthon cyanellus in Mexico, we found that it belongs to the lineage formed with populations from the Pacific. This is the first molecular study in demonstrating the route from the Pacific coasts to the center of the Mexica Empire.

R Ritual and/or Transformation: The Anadara granosa—Dominated Shell Mounds of the Australian Tropics

Through its many global missions, the United States Army has had an unfortunate history of failing to recognize and allocate sufficient resources to protect cultural heritage sites in active military zones. This pattern has begun to change, especially as a result of incidents that have occurred during the War on Terror. The Engineer Research and Development Center of the U.S. Army Corps of Engineers is currently designing an interactive map program providing information on possible locations for future military movement and campsites. As part of this project, and in light of the historical friction between military actions and cultural heritage protection, both cultural anthropologists and archaeologists have contributed information about the locations of sacred sites, heritage landscapes, archaeological remains, and locations of cultural and religious importance. These locations are then noted within the mapping program as areas that are culturally unsuitable for military movement or settlement, similar to areas that would be logistically or environmentally unsuitable. This paper discusses the project and its plans for implementation, in hopes to decouple the historical link between military action and unintentional damaging or destruction of cultural heritage sites, and expand the knowledge base on these issues in the military community.
Stemmed Points and “Expedient Stone Tools”: Early Post-Glacial Archaeology on the British Columbia Coast

Over 35 years ago Al Bryan and Ruth Gruhn were promoting the concept of a very early “Stemmed Point Tradition” associated with “simple” flake and core tools. They saw this “Far West” area construct as being of similar age to Clovis and possibly even older. Al and Ruth were keenly interested in the assemblages of stemmed points and “expedient stone tools” recovered by Fedje and others from a series of sites in the Eastern Slopes region of the Canadian Rocky Mountains in the 1980s, an interest Fedje carried on to the BC coast. Over the past decade we have been finding increasingly strong evidence for an early Stemmed Point and expedient tool technology, with many elements in common with Al and Ruth’s ideas, at a number of locations along the west coast of British Columbia. This presentation provides a brief synopsis of the results of some of these investigations, including recent work in Haida Gwaii, the central coast and the south coast.

3D Modeling and Virtual Reality for Condition Assessments and Educational Outreach Tools Documenting Rock Art in Little Petroglyph Canyon, Naval Air Weapons Station China Lake, California

Aerial photography with unmanned aerial systems (UASs), 3D modeling through photogrammetry, and the development of virtual reality environments are methods that are taking root within the discipline of archaeology. Developments in hardware and software over the past several years have led to greater numbers of archaeologists to adopt these methods with more diverse applications. PaleoWest Archaeology, working under contract with our partners at PacArctic for Naval Facilities Engineering Command (NAVFAC) Southwest is using these methods to document one of the densest concentrations of rock art in the New World. Little Petroglyph Canyon is part of the Coso Rock Art District, a National Historic Landmark on the Naval Air Weapons Station base in China Lake, California. 3D modeling using photogrammetry provides a baseline for the development of a GIS-based condition assessment database to be used by Navy archaeologists working on the base, as well as the baseline for two virtual reality outreach tools for academic and general audiences. This poster presents the initial results of our work on this site.

Fehren-Schmitz, Lars (UCSC Anthropology) and Kelly Harkins (UCSC Anthropology) [143] The Impact of Climate Dynamics and Cultural Change on the Demography and Population Structure of Precolumbian Populations in the Atacama

Archaeological studies in the Central Andes have pointed at the temporal coincidence of climatic fluctuations and episodes of cultural transition throughout the precolumbian period. Although most scholars explain the connection between environmental and cultural changes by the impact of climatic alterations on the capacities of the ecosystems inhabited by precolumbian cultures, direct evidence for assumed demographic consequences has been missing so far. Desert margin areas, as we find them at the Andean foothills and along the Pacific coastline of the Atacama are ideal research areas to study the dynamic relationship of climate and demography because they are reactive ecosystems with low resilience. Thus, even minor climatic changes can force these ecosystems into transition potentially altering the ecological conditions for the populations living in them. Here we present a large body of mitochondrial and genome wide genetic data from precolumbian populations living at the fringes of the Atacama. We test demographic models informed by genomic, paleoclimatic, and archaeological data and show that especially in later precolumbian phases climatic changes do coincide with demographic transitions and migration events. We conclude that increasing socioeconomic complexity and agricultural specialization increased the vulnerability of populations living in the desert margin ecosystems of the Atacama.

Fei, Li [271] Ideas of Immortality and the Clay Buddha Image from Yibin, Sichuan, China

In 2012, the Sichuan Provincial Institute of Archaeology excavated a group of cliff tombs in Nanxi County, Yibin; grave M12 at this site revealed a clay Buddha image. This paper argues that this is the base of an object dating between the late Eastern Han and the Shu Han period (AD 25–263) that is similar to the bases of money trees molded in the shape of a seated Buddha or Queen Mother of the West. The image thus likely developed from the image of the Queen Mother of the West as seen at the base of such objects. Even though the Buddha image from Yibin is rather different from the Buddha images seen on money trees from Sichuan, this paper argues that both images reflect a shared belief in immortal beings. The paper furthermore shows that this image shows local traits that are particular to early Buddha images from southern Sichuan.

Felipe Lopez, Aarón (Universidad Veracruzana) [7] Petroglyph panel in Tlaltetela, Veracruz, Mexico

The Rio de los Pescados runs in a mountainous zone of the state of Veracruz, Mexico. The river passes through various ecological zones of varying terrain before emptying into the Gulf of Mexico. Tlaltetela is a small town located on a plateau approximately 60 m above the basin of the Rio de los Pescados in central Veracruz. Approximately 1 km from Tlaltetela, there is a large petroglyph panel on a 7.6 m high rock wall in the river basin. There are over 100 elements covering the panel, including 10 anthropomorphic depictions. Other figures appear to represent plants, animals, lightning bolts, and symbols similar to war shields and gods from various eras and cultures. Because of the variety of representations, it is believed the symbols were created over numerous centuries as the site lies along a route used for many years for trade and travel.

Feng, Yue and Youping Wang (School of Archaeology and Museology, Peking University) [33] Lithic Technology and Human Adaptation in Pleistocene Central China

Nearly half a century ago, Prof. Grahame Clark summarized the five modes of lithic technology in Paleolithic times: Oldowan, Acheulian, Mousterian, Blade and Microblade Techniques. Major areas in the western part of the Old World followed this sequence, however, going east to the Tibetan Plateau and the deserts of Central Asia, China, and East Asia, the core-and-flake and cobble–tool industries persisted majorly throughout the Pleistocene. This paper introduces the new discoveries in the central part of East Asia, mainly focused on findings in Luonan Basin, Shaanxi Province and the eastern areas of Mt. Song in Zhengzhou, Henan Province, China. Based on these new materials, further discussions will be made on the uniqueness and importance of the lithic technology and human adaptation strategy in this region.

Fenn, Thomas (Cal Poly Pomona) and Doug Anderson (Haffenreffer Museum and Brown University) [387] Glass Beads and Evidence for Early “Precontact” Trade in Northwestern Alaska

Exploring early contact between native peoples of Alaska and Eurasian cultures provides important information on the movement of people and materials throughout greater Beringia. Glass trade beads are particularly well suited to explore these relationships, as they were not made locally and high-precision chemical analyses can provide string evidence to the production origins of the beads. Glass beads were recovered from excavation of a site dating from the late 1700s to early 1800s, just before official contact with non-native explorers, on the Kobuk River near Kiana, northwestern Alaska.
Questions regarding these beads are whether they originated from the west, from or through Asia, or from the Alaskan interior via North American trade from the east. This paper reviews evidence for early glass bead trade into Alaska and presents new chemical analyses of the Kobuk River site. Results suggest Asian and trans-Asian origins for the glass beads. Discussion of the potential trade routes and mechanisms are explored.

Evidencias bioarqueológicas de los grupos sedentarios en el semidesierto de Querétaro

El semidesierto de Querétaro guarda en su interior una gran cantidad de información que nos indica la presencia de grupos sedentarios desde épocas muy tempranas. Ejemplo de ello lo constituye el entierro de Peña Blanca, uno de los contextos más interesantes que se han recuperado en el Estado en los últimos años. Otros hallazgos nos permiten vislumbrar las dinámicas culturales que establecieron estos grupos caracterizados a partir del estudio de sus sistemas de enterramiento, los cuales destacan por una serie de particularidades tanto por la forma en que eran depositados los cuerpos y los objetos asociados a éstos como por los resultados de los análisis realizados para su datación. En esta ponencia daremos a conocer las características generales de los hallazgos y su importancia para la investigación de las sociedades prehispánicas de la región.

Chemical Characterization and Source Identification of Obsidian Projectile Points in the Southern Southwest

A sample of over 800 obsidian projectile points collected during 40 years of archaeological survey and excavation on Fort Bliss Military Reservation of south-central New Mexico and western Texas was submitted for chemical characterization and source identification using X-ray fluorescence (XRF). Obsidian projectile points representing all major temporal periods were analyzed, including Paleoindian Folsom points, several forms of dart points produced during the Early, Middle, and Late Archaic Periods, and arrow points of the Ceramic and Protohistoric Periods. Geologic obsidian sources from across the Southwest and northern Mexico and secondary sources along the Rio Grande Valley were identified among the samples and the temporal and geographic distributions of those sources were reviewed. The use of temporally-sensitive projectile points provided a much broader time depth than previous studies of obsidian sources based on groups of samples relating to one or two phases or periods and allowed for changes in territorial mobility ranges during the Archaic Period to be contrasted with shifting social and economic relationships during the Ceramic Period. The analysis provides an unprecedented insight into 8,000 years of prehistoric adaptations, mobility, and social evolution in the northern Chihuahuan Desert of southern New Mexico and Trans-Pecos Texas.

I Know Why the Caged Parrot Squawks: A Distributional Analysis of Casas Grandes Macaw Cage Stones and the Organization of a Ceremonial Industry

The prehistoric exchange of macaws and their feathers was a ritually charged cultural phenomenon observed across the Southwestern United States and portions of Northern Mexico. Nowhere was the integration of this industry more apparent than at Paquimé, the principal center of the Casas Grandes culture, in present day Northern Chihuahua, Mexico. The residents of Paquimé and some of its outlying community members imported, bred, raised, and ritually sacrificed various species of macaws by the hundreds. A central component of the aviculture program was the development of a ground stone cage door ring and corresponding cage plug. The rings and plugs are found in a variety of forms and finishes, though they are normally referenced as a general artifact type. Using Geographic Information Systems software, the site-wide distribution of the cage stones was evaluated by type and location. My results suggest a division between full-time aviculture specialists and part-time domestic practitioners, based on the preferential use of high-quality finished stones in some areas over others where rough and repurposed stones were adequate.

Baseline Remote Sensing Survey of the Mayan Biosphere Reserve (MBR) in Petén Guatemala

The Fundación Patrimonio Cultural y Natural Maya (PACUNAM), a nongovernmental-organization (NGO) from Guatemala, works for the promotion and preservation of cultural and natural patrimony contained within the Mayan Biosphere Reserve (MBR) in the department of Petén in Guatemala. To aid with their preservation and promotion goals, PACUNAM, has developed a plan to perform an airborne lidar and hyperspectral survey of nearly 14,000 km² of the MBR and neighboring regions over a three-year period. PACUNAM has contracted the National Science Foundation (NSF) National Center for Airborne Laser Mapping to perform the survey. NCALM started the first phase of the project in July of 2016 and within a period of three weeks mapped approximately 1,700 km² of the reserve with a multispectral lidar. This coverage is spread among 11 macro areas-of-interest, which cover the archaeological sites of Tikal, Holmul, Naachtun, La Corona, El Zotz, El Peru, Waka, Uaxactun, San Bartolo, Xultun, El Tintal, Achiotal, Witzna, and four other critical environmental study regions. This presentation will provide a rationale for this multiyear project as well as cover technical, logistical and scheduling details regarding the completed first phase and upcoming data collection and processing phases.

Food and Foodways at Sihó, Yucatán: Understanding Socioeconomic Diversity

In the past as in the present, foodways and cuisine have been expressions of identity and status. Different social strata had different access to natural resources and offered a variety of material expressions related to food, preparation and service, from grinding stones to exquisite art works. In Classic...
Maya society, some foodstuffs such as cacao, were mentioned and painted in beautiful elite wares, as well as in murals and carvings. At Sihó, Yucatán, archaeological projects developed by the Autonomous University of Yucatán have explored house compounds from different socioeconomic levels, by excavating buildings from range structures to small house foundations. Our results show an important difference in meat consumption between high and middle or low strata, but perhaps surprisingly, there is the presence of cacao in a nonelite compound, showing a complex and rich panorama of food choices. Our goal in this paper is to identify similarities and differences in access to resources and food consumption practices in Sihó’s Classic society in order to discuss how these can be related to socioeconomic stratification and identity. We utilize spot test chemical analysis and starch grain analysis of ceramics and grinding implements from five house compounds to test our hypotheses.

Breastfeeding, Weaning, and Childhood Diet in Cave and Megalithic Populations of Late Neolithic North-Central Spain

Stable carbon and nitrogen data of adult/adolescent human bone collagen from north-central Spain’s Late Neolithic (ca. 3500–2000 cal. BC) provide evidence for the existence of significant isotopic differences among and between communities living in close proximity and burying their dead in caves and megalithic graves. This, together with previously identified distinct funerary selection patterns, suggests an unsuspected complex social or cultural differentiation. The purpose of this paper is to extend the isotopic investigation to infants and young children, in order to determine at what age isotopic/dietary difference appears and if divergences can also be seen in breastfeeding and weaning practices. This may have implications for whether these are two distinct populations, or some other division within society that occurs from a certain age. To this end, stable carbon and nitrogen analyses on infant bone collagen and on high-resolution incremental dentine samples of first permanent molars are conducted, increasing precision in considering weaning chronologies.

Fernandez-Gotz, Manuel (University of Edinburgh)

[324] Collective Action in Iron Age Europe: Public Assemblies as Arenas for Participatory Government

Public assemblies were a common phenomenon in Iron Age and Early Medieval Europe. In these large collective meetings, important decisions concerning war, the choice of military leaders, legislation and the administration of justice were taken. Together with their political role, they also fulfilled other simultaneous functions, including religious festivals and the holding of fairs. Once believed to be archaeologically invisible, recent research has identified the remains of a large number of public assembly places within Late Iron Age fortifications. This paper will summarize the archaeological and literary evidence for Iron Age public assemblies, setting them into the wider comparative framework of collective action theory.

[165] Late Glacial to middle Holocene demographic dynamics in Iberia: a chronological modeling approach

This paper presents the preliminary results of the research project MULTI-SCALEARDEM and our current work in the context of a new ERC supported project: PALEODEM. Both projects aim to reconstruct the population history of the Iberian Peninsula from the Late Magdalenian to the Late Mesolithic (c.16,000–8000 cal BP), a time framework of major cultural and socioeconomic adaptations to climatic and environmental change. For this presentation, we will focus on the analysis of the radiocarbon record (summed probability distributions approach of calibrated radiocarbon dates) to infer past demographic dynamics. A new georeferenced database of radiocarbon dates has been created ad hoc for this research. In order to critically assess the quality and resolution of the Iberian radiocarbon record, and different filtering criteria and calibration procedures have been implemented. Our analytical approach includes taphonomic bias corrections, non-parametric bootstrapping to test the statistical significance of the observed results and hypothesis testing of different models of demographic growth. Finally, we will discuss general trends and regionally-specific relative population changes in the context of the Late Glacial to middle Holocene climatic variability.

Fernandez-Perez, Natasha (University of Puerto Rico–Rio Piedras) and Isabel Rivera-Collazo (University of California–San Diego)

[370] Beyond Subsistence: Food Consumption in the Military Garrison of San Juan de Puerto Rico from the Eighteenth to Nineteenth Centuries

This case study explores how food consumption in the military garrison of San Juan de Puerto Rico played a role in the negotiation of status and identities during the Spanish colonial period. Since defense of the territories was the primary task, the military tended to have priority to the access of exotic foods, and if there is variation of this pattern throughout time. To answer this, we conducted an exploratory excavation in the kitchen and latrine of the Morro de El Castillo San Felipe del Morro and took sediment samples for phytolith analysis. Given that these areas are integral to food preparation and excretion, we can expect both to contain food remains. The results of this analysis will contribute to discussions about the relationship between food and status, and discussions about the negotiation of identities.

Fernandini, Francesca (Stanford University)

[170] Cerro de Oro and the Year AD 600: Changing Settlement Patterns in the Lower Cañete Valley

The year AD 600 seems to be an important turning point in the settlement pattern of the lower Cañete valley. While settlements prior to this date tend to be small sized and located close to the river margin, the period after AD 600 shows settlements tend to be placed a few kilometers away from the river margin. The largest of these is Cerro de Oro, a 150 ha densely populated settlement located at the top of a mound, 13 km away from the river margin. The construction and use of Cerro de Oro seems to coincide with the creation of an extensive irrigation system as well as a well-managed exploitation of agricultural products at the site. This study will attempt to establish an association between the unprecedented nucleation of people on top of the Cerro de Oro mound, the increase of the agricultural frontier through the installation of a new irrigation system in the lower Cañete valley and the well-documented climatic oscillations that characterized the years circa AD 600.

[181] Reconstruction of Genetic Diversity prior to Recolonization of Nearly Extinct Alpine Ibex (Capra ibex) using Ancient DNA

Human activity has driven several mammal species close to extinction. The Alpine ibex (Capra ibex) suffered a severe bottleneck during the nineteenth century, when overhunting and habitat loss resulted in less than a hundred individuals surviving in the Italian Alps. Since then, the Alpine ibex has been successfully reintroduced across the Alpine ridge. Genetic analyses reveal a low genetic diversity in all extant populations, a common phenomenon in
species that have gone through a recent bottleneck. Historical and zooarchaeological records of the Alpine ibex from the period of the population collapse are sparse. We are therefore using museum and archaeological specimens that predate the human induced bottleneck to address the historical archaeological question of whether the current low diversity was caused by recent human influence or by prior events (e.g., population reductions during the glacial maxima). We are reconstructing complete mitochondrial genomes from skeletal remains of twelve Alpine ibex individuals: six 150- to 300-year-old museum specimens, five individuals found in a cave system in central Switzerland and radiocarbon dated to between 3000 and 8000 years BP, and one sample, likely a hunting trophy, from a Roman settlement in eastern Switzerland dated to around 2000 years BP.

[294] Fire and Death: Cremation as a Ritualized Funerary Practice in the Southern Brazilian Highlands

Archaeological evidence from southern Jê mound and enclosure complexes in the southern Brazilian highlands points to the development of a complex funerary ritual focused on the practice of cremation from 1000 BP onward. Drawing upon bioarchaeological, ethnographic and ethnohistorical analysis, this paper discusses the role of cremation as a ritualized practice aimed at transforming the dead, their body and their relations with society. Patterns of similarities and differences in such practice are observable in the archaeological record at eleven mound and enclosure complex sites with repeated evidence for cremation and the secondary deposition of cremated remains. These patterns are interpreted as negotiable and nonnegotiable strategic responses to death.

Ferris, Neal (University of Western Ontario)

[18] Searching for Reflexivity in Digital Archaeology and Heritage

The general enthusiasm for all things digital applied to archaeological method and research makes teaching a course on digital archaeology tailor-made for the kinds of experiential learning approaches archaeology does so well within the academy. That enthusiasm facilitates an archaeologically creative engagement with digital technologies and information management that, at its best, reimagines the archaeological enterprise and advances stunning new research applications. But what is sometimes lost in all that enthusiasm is a reflexive gaze: just because we can do it (scan, print, share, make accessible online, etc.), should we do it? For what purposes? Is it ever not okay to do “it”? And how do the technologies obfuscate those decisions, or facilitate a wider reflexivity on archaeology and heritage? In this paper I consider my own attempts to balance coming up with a digital archaeology and heritage cross-listed course, while trying to find ways for that class to ponder the reasons why.

Fertelmes, Craig (Gila River Indian Community)

[335] Geochemical Evidence for Dispersed Ground Stone Tool Production at Hohokam Villages in the Middle Gila River Valley, Arizona.

A recent geochemical provenance analysis of Hohokam vesicular basalt grinding tools argued for the nucleated production of trough manos and metates during the Preclassic (AD 500–1100) and Classic (AD 1100–1450) periods (Fertelmes 2014). One locus of production was suggested to have been the primary village of Upper Santan, which acquired vesicular basalt from the Santan Mountains and then distributed finished or nearly complete grinding tools to settlements across the Middle Gila River Valley. However, this model of vesicular basalt tool production is rejected in light of new research completed by the Gila River Indian Community—Cultural Resource Management Program (GRIC-CRMP). Additional sampling and geochemical analysis of vesicular basalt from the Santan Mountains has identified two spatially and geochemically distinct source groups. Differential consumption of these two source groups by local settlements indicates that the production of vesicular basalt grinding tools was not concentrated at Upper Santan. Resultantly, it is suggested that Hohokam vesicular basalt groundstone tool production in the Middle Gila River Valley is better characterized as dispersed and also that the nexus of production and distribution was organized at the household level.

Fiehiring, Benno (Instituto Nacional de Antropologia e Historia) and Hans Martz (Escuela Nacional de Antropologia e Historia)

With only scarce information on the topic, we have undertaken an archaeoastronomical investigation in Tamtoc, because we consider that the relations between its architecture and phenomena in the sky constituted an important element for the harmonic integration of its urban space, which probably supported oral discourse in the past. The measurement of the building’s orientation in relation to the local horizon, allows us to know the specific calendric dates at which the sun aligns with the axis in question, a fact that contributes important information with respect to the settlements formation. In this paper we present the results of several archaeoastronomical measurements and argue that Mesoamerican calendric intervals have been operated in Tamtoc. It seems to be clear, that pairs of calendric dates (that are part of particular calendric families) as well as conmensurative intervals were used to orientate and position buildings and formally integrate the urban center.

[123] Push and Pull Factors in Inland Settlement

Archaeological investigation along the coastlines of the islands of the Western Pacific have documented the distinct deposits of human colonizers and their descendants. Recent research has indicated that the first colonists were marine foragers, but also directed their forays into the interiors of islands to collect reptiles, bats, and birds. The research presented here reveals how predictive modeling and directed survey can aid in the detection of post-colonization sites located in the interiors of larger islands, in this case Viti Levu, Fiji. The examination of island interiors as a critical component of colonization can aid in furthering our understanding of ecological change and human population growth and settlement.

[301] Large-Scale Aerial Photogrammetry: A Comparative Case Study of Changes in the Archaeological Landscape surrounding Pueblo Pintado, New Mexico

In this poster, I explore shifts in the geomorphic landscape surrounding Pueblo Pintado, outside of Chaco Canyon National Cultural Park, New Mexico, in order to assess modern impacts on the ancient road systems which connect Great Houses throughout the Chacoan region. Utilizing high-altitude
aerial imagery gathered by Jacob Smith III, I am working to create a high-resolution, large-scale photogrammetric model surrounding Pueblo Pintado. This model will provide support for geospatial analyses of Chacoan road systems through two avenues: 1) it will aid in identifying the full extent of the Pueblo Pintado to Chaco Canyon road, as well as a smaller connecting road between Pueblo Pintado and the Chacra Face road; and 2) it will act as a more precise model from which higher resolution DTM’s and DEM’s can be created to service increasingly accurate Least Cost Path Analyses. This model will additionally operate as a comparative dataset to analyze shifts in the geomorphic landscape over a twenty-five year period; juxtaposed against modern high resolution aerial imagery supplied by a NASA DEVELOP project. Lastly, I discuss the effect of modern land easement and natural resource permits on the archaeological landscape of the area as well as future research implications.

How Many Birds Does It Take to Make a Feathered Shield? The Resources and Techniques of Mexica Featherworkers
Filloy, Laura (Museo Nacional de Antropologia) and Maria Olvido Moreno-Guzman (IIE-UNAM)
[225] 
How Many Birds Does It Take to Make a Feathered Shield? The Resources and Techniques of Mexica Featherworkers
The Florentine Codex is an excellent source for understanding the manufacturing techniques used by Mexica featherworkers to make luxury items. It records many of the tools and steps necessary to tie feathers and produce multicolor mosaics. Historical information about the selection of the raw materials, their storage, preparation, and handling, however, is scarce. The meticulous study of two Mexico feathered shields has allowed us to understand, not only the materials used in their manufacture, but also to estimate the number of feathers required to make these objects. This presentation will examine the resources and techniques employed by featherworkers in the capital of the Mexica Empire.

Developing Dialogue: A Developer, First Nation Band Member, and Archaeologist Discuss the Role of Meaningful Consultation in CRM
As stated in the SAA’s Principles of Archaeological Ethics, “Responsible archaeological research [requires a commitment to] consult actively with affected group(s), with the goal of establishing a working relationship that can be beneficial to all parties involved.” In the context of professional consulting archaeology, meaningful consultation with descendant communities is often held as a primary goal. However, CRM archaeologists are faced developers’ timelines and budgets, which can preclude anything more than superficial consultation. In British Columbia, consultation with First Nations is mandated by the Province, and most developers see liaison and communication with First Nations as a necessary step. Unfortunately, First Nations involvement in projects rarely exceeds the opportunity to employ local field assistants and for First Nations governments to comment on findings. Rarely are design plans developed in conjunction with and in true collaboration with First Nations. This paper, presented by a Vancouver-based residential developer; a member of the First Nation most affected by development; and the archaeological firm contracted for the development, offers a new model for truly collaborative consulting archaeology. True and meaningful inclusion of descendant communities in development and design plans is more than routine “consultation”; we argue that it is good business practice.

Finlay, Nyree
[100] 
The Avocational Atelier: A Portrait of Lithic Collection Practice
Adapting contemporary archaeological techniques used in the recovery of Francis Bacon’s Reece Mews studio, this project documents the collecting practice of an avocational lithic fieldworker on the Isle of Arran, Scotland, who assembled a substantial heritage archive including significant archaeological objects, prehistoric assemblages and geological specimens. Treating her abandoned artifact analysis table and intact workrooms as sites
it used traditional and multimedia techniques to record her working environment and explore modes of engagement and analytical methodologies. It presents a rare opportunity to capture in situ work practices to produce an intimate life-course portrait of a female collector that also offers broader comparative insights into twentieth-twenty-first century collaborative recreational research activity. In addition, intergenerational and entangled networks and issues around object divestment are explored with a view to anticipating future ancestral legacies and needs in light of Scottish national strategies promoting wider heritage participation.

Finding Buddha: Hi-Tech Approach to the Study of Buddhist Transition at the Angkorian Center of Preah Khan of Kompong Svay, Cambodia (Tenth to Sixteenth Centuries CE)
The Two Buddhist Towers Project seeks to identify material culture evidence of the important shift from Mahayana to Theravada Buddhism during the decline of the Angkorian Khmer Empire. At the regional center of Preah Khan of Kompong Svay, also known as Bakan, the most representative iconography, found for example at the Tower of Preah Thkol and the temple of Prasat Stoeng, shows the religious foundations of Mahayana Buddhism, which was probably practiced at the site since its inception. On the other hand, Theravadin evidence is scarce and best exemplified by the tower of the four-faced standing Buddha of Preah Chatumukh and the numerous recarved lintels depicting five meditating Buddhas. The difficulties encountered in finding and studying remains of this religious change using traditional methods has prompted the adoption of new technologies for this inquiry, including lidar, drone photography, 3D photogrammetry and field spectroscopy. In this paper, we present initial results and discuss challenges and issues related to the application of these techniques at Preah Khan of Kompong Svay.

Fish, Paul (Arizona State Museum) [335]

Visiting a “Villagescape”: The Early Classic Period Marana Mound Site
We explore Early Classic Period Hohokam society through the medium of inhabitants’ lives in the center with a platform mound and over 40 residential compounds in the northern Tucson Basin. We approach the topic as a retrospective based on 30 years of intermittent mapping and excavation at the Marana Mound Site, coupled with insights from advancing Hohokam studies. We ask how the spatial and architectural configuration or “villagescape” of this center reflected and embodied the principles of communal and regional organization at this time and place. Envisioning the experiential backdrop of the Early Classic Period reveals the partitioned nature of domestic and public space in which pervasive compound walls segmented both societal domains with physical and symbolic barriers. How did compound dwellers come together and establish collective identities as new social entities? We identify patterns of differentiation within and between compounds and in mound precincts, especially considering evidence that might pertain to the identity and whereabouts of the elusive emergent elites long attributed to the Classic Period. We discuss the developmental trajectory of the center from initial settlement to the cessation of residential occupation and subsequent revisitation.

Fish, Suzanne (Univ. of Arizona) and Paul Fish (Univ. of Arizona) [335]

Tucson Platform Mounds in the Context of Classic Period Variability
The variability among Hohokam platform mounds and their related architectural complexes, the predominant form of public architecture during the Classic period, has now been well documented through ongoing field studies and archival research. Recognition of that variability encompasses multiple dimensions linked to perceptions of leadership, social structure, territorial configurations, civic and ritual affairs, and external relationships. The Tucson regional sector in southern Arizona is no exception, with platform mounds mirroring much of the diversity seen in the greater Hohokam domain. As elsewhere, untangling the expressions and sources of Tucson variability is challenging due to incomplete data and poorly understood factors such as chronological tendencies and intraregional stylistic spheres. We begin with mound complex attributes and developmental histories at two Tucson Classic centers where we have worked, one restricted to the Early Classic period and a second occupied from Early through Late Classic times. We then examine these two cases against a backdrop of broader variability at local through region-wide scales in order to strengthen insights into the roles of these iconic precincts in Classic period Hohokam society.

Methods for the Identification of Dog and Dog/Wolf Hybrids from Wild Canids in the Northern Plains
In Native North America, dogs (Canis familiaris) were an important resource, used for traction, food, security, and ritual. Given their ubiquity in settlements and their tendency to consume human food waste, dog’s remains can provide significant information about past human diet. Stable carbon isotope (δ13C) ratios may be used to reconstruct maize consumption, while nitrogen (δ15N) isotope ratios increase by trophic level, and can be used to differentiate between marine, freshwater, and terrestrial inputs. Studies comparing human and dog δ13C and δ15N indicate general uniformity, showing that domestic dogs may be used as proxies for human diet, specifically when addressing maize production. Yet the archaeological identification of dogs is complicated by their hybridization with wild wolves (Canis lupus). Furthermore, in the northern Plains, both wild and domestic canids were used for different purposes by people. By combining qualitative and quantitative zooarchaeological analyses, geometric morphometrics, and molecular analyses, this research presents a method for using two independent lines of evidence for the differentiation of wild and domestic/semi-domestic canids at agricultural sites along the Middle Missouri in North Dakota.

Integrating Generations on the Formative Maya Landscape: Households and Communities at Tzacauil
Many Maya centers owe their longevity to the long-term persistence of their households, which were integrated as continuous social units throughout multiple generations. Yet how did the integration of the multigenerational Maya household first emerge? I address this question through the lens of the early farming village of Tzacauil, Yucatán, Mexico. In the Late Formative period (250 BC–AD 250)—the era in which Tzacauil was occupied and abandoned—people in the Maya area began using stone to construct their houses. Houses could outlive their builders for the first time in Maya history. This investment in permanence was tied to increased reliance on gardening and agriculture, and with it, a growing commitment to improving and claiming the landscape over multiple generations. In this paper I discuss the early integration—and later disintegration—of multigenerational households using data collected from house group excavations, lidar, and survey at Tzacauil. Three aims of this paper are: 1) to interpret differences in Tzacauil
house groups’ spatial organization as variable investment in multigenerational integration; 2) to move beyond physical houses to address how entire landscapes were integrated by household efforts; and 3) to question why the Tzacauli community ultimately disintegrated.

[251] The Environmental Conquest of West Mexico: The Lake Pátzcuaro and Malpaso Valley Case Studies

Though the next century will bring great environmental challenges the impact of global warming pales in comparison to the dramatic environmental changes associated with European Colonialism, beginning in the late fifteenth century. Chief among them is the Conquest of the Americas involving the breakdown of millennial-aged systems of land engineering and tenure, compounded by depopulation, and the introduction of the Euro-agro suite. Throughout Central Mexico the initial century of Conquest Europeanized the landscape limiting subsequent land use to an adapted Mediterranean-style system of extensive agriculture and pastoralism. Here we explore the environmental implications of these changes—pre- and post-conquest—for two disparate regions of Mesoamerica, the Lake Pátzcuaro Basin, Michoacán, and the Malpaso Valley, Zacatecas. I will also demonstrate how the Postcolonial and modern landscape are products of this critical transition, and suggest future implications for conservation and global change.

[85] An Updated GIS-Based System for Calculating MNE and Quantifying Bone Surface Modification Frequencies and Spatial Location on Skeletal Elements in Faunal Assemblages

Zooarchaeology continues to suffer methodological problems in that analysts use methods for calculating skeletal element and surface modification abundance that vary widely, are non-transparent, and almost certainly produce data that is not comparable across analysts. In 2001, Marean, Abe, Nilsson, and Stone presented a method to overcome these problems by using a GIS-based approach to calculate minimum numbers of skeletal elements (MNE) and surface modification frequencies corrected for preserved surface area. That software was designed in ESRI ArcView and has been widely used and cited. Here, we present an improved and expanded version of their methodology that now runs with ESRI ArcGIS 10.x software. This new software package, which will be available freely, is called “Faunalyze 2.1,” and it implements the open-sourced Python 3.4 computing language, which is native to ArcGIS geoprocessing. We will also provide an overview of the program architecture as well as a brief example of the software in use.

Fisher, Jacob (California State University, Sacramento)

[251] Demographic Collapse and Deintensification in Protohistoric Alta California

Decreased human population densities associated with European exploration and colonialism in western North America may explain the historic observations of bountiful game that contrasts so drastically with the archaeological record on resource intensification. At Kathy’s Rockshelter in the northern Sierra Nevada foothills, California, there is a clear prehistoric trend toward resource depression of artiodactyls and increased dependence on small mammals, freshwater mussels, geophytes, and other higher cost resources. A reversal of this trend corresponds with the initial European exploration of the California coast in the sixteenth century. This suggests that interior Native Californian populations were impacted by epidemics spreading in advance of direct contact in the nineteenth century. When human population densities declined significantly, the relaxation of hunting pressures allowed for an increase in large game populations to historic baseline levels.

[97] On-Site Public Interpretation of Bison Kill Sites

Translating professional archaeological research into meaningful educational experiences for the public has taken on increased urgency in recent years. Several archaeologically investigated ancient bison kill sites in North America, located in Alberta, Saskatchewan, Montana, Wyoming, Nebraska, and Texas, have an on-site public interpretive facility. The experiences at seven of these sites in moving from archaeological research to developing a public interpretive center are chronicled in a recently published book entitled Pisakan: Interpreting First Peoples Bison Kills at Heritage Parks (edited by Leslie B. Davis and John W. Fisher Jr., University of Utah Press, 2016). Each case study followed its own unique path. Shared perceptions come through on certain issues pertaining to public education. These include the importance of conveying to the public that archaeological method and theory change through time, and that the same body of evidence is open to alternative interpretations. Debate among archaeologists is healthy and engenders advances in knowledge and understanding. This presentation conveys perspectives of archaeologists who have been deeply involved in public education at on-site interpretive centers.

[257] Late Pleistocene and Early Holocene Alaska: Placing Archaeological Data on Projected Paleocological Landscapes

Understanding ecological responses to climate change are essential before inferences can be made regarding past culture change and human adaptation to the environment. This study focuses on modeling the paleoecology of central Alaska at the Pleistocene-Holocene Transition using predictive modeling. Quadratic Discriminant Analysis is used to determine which modern climate variables, including minimum and maximum temperature and precipitation, as well as topographic data, best predict modern vegetation land coverage. This method is then applied to the Pleistocene-Holocene Transition in Alaska to predict and project the boundaries of ancient plant communities by altering the climate variables to estimates based on proxy data. This study focuses on three climatically defined chronozones: the Belling-Altered interstadial, the Younger Dryas stadial, and the Holocene Thermal Maximum. The purpose of this study is twofold: 1) to use predictive modeling to assess the sensitivity of central Alaska’s ecology at the Pleistocene-Holocene Transition to climate change and to infer what these ecological shifts entailed; and 2) to examine how changes in the lithic technological organization at archaeological sites comprised of the Nenana and Denali artifact complexes correlate to areas with predicted ecological perturbations.
The onset of puberty, characterized by menarche in females, marks the important transition from the juvenile to the adolescent life-history stage. Limited research has been done to investigate the relationship between this transition and indicators of skeletal and dental maturation. This study examines the association between age of menarche and stages of skeletal and dental development seen in radiographs of the hand/wrist and dentition, using a sample of 33 females followed longitudinally in the University of Montreal Growth Study. Correlation analysis was used to test the relationship between the age of menarche and the skeletal/dental maturation stages assigned to eight teeth as well as the bones in the hand/wrist. Maturation of the ulna and PM2 provided the strongest relationships with age of menarche. Regression analysis showed that combining these two indicators strengthens that relationship, with the PM2 as the strongest predictor of age at menarche. These findings can provide a reliable method for estimating the age of menarche in skeletal remains, providing insight into the reproductive life span, social and nutritional status of past populations.

[302] X-ray Fluorescence (XRF) and Morphological Analysis of Trade Beads from Palau, Micronesia

Glass beads have long played an important role in Micronesian societies. Oral histories and ethnographic accounts describe how clay and glass beads ("udoud") in Palau functioned as traditional forms of currency in exchange relationships and were apparently used by islanders from Yap several hundred miles away to negotiate access to limestone quarries that enabled them to carve their famous stone money disks ("rai"). Evidence shows that both stone money quarrying and the exchange of high-valued items such as beads increased after European contact. In this study, we have conducted the first compositional analysis of glass beads from Palau, which were recovered at the multicomponent site of Chelechol ra Orrak. X-ray fluorescence spectrometry (XRF) and morphological analyses indicate that the beads were manufactured in both Europe and Asia and date to the mid-nineteenth century. Detailed examination of several dozen of these beads not only provides insight into Yapese-Palauan interactions at the time of European contact, but helps anchor activities at the site with much greater chronological resolution.

[125] Painted Pots and Royal Routes: Hieroglyphic and Ceramic Traditions in the Western Petén

The cities of the western Petén shared a common history and several ceramic traditions. In the northwest along the San Pedro Martir River, archaeological sites like El Peru (Waka'), Zapote Bobal (Hiix Witz), La Joyanca, and La Florida (Namaan) flourished with seemingly few—if any—clashes between them for the entirety of the Classic Period. That being said, we know that this region was greatly affected by the Tikal-Calakmul wars. There was even a "road" or route between the sites allied to the "Snake" kings that ran right through this region, ostensibly through El Peru and Zapote Bobal; indeed this route was one of the keys to their dominance in the Maya area during the seventh and early eighth centuries AD. It seems plausible to suggest that the bonds between the local communities here, with their shared traditions and apparently peaceful relations, may have formed in opposition to these larger geopolitical events. This paper will explore what we know from the hieroglyphic record and how it accords with the ceramic evidence for mutual cooperation in the western Petén.

[76] Large Walled Sites on the Chengdu Plain, Sichuan, China: Shifting Centers of Regional Emphasis
In the third millennium BC, several walled sites were inhabited in the Chengdu Plain of Sichuan, China. These late Neolithic settlements varied in size and shape, and they had mounded earth walls, some encompassing the largest areas of any known sites of their time in China. The site of Baodun is the largest known example, and has recently been the focus of extensive excavations. Other known sites in the region include Gucheng in Pi Xian County, the most completely preserved of these walled sites, and Sanxingdugui, which became a central settlement of the Bronze Age Sanxingdugui Culture following the late Neolithic Baodun Culture. This talk examines the cultural and social context of these large walled sites and discusses landscape and settlement pattern changes during the transition from the Neolithic to Bronze Age periods in the region.

To and from Hopi: Negotiating Identity through Migration, Coalescence, and Closure at the Homol’ovi Settlement Cluster

The Homol’ovi Settlement Cluster (HSC) holds a significant place in Hopi history as a source of immigrants and a destination for emigrants. In addition to representing an important location along the migration route for groups from the South and East, these villages also housed people who temporarily emigrated from the Hopi mesas. As such, the HSC provides a unique perspective on the processes of population and social movement that contributed to the current form of Hopi society. Using the material record and ethnographic accounts, we examine the complex and multifaceted negotiations of identities that occurred within these villages. These negotiations began as immigrants arrived and established new villages in the region, and continued through the processes of coalescence and the final practices of closure that marked the end of occupation around 1400. We address the diversity of groups that persisted at the HSC through the expressions of passive and active identity in artifacts, such as ceramics, and practices of deposition and closure in order to highlight the accumulation, flexibility, and persistence of social identities that define Hopi people past and present.

Plucked Macaws: Evidence of Regular Feather Harvesting at Chaco Canyon

Macaws are not native to the American Southwest, but were imported into this region from central Mexico for hundreds of years. Recent research has demonstrated that the wing feathers of Southwestern macaws were regularly plucked, as evidenced by significant scarring on the birds’ ulnae. This paper provides a macroscopic analysis of macaw skeletal remains from Pueblo Bonito and Pueblo Arroyo in Chaco Canyon, New Mexico, and argues that these elements also show evidence of a practice of regular feather harvesting from live macaws. This information lends insight into the husbandry practices of macaws in the prehistoric Southwest, and aids in reconstructing the life histories of both the transplanted macaws and the humans that supported and utilized them.

Discussing Early Societies Fishtail Points and Early Social Practices Seen from the Southern Cone

The early peopling of South America is related to great environmental and material variability. Discussions must deal with early archaeological records including a variety of lithic assemblages in tropical lands, the Pacific coast, the Andes and the extensive southern plains and plateaus. In this context, fishtails are the most widespread point type exhibiting a dispersed pattern throughout most of South America during terminal Pleistocene times. They are therefore useful to think about with respect to situated social practices of the people who made and used them. Some practices related to these early settlers were identified throughout the southern cone including a very selective choice of raw materials and of landscapes. Point manufacture is described as sequential both in the Pampas and Patagonia reinforcing the existence of similarities in distant regions. Through the detailed study of manufacturing reduction events and of flakes we propose that some production choices conform a corpus shared in a very large area and are independent of local environmental circumstances. This situation is adequate to assess how these shared practices could have constituted traditional memories which were socially incorporated and transmitted, providing a sense of meaning among dispersed groups settling into a mostly empty landscape.

Fleming, Lacey (University of Alberta) and Robert Losey (University of Alberta) [35]

Application of the Canine Surrogacy Approach to Holocene and Iron Age Sites in Siberia

Humans and dogs have been living together for thousands of years, participating in various forms of relationships. One of these relationships involves the partial or complete provisioning of dogs by humans. Because of these practices, it has been argued that a dog’s diet should generally resemble that of the humans with whom it lived. This proposed interspecies dietary similarity has been an important aspect of some archaeological studies in that dog stable isotope values are in many cases used as direct proxies for human values. This perspective is known as the Canine Surrogacy Approach (CSA). In this paper, we explore the applicability of the CSA using dietary stable isotope data from Holocene coastal sites in Primorye, and from a large assemblage from the Iron Age Ust’-Polui site in the Siberian Arctic, both in the Russian Federation. The Primorye dogs were living in hunter-gatherer societies and feudal kingdoms, and likely were both working animals and human food resources. At Ust’-Polui, foragers’ dogs were sometimes butchered, but also occasionally sacrificed and carefully buried. We compare dog dietary stable isotope data to that of local humans at both locations to assess use of the CSA and to better understand dog provisioning strategies.

Exploring the Archaeological Applications of ITRAX XRF Soil Analysis in Southern Ontario

Prehistoric human occupation in Southern Ontario, Canada spans the gamut of ephemeral hunter-gatherer usage to intensive Iroquoian village settlements. ITRAX core scanning has the capacity to explore some of this rich history. Initially developed for environmental core analysis, ITRAX technology can highlight differences in culturally generated chemical signatures between intensive and ephemeral occupations. This automated, nondestructive X-ray fluorescence (XRF) analysis has the potential to contribute to site prospection techniques, investigations of landscape use, and challenges to site-centric notions of archaeology. This paper presents an initial evaluation of the utility of ITRAX core scanning in archaeological applications. It compares soil cores and bulk soil samples taken from a variety of contexts in Southern Ontario including locations of palimpsest hunter-
gatherer occupations and Iroquoian village sites. Comparisons with the results of phosphorous colorimeter and micro-debitage analyses show the capacity for XRF analysis to corroborate and enhance other forms of intensive small-scale analysis.

Fletcher, Roland (University of Sydney)

Here There Be Dragons: Trajectories and the Classification of Settlements

Urban as a label is a problem. This was recognized by Child and Adams and is re-iterated in the twenty-first century. Varied definitions apply in different regions, some huge settlements are excluded—apparently arbitrarily, others go in and out of "urban" fashion. Concurrently, the term "urban" has huge cachet, providing social dignity, national respect and access to research funds. The news media rarely refer to "The Lost Village" with awe. The conundrum is that while western European languages generally use a tripartite size and status classification such as camp, village and town/city to organize all settlements, other languages use many other terms with different meanings and associations. Plainly the term—urban—is not inherently a true or natural classification. The persistent default on to "urban" would not matter if the phenomena being referred to did not matter—but they do. And if the term is inconsistently spread across divergent trajectories of settlement growth with different magnitudes, rates of growth and outcomes then while local analytic inquiry might be unaffected, the capacity to ask and answer the globally consistent questions which are implied by the label will require either new terms or careful differentiation of terms.

400 Years of History and Cross-Cultural Interactions in a Ritually Mounded Landscape of South Tanna, Vanuatu

A mounded landscape in south Vanuatu provides archaeological evidence relating to chiefly performance, voyaging, and ritual transformation during a period of cross-cultural contacts spanning 400 years or more. The site of Kwaraka is located at the southern end of Tanna Island. The area has a view on clear days of the neighboring islands Futuna and Aniwa, and there is ethnohistoric evidence of long-term patterns of interaction between Tannese people and the people of these nearby islands. Kwaraka is somewhat unique on Tanna for its large-scale stone constructions, which are rare elsewhere on the island, though common on Futuna and Anietyum. The site is also notable as the location where the first Christian missionaries, recent Samoan converts settled in the 1850s. This arrival brought about a new wave of mound construction, this time in the form of house mounds built by the ritual specialists. The Kwaraka mounds provide interesting material for thinking about long-term patterns of communal rituals, including feasting, exchange, and magical practices on Tanna.

Yumbos and the Construction of Their Cultural Landscape

Archaeology as an academic practice in the northern Ecuadorian Andes has concentrated on a constant exploration of hypothesis about the past with the intention to acquire better and more accurate understanding about the origins and development of complex societies. Since the 1970s, scholars have produced valuable outcomes directed to those goals analyzing evidences concerning to the dynamism of Prehispanic societies in terms of regional distribution, social relations, environmental constrains, ideology, and political organization. The presence of nucleated and disperse patterns of mounds have fostered diverse debates about their origin, function, cultural affiliation, significance for social and political organization, and economic implications. However, conclusions remain obscure due to several factors, including conflicting theoretical perspectives, and the absence of complementary research projects in the region that contribute to the debate about the nature of those monumental constructions. The present research seeks to emphasize the comparative analysis of mounds distribution between the northern highlands Palmotpamba and Tulipe regions. This analysis will consider space and projects in the region that contribute to the debate about the nature of those monumental constructions. The present research seeks to emphasize the capacity for XRF analysis to corroborate and enhance other forms of intensive small-scale analysis.

[337] Preclassic Platforms at Yaxnohcah: Central Eminences for a Multinucleated Site

Yaxnohcah is an important Maya settlement in the southern Campeche lowlands, which, according to what present evidence suggests, had its main civic development during the Middle and Late Preclassic periods. The city’s layout includes some features that are specific to Yaxnohcah, as well as others shared with nearby and distant centers. One of central features of the Yaxnohcah settlement, which it shares with other sites, has been described as “clustered nucleation” or “dismembered” pattern for neighboring Southern Quintana Roo region. During the Preclassic at Yaxnohcah, this type of settlement pattern centered around huge terraces and building platforms, with an acropolis-like form. In this paper, we will examine the formal and architectonic characteristics and construction sequences of Yaxnohcah’s early civic complexes. In addition, we will analyze their placement in the landscape and the spatial relationships between groups. Finally, we will address the possible meanings of those characteristics.

Análisis Bioarqueológico de los Restos Óseos Recuperados en “El Tropel,” Colima

Dos cementerios no contemporáneos fueron parcialmente excavados en el sitio El Tropel, Villa de Álvarez, Colima, en 2004. En el cementerio correspondiente a la Fase Comala fueron excavados seis entierros, mientras que en aquel de la Fase Armería fueron excavados 23 entierros, uno de ellos doble. Además fue excavado un solitario entierro de la Fase Chanal. Los restos de los 31 individuos fueron estudiados bioarqueológicamente, buscando determinar edad, sexo, características físicas, estado de salud (patologías, traumatismos), modificaciones culturales como la deformación craneana y huellas de actividades físicas. Además se reconstruyeron prácticas funerarias de las fases Comala y Armería de Colima. Los resultados de este análisis, dentro del contexto social, cultural, económico y político de las fases Comala y Armería de Colima, nos permiten conocer y comparar datos relativos a la estratificación social, cuestiones de género, actividades ocupacionales y costumbres funerarias de estas sociedades pasadas.

Flynn, Erin (PAL)

Archaic Period dwellings have largely gone unnoticed in New England due to poor preservation and thousands of years of bioturbation. However, a concentration of post molds, large and small pits, and fire hearths uncovered at the Halls Swamp Site in southeastern Massachusetts are attributes that...
characterize, and have been associated with, the few Native American semi-subterranean dwellings identified in New England. Recognizing structural attributes is essential for understanding Native American settlement patterns, intrasite complexity, sociopolitical structure, and population data. Small groups or families during the Archaic Period may not have only used the typically-portrayed wetus of the Contact Period, and it’s important to think beyond the norm. Furthermore, the Halls Swamp Site has evidence for a fall and winter inland encampment, which necessitated a harder dwelling than a summer wetu. High investment in the construction of features was not unusual for Archaic Period peoples. Comparisons of sites from Native cultures along the east coast and further west, where archaeological signatures are better preserved, have provided data in regard to structure preference in certain environmental climates or zones.

Folan, William J. (Univ. Autónoma de Campeche), Maria del Rosario Dominguez C. (Univ. Autónoma de Campeche) and Joel D. Gunn (Univ. of North Carolina, Greensboro) [217] Maya Palaces: Royal Courts of the Ancient and Not-So-Ancient Maya The Palaces of the Petén Campechano and the remainder of the Yucatán Peninsula represent single and composite, royal multipurpose households of varying shapes and sizes often associated with triadic relationships representing religious, civic, and military responsibilities. These relationships are manifest in structures at Calakmul, Oxkintok, Becan, Santa Rosa Xtabak, the triadic Monjas Quadrangle of Uxmal, Structure #385 of Dzibichaltun, the triad of Noh Cah Chan Santa Cruz, El Palacio de Nachi Cocom, the Lacandon triad of Sac Balam in Chiapas and perhaps, the three brothers of Chichén Itzá. They represent continuity in Maya Lowland culture from Preclassic times to the present.

Foias, Antonio (Williams College), Jeanette Castellanis (San Carlos University, Guatemala) and Kitty Emery (University of Florida-Gainesville) [125] Ceramics and Polity at Motul de San José and its Periphery Motul de San Jose entered its Golden Age during the Late Classic. It was located at a critical crossroads in the Central Petén Lakes region, sitting between the east-west San Pedro Martir River that connected it to the Western Petén kingdoms all the way to Yaxchilan, and a north-south route that tied it with Tikal in the north and Dos Pilas and the other Petexbatun centers in the south. The political alliances between Motul and these kingdoms were materialized through the gifting of Ik’ Style polychromes to the royal families and secondary elites of these centers, and recorded in hieroglyphic texts. In this paper, we will be exploring further ceramic connections between Motul and the other Western kingdoms, while at the same time querying the ceramic differences which created a separate political identity for the people of the Ik’a kingdom.

Follensbee, Billie (Missouri State University) [60] Nets, Gauges, and Weights: More on Formative Period Gulf Coast Textiles and Technologies While considerable research has been conducted on the importance of textiles in Mesoamerica, little study has been done on textiles among Formative Period cultures such as the Gulf Coast Olmec. This is in great part because direct evidence of early textiles is scanty, consisting only of a fabric-impressed clay sherd, some hand-formed spindle whorls, and fragments of cordage and woven mats. As noted in my recent publications, however, depictions of textiles in Olmec sculpture provide additional material for analysis, and further evidence can be found in the reexamination of small stone artifacts recovered from Gulf Coast sites. Close analysis has revealed, for example, that objects previously identified as “bloodletters” much more likely served as functional weaving picks and awls, and that “spoons,” in their original, long-tailed form, closely resemble and function well as small weaving batten.

Fonseca Ibarra, Enah Montserrat (INAH), Sharon Herzka (Centro de Investigación Científica y de Educación), Miguel Téllez (Universidad Autónoma de Baja California [UABC]), and René L. Vellanoweth (California State University, Los Angeles) [142] Year-Round Shellfish Harvesting during the Middle to Late Holocene on the Northwest Coast, Baja California Knowledge of patterns of subsistence and seasonal settlement strategies on the northwest coast of the Baja California Peninsula is still scarce. In order to identify shellfish harvesting patterns from Middle to Late Holocene, oxygen isotope determinations from 66 California mussel shells (Mytilus californianus) from three archaeological sites in the coastal area of Bajamar-Jatay were analyzed. The results suggest that mussels were collected mainly during the fall and winter seasons (63.6%); followed by summer (24.2%), spring (9.1%) and to a lesser extent in late summer/early fall (3%). Except for one stratum in which the capture seems to have taken place primarily during the fall, most shellfish harvesting occurred year-round, both in the shell middens of the Anchic (4657 cal BP) as of Late prehistory (1352–846 cal BP). Shellfish harvesting may have been essential in the diet of the prehistoric human groups that seem to have occupied residential bases throughout the season cycle.

Fontes, Lisa (University of New Mexico) [165] The Elusive Vasco-Cantabrian Middle Magdalenian: Reflections from Urtiaga Cave, Guipúzcoa, Spain The Vasco-Cantabrian Middle Magdalenian (14.3–13.2 ka uncal. BP) remains intangible—known in the region from relatively few archaeological sites and principally defined on the basis of portable art items with Pyrenean origin. Recent research undertaken with collections from Urtiaga cave (Guipúzcoa, Spain) has included two radiocarbon assays of Level E that date to the Middle Magdalenian interval. This level lacks diagnostic portable art items, however, lithic and faunal analyses (conducted by Altuna 1972) have been made, which permit analyses of Middle Magdalenian economic behaviors. This paper will convey how human behaviors shifted between the well-defined Lower and Upper Magdalenian periods in the Vasco-Cantabrian region, and identify economic patterns that archaeologists can use to explore and compare Magdalenian groups’ adaptations at sites with and without temporally diagnostic artifacts.
From Mining to Mercury: Preservation of the Historic Industrial Landscape of Jackson, California

Nestled in the foothills of the western Sierra, the city of Jackson in Amador County, California was the location of some of the richest gold deposits mined in the Gold Rush era Mother Lode. Over the last few years, several projects have been initiated on this historic industrial landscape. The City of Jackson began raising funds to help preserve the uniquely stunning tailing wheels that have dominated the skyline for more than a century. Conversely, well beyond locally available funds is the problem of toxic cleanup as a result of nearly a century of mining efforts. Mercury, arsenic, and lead currently rest under significant portion of the city. Recently, the Environmental Protection Agency's National Priority List, commonly known as the Superfund, has added the Argonaut Mine in Jackson for federal aid in toxic cleanup. This poster will summarize the challenges of both preservation and hazardous cleanup on this cultural landscape.

CRM Archaeology and Collections Management—A Comparison between two Canadian Provinces

My CRM career has included positions in both British Columbia and Ontario, two provinces situated on opposite sides of the country. Working for the same consulting firm in both provinces, I have had the opportunity to manage the analysis and curative preparation of large precontact Aboriginal collections. This experience has resulted in the observation of strengths and weaknesses in current British Columbia and Ontario heritage legislation, archaeological permitting regulations, and collections management. In this paper, I will demonstrate the need for and advantages of better communication between:

- the Canadian provincial departments overseeing heritage management;
- Canadian CRM archaeologists and archaeological firms;
- Canadian museums and academic institutions serving as curatorial facilities; and
- CRM archaeologists and collections curators.

CRM archaeologists need to work closely with curators to develop consistent collections curation standards and practices that fit within project budgets and schedules. Further, more Canadian CRM firms need to recognize the importance of hiring and maintaining staff with collections management and curation experience. Without these improvements, the success of preserving our country’s heritage for future generations will remain subjective.

From Compass to Lidar: Forty Years of Mapping the Tarascan Cities of the Malpaís of Zacapu, Northwestern Mexico

Since their discovery in the late XIXth century, the large prehispanic urban settlements located close to the modern town of Zacapu (State of Michoacán, Mexico) have confronted the archaeologists to a great challenge: mapping, and understanding 200 hectares of dense and well preserved urban features founded on the Malpaís of Zacapu (a complex formed by ancient lava flows). Interpreted as premises of the Tarascan State (occupation AD 1250–1450), these cities constitute an unprecedented regional urban transition. In 1983, more systematic archaeological surveys and excavations were initiated at the region, starting 30 years of mapping method applications and tests aiming to assess this important archaeological data. After 30 years of fieldwork, the Malpaís of Zacapu sector has been covered by a full high-resolution lidar map that opened various analysis opportunities, and archaeological record confirmation or correction. In this presentation we aim to reconstruct the evolution of mapping methodologies used between 1983 and 2015, and present the advances of the lidar data analysis conducted since 2015. The case of Malpaís Prieto, one of the most important agglomerated settlements on the Malpaís terrain will be presented as a case study.

Ceremonial Artifact Breakage in the Archaic Period of Eastern North America

Intentional breakage of artifacts proliferates throughout the archaeological record in Eastern North America. Using the case of a Middle Archaic site (ca. 5000–4500 BP) from Ontario, this paper seeks to examine and compare the strategies for purposely damaging artifacts, with focus placed on gaining insight into motivations for breakage. Through the refitting of artifact fragments it is possible to identify when breakage was intentional and implemented
for purposes beyond subsistence activities. Similar patterns found in the experimental breakage of reproduction artifacts offer novel perspectives into the social conceptions of tools for Archaic hunter-gatherers.

[38] The Neolithic Transition in Europe: Archaeology versus Genetics  
There are two mechanisms of Neolithic spread: demic diffusion (dispersal of populations) and cultural diffusion (acculturation of hunter-gatherers). Archaeological data imply that demic diffusion was more important than cultural diffusion in determining the spread rate of the Neolithic in Europe. But those results are very uncertain. We now use ancient genetic data in addition to archaeological data, and estimate the relative importance of demic and cultural diffusion. We find that demic diffusion was, indeed, substantially more important than cultural diffusion at the continental scale.

[390] Corridors of Interaction: Using Chuskan Ceramics and Lithics to Reveal the Larger Sociopolitical Hierarchy of Chaco Canyon  
Unraveling the complex relationships that existed between Chaco Canyon and outlier communities is essential to understanding how and why Chaco rose to prominence and the nature of its sociopolitical authority. Key to this debate is evaluating the interactions between Chaco Canyon and the great house communities of the eastern slope of the Chuska Mountains. This region produced substantial quantities of the lithics, ceramics, timber, and food found within Chaco Canyon. The social conditions that brought these materials to the canyon has been central to various interpretations of the Chaco Regional System. My study aims to shed light on this exchange of materials by comparing the ratio of Chuskan goods (trachyte-tempered ceramics and Narbonna Pass chert) found in San Juan Basin great house communities lying between Chaco Canyon and the Chuska Mountains. This allows us to see where Chuskan goods were being distributed across the San Juan Basin, and whether certain communities were participants in the funneling of goods to meet the material needs of Chaco. This study evaluates several models of the sociopolitical structuring of Chaco and addresses the complex and potentially diverse relationships that existed between Chaco Canyon and outlier great house communities of the San Juan Basin.

[154] Of Ostrich and Ochre: The Application of pXRF to Detect Experimentally Pigmented Ostrich Eggshell  
Ostrich eggshell (OES) is a somewhat common occurrence in Middle and Later Stone Age archaeological contexts. Ethnographically, OES are known to be used as containers, raw material for bead production, and the egg itself as a valuable food source. Archaeologically, it is difficult to determine which of these potential functions the OES fulfilled. The application of mineral pigment powder to OES may suggest a non-subsistence function for that particular piece. For this study we experimentally produced mineral pigment powder out of hematite and applied it to modern OES. We then proceeded to wash, cook, and otherwise remove the powder and subsequently sample the modified OES with portable X-ray fluorescence (pXRF). Results from this study may suggest the utility in identifying pigmented OES within the archaeological record.

[375] Comparative Analysis of Petroglyphs at the Crack-in-Rock Community  
Recent archaeological research in Wupatki National Monument has led to a complete baseline documentation of a suite of petroglyph assemblages located at the Crack-in-Rock community in Northern Arizona. Through collaborative efforts between the Museum of Northern Arizona, the National Park Service, and Northern Arizona University, this paper details a comparative analysis approach to understanding the use and placement of rock art within the region. The Crack-in-Rock community boasts numerous standing architectural features and over 300 petroglyph panels, yet the area is surprisingly devoid of cultural artifacts. In an area well-known for its abundance of cultural remains, the community stands as an outlier in the national monument. In an effort to better understand Crack-in-Rock’s placement in the regional context, the petroglyph assemblages at the three sites in the community—Crack-in-Rock, Middle Mesa, and Horseshoe Mesa—were subject to both statistical and spatial analysis. The findings of this paper demonstrate how rock art research can broaden our understanding of the cultural landscape of the past.

Fowler, William (Vanderbilt University)  
Mapping and excavations of the Conquest-period and early colonial site of Ciudad Vieja, the ruins of the first villa of San Salvador, El Salvador, afford a view of material culture encounters and indigenous transformations in northern Central America. The Ciudad Vieja archaeological research has focused on material culture encounters between Spanish and indigenous populations in the realms of landscape, architecture, technology, economy, society, and religion. The time span for Ciudad Vieja runs from the Conquest to the mid-sixteenth century, from 1525 to about 1550. Subsequent developments are investigated at the site of Caluco, in the Izalcos region of western El Salvador, during the last quarter of the sixteenth century. A theoretical framework inspired by Pierre Bourdieu’s structural theory of practice allows for interpretation of differing strategies of practice during the early Spanish Colonial period of the sixteenth century. The early “Spanish” community of San Salvador, sited on an already ancient Mesoamerican ritual site, was an incubator of experimentation and transformation of Mesoamerican roles and identities. By the time of Caluco’s colonial community, practices and structures found in later Latin American communities, built on tensions between indigenous communities and state extraction, are increasingly apparent.

Fowles, Severin (Barnard College, Columbia University)  
[34] Choosing Nomadism: On Northern Tiwa Flights to the Southern Plains
In Southwest archaeology, we are accustomed to thinking about the relationship between the Southern Plains and the Pueblo region in terms of the movement of objects in a continental economy of mutualistic exchange. Hunters moved buffalo meat and hides west; horticulturalists moved corn, lithics and ceramics east. With the onset of the Spanish colonial project, the movement of objects within the Plains-Pueblo macroeconomy intensified. Guns, knives and horses were added to the flow of goods. And the traffic in human captives—which had surely been present in precolonial times at low levels—grew dramatically. There is much more to this tradition of Plains-Pueblo exchange, however. Indigenous testimony, archaeological evidence and colonial documents all point to a persistent history of the movement of social groups, and sometimes of entire societies, back and forth, as formerly Plains nomads became settled Pueblo people and vice versa. This paper looks to the rich case of the Northern Tiwa-speaking pueblos of the northern Rio Grande valley, whose precolonial and colonial histories reveal that such interregional movements not only were socially constitutive but also served as vital political strategies.

Excavation of a Plaza Platform at Group A of the Medicinal Trail Community: A Hinterland Maya Site in Northwestern Belize

Previous excavations at Group A of the Medicinal Trail Community indicated a long occupation of the area, possibly dating back to the Middle Preclassic. In an effort to identify the earliest occupational phase at the group, we excavated the Middle Courtyard plaza platform of Group A to a depth of just over 2 m below surface. Results of the 2016 field season brought greater understanding of the extensive amount of energy expended in building from the original foundation of the structures to what is visible on the surface today at this hinterland site. This poster presents a discussion of the 2016 excavations which included the exposure of eight floors and at least as many construction phases, revealing a shift in structure alignment and construction techniques through time. While the season only allowed for exposure down to Late Preclassic features, there is great promise that Middle Preclassic features at the site will be present below this phase of construction and revealed next season.

Micromorphology and Isotopic Geochemistry of the Yangguanzhai Moat Deposit

Geoarchaeological research conducted at the Yangguanzhai Site was tasked with identifying the composition and formation processes associated with one of the most striking features of the site, the Yangguanzhai “moat.” Originally, it was hypothesized that this moat was filled with thick packages of ash related to the manufacturing of pottery at the site. Therefore, micromorphology and isotopic geochemistry were employed to further examine moat sediments. Samples collected from the moat have δ13C values that range from ~12.90‰ to ~5.17‰ and δ18O values from ~11.41‰ to ~8.72‰. Thirteen out of the seventeen samples have isotopic values that are identical to bulk soil carbonates. This indicates that most of the sediment is natural. Only two samples have isotopic values that are positively correlated and fall on an ash regression line. Micromorphology of the sediment is also in good agreement with the isotopic results. A majority of the sediment is composed of either soil/floess aggregates, or the inedible fraction of plants and animals. Diagnostic aggregates of micritic calcite (ash) were accurately identified, but are found in isolation and represent ~2–3% of the deposit. Our results suggest that the Yangguanzhai moat was largely filled in by localized colluviation and the dumping of refuse.

Sacrifice in the Name of Ancestors: An Analysis of the Relationships between Terminus Groups and Site Cores in the Belize Valley

The functions of cosmosologically oriented structures within the site core of Ancient Maya sites have been analyzed by archaeologist throughout time. However, the role of terminus groups in relation to the function of site cores have received little attention. In this paper, we analyze the function of the Zopilote Complex, a Terminus group located south of the Cahal Pech site core. Excavations on Str. 1 at Zopilote uncovered two elite burials accompanied by evidence of human sacrifice. Furthermore, a Terminal Classic (AD 600–900) deposit was excavated on the west side of STR 2 containing over 50,000 ceramic sherds, chert cores and flakes, obsidian blades, and fragments of a Pedregal Modeled Incensarios. We argue that archaeological evidence from both structures indicate that extensive ritual activities were conducted at Zopilote from, Late Preclassic (300 BC–AD 250) to Terminal Classic times, in association with ancestor rituals. Our hypothesis of the function of Zopilote as a ritual center will be cross compared with the site core of Cahal Pech in order to establish any correlates that illustrate the relationship between terminus groups and site cores and how this relationship coincides with the ancient Maya worldview.

Terra Cognita: Technological approaches along the High Mountain Silk Road

Using remote sensing techniques along with standard archaeological survey in 2011 our collaborative team discovered the Silk Road city of Tashbulak, located at roughly 2,000 m elevation, in the mountains of Uzbekistan. The modern environmental and political particulars of this high-altitude city made the use of aerial photography and Geophysics essential tools for documenting this unexpected mountain site and allowing for clear documentation and targeted research in a (geographically) restricted and remote territory of Central Asia. Our archaeological investigations make full use of a broad suite of digital technologies, including kite photography, 3D photogrammetry, magnetometry, and ground-penetrating radar, GIS, and digital simulation to reconstruct a “live view” of a unique and alternative form of urbanism pioneered by medieval nomads in the high-mountains of Inner Asia (ca. 1000 CE). Ultimately, these approaches allow us to tell a new story about the complex interactions, economic relationships, and political and ideological lives of the Qarakhanid Empire, Asia’s largest nomadic Empire before “the Mongols.”

Francigny, Vincent (SFDAS) [219] The Elite Meroitic Necropolis of Sai Island Part I: Mortuary Interpretations

Sai Island, located in northern Sudan between the 2nd and 3rd Nile cataracts, boasts a rich archaeological history spanning from the Paleolithic to modern times. Recent archaeological excavations conducted by the French Unit of the National Corporation for Antiquities and Museums have focused on a small elite Meroitic necropolis (300 BC–AD 350). Similar to other fringe elite Meroitic cemeteries such as Sedeinga, the Sai Island cemetery features pyramid mortuary structures with descendencies leading into burial chambers located under the pyramid structures. While burial chambers appear to have been only used for adults, Meroitic elite subadult burials have been located within the walls of the pyramid structures. Complicating the archaeological interpretation are Christian subadult burials (AD 600–1500) that were interred in the descendencies, later Ottoman burials (1820–1881) interred throughout the necropolis, and significant comingling due to looting. Here we present the initial interpretations of the mortuary complex and what it has revealed about the Meroitic elite of Sai Island.

Franco, Nora V. (CONICET-UBA), Danae Fiore (CONICET-UBA), Agustín Acevedo (CONICET), Maria Virginia Mancini (Universidad Nacional de Mar del Plata) and George A. Brook (University of Georgia) [62] The Southern Deseado Massif (Patagonia, Argentina): Spatial Knowledge and Changes in Its Use from the Pleistocene-Holocene Transition to the Late Holocene

The semiarid Southern Deseado Massif (SDM) is highly variable in geology, geomorphology and the spatial and temporal availability of water. To the south it transitions into open lowlands and basaltic plateaus dissected by canyons that extend to the Chico River. The La Gruta 1 rockshelter in the extreme south of the SDM has provided the oldest evidence of human logistic occupation in the area, with ages between ca. 12,800 and 12,000 cal yr BP, when conditions were wetter than today. Human use and knowledge of the area’s lithic resources increased between ca. 10,700 and 7700 cal yr BP, although rock art is scanty and isolated. Following a dry period, there was an increase in human presence from ca. 5550 cal yr BP, a change in lithic technology, and more frequent rock art, including adult and child hand motifs, in places with better water availability. Hunting blinds in areas devoid of outcrops and complex geometric rock art motifs are attributed to the last 2,000 years, being the only gap in occupation during the Late Holocene probably related to the effect of the Medieval Climatic Anomaly.

Commendador (Idaho Museum of Natural History), Rebecca Hazard (Idaho State University) and Michael Dega (Scientific Consultant Services, Inc.) [123] Bioarchaeological Evidence for Diet in a Late Period Assemblage from Saipan, CNMI

Garapan, a Late Period (AD 1000–1521) archaeological site in Saipan, Northern Mariana Islands, was excavated under mitigation efforts by Scientific Consultant Services, Hawaii in 2015. The recovery produced over 400 sets of skeletal remains, of which forty-eight were submitted for dietary bioarchaeological analysis in the Center for Archaeology, Materials and Applied Spectroscopy. This research focuses on the importance of marine versus terrestrial protein sources and introduced plant cultivars to investigate possible cultural affiliation via diet at Garapan. A stepwise methodology is employed to identify dietary patterns, including the evaluation of bone preservation using ATR-FTIR, extraction and analysis of collagen and carbonate stable isotopes, and extraction of microfossil and organic residues from dental calculus. Whereas stable isotope analysis of archaeological bone can offer probabilistic insights into major classes of proteins and starches in the diet, microfossil analysis may produce a more deterministic evaluation of particular components of the diet, through identification of taxon-specific starches, phytoliths and organic molecules embedded in the calculus matrix. Using this combined approach, we present our bioarchaeological dietary assessment and offer insight into how this stepwise method for investigating diet in archaeological samples provides additional data points for understanding cultural affiliation through subsistence in Micronesia.

Franklin, Jay and S. D. Dean (East Tennessee State University) [160] Pisgah Archaeology in the Upper Reaches of the Tennessee Valley

Pisgah in upper East Tennessee appears to represent fluid, adaptable communities of practice in the upper reaches of the Tennessee Valley. It reflects various but limited elements of Mississippianization. Pisgah also appears to have crosstraffic ethnic boundaries. On the Holston, it was associated with the Dallas archaeological culture, while on the Nolichucky and Watauga, it was associated with Qualla (Cherokee) and also perhaps proto-Catawban wares. Pisgah in the region does not appear to have been associated with chiefdoms, nor was it associated with mound centers. We explore Pisgah variability in terms of chronology, material culture, and Mississippianization.

Franklin, Kathryn (School of the Art Institute of Chicago) and Astghik Babajanyan (National Academy of Sciences Institute of Archaeology) [221] Medieval Worldbuilding and Cosmopolitics: Armenia on the Silk Road

This paper presents observations from recent seasons of research in the Vayoc Dzor region of southern Armenia, in the context of a long-term and multi-sited program of investigations into the intersections of locally situated highland social phenomena within the broader Silk Road cultural ecumene during the late medieval period (AD twelfth–fifteenth centuries). This ongoing project builds on an understanding of late medieval Armenian participation in and coproduction of the worlds of the Silk Road, developed from excavations and epigraphic research sited in transit and monumental spaces of the highlands. The current research deepens a distributed focus on material worlds produced and imagined at rural village sites in addition to, and conversant with, urban medieval life. The most recent two seasons of work have centered on Armenia’s Southern Silk Road Heritage Corridor, a dense web of archaeological palimpsest landscapes ranging over the regions of Vayoc Dzor and Syunik. This paper will explore the potentials of new datasets produced through survey in Vayoc Dzor and excavations at the site of Arpa, and the implications of these datasets for innovative spatial, material and historical understandings of medieval Armenia and the situatedness of the medieval Caucasus within a practice-based Silk Road cultural ecumene.
Franklin, Moea (College of Wooster) and Paul Nick Kardulias (College of Wooster)  
[342]  Age-at-Death Estimations from Helton Mound 20  
The original age at death estimations of the adult individuals excavated from Helton Mound 20 (Middle to Late Woodland) in the Lower Illinois Valley were reevaluated using Transition Analysis. In addition, a taphonomic evaluation of each individual was undertaken to determine the ways in which the bones would have been modified during their interment. The goal is to understand how the current recognition of taphonomic processes differs from the original estimations from the 1970s and how that affects the estimations of age at death. The results suggest that taphonomic damage had an effect on the original age estimation because the current works suggests the individuals were younger than the originally suggested. These results are the product of a better comprehension of taphonomic processes that scholars have acquired in the past four decades. The new information can provide a more precise understanding of mortuary rituals, health patterns, and social structure of this population. The amount of weathering suggests postmortem treatment of the remains, with exposure to the elements for extended periods of time. Transition Analysis and other basic methods for estimating age at death are discussed to gain an understanding of their benefits and drawbacks in such research.

Frederick, Kathryn (Michigan State University) and Meghan Howey (University of New Hampshire)  
Physical food storage is one mechanism hunter-gatherers use to even out the variability of subsistence resources throughout seasonal cycles. Food storage facilities are typically plain, undecorated constructions basic to mundane needs and as such, food storage features do not necessarily appear at first look as social technology, that is, as objects that extend personhood. However, we suggest food storage facilities, in ensuring the fundamental continuance of the human body, can never be separated from issues of personhood, biologically but also beyond—morally, socially, symbolically. Here, we examine interactions between local hunter-gatherer communities and their immovable food storage cache pit features in the inland lake landscape of Douglas and Burt Lakes in Northern Michigan during Late Precontact (ca. AD 1000–1600). Our archaeological data indicates that these storage features were not only more widespread than previously recognized, but also intensely planned within the landscape. When storage features are considered a social technology, we can begin to understand them as features that inscribe knowledge and memory densely across the landscape.

Freeland, Travis (Simon Fraser University)  
[123]  Monuments, Boundaries, and Chiefly Competition in the Development of the Tongan State  
The principal Tongan island of Tongatapu was the epicenter of a hierarchical and geographically integrated society which some archaeologists contend reached the level of archaic state by AD 1300–1400. Dynastic chiefs affirmed their power and rights to land through monumental construction and a dispersed settlement pattern that fully occupied their inherited territories with lower-ranking members of their kin-based corporate groups. Recent archaeological survey, aided by lidar, reveals the surviving totality of monumental and community-level construction on Tongatapu. Thousands of mounds and other features, products of some 1,000 years of funerary behavior, chiefly competition, and conflict, are highly structured in their arrangement on the landscape. In this paper, I describe this new, detailed understanding of community-level and monumental architecture on Tongatapu, with a focus on the form and distribution of earthen mounds, the latter suggesting a demarcation of territories and boundaries with significant time depth. I consider the utility of the peer-polity model for understanding chiefly interaction during the development and consolidation of the Tongan state. I argue that monumentality, whether in the context of ritual, residential, or funerary architecture, is significant as a visual reminder of inter- and intra-group relations and the maintenance/reconfiguration of the social order.

[383]  The Effect of Property Rights on Low-Level Food Production  
A basic premise of economics is that more secure property rights reduce conflict and provide an incentive for individuals to invest capital to increase productivity. This premise underlies recent theories developed by archaeologists that food production and more secure property rights, by necessity, coevolve. The argument goes like this: Dense and predicatable resources provide an incentive for more secure property rights and more secure property rights provide an incentive for individuals to modify ecosystems and make them more productive. In turn, more productive ecosystems favor more investment in property rights. In this paper, we evaluate the effect of property rights on low-level food production among ethnographically recorded hunter-gatherers. We use path models to control for confounding variables and explore whether the causal structure proposed by recent arguments for the coevolution of property rights and food production fit the data. The effect of property rights on low-level food production is always positive, but does not mediate ecological variables, as recent coevolutionary theories would predict. Moreover, the effect size of property rights on low-level food production is very weak relative to other ecological variables. We discuss the implications of these results for predicting trajectories of hunter-gatherer intensification in the archaeological record.

[273]  A Tale of Two Management Plans: Comparing Visitor Impacts to Rock Art Sites on National Park Service Land vs. San Bernardino County Land  
On July 6, 2016, it was announced that management of the Coyote Hole rock art site located near the village of Joshua Tree, California, would be transferred from the San Bernardino County Flood Control District to the Native American Land Conservancy. The site’s proximity to Joshua Tree National Park (JOTR) provides a unique opportunity to compare this highly-accessible site with unregulated visitation to similarly threatened sites that are managed by JOTR. The publication of sensitive information pertaining to JOTR rock art sites, particularly through social media, has increasingly threatened sites and raised concerns regarding the effects of increased visitation. JOTR staff conducted a study of three panels at Coyote Hole and three panels within the park that exhibit variable degrees of accessibility, visitation, and histories of graffiti remediation. A methodology was developed to monitor and compare the transformational processes affecting rock art sites providing a better understanding of how increased visitation may adversely affect these cultural landscapes.
affect sites on public land. The methods and data here presented will be used to develop management plans for Coyote Hole and JOTR to determine appropriate visitation management strategies for rock art sites.

Quintessential Queen of Kaanul: K’abel of Waka’ in the age of empire.

Classic Maya civilization witnessed the reigns of many great queens, but the greatest in the southern lowlands was Kaloomte’ K’abel of Waka’. She presided over the routes of conquest in western Peten during the seventh century wars of Yuknoom Ch’een the Great. During her lifetime she and her consort King K’inch Bahlam turned the power of the ancient Wite’ Naah Fire Shrine, its Moon Goddess, its Death God Akan, and its other gods to the conquest and subjugation of Tikal. She and her city knew glory and violent defeat etched into buildings, monuments, and tombs. We trace the ark of the Queen of the West in the archaeology of her city.

A Step-by-Step Guide to Excavating Burials, or How a Bioarchaeologist Can Be in Two (or Three) Places at Once

Bioarchaeologists often are faced with the challenge of managing field excavations and lab analyses of skeletal remains at the same time, along with student and staff training and curation of osteological remains. I present results from recent fieldwork at the Classic Maya sites Actuncan and San Lorenzo, Belize that were excavated using a method designed for non-osteologists. This includes complex burial deposits that were re-entered, secondary burials, and comiled and disturbed remains that seemed to require a highly experienced osteologist. Careful taphonomic observations reveal minute details about bones, burial grounds, and ancient Maya beliefs about death and the afterlife. The presentation includes a review of published excavation protocols, and then describes a variation that does not require the excavators to be osteological experts, meets the ethical obligations anthropologists have when excavating human remains, and illustrates some of the challenges faced by osteologists working with fragmentary remains in tropical environments.

Obsidian Characterization at the McMaster Archaeological XRF Laboratory: Case Studies from the Italian Island of Sardinia

The McMaster Archaeological X-ray fluorescence Laboratory (MAX Lab) was established in 2010 with the goal of using compositional analyses of archaeological objects to engage with broad-level questions about past human behavior. In this context, obsidian has been the primary artifact type analyzed, taking form through the sourcing of artifacts to the geological sources from which they originated. As an example, this presentation focuses on prehistoric obsidian exploitation on the central Mediterranean island of Sardinia (ca. sixth–second millennia BC). Using data obtained through the collation of published sourcing studies along with primary analyses of individual assemblages this study contextualizes changes in obsidian consumption through time. Key issues surrounding the recognition of various exchange mechanisms in the archaeological record are discussed as well as the specific circumstances behind the development of large-scale Sardinian obsidian circulation networks, the contraction of these same networks at the time of the first metalworking, and the reconfigured modes of consumption characteristic of the Bronze Age and Nuragic eras. This presentation highlights how the MAX Lab has been instrumental in promoting integrated characterization programs that are critical in interpreting the role of obsidian and other materials within larger socioeconomic processes throughout the Mediterranean, Anatolia, and beyond.

Something Other: Birds in Early Iron Age Slovenia

Human-bird relationships in Early Iron Age Slovenia are marked by apparent contradictions—birds are extremely rare in the zooarchaeological record as a whole, and completely absent from mortuary contexts that are otherwise notable for the deposition of animal remains. Yet birds are the most frequently represented animal in Early Iron Age art. Experience of birds would have been relatively constant—birds are almost always present, yet human relationships with them were likely based more on observation than direct interaction. The distinction of these animals was drawn upon and reinforced in local artistic representations, cementing their place as ideologically significant and set apart from domesticates and other wild animals. In this case study, patterns in the depiction of birds from the Dolensjska Hallstatt culture will be juxtaposed to depictions and zooarchaeological remains of horses and red deer, respectively the most common domesticates and wild animals depicted in Early Iron Age art. It is proposed that due to their categorization as neither wild nor domestic, birds may have played an important role in local ritual, mediating between humans and other animals as well as between humans and extra-human forces.

Frieman, Catherine (Australian National University) [168] Barrow Roads and Bronze Age Wayfaring
The idea of the journey is central to many narratives of European Bronze Age social structure, economy, and cosmology, but the mechanics of journeying in the Bronze Age are rarely discussed. We know that objects and raw materials traveled great distances, we think that exotic things and ideas were sought after, and it appears that Bronze Age people maintained ties with kin and trading partners over very great distances. Much of this distance was inevitably traversed on water; and riverine distribution maps and scarce finds of boats and maritime assemblages have been scrutinized for details about the intensity and directionality of Bronze Age trade and transport. Overland routes are much less frequently encountered or discussed. Bronze Age monuments are often seen as existing outside settled landscapes, but hypothesized ‘barrow roads’ in some areas, imply that monuments were not so much placed outside settled places as they were located between them and along the way. This paper will use the idea of barrow roads to consider overland wayfaring in the Bronze Age, a period when some people may have traversed continents while others inevitably walked the same paths season after season, watching out for landmarks and following their sheep.

Frierson, Andrew (Washington State University) [184] Lithic Technology and Other Archaeological Investigations of Rock Creek Shelter (35LK22)
Excavations in 1967 at Rock Creek Shelter (35LK22), located within the Hart Mountain National Antelope Refuge in Lake County, Oregon, revealed a stratified record of frequent occupation that may potentially extend into the early Archaic. The artifacts recovered from the rockshelter include a chipped stone assemblage (n = 1307), cordage/basketry and other perishable material (n = 464), ground stone (n = 24), faunal remains (n = 1046), and numerous samples (n = 68). The lithic material, which consists of mostly obsidian, provides an opportunity to utilize X-ray fluorescence analysis to investigate important questions in the Northern Great Basin related to prehistoric land use, mobility, and the movements of populations including significant events such as the Numic expansion. This presentation will report on these analyses and the initial baseline study conducted that included an evaluation of the site stratigraphy and establishing a site chronology from radiocarbon dating and typological distinctive bifaces and perishable artifacts. The objective is that these analyses and site report will allow us to fit Rock Creek Shelter within the larger archaeological sequence of the Northern Great Basin.

Fries, Eric (UMAP) and John Morris (National Institute of Culture and History, Belize) [243] What Lies Between Two Regions: Settlement and Landscape Archaeology at the Aguacate Sites, Belize
A series of exploratory surveys along the northern edge of the Belize River Valley in the area of the Aguacate lagoon has gradually revealed a surprisingly dense distribution of minor centers of the Classic Period Maya. These centers are situated in a zone of intersections, the nature of which shaped their presence in the landscape. Politically, the region lies at an interstice between the spheres of influence of several powerful, well-known polities. Geographically, the site complex is distributed across a transitional zone of ridges and wetlands that separates the Belize River Valley from neighboring regions. The location of this settlement system at the intersection of multiple types of spatial differentiation contributed to the development of an intensely heterarchical, tightly networked series of sites where local elites attempted to secure power and legitimacy through the deployment of a number of different elements of Maya architecture, cosmology and symbolic representation.

Friesen, Max (University of Toronto) and Andrew Stewart (Strata Consulting, Inc.) [35] Covering Bones: The Archaeology of Respect on the Kazan River, Nunavut
Complex relationships between people and animals define life in the northern past. For Inuit these relationships are manifested in many ways; particularly in practices that are often described as “showing respect” for animals, thus promoting stable relations between animal and human societies. Frustratingly, many of these activities, which are so prominent in the ethnographic record, have few archaeological correlates. Here, we examine one important practice with a relatively high level of archaeological visibility: the concealment of caribou bones under stones and in other inaccessible areas, thereby protecting them from dogs and other disturbances which could offend the caribou’s inui. We examine this phenomenon at several important caribou crossings and elsewhere at inland Inuit archaeological sites on the Kazan River, southwest Nunavut, where we have mapped hundreds of features and collected bones from some of them. This research was performed in collaboration with Baker Lake community members who have direct knowledge of these localities, including aspects of bone disposal. Together, these studies reveal a cultural landscape in which the human-caribou relationship is omnipresent not just in terms of features relating to hunting and storage, but also with regard to the spiritual connection between these two interdependent categories of being.

Fritz, Carole (CNRS) and Gilles Tosello (Maison des Sciences de l’Homme de Toulouse, CNRS) [210] Perception et analyse des scènes dans l’art paléolithique européen
En art paléolithique, les “scènes” sont rares et leur identification repose le plus souvent sur la présence d’un acteur humain ou anthropomorphe. Paradoxalement, la thématique paléolithique compte moins de 5% de figures humaines pour 95% d’animaux. Cela signifie que la majorité des assemblages que l’on retrouve dans les grottes sont constitués d’images animales. Or dans nos cultures, l’image humaine est centrale et lorsque nous parlons de scène, nous recherchons intuitivement la référence à notre propre image. À l’évidence, cela ne semble pas avoir été le cas pour les cultures du Paléolithique supérieur. A la suite de ce constat, nous pensons que la reconnaissance et l’étude des scènes devraient s’appuyer sur d’autres critères d’identification. Des notions précisées et développées par la théorie de la Gestalt dans les années 1930 puis par les psychologues de la forme
contemporaires nous offrent des outils analytiques. Les résultats d’une telle démarche nous orientent vers une interprétation mythologique de l’art des grottes dans laquelle l’image humaine n’est pas au centre du dispositif. Les exemples choisis dans les grottes ornées (Chauvet, Marsoulas et autres) illustreront notre propos.

[388] Harvesting, Management, and Possible Cultivation of Chenopods (Chenopodium spp.) in the North American Southwest  
Chenopodium seeds are ubiquitous in archaeobotanical samples from sites across the U.S. Southwest, commonly interpreted as representing the harvest of wild populations or weedy plants that were encouraged to grow in garden plots and agricultural fields. Up to 75% of projects from various SW U.S. regions contained Chenopodium, and/or Atriplex, and/or Chenopodiaceae seeds. Archaeobotanists differ in how they recognize and report these seeds. At least 26 wild species of Chenopodium are native to one or more of the Four Corners states, and a detailed study of their seed traits would solidly ground any prehispanic domestication claim. We examine ethnographic and archaeological evidence for chenopod use by native Southwestern farmers that may—or may not—indicate their incorporation into active food production systems. We propose criteria of domestication such as: (1) morphological indicators (seed coat thinning, etc.); (2) archaeological evidence of increasing reliance on Chenopodium seeds over time, and/or their association with food storage loci of other known crops; and (3) plausibility arguments including apparent economic importance, the cultivation of similar species elsewhere, and ethnographic evidence of cultivation. Our discussion is framed by scenarios of early agricultural developments across the Desert Borderlands.

[252] The Philistine Cemetery at Ashkelon: Funerary Remains and Mortuary Practice  
During the 2013–2016 seasons, an extramural cemetery was discovered at the coastal site of Ashkelon in Israel. Dated almost entirely to the Iron IIA period, more than 200 sets of remains were exposed and excavated, providing for the first time a secure and sizeable number of burials from which to generate an understanding of Philistine burial practices and mortuary ritual. The majority of bodies were found in primary inhumation with various depositional practices observed, among them simple pit, individuals covered with sherds, and cist burials, with both sexes represented and a dearth of infants. In this paper, we discuss the cemetery, the ceramic assemblage, and objects of personal adornment in order to help to shed light on these remains and the funerary practices that accompanied them in death. We then provide a short sketch of comparative material in order to situate the findings at Ashkelon within the southern Levant and the wider eastern Mediterranean world.

[56] Settlement Pattern Transformation in the Arica Highlands during the Late Intermediate and the Late Periods (XIV–XV Centuries): The Role of Zapahuira and the Incan Tambo Network System and Its Relationship with Local Communities  
I will discuss the settlement pattern transformation of the Arica Highlands during the Late Intermediate Period and the Late Period (XIV–XV centuries) and the role of Zapahuira Tambo and the Inca Settlement Network System and its relationship with local communities. The latter will be carried out from an architectural and spatial characterization of some of the main Incan and Local settlements of the area. Some of the data integrated in this discussion have been gathered in my current research project in the area. The general objective of this paper can be summarized in this research question: What was the settlement strategy applied by the Inca in the Arica highlands and what was the role of local communities in the construction– of imperial power? According to the above, several themes and complementary research questions can be raised such as:

- What are the main architectural and spatial characteristics of LIP and Incan settlements in the area?
- Is it possible to differentiate economic and social functions of LIP and Incan architecture?
- Is it possible to define the existence of an Inca Settlement Strategy for the Arica Highlands? If so, how did this settlement strategy compare to others settlement strategies applied in neighboring regions?

[293] Living in Early Urban Center: Preliminary Results of the Tlalancaleca Archaeological Project, Puebla  
The archaeological site of Tlalancaleca was one of the largest urban centers in Central Mexico during the Middle to Terminal Formative periods (ca. 650 BC–AD 200/250). The site consists of a central plateau with civic-ceremonial cores and its surrounding areas, which are divided into the Northern Sector and the Southern Sector. Our research over five field seasons indicates that the urban landscape underwent significant changes through time, including initial urban growth during the Middle Formative, a grand-scale urban transformation during the Late Formative, and further expansion during the Terminal Formative. This paper presents preliminary results of mapping, ground survey, surface collection, manual auger probe, and excavations, which were carried out at the Northern Sector of Tlalancaleca. Preliminary evidence suggests there was an extensive occupation in the peripheral areas during the Terminal Formative (ca. 100 BC–AD 200/250). The paper discusses the process of urban expansion, socio-spatial organization, and the use of public space in residential areas along with implications for regional sociopolitical processes during this dynamic period in Central Mexico.

Fulkerson, Tiffany (Washington State University) and Shannon Tushingham (Washington State University)
The steppe zone of northern China and the savanna zones of India both produced indigenous domestication of numerous small-grained Panicoid cereals, i.e., millets. This presentation will explore parallels in the processes of domestication of these crops, including comparisons of ecological characteristics of wild progenitors, the seasonal mobility of early cultivators, and shared domestication traits and the current state of the their available archaeobotanical evidence. This contrasts with the more intensively managed, and often household focused processing of early large-grained cereals such as rice and wheat.

Multigenerational, Multipurpose Landscapes and Seascapes in the Western Aleutian Islands

The landscape and seascapes surrounding tiny Corvie Bay (400 m wide) on southern Kiska Island in the western Aleutian Islands were occupied by the Qaχnun for 3,000 years. During their use of the area, they transformed the surrounding seas and lands from narrowly defined water tracks and lightly encamped places to deeply imbued, intensively inhabited, and probably owned sea and land spaces. This same pattern of imbuement, use, and ownership was reenacted throughout the western Aleutians over the past 6,000 years. Our intensive survey of the Peninsular Peninsulas surrounding Corvie Bay in 2014 revealed a diverse suite of village, camp, and nonutilitarian feature clusters. Few of the clusters were occupied simultaneously and all would have been visible to later occupants of the area. The archaeological record of the Corvie Bay area offers evidence for complexly accreting history, but little explanation. Because the Qaχnun were ancestral Aleut/Unangan people, traditional Aleut stories offer sources for hypotheses about the changing meaning of landscapes and seascapes across generations.

Morphological and Functional Analyses of Northern Archaic Side Notched Bifaces

The Northern Archaic tradition (6000–1500 years BP) represents one of the longest cultural continuities in central and northern Alaska, characterized through continuity in lithic technology, basic settlement, and subsistence patterns. However, this tradition does not have clearly defined characteristics and is commonly used to describe any site in central and northern Alaska with side notched bifaces present in the tool assemblage. Few studies have been performed on the morphological and functional traits of Northern Archaic side notched bifaces, despite their prevalence in the archaeological
and non-band members. As an element of the animic landscape that served simultaneously a number of social and spiritual functions, rock art helped to strongly associated with travel routes often acting as a landmark and a liminal place in a journey where the assistance of other-than-human persons structure relationships between people, other-than-human persons and places.

Gaignerot-Driessen, Florence (Humboldt Foundation/University of Heidelberg)

Nature of rock art was revealed, as well as a gamut of sites ranging from private to public was identified. Rock art sites were sacred places. They were art of Temagami area is discussed. This large concentration of pictograph sites has enabled a rare regional study through which the multifunctional potential effects on NRHP-eligible/listed historic properties. In this discussion, the author explains that the ideal survey interval and strategy should take into account the likelihood of identifying sites that are eligible for listing on the NRHP, through the use of variables that have been considered in the placement designed to characterize basal morphology allowed the analysis to include tool fragments. Functional analyses included macroscopic use wear and examination of impact fractures. This exploratory study examines Northern Archaic tool kit variation and risk mitigation strategies related to technological continuity and diversification, as well as a spatial examination of Northern Archaic sites across Alaska.

Places, Paths, and Territories: Exploring the Multifunctional Nature of Northeastern Ontario Rock Art

The rock art of northeastern Ontario is less well-known than its counterpart in northwestern Ontario. However, recent explorations of the numerous lakes and meandering rivers in the Canadian Shield have led to the identification of previously unknown sites, as well as to the proper documentation of previously known sites, thus increasing greatly the sample and allowing for the emergence of a more complex regional picture. As an example, the rock art of Temagami area is discussed. This large concentration of pictograph sites has enabled a rare regional study through which the multifunctional nature of rock art was revealed, as well as a gamut of sites ranging from private to public was identified. Rock art sites were sacred places. They were strongly associated with travel routes often acting as a landmark and a liminal place in a journey where the assistance of other-than-human persons could be solicited. Some prominent sites were suited for rituals where social boundaries were negotiated between the local Teme-Augama Anishnabai and non-band members. As an element of the animic landscape that served simultaneously a number of social and spiritual functions, rock art helped to structure relationships between people, other-than-human persons and places.

Gagnerot-Driessen, Florence (Humboldt Foundation/University of Heidelberg)

Old Deities for New Men? The Social, Cultural, and Political Role of Religion and Ritual Practices during the Late Bronze Age/Early Iron Age Transitional Period on Crete

It is generally assumed that the Minoan Goddess remained venerated on Crete after the destruction of the Minoan and Mycenaean Palaces. In the Late Bronze Age, in the aftermath of the collapse of the palatial system, freestanding bench sanctuaries housing large terra-cotta female figures with uplifted arms and their ritual vessels appeared in a series of newly founded Cretan sites. Since their typical gesture recalls Minoan scenes allegedly representing the epithany of a female divinity, these figures have traditionally been interpreted as a survival of Minoan cult practices and labeled “Goddesses with Upraised Hands.” However epigraphic, iconographic, technological, and archaeological evidence makes this assumption questionable. This paper aims showing that they most likely represented votive offerings emblematic of emerging social groups. On the basis of this hypothesis, the reference to
ancient cult motives in a new religious system is considered. In a more general sense, the Cretan case is used here to evaluate the role of religion in shaping a new social order and political organization during a period of transition.

The Precolumbian Sculptures After the Conquest: Reutilization and Re-Significance in Amecameca, Mexico

The town of Amecameca is located in the southwest of Mexico City, near the volcanoes Popocatepetl and Iztaccihuatl. Its origin dates back to pre-columbian times. The city was part of Chalco empire, which was known for its artisans who made extraordinary sculptures. Over time, many of these sculptures have disappeared, mainly by of the destruction of the Spaniards during the conquest. Currently, there are few examples of sculptures from Amecameca in the museums. Despite this, some inhabitants have reused the sculptures that have been accidentally located in their homes or farmlands. We can see examples of facades of public buildings and modern houses around the entire city. In this paper, I will analyze a group of sculptures which are related to the buildings of the city of Amecameca. I will study these pieces through their iconographic elements, trying to elucidate its symbolism. The principal goal of this work is to show the new meaning of precolumbian sculptures in the modern imaginary of the inhabitants of Amecameca.

When the Desert Meets the Sea: The Annual Journey of Quitovaquenses to the San Jorge Beach as a Community of Practice

This paper presents an ethnographic account of the people of Quitovac, Sonora’s yearly journey to the sea. The village is set amid the Altar desert. Every year the people of this town take a trip to the Sea of Cortés and make the shore a very special place. I present this account from the perspective of communities of practice emphasizing how the activities they undertake are the result of a continual interaction between people and places and between the distinct actors present. I also take into account the ephemerality of the material remains of such an important ritual that leave scarce evidence of its importance. This interplay gives particular meaning to the encounter with the sea that result in reinforcement of community identities. Moreover, the details of dwelling at the sea are maintained and passed on through this yearly practice to folks that carry out their daily existence in their village in the desert.

Gallaga, Emiliano (EAHNMM)

The Macaw from Cueva de Avendaños, Chihuahua

At the beginning of 2016, an EAHNM archaeologist performed a rescue project in the Cueva de Avendaños, municipality of San Francisco de Borja, Chihuahua, as a result of a complaint. There, the land owner decided to level the cave surface with a bulldozer not knowing that an archaeological site lay beneath. The result was the destruction of a prehispanic funerary context which included the remains of at least three mummified individuals accompanied by textiles, basketry, string, leather, shell and animal bones. Unfortunately, only the head of the macaw was preserved. This presentation will focus on the macaw remains and the importance of this animal in the prehispanic world, especially because is the first evidence of this species outside the site of Paquimé in northwest Mexico.

Ceremonial Practices, Feasts, and Persistent Places: A Ritually Mounded Landscape Constructed by Hunter-gatherers in Southern California

Shell mounds have not been recognized as prominent ritual features in southern California, despite evidence to the contrary. The largest extant shell mound in the region is on Santa Cruz Island, measures 270 by 210 m (roughly 45,000 m² in area), is 8 m higher than the terrace it rests on, is covered with 50 house depressions, and dates to 6000–2500 BP. In the 1920s, three cemeteries were excavated at the top of El Montón; one young woman stood out among the over 200 individuals in that she was buried with 157 stone effigies. Analysis of multiple lines of evidence, including stratigraphic profiles of features, 85 radiocarbon dates, ground-penetrating radar, and mortuary data, support my claim that the mound was a persistent place where early visitors had significant feasts, constructed dwellings, buried their dead, and performed ceremonies where select groups of infants, children, and adults were revered. These mortuary rites conveyed the symbolic power of the place and created a history of events that became part of a mythical and real past that was repeatedly visited, modified, and interpreted as social relationships were reinforced. This study supports the idea that shell mounds are socially constructed landscapes, not just accumulations of refuse.
tarea breve, se prolongó durante toda la temporada por la gran cantidad de hallazgos arqueológicos tanto en las laderas como en la cima del Cerro. La integración de los datos en un sistema de información geográfica permitió un acercamiento a la densidad y diversidad de los hallazgos. Los resultados no dejan duda alguna sobre la importancia del sitio y el gran reto que implica continuar con las investigaciones.

The Kambos Project: Remote Sensing Applications and Archaeological Approaches for the Reconstruction of the Disappeared Cultural Record of the Western Thessalian Plain

La Plaine Thessalienne a été au centre de la répartition des objets dans les deux Préhistorique et Historique périodes. Malgré la Thessalienne plaine potentiel pour les recherches archéologiques, le Thessaly a fourni assez claire information de l’occupation. Cela pourrait être lié à l’extensive modifications it has been subjected. During the last 45 years. These have rendered the Western Thessalian landscape sterile for the application of standard archaeological remote-sensing techniques (such as multispectral imaging) and other extensive survey methods. The combination of its long occupation history and highly modified landscape make Kambos an excellent study area to develop and test new methodologies for prospection, analysis and reconstruction of past landscapes. In this paper new methodological approaches employing photogrammetry-based landscape reconstruction and multi-temporal image analysis combined with pedestrian surveys will be presented and their results discussed. The location of more than 250 new archaeological features attests to the immense potential of the Western Thessalian Plain and provides new important information on the prehistoric and historical periods of the area.

García, Damian (Acoma Historic Preservation Office) and Kurt F. Anschuetz (Río del Oso Anthropological Services/Acoma Tribal) [34] Movement as an Acoma Way of Life: An Archaeology of the Pueblo’s Pathways and Impressions

Throughout its history, the Pueblo of Acoma has been a community on the move. Even after having located their promised homeland—Haak’u, the “place prepared”—at the conclusion of a journey that began at Shipap, the “place of emergence,” Acoma’s people have continued to move. With Sky City at its center, the people have engaged with their landscape in choreographed seasonal, interannual, and multigenerational movements informed by three tenets of Acoma’s traditional stewardship: Rest, Renew, and Reuse. As such, archaeological traces of Acoma’s movements represent the “footprints,” “fingerprints,” and “impressions” of the “living, sacrifice, and history” of Acoma’s cultural heritage.

García, Johan (University of Kent—Universidade do Porto) [135] Indigenous Copper Production in Colonial Mexico (1533–1630)

During the entire colonial period, the south-central region of Michoacán, Mexico was the main producer of copper in New Spain and one of the most important loci of production in the whole Spanish Empire. Copper was a fundamental material for artillery, coinage and silver extraction, not to mention its importance in the manufacture of all sorts of daily life items. However, Spanish colonizers had an almost complete lack of copper extraction knowledge. On the other hand, the region had a natural occurrence of rich ore deposits and a well-established indigenous metallurgical tradition based on copper developed during the course of eight centuries. These set of factors led the Spaniards to heavily rely on native knowledge, technology and labor. This paper will focus on the social and technological aspects of copper metallurgy during the contact and early colonial periods of Mexico, and how the specialized communities of indigenous metallurgists and their traditional technology had an important role in the development of the colonial economy as key suppliers of strategic materials and objects. Furthermore, this paper aims to approach the changes suffered by these communities with the shift of the productive paradigm and the encounter with the European technology.

García, Jorge (University of Florida Department of Anthropology) [220] Social Inequality as Reflected in Dietary and Mobility Practices of South American Maritime Chiefdom Societies: Contextual and Isotopic Analysis of Burials Excavated in La Tolita, Ecuador

This project explores social inequality in relation to dietary and mobility practices of maritime Pacific polities in La Tolita (600 BC–AD 200) of Ecuador and Colombia. The research question driving this project aims to identify: How is social inequality reflected in the diet and spatial mobility as practiced by maritime chiefdom societies through time and space? A cross-site comparison between the dietary and mobility practices of individuals buried in mounds associated with the chiefly class to individuals buried in shallow/mass graves at the site of La Tolita will be assessed to test if variables including time, space, age, sex, and/or social inequality influenced these aspects of life. In addition, a statistical analysis of mobility patterns will be conducted to distinguish the degree of spatial mobility by individuals in relation to social class and the variation of their dietary practices (e.g., luxury-non-luxury foods). Material and human remains recovered from excavated burials in La Tolita, indicating a variable population (e.g., age, sex, rank, time period), will be examined through a distributional and contextual analysis, complemented by an isotopic analysis of human bone and teeth to assess the paleodiet (15N/14N, 13C/12C) and individual’s degree of mobility (87Sr/86Sr, 16O/18O).

García-Albarido, Francisco (Graduate Student, Department of Anthropology, Colorado State University) [331] Arqueología de los repartos mercantiles en los Andes coloniales: endeudamiento, elites locales y cultura material.

La colonización de los Andes representó una oportunidad de enriquecimiento individual para peninsulales, criollos y nativos. Esto se logró mediante el mercantilismo forzoso de productos europeos y americanos, promovido por mercaderes límites y tempranamente ejecutados por los corregidores (entre otros). El reparto de mercaderías a precios excesivos generó el endeudamiento forzado de las comunidades nativas. En muchos casos, los curacas también buscaron beneficiarse de esta práctica, colaborando activamente en el reparto. De esta manera, la cultura material fue conscientemente utilizada para la generación de deudas y la consolidación de posiciones de dominación económica. Las grandes rebeliones de la década de 1780 terminaron con los repartos. Proponemos que esta importante práctica generadora de asimetría económica debe ser estudiada desde sus vestigios materiales y una detallada discusión historiográfica de la cultura material utilizada. Estos objetos se encuentran en depósitos domésticos y como parte de ajuares funerarios indígenas. Algunos son claramente exóticos mientras otros son normalmente asociados a actividades cotidianas. Proponemos la arqueología de los repartos mercantiles como una manera de analizar la consolidación de elites y asimetrías locales. Consideramos como caso de estudio sitios coloniales del Corregimiento de Atacama (Alt Perú) y discutimos el potencial comparativo de este tipo de arqueología.
Durante el Clásico, las figurillas Teotihuacán, han sido consideradas representaciones de deidades. Recientes estudios, se han enfocado sobre la posibilidad de que esas figurillas representen retratos de altos dignatarios, como gobernantes o guerreros, y cuyas imágenes habrían sido veneradas como parte de una ideología de estado. Las figurillas despliegan una gran variedad de “tocados” entre los que destacan los de mariposas, que se asocian con altos dignatarios y el poder político. Con la destrucción de Teotihuacán el sistema político y religioso, se desintegró. Unos años después de la destrucción, durante la fase Coyotlatelco (600–800 dC), los nuevos pobladores de la Cuenca de México retomaron algunos de los viejos emblemas Teotihuacán, para ser usados por sus dirigentes, un contexto de fragmentación política, muy diferente al del lapso de poder del periodo clásico Teotihuacán.

[201] Cave Myths Past and Present: Cerro Bernal as a Sacred Landscape  
En el municipio de Tonalá, Chiapas, Cerro Bernal representa a unique feature on the Pacific coastal plain—one that is both strategic and of economic importance as well as representing a deeply potent sacred landscape. Among the important features of this landscape that have become the focus of contemporary folklore are a series of caves, or more specifically rockshelters, that have entered the imagination of local residents as important elements of a living and enchanted landscape. However, upon further research it is not difficult to see how these contemporary myths embody ideas that have a precolombian origin. The conception of Cerro Bernal as an enchanted landscape has very ancient roots, at least going back to the Early Classic, and perhaps earlier. This paper explores the importance of caves in the conception of Cerro Bernal as a place on the landscape—both real and conceptual on the Pacific Coast of Chiapas.

García Ferrusca, Víctor Hugo (Centro INAH Sonora) and Alejandra Abrego Rivas (Centro INAH Sonora)  
[91] Las puntas de proyectil de las planicies costeras de Sonora, del desierto al bosque espinoso  
Durante los trabajos de excavación y recorrido de superficie en el Proyecto de Salvamento Arqueológico Gasoducto Puerto Libertad-Frontera Estatal, llevado a cabo en Sonora, México, se ha recuperado una numerosa muestra de puntas de proyectil sobre un área que cubre cerca de 600 kilómetros lineales, desde Puerto Libertad, en la costa noroeste del estado, hasta el límite con Sinaloa. Estas puntas están afiliadas a determinados contextos en diferentes periodos, como el arcaico, el de agricultura temprana, prehispánico y posterior y atestiguan la larga trayectoria ocupacional en el territorio sonorense. El estudio de los materiales mencionados contribuye a la integración de una tipología regional más amplia, donde se incluyen morfologías recurrentes que no han sido establecidas como Tipos, también, traza la distribución espacial de los Tipos ya existentes y aporta datos sobre la adaptación de los grupos humanos a la morfología del entorno. Se presenta el resultado del análisis realizado a las puntas de proyectil.

[120] Estudio comparativo de la cerámica epiclásica de la región de Tula: Cerro Magoni, Tula Chico, y La Mesa  
El presente trabajo se enfoca en un estudio comparativo que se enfoca en los atributos formales de la cerámica proveniente de contextos arqueológicos en tres sitios epiclásicos de la región local de Tula, Hidalgo conocidos como La Mesa, Tula Chico, y el Cerro Magoni. El objetivo del estudio es obtener un primer acercamiento a las pautas de interacción entre los sitios y entender el panorama social que prevalecía en la región local. En este ensayo, consideramos las particularidades del tipo ampliamente conocido como Coyotlatelco, que hasta ahora ha sido considerado como elemento cultural compartido entre las tres comunidades. Evaluamos una hipótesis alternativa que pronostica diferencias en cuanto a la prevalencia de distintos rasgos formales de la cerámica Coyotlatelco encontrada en cada uno de los sitios. El fin estratégico del estudio es juntar el análisis de varios tipos cerámicos al estudio actual para trazar las pautas de intercambio económico y social entre los sitios y así investigar las relaciones sociales y políticas que existieron entre las comunidades durante el Epiclásico.

García Vilchis, Tobias (Professor) and Emiliano Gallaga (Doctor)  
[201] The Cave Dwellers of the Sierra Tarahumara  
The Raramuri, an indigenous people from Chihuahua, Mexico, has occupied the western part of the country for over 1,000 years. As many authors claim, their ways of life have changed little, and they remain as one of the only, if not the only, living seminomadic groups existing in North America. In this paper, we will focus on recent ethnarchaeological research carried out by students and professors of the EAHNM. This research allows us to create an explanatory model to comprehend the nature of the archaeological record produced by other seminomadic groups from Chihuahua and the North American Southwest.

Gardner, A. Dudley (Western Wyoming College) and William Gardner (WAARI)  
[184] A Comparison of Lithic Types from a Multi-Stratified Site in West Central Colorado (13,000–3,000 BP)  
This presentation will focus on the analysis of Projectile Points recovered in excavation at Eagle Rock Shelter that date from 13,000 to 3000 BP. Eagle Rock Shelter is located in west central Colorado on the east side of the Gunnison Gorge. Eagle Rock contains occupation horizons dating from 13,000 to 150 BP. The shelter contains a full range of projectile points dating from the Paleo to Prethoristic Period. In this presentation we will examine some of the size, shape, and structural traits of projectile points noted in the horizons that date from the Paleo to the Middle Archaic period at the site. We will emphasis what we consider to be distinctions in the projectile point assemblage at the site and briefly compare the projectile points to other similar dated points found in the region.
Breastfeeding and weaning practices (BWP) are deeply personal, influenced by individual choices, circumstances of health and opportunity, community support, and cultural norms. This presentation will discuss the advantages and challenges of using bone collagen composition to interpret breastfeeding and weaning practices, using data from the Yukisma Mound (CA-SCL-38), a Late Period (~740–230 BP) ancestral Ohlone mortuary site in Santa Clara County, California. Stable carbon and nitrogen isotope values from bone collagen are available for 202 individuals from this population, including 24 subadults. A statistical approach, using linear regression and standard residual values, provides an objective method for differentiating breastfeeding infants from nitrogen enrichment due to consumption of other food sources (e.g., marine foods). Results are consistent with contemporaneous regional studies which used serial sampling of collagen from tooth dentin, but differ from ethnohistoric accounts of Ohlone breastfeeding practices from the eighteenth century. Possible explanations for the change through time will be discussed in historical context.

*Relocating the Platform Mound at La Plaza: Recent Archaeological Investigations on Arizona State University’s Tempe Campus*

Recent archaeological and historical investigations at the Hohokam site of La Plaza revealed robust evidence that a Classic period platform mound once stood in the north part of Arizona State University’s Tempe campus. Maps from the late 1800s and early 1900s documented three Hohokam platform mounds within La Plaza. However, these mounds were leveled by the early to mid-1900s, and archaeologists today can only approximate their locations based on old maps of dubious accuracy. An earlier archaeological investigation showed tentative evidence for a platform mound in the north-campus location, and our more recent investigation corroborates and refines that finding. In this paper, we present multiple lines of evidence for the platform mound: a comparison of ancillary features from known platform mound contexts; examination of historical photographs; and a reconstruction of the ancient surface grade. Analysis of ancillary features beneath and adjacent to the inferred mound footprint provides new insights concerning the organization of public space in La Plaza and, more broadly, the mobilization of labor for communal construction projects in Hohokam society.

*Hilltops and Boundaries: The Lidar Survey of El Zotz and Tikal*

The ancient Maya kingdoms of El Zotz and Tikal, while not comparable in size or influence, share a geographical region in the central Petén of Guatemala. Tikal is located at the eastern head of the Buenavista Valley, the northernmost east-west corridor of the Petén Karst Plateau, with El Zotz situated 23 km to the west at the intersection of the valley and a north-south drainage leading to El Mirador and the northern Petén. A steep limestone escarpment and the karstic uplands north of it bind the top of the valley and are replete with settlement. The 2016 Petén lidar survey acquired 175 km2 of topographic data over this region, with a 1 km wide strip connecting the two major settlements. This paper examines the reliability of the data for detecting ancient settlement in rolling karstic hills and also examines issues of ancient political boundary detection in the densely settled central Petén. Thoroughly mapped, central Tikal provides a great baseline for assessing the reliability of lidar data in this area of the Petén, while extensive reconnaissance of the El Zotz uplands aids in identifying remotely sensed hilltop settlements. The paper concludes with suggestions for future lidar-aided field methods for settlement survey.

*Producing Knowledge through the Production of 3D Digital Artifacts*
It is becoming more common to see 3D digital artifacts used for analysis and interpretation, often as if these digital forms are equivalent to the original. This paper discusses the process of creating a 3D model as an essential but often under considered aspect of the final product that should be taken into consideration in their use in any archaeological analysis and interpretation. Digital artifact models inhabit a strange place among the suite of traditional archaeological data—their visual appearance may seem accurate to the original but they are lacking many features (surface feel, mass, etc.) that compose a physical thing. If new archaeological knowledge is to be gained from our use of these digital artifact models, then the significant human input that is involved in the production of these models should be explicit. As representations, digital artifact models have the potential to expand the way we reconstruct the past through material culture, but we should consider how these digital models are produced with specific technologies, techniques, and human choices that may impact the final data and their use in archaeological research.

[220] Results of Survey and Analysis of Manteño Archaeological Sites with Stone Structures in the Las Tusas River Valley, Rio Blanco, Ecuador
The Manteño (1500 BP–1532) of coastal Ecuador are known for their long distance maritime trade networks along the Pacific coast of the Americas; they occupied a large territory that was geographically and environmentally diverse. This diversity allowed the Manteños to exploit a multitude of resources from each unique environment resulting in distinct settlement patterns for each region. One of the least known of these occupied environments and the focus of this paper is the cloud forest of the coastal mountain chain of Chongón-Colonche. The cloud forest offers a plethora of resources and a multitude of challenges. A two field season intensive survey of the Las Tusas River valley focused on Manteño archaeological sites with structures resulted on 46 structures across 10 sites. Structures were identified by the remaining stone foundations that are primarily still visible on the surface. The survey was conducted by the Florida Atlantic University Archaeological Fieldschool in Ecuador during the summers of 2015 and 2016. The significant number of structures in a terrain that offers very limited space for occupation suggests that the Manteño did not only occupied the extent of the territory but thrived in this challenging environment.

Gasco, Janine (CSU-Dominguez Hills) and Yahaira Nunez Cortes

[218] Interaction and Exchange in Late Postclassic Xoconochco
Xoconochco is located along a well-traveled transportation route that links what is today central and parts of southern Mexico with Central America. The region has had cultural and economic ties with its neighbors to the north and to the south for millennia, a pattern that continued into the Late Postclassic period. In this paper we examine the nature of Xoconochco’s involvement in Mesoamerican exchange systems in the Late Postclassic period. We know that Xoconochco’s forest resources—particularly cacao—were found as far away as the Valley of Mexico and beyond, that obsidian from Central Mexico and the Guatemalan highlands was used in Xoconochco homes, and that some residents had access to metal goods produced in West Mexico. Here we focus on ceramics and what Neutron Activation Analysis can tell us about where the ceramics found in Late Postclassic Xoconochco communities were produced. Analyses currently underway will bring our sample to almost 200 sourced sherds, and these data, together with the data for obsidian and metal goods and the documentary evidence will allow us to better understand patterns of interaction and exchange in Late Postclassic Xoconochco.

[84] New Approaches to Sambaqui Archaeology in Brazil
Sambaquis (shell mounds) have attracted attention since colonial times due to their monumentality, and to the presence of human burials and stone sculptures. Discussions on their natural or human origin dominated up to the 1960s, when debate shifted to cultural history and diet, and moundbuilders were taken as nomadic bands with shellfish-based subsistence. The 1990s, a time of changing paradigms in sambaqui archaeology, coincides with the coming of Suzy and Paul Fish to Brazil. They helped to open new research perspectives as regards site formation processes and interpreting the sambaquis into their landscape and symbolical context. This paper will highlight some advances related to that.

[124] Protecting Historic Structures during Wildfires
The increased wildfire activity in Western North America is endangering most if not all historic and prehistoric archaeological sites on American’s public lands. This paper looks at how archaeologist can work with fire fighters during these emergencies to protect the most susceptible sites, historic structures and wooden buildings and structures to fire, and how to plan for such event and what steps are needed to best protect these sites during a fire event.

Gates St-Pierre, Christian (Université de Montréal)

[178] Needles and Bodies: A Microwear Analysis of Experimental Bone Tattooing Implements
Tattoos are embodied experiences, ideas, and meanings expressed by groups and individuals. Many Iroquoian populations of Northeastern North America from the Contact period were known for practicing body transformations of this sort. Moreover, the archaeological literature abounds with cases of Iroquoian bone objects interpreted as tattooing objects. However, such functional interpretations are often proposed without any clear demonstration. In this paper, we present the results of an experimental microwear analysis of replicated bone tattooing implements. We then suggest avenues to further investigate the social dimensions of tattooing practices.

[D368] Drought Variability and the Robustness of Agrarian Social Networks  

How robust were agrarian social networks to drought? Social networks can absorb climate shocks by facilitating resource flows to afflicted nodes and population flows away from them. Because this property of social networks depends on their ability to connect regions with negatively correlated rainfall, we expect the interaction between landscape connectivity and drought spatio-temporal covariance structures will select for particular network configurations. To test this hypothesis, we compare diachronic social-network proxies from the U.S. Southwest to an ensemble of paleoclimatic model simulations. We first use outputs from the Community Earth System Model Last Millennium Ensemble project to calculate a multi-scaler drought index for the period AD 1150–1450. We then use Empirical Orthogonal Function analysis to decompose these complex space-time fields into maps of the leading modes of drought variability. Finally, we compare these maps to network data produced by the Southwest Social Networks project, testing whether ties between nodes in opposing climate dipoles are stronger than would be expected by chance alone. Mobilizing these two spatially explicit and diachronic archaeological and climatological datasets allows us to quantitatively assess the complex interplay between social and ecological dynamics on large regional scales.

[E9] Long-Term Culture Landscape Development at (EkTb-9) Triquet Island, British Columbia, Canada  

EkTb-9, a Heiltsuk First Nation village site located on Triquet Island, British Columbia, Canada, has an occupation span of over 11,500 calendar years. Archaeological and paleoenvironmental research indicates that local sea level was relatively stable during that time, EkTb-9 is rich in archaeological strata including a five m deep shell midden and nearby water-logged deposits which contains perishable materials, most notably parts of bent wood and compound fish-hooks and wooden bi-point technology. Preliminary faunal analysis suggests that diversified marine-based subsistence occurred for millennia; although shell is mostly absent from the peat deposits, an abundance of periostracum reveals that shellfish were intensively used over time, and that an early focus on sea mammal hunting later shifted to fishing rockfish and other species between 7000–5000 BP. Two distinct layers of sand revealed in the stratigraphy suggest that the site experienced two extreme high tide and/or tsunami events. This data, coupled with Heiltsuk First Nation’s rich oral traditions and system of prerogatives, is used to explore and build on the notion of “persistent places” and to gain a more thorough understanding of land use and occupation of the region from the early Holocene until the present day.

[134] Where Are the Camelids? II: Contributions from the Stable Isotope Ecology to Understand Mobility and Exchange Patterns in the South Central Andes  

There is a growing volume of literature arguing that camelids were a local resource for prehispanic societies that inhabited the coastal and intermediate Andean valleys from Peru. Indeed, existing evidences show uninterrupted herding practices along the Peruvian lowlands (>2,000 msl) at 8°S-16.5°S during the interval 800 BC–AD 1100. Although camelids archaeofaunal remains, textiles and iconographic representations are recurrent in low-elevation sites from the northernmost Chile (17°-19°S), the relationship of these records with the widespread husbandry pattern detected across the neighboring region has not yet been explored. Moreover, the traditional view that camelids in low-elevation archaeological contexts were brought about by social-economic trade networks with the adjacent highlands (>3,500 msl) still persists. Here, I tackle these issues by reconstructing the origin for camelid in-bone charki found in a caravan site (AD 1000) from the Lluta Valley (18°S, 1100 msl). Specifically, by implementing zooarchaeological analyses, stable isotopes characterization of bone-collagen and Bayesian statistical analyses we attempt to delineate a quantitative case study for evaluating life-history traits of low-elevation camelids that could provide insightful means for identifying converge/divergences in mobility patterns along the south-central Andes.

[60] Rare Glimpses: Well-Preserved Weaving Tools, Technologies, and Textiles from the North American Southwest  

Perishable materials that provide information about prehistoric weaving traditions rarely survive in archaeological contexts. The arid environment in the U.S. Southwest, however, has allowed many perishable materials to preserve in excellent condition. Numerous objects collected from the U.S. Southwest, and which are spread out in museum collections across the United States, represent a varied range of textiles and also the material correlates of textile production, including wooden spinning and weaving tools, loom parts, and loom anchors, yucca needles, spun yarns, raw fiber, and
p pigments. This diverse array of weaving accoutrement provides rare evidence of techniques, materials, and style for prehistoric cloth production in North America from raw materials to a finished product. Furthermore, in many cases, the archaeological sites themselves provide insights about the method and process of prehistoric weaving in the U.S. Southwest, and help to place the objects within the environment in which they were created.

[252] **A Megalithic Cemetery with a Cult House in Early Neolithic Denmark**

The paper presents a study of a small cluster of three megalithic tombs and a cult house at Tustrup, Jutland, dating from the period of the first farmers in Denmark during the Funnel Beaker period about 3300–3100 BC. The history of this group of monuments is pieced together using the architecture and the building sequence of the monuments combined with events reflected in the pottery depositions. New insights are discussed in relation to the pottery depositions taking place at the tombs as well as the cult house with regard to types of pottery, degree of fragmentation and methods of deposition. Finally based on the Tustrup site, the role of such monument clusters in the early farming communities is addressed.

[341] **Reconstructing Seasonal Subsistence Patterns: A Case Study in Michigan’s Saginaw Valley**

The Saginaw Valley provides one of the most robust records of Michigan’s prehistoric subsistence history. Of this 10,000-year history, the Middle Woodland to Late Woodland regional transformation has been a particular point of interest concerning local subsistence practices. Previous research has hypothesized a three-zone seasonal subsistence strategy as an essential element of the Saginaw Valley Late Woodland adaptive shift. In particular, this regime included a reliance on riverine and wetlands resources. This poster focuses on the interpretation of archaeobotanical macroremains from Midland Michigan site 20MD263 in the context of this regional pattern.

Gentil, Bianca L. (Pennsylvania State University)

[9] **What Does “Collapse” Look Like for Hinterland Sites: Site Distribution and Settlement Pattern in the Valley of Puebla Tlaxcala during the Classic-Postclassic Transition**

This study aims to identify patterns of resilience by distinguishing diachronic socioeconomic processes through the measurement of change and continuity of multilevel sites in the Puebla-Tlaxcala valley. This will be done via demographic, political, and economic markers during the Classic-Postclassic transition. This project focuses on identifying specific processes that lead toward socioeconomic resilience during times of stress. Based upon surveys conducted in the 1960s and 1970s, presented here are the preliminary results of intensive survey of several secondary sites in the Puebla-Tlaxcala valley during the Classic-Postclassic transition and the methodology for systematic key site survey in a broad region. This poster not only displays the preliminary results of the collection, but also the beneficial tools and challenges facing survey archaeology in the past and the twenty-first century.

[243] **Recent Investigations at the Ancient Maya Port Site of Conil, Quintana Roo, Mexico**

The site of Conil is located in the modern community of Chiquiulá on the north coast of Quintana Roo, Mexico. In 1528 Francisco de Montejo, a Spanish conquistador, reported that Conil was a large town consisting of 5,000 houses. Conil was abandoned in the middle of the seventeenth century and was not reoccupied again until the nineteenth century, when it was named Chiquiulá. William Sanders was the first archaeologist to work at the site in 1954, but the site core was not mapped until 2005 by Glover. Further work around the monumental site core was conducted in 2014 as part of the Proyecto Costa Escondida, directed by Glover and Rissolo. Based on this work, Conil appears to have one of the largest coastal sites along the north coast of the Yucatán during the Late and Terminal Preclassic and again during the Late Postclassis. This paper presents the results of the 2016 field season at Conil. Survey efforts extended beyond the site core in order to document the spatial extent of the site. By using a combination of advanced geospatial technologies alongside terrestrial survey methods, this recent work has extended the boundaries of the site to c. 5 km in diameter.

[284] **Stable Isotope Analysis of Animal Diets at the Postclassic Regional Capital of Mayapán**

Subsistence economies during the Postclassic Period (ca. AD 1000–1524) in the northern Maya lowlands were shaped by a range of strategies that included agriculture, the cultivation of wild plants, hunting, trade and market exchange, and the management of animals. Stable isotope data from archaeological faunal remains offer important dietary information to reconstruct the subsistence strategies during this period. In this paper, we present paleodietary data from faunal remains recovered from domestic contexts at the Late Postclassic Maya center of Mayapán. Stable carbon (δ13C) and nitrogen (δ15N) isotope analyses of bone collagen are used to identify the diets of wild herbivores and managed animals. The isotopic data indicate two
distinct groups consistent with the consumption of wild tropical plants and diets high in maize. The heterogeneity of wild species at Mayapán suggests the hunting of wild game composed an essential component of the coastal-inland economic system. The results also indicate that the dogs and some turkeys had distinctive isotopic signatures indicative of animal management by humans. Based on comparisons with a large sample of isotope measurements on humans from the site, we distinguish managed animals with isotopic values within the range of human diets.

Gerard-Little, Peregrine (Cornell University) [265] “The horrors of a wilderness with the beauties of a fertile nature are blended in our prospects at this place”: Seneca Ecologies and Colonial Military Expeditions in Seventeenth- and Eighteenth-Century New York

The shifting settlement pattern of Haudenosaunee groups in what is today central New York state was intertwined with the political order on which the League of the Haudenosaunee was based. These entangled political and ecological practices produced a landscape of significant places and a unique ecology, which impressed European missionaries, travelers, and soldiers exploring this frontier. In the seventeenth and eighteenth centuries French and later American frontier military efforts were directed toward the destruction of not only Haudenosaunee settlements but also food and seed stores and standing crops—the means by which communities’ survived in and maintained this ecology. This paper focuses on the archaeologically and historically examined responses of Seneca communities, the westernmost member of the confederacy, to the Denonville campaign of 1687 and the Sullivan-Clinton expedition of 1779 and the ways in which physical and ideological appropriation of Seneca landscapes and ecologies was critical to colonial settlement and domination.

[127] The Upper Paleolithic Beginnings of the Domestication of the Dog

With this contribution, we would like to present our ideas concerning the first steps in the domestication process of the dog. Two main hypotheses on the origin of the dog have been proposed: 1) “Self-domestication” by wolves: Some wolves were following Paleolithic hunter-gatherers to scavenge on the remains of prey left by the prehistoric people at the human settlements. Generation after generation, these wandering wolves adapted themselves to the human dominated environment; and 2) “Social domestication” by prehistoric people: The Upper Paleolithic hunter-gatherers had a cultural tradition that regarded carnivores with a high esteem. Some aspects of such a tradition could have been the keeping of young carnivores for practical reasons (e.g., fur) and for ritual motives (e.g., the keeping of the young as honorable guests or as intermediaries between the hunters’ families and the spiritual keepers of the game). The most docile wolves could have been permitted to reproduce. After several generations of unconscious or conscious selection of human-defined behavioral traits, the first dogs emerged. The place that the first domesticated dogs could have occupied in Upper Paleolithic societies can be deduced by artificial modifications of several canid skulls by prehistoric peoples. We review the pros and cons of each hypothesis.

Getino Granados, Fernando [288] Iconografía de la mariposa en Tula, Hidalgo

Representaciones de mariposas en la escultórica de la antigua ciudad de Tula, se observan en edificios monumentales y conjuntos habitacionales comunes. Aparece en forma de pectoral de las cariátides que sostenían los techos de los templos principales. Este distintivo también identifica a guerreros sacrificados, representados como altare dentro de espacios ceremoniales. El pectoral lo portan además gobernantes en pilastras y seres mitológicos en lápidas. Atributos de la mariposa se distinguen en representaciones de deidades, como en lápidas con rostros humanos que portan narguera en forma de mariposa, surgiendo de un ser serpiente-felino-ave. Además hay imágenes de deidades con alas de mariposa: mujer con rostro descarnado y anciano. También hay representaciones realistas de la mariposa en lápidas de conjuntos habitacionales, colocadas en los paramentos de los patios centrales, las cuales se relacionan con los rituales cotidianos de la población tolteca. El simbolismo de la mariposa, está vinculado a la religión y militarismo, cuya imagen está ligada a deidades, seres mitológicos, antiguos gobernantes, guerreros paradigmáticos y guerreros sacrificados. En contraparte, las representaciones realistas encontradas en los conjuntos habitacionales, señalan las características rituales dentro de una concepción religiosa popular.

Geurds, Alexander (University of Oxford) [158] Mohammed’s Paradise: Indigenous Society and Natural Surroundings in Southern Central America

Human-environment relations are a point of interest in the archaeology of indigenous southern Central America, defined here to encompass Honduras, Nicaragua, Costa Rica and Panama. As such, it does not seem to deviate from other world regions. This focus in past and contemporary research reflects the weight given to the idea of natural surroundings as resource endowments, following the cultural ecology approach. Elsewhere, such emphasis on material, and indeed economic, sides of human interactions with their surroundings were met with criticism in social and human geography and later also in archaeology. This led up to the manifold contributions by what came to be known as landscape archaeology, or the interest in relations between people and place. This paper examines the status of such conceptual rethinking for the regional archaeology of southern Central America. Certainly, the widespread volcanism situated in a unique continental isthmian setting with significant tectonic activity, offers a geography with a particular set of conditions for human societies living there. Alongside regional trajectories of cultural development demonstrating remarkable stability, it seems feasible therefore to develop particular regional notions on the natural surroundings. But which concepts are mobilized in analyses of the archaeological record in this region?

**Icelandic Livestock and Landscapes: Biometrical Signatures of Land Surface Change**

Zooarchaeologists have typically employed faunal biometric data to address questions of domestication, breeding and improvement strategies, animal population demographics, market economies, and the movement of livestock. However, an historical ecology approach to biometrics also suggests the utility of investigating relationships between livestock management strategies and landscape change. Building on over twenty years' worth of standardized zooarchaeological datasets from across the North Atlantic, this paper examines trends in livestock management across the Scandinavian diasporic world from the ninth to eighteenth centuries and engages with geomorphological data to explore the use of animal remains in recognizing abrupt transitions between contrasting land surface states. Iceland, in particular, offers a unique setting to explore the relationship between vegetation cover and livestock morphometrics thanks to existing regional tephrochronological records. Biometrical data offer new insights on the impacts that livestock grazing had on vegetation cover and the resulting nutritional stresses on stock animals as landscapes flickered between alternative stable states as a potential precursor to crossing an erosional threshold. Were livestock managed at the expense of losing natural capital through soil erosion? Understanding these management decisions allows us to engage with larger issues of climate change, environmental conservation, and sustainable resource management systems.

**Raising the Ground, Building a Mound: Bronze Age “Barrowscapes” in Southern Britain**

The prehistoric record of Britain is punctuated by episodes of monumental building, with the Early Neolithic and the Early Bronze Age being particular cases in point. Yet the Neolithic megalithic monuments and long barrows are quite different forms of funerary and ritual architecture compared to the succeeding Bronze Age barrow traditions. The former could be continuously accessed and activated until their final blocking. On the other hand, once a mound was erected over a Bronze Age grave, that burial was effectively covered, closed off and hidden from view. This paper will consider the various factors that led to the emergence and seemingly sudden explosion of “barrowscapes” throughout southern Britain. It will trace their nascent origins in the preceding Beaker period, and explore the socio-ideological and ritual developments bound up with such transformations. I will argue that the motivators behind mound building were not only related to increasing monumentality, visibility and landscape-marking concerns, but that other dynamics were also involved in their creation and subsequent elaboration. These include the changing attitudes to death, mortuary rituals and the potential roles ancestors played. I will draw upon case studies from recent excavations on the classic Wessex chalklands to illustrate this.

Giersz, Milosz [316]  
**Recent Advances on Multidisciplinary Research at Castillo de Huarmey**

The Peruvian site of Castillo de Huarmey located on the desert coast some 300 km north of Lima and 4 km east of the Pacific Ocean, is widely known for the 2012–2013 discovery of the Middle Horizon imperial mausoleum with the first undisturbed Wari high elite women’s multiple burial. The tomb, which concealed 64 individuals was accompanied by an abundance of valuable grave goods such as gold and silver jewelry, fine pottery, religious paraphernalia, and textile production materials and tools. Since the discovery an international team of specialist performs research within the framework of the Proyecto de Investigación Arqueológica Castillo de Huarmey (PIACH) using a broad methodological spectrum, including bioarchaeological and biogeochemical analyses, archaeometry, geoarchaeology, 3D HDS scanning and architectural analysis. This multidisciplinary approach ensures high quality of obtained results allowing more precise and accurate interpretations. This makes Castillo de Huarmey invaluable for improving our state of knowledge on the Middle Horizon cultural panorama and the importance of Wari Empire in facilitating intergroup relationships and forging of new identities established and negotiated by imperial elites.

Gies, Thornton (University of Colorado Denver) and Jamie Hodgkins (University of Colorado Denver) [90]  
**More Than One Way to Skin a Goat**

Cutmarks on faunal remains are vital for interpreting the tool use and butchering behavior of ancient peoples. To further explore the inferential possibilities of cutmark analysis, and to determine how easily different butchering behaviors can be identified we conducted a series of preliminary experiments to test the hypothesis that the number, and orientation of cutmarks left on carcasses that were butchered while hanging differ from those left on a carcasses butchered on the ground. Preliminary results indicate that marks on long bones were nearly twice as numerous on bones defleshed on the ground versus those hung up. In addition, cutmarks on long bones from the carcass on the ground were more evenly distributed over the bones than those on the hanging carcass. Although preliminary, the results suggest that the avenues of research into cutmark analysis explored here might prove to be fruitful.

**Interpreting West Ashcom: Drones, Artifacts, and Archives**

Archaeology from St. Mary’s College of Maryland began looking for the former homestead of West Ashcom in the spring of 2012. West Ashcom was established on the south bank of the Patuxent River in what is now St. Mary’s County, MD, by John Ashcom in 1651. At its height in the early eighteenth century it contained a manor house, kitchen, dairy, orchard, port, haberdashery, and various other barns and dependencies. Using traditional sources such as archives and methods like pedestrian surveys and surface collections, a late seventeenth-early eighteenth-century site was identified in a
plowed field. Since then, archaeologists from SMCM have employed a range of sources, field methods, and mapping techniques to define the parameters of the site, past structures, and identify activity areas in a largely compromised area. This paper summarizes the results of more traditional uses of GIS mapping paired with experimental drone data to demonstrate the benefit of mixing old and new technologies when interpreting sites subject to continuous plowing and planting.

Gilbert, Steven and Kye Miller [266]  Early Pueblo Pit Structure Architectural Practice in the Southwest Cibola Region

Researchers studying architecture in the southwest Cibola region have generally focused on Pueblo II to Pueblo IV aggregated above-ground masonry pueblos. Although these structures provide abundant information about past lifeways, little research has been conducted on pit structure architecture in this region. As such, there is much to be learned from earlier structures dating to the Basketmaker and early Pueblo periods in the southwest Cibola. By characterizing early architectural practice in the southwest Cibola region, as well as architectural practice on the periphery of this culture area, a greater understanding of settlement, mobility patterns, migration, and identity among early Pueblo residents becomes available. Utilizing the communities of practice approach, this paper characterizes architectural practice in the region and discusses how changes in architectural style over time may provide another avenue for understanding past lifeways in the southwest Cibola region.

Giles, Bretton (CEMML, Colorado State University), Eric Skov (CEMML, Colorado State University) and Shannon Koerner (CEMML, Colorado State University) [376]  A Comparison of Two Bluff Top Prehistoric Sites at Fort Riley, Kansas

We compare two sites (14RY3180 and 14RY3184), located on the bluffs above the Kansas River valley on the Fort Riley Military Installation. We examine how these sites were initially interpreted and reassess their significance. This reassessment is based on recent field work at 14RY3184, while our insights about 14RY3180 derive from a reexamination of its lithic assemblage and a new AMS date. We demonstrate through this comparison that 14RY3180 and 14RY3184 were used for different activities, even though they are located early in similar physiographic settings. For example, 14RY3184 is associated with outcrops of tabular chert that occur along the bluff edge; while the site is a lithic scatter composed of several loci of early stage core reduction. Alternately, 14RY3180 was probably a Smoky Hill camp, given the presence of an assortment of lithic tools, dense lithic debitage, a potsherd, and animal bones. Yet it is also possible that Smoky Hill peoples collected chert from outcrops adjacent to 14RY3180 and that early stage reduction might have occurred there, since the 1990s excavations primarily focused on the central site area. Our comparison illustrates the variability of upland sites at Fort Riley and their research value.

Gilleland, Sarah (Binghamton University) [364]  Investigating Late Woodland Aquatic Catchments through the Reconstruction of Freshwater Mussel Habitats in Mississippi and Alabama, USA

Throughout the Late Woodland of the American Southeast, prehistoric communities appear to have expanded the range of species used for food to include lesser ranked resources, resulting in increased exploitation of freshwater mussel beds. These mussel remains provide a valuable source of information about past environments during the Late Woodland. Because many mussel species are extremely sensitive to the characteristics of the waterways in which they live, the pattern of species distribution and densities potentially enable one to reconstruct past environments. Here, I use assemblages of mussel shell from the Yazoo River Basin, MS, and Tombigbee River Basin, AL to construct hypothetical aquatic catchments that were
Looking Outward from the Village: The Effects of Soil Moisture on Prehistoric Cropland in the Central Mesa Verde Region

Ancestral Pueblo communities of the central Mesa Verde region (CMV) became increasingly reliant on maize agriculture for their subsistence needs by AD 900. Researchers have been studying the Ancestral Pueblo people for over a century using a variety of methods to understand the relationships between climate, agriculture, population, and settlements. While this research has produced a well-developed cultural history of the region, studies at a smaller scale are still needed to understand the relationship between farming landscapes and settlement patterns. Ancestral Pueblo farmers were dependent on having sufficient soil moisture for successful plant growth. A static geospatial soil moisture model was developed to predict potential agricultural field locations in the semiarid region of the Goodman Point watershed in the CMV. The results of the model and its application help to clarify subtle changes within local farming communities. Farmers shifted away from preferred farmland during Terminal Pueblo III (ca. AD 1260–1300), probably because of other factors such as a desire to protect and surround critical water sources. The general outcome of this research is an improved understanding of human-environmental relationships across the local landscape in the CMV.

Regional Practice in Poly-Chrome Painting Technology in Late Neolithic China

The Yangshao phase of the Chinese Neolithic is defined by the sudden occurrence of high quality poly-chrome painted pottery in the lower Yellow River basin. In this region there is no precedence for such high quality painted pottery, suggesting it had been imported from further afield. Production origins were previously investigated through examinations of chemical composition by NAA. While this study does not demonstrate the potential origins of this pottery technology, it provided new insight into regional patterns of production, exchange and consumption. Further still, it defined compositional signatures for at least three places of Neolithic pottery production within the study region. Through an integrated framework of microanalysis combining LA-ICP-MS and SEM-EDS, this paper takes the project a step further by reconstructing painting technologies and firing practices of the newly identified production groups. Upon comparison of these final stages of pottery production it becomes evident that specific technological practices, including the use of manganese and iron oxide-base minerals as the foundation of black and red paints, are widespread. However, there are noticeable intraregional differences in the production of white paint. These results suggest that discrete potting communities employed different technologies to achieve a common goal of poly-chrome pottery production.

Dogoszhi-Style Ceramics as Markers of Elite Status within the Chacoan Regional System

Dogoszhi-style ceramics are prevalent throughout the Ancestral Puebloan world during the eleventh-thirteenth centuries, and have been suggested as a marker of elite status within the Chacoan World. The replication of the style across different wares and media, occurrence on special forms, and in some
cases highly skilled painting, suggests a shared social significance at the regional scale. We investigate this proposition by examining the distribution of the style across the Chacoan World using the Southwest Social Networks database. Included are ceramic and architectural data on Chacoan Great Houses, great kivas, and other monumental architecture dating from AD 800 to 1200, as well as small house data from several Chaco outliers. Using 50-year periods we investigate (1) the timing and occurrence of Dogoszhi-style at some 300 sites with Chacoan monumental architecture, comparing Chaco Canyon, the “Chaco Halo,” and further outliers; (2) the distribution of Dogoszhi-style ceramics within Chacoan communities comparing great houses to surrounding small houses, in terms of both network centrality and Dogoszhi-style occurrence. These analyses define the transformation of Dogoszhi-style from highly localized to a wide-spread, and help evaluate whether it was a marker of elite status associated with the Chaco World.

Giovas, Christina M. (University of Queensland)
[340] Using Multi-Proxy Evidence to Evaluate Captive Animal Management in the Prehistoric Caribbean

For some time archaeologists have speculated that non-native mammals introduced to the prehistoric Caribbean may have been managed in captivity, but direct evidence for this practice has been wanting. The question of management is complicated by ambiguous and conflicting data from ethnohistory, animal behavior, and archaeology, as well as potentially unwarranted assumptions about human interaction with synanthropic animals. I examine this issue for introduced agouti (Dasyprocta sp.) and opossum (Didelphis marsupialis) in the precolombian Lesser Antilles, using multi-proxy evidence to evaluate their potential captive management. Data from dental eruption sequences, rates of epiphyseal fusion, and stable C, N, Pb and Sr isotopes are employed to examine the cultural role of agouti and opossum and potential management strategies employed by Amerindians. These data provide baselines for addressing the impact of introduced agouti and opossum on fragile island environments and potential incipient domestication in the precolombian era.

[90] Petrographic and Chemical Analysis of Grinding Stones Collected in Shkodra, Albania

The Shkodra Archaeological Project (PASH) took place in the Shkodra region of northern Albania. Shkodra presents a wide variety of ecosystems and landscapes, which interact with each other, leading to variation in human settlement, social behaviors, and land use, from prehistory to modern times. During the project, fifty-nine grinding stones were collected from various sites. Preliminary analysis shows that they vary in size and type, are composed of different materials, and belong to different periods, from prehistory to Medieval times. My study incorporates petrography, chemical analysis, and residual analysis in order to determine the source of the grinding stones and how they were used. These data will help us to reconstruct trade, economic and social interactions, and, tentatively, diet, through time.

Glascock, Michael D. (University of Missouri)
[231] A Geochemical Database for Indigenous Ceramics from South America

The indigenous peoples of South America have been producing pottery for more than 7,500 years. Pottery was made into vessels for the cooking and storage of foods, funerary urns, toys, sculptures, and a wide range of art forms. Due to the regional differences in the composition of raw materials used to manufacture and decorate pottery, geochemical investigations of pottery have proven successful for studying trade and exchange, changes in technology, provenance, etc. Some of the methods used to analyze pottery are neutron activation analysis, X-ray fluorescence, and inductively coupled plasma-mass spectrometry. All of these are capable of producing large quantities of data. Until recently, access to the geochemical data for pottery from South America has been lacking. A symposium describing several investigations of pottery from South America was held during the 2016 SAA meetings. Presentations from that symposium are now available in a publication from the University of New Mexico press entitled Geochemical Studies of Indigenous Ceramics from South America edited by M. D. Glascock, H. Neff, and K. J. Vaughn. The geochemical and descriptive database associated with that volume are publicly available from the following website: http://archaeometry.missouri.edu/datasets/index.html.

[27] The Lost Dimension: Pruned Plants in Roman Gardens

This paper focuses on previously unnoticed evidence for the pruning and dwarfing of plants represented in Roman garden paintings, such as the well-known example from the Villa of Livia at Prima Porta. Dozens of other examples of detailed garden scenes are preserved at Pompeii and Herculaneum. Their trompe l’oeil effects created interior garden settings for both living and dining spaces, as well as to extend the perceived extent of actual gardens in exterior courtyards of shops, houses, and villas. In the finer examples of this type, the artist has carefully portrayed pruning marks and other horticultural practices that altered the size and natural habit of the plants portrayed. This evidence complements archaeobotanical findings by showing the above-ground appearance of garden plants attested in the archaeological record. The remains of a garden that may be linked to garden paintings were found in 2007 in the Great Peristyle at the Villa Arianna at Stabiae, near Pompeii. The author combines archaeobotanical evidence with analysis of Pompeian garden paintings and texts, to create a reconstruction of the garden that shows how the painted gardens were experienced in three dimensions.

Glerstad, Zanette (Museum of Cultural History/University of Oslo)
[379] Garnets for the Vikings: Charismatic Jewelry and Family Memories in early Viking Age Scandinavia

The paper presents how continental-inspired elite jewelry from the Merovingian period (AD 550–800) continued to play an important role in the Viking Age Scandinavia (AD 800–1050). The so-called disc-on-bow brooch were covered with garnets, and is one of the most spectacular jewelry types we know from this period in Europe. They nevertheless appear in a number of female graves from the Viking Age, revealing traces of having been used a
long time, most likely passed down through several generations before they were placed in a grave. This opens up for exploring how tradition and memories were perceived and conveyed in a society where written text was hardly present, and disseminated and preserved through material culture. By seeing the brooches in such a context, it contributes to shed light on the fundamental changes in social structure and mentality that occur during the transition to the Viking Age. The paper will discuss the necessity to take into account how Scandinavian society in the Viking Age was influenced by its own past, and how this historicity, expressed through the brooches, contributed to shape self-recognition and social strategies within various Norse groups.

Glover, Jeffrey B. (Georgia State University), Brennan Collins (Georgia State University), Robin Wharton (Georgia State University) and Marni Davis (Georgia State University) [18] Teaching Atlanta: Using Local Projects to Bring Digital Heritage into the Classroom
How do English, History, and Archaeology professors begin collaborating? In our case it was our mutual interests in the history of Atlanta and incorporating digital methods into our courses. In this paper we discuss our intertwined collaborations at Georgia State University. These involve Wharton's incorporation of archaeological materials from the MARTA archaeological collection in her Expository Writing course. Students in this course take advantage of the computing resources in the library's Collaborative University Research and Visualization Environment (CURVE) and prepare 3D digital models and material culture studies analysis of objects from the MARTA collection. Similar projects using the MARTA collection are occurring in more traditional archaeology classes as well. Eventually, the models, object descriptions, and historical analyses created by students will be integrated into the 3D Atlanta Project, an effort to create a digital, three-dimensional, interactive view of a city block in the heart of GSU's downtown Atlanta campus as it looked in the 1920s-1930s. Paralleling these student-focused efforts is an effort to build pedagogical infrastructure for local instructors. In general, we have found that local projects are an easier way for faculty to get students involved in hands-on research, and the local lens inspires students' excitement and curiosity.

Glover, Jeffrey B. [44] see Tucker, Carrie

Glover, Lauren [271] Carnelian Beads in Korea and Japan (c. 100–700 CE): Style, Technology, and Trade Patterns
This regional study of carnelian beads in Korea and Japan (c. 100–700 CE) provides new perspectives on patterns of regional and long-distance trade and exchange. Possible source areas for carnelian will be presented along with the major stylistic and technological features recorded from carnelian beads. Preliminary analyses confirm the existence of intraregional exchange between polities on the Korean peninsula and the Japanese archipelago proposed by earlier scholars. Long distance exchange with South Asia and possibly Southeast Asia is indicated on the basis of bead shapes and manufacturing technology. Many of the carnelian beads appear to have been drilled using diamond drilling technology that has its origins in South Asia. Additional drilling technology using stone drills or abrasives with metal drills may indicate local production or trade with regions in what is now China. Quantitative analysis of drill hole size and overall shape and size of the beads points to multiple workshops supplying the imported beads and additional workshops producing the regional or local forms. The distribution patterns of the beads in different polities may reflect changes in trade networks over time as well as stylistic choices of bead shapes used as a means of differentiating specific groups or individuals.

Glowacki, Donna (University of Notre Dame) [278] (Trans)Formation, Centralization, and the Making of a Mesa Verde Village
Our understandings of how socio-complexity developed and the role households played in those developments are often hampered because we lack adequately fine-grained chronological data to identify when and how the relationships among households change. A detailed analysis of architecture and 260 tree-ring dates at Spruce Tree House cliff dwelling has produced a new reconstruction of how the village grew and changed over time at a decade-by-decade level. The village was occupied during the 1200s—a time of significant social and religious transformation, violence, climatic hardship, and the exodus of ancestral Pueblo people from the Mesa Verde region. This new information reveals how village life and social organization was fundamentally altered through increasing centralization that created a locus of social and religious power within the village during the 1240s. This transition co-occurs with an apparent shift in power from the families who founded the alcove village to newcomers, who likely had new rituals and stronger influence in the community. Evidence of burning and remodeling in specific rooms suggests this transition was also contentious. Insights gained from this study bear on understanding the evolution of social hierarchy in Pueblo society and its fourteenth-century transformation that de-emphasized rank differences.

Gnivecki, Perry and Mary Jane Berman (Center for American & World Cultures, Miami University) [395] Colonial Encounters in Lucayan Contexts
There are numerous examples of material and bodily flows (e.g., human transfer, enslavement) between the Lucayans and the Spanish during the period of late fifteenth- and early sixteenth-century colonial encounters. A variety of indigenous and Spanish items circulated, as relationships were established. These were known from ethnohistoric accounts and archaeological evidence from several different islands and sites located in the Bahama archipelago, including San Salvador, Andros, Long Island, Middle Caicos, and others. In this paper we will examine procurement and exchange from the perspective of the givers and receivers and those who recorded these acts. We will examine what objects and bodies were circulated; the intentions of the givers and receivers; the acts of procurement, giving, and receiving; the meaning of the items and bodies in the contexts in which they were procured and distributed; the changing values of the objects and bodies in these contexts, and the relationships that were established as a result of these acts.

Gobbo, Diego [56] see Moralejo, Reinaldo

Goddard, Jennifer [360] Cultural Amnesia, Archaeological Vandalism, and Loss Aversion in Heritage
Loss aversion theories contend that people prefer to avoid losses than acquire gains. Further, this tendency increases with object possession and ownership history. Although loss aversion implies a preference for heritage conservation practices, Holtorf (2015) argued that material losses could provide greater heritage gains. This paper asserts that loss aversion tendencies are relative to the referent's valence perceptions. Positive or negative valence embedded in heritage values will differentially influence the preference to avoid loss or embrace it. Whereas people tend to avoid the loss of
positively construed heritage, negatively construed heritage is often destroyed, forgotten, or omitted. Using examples of cultural amnesia in heritage as well as various types of archaeological vandalism, this paper will demonstrate how negative and positive valence differentially affect loss aversion tendencies and further suggests how this might play a role in heritage management.

[338] **The Middle Paleolithic Artifacts from Manot Cave (Western Galilee), Israel**

Manot Cave is situated within the Levantine Mediterranean region. The site has an extensive Upper Paleolithic sequence, including both Aurignacian and Ahmarian traditions. Several of the artifacts found within these assemblages belong to the Levallois technology. A small number of the artifacts, found in association with Upper Paleolithic occupational surfaces, have a double patina, possibly due to reuse. The majority are fresh suggesting the presence of a Middle Paleolithic occupation at the site. This study will present the Levallois Middle Paleolithic artifacts from the cave. The Levallois techno-typological traits indicate resemblance to other mid-late Middle Paleolithic techno-complexes present in the region. One of the Levallois centripetal cores from the collection exhibits a series of line engravings on its cortex-covered face. These incisions are organized radially, in a fan-shaped design, and are thought to reflect a non-utilitarian practice. The incisions were performed prior to the last removals from the flaking surface, and thus cannot be related to reuse of the core at a later period. Two other examples, dating to the Middle Paleolithic, are known from Quneitra and Qafzeh. Both present engravings on cortex-covered surfaces of flint plaques.

[318] **Inclusive Heritage: Learning from Urban Art in Berlin**

Alternative, subcultural, or otherwise non-mainstream forms of heritage are increasingly being recognized, both in the social imaginary and in the discipline. Such moments provide archaeologists with opportunities for actively working toward a more inclusive and diversified heritage practice. Specifically, my work explores the potential of urban art walking tours and workshops in the borough of Kreuzberg (Berlin, Germany) from a contemporary archaeological standpoint. As tour guides present painted surfaces to an audience, public views of urban place-making and of the right to the city are transformed. As a result of making visible the often-marginalized practice of urban art, its legitimacy is increased and, consequently, the notion of what constitutes cultural heritage is challenged. Employing queer pedagogy, tours and workshops take on an archaeological dimension, as explicit and embodied knowledge is shared horizontally between writers/artists/guides and tour goers. I contend that these small-scale gestures of showing graffiti and street art work toward breaking down the broader barriers between mainstream and alternative, experts and communities, as well as authorized and marginalized ways of being in cityscapes.

[226] **On the Trail of the Stemmed Point: A Circum-Pacific Perspective**

Half a century ago, Alan Bryan proposed that two distinct early Paleoindian traditions occurred in North America—Clovis Fluted east of the Rocky Mountains and Great Basin Stemmed in the far west—and that these co-traditions potentially represented different founding migrations from the Old World, with Great Basin Stemmed potentially being tied to a coastal north Pacific route. Much of the research that Ruth Gruhn and her partner Bryan conducted during the successive several decades, certainly into the 1980s, was devoted to further exploring this theory, for example their excavations at Smith Creek Cave and Handprint Cave in Nevada and Wilson Butte Cave in Idaho, as well as Gruhn’s important essays on the coastal-migration route in 1988 and 1994. Given renewed interest in the co-tradition/co-migration theory today, here we consider the current archaeological and genetic record in light of the following questions: What are the space-time systematics of stemmed points in western North America? Did stemmed points of the Great Basin originate from a Pacific coastal source? How do they relate to the Paleolithic records of Alaska and northeast Asia?

[238] **Herds for Gods? Sacrifice and Camelids Management during the Chimú Period**

Although domestic Andean camelids are native from the highlands they have been largely present in the Peruvian coast since the end of Early Horizon (nearly 200 BC). This presence stresses the symbolic, ritual importance and economic values of camels. In 2011 an impressive human and animal sacrificial context dating from the Chimú period was found in Huanchaquito near Chan Chan on the northern coast. At least 130 children and 200 camelids were uncovered during the successive excavations that took place between 2011 and 2016. This is undoubtedly the biggest sacrificial deposit of camels dating from the prehispanic times found in the Central Andes. This exceptional context raises questions about herd management by Chimú populations. During the Inca period camelids were separated according to their color pattern and some colors especially devoted to the divinities and rituals ceremonies. Was this system created by the Incas or did it have predecessors? We hypothesize that Chimú had similar practices which may have inspired the Incas. In this paper we will use different elements, such as mortality profiles and coat color, to test this assertion and the possible descent link between the two periods.

While chenopod cultivation has been documented extensively in North and South America, evidence for similar practices in the Maya area is lacking.  
Macrobotanical evidence of Chenopodium recovered from prehistoric Maya archaeological sites is limited to a few seeds. In contrast, the palynological  
Maya populations strongly suggests that the primary use of chenopods among the Maya is as a source of greens and medicine.

Goldfield, Anna (Boston University)  
The Fat of the Land: An Energetics Approach to Paleolithic Bone Fat Exploitation  
I present an energetics approach to Neanderthal and anatomically modern human (AMH) exploitation of prey carcasses for bone marrow and bone fat, crucial nutritional resources during glacial periods in Paleolithic Europe. Previously established differences in daily caloric budget between the two groups predicate variation in behavioral cost thresholds, or a point at which an individual decides that the cost of processing a food resource outweighs the gain and abandons the task. A higher metabolic baseline cost has been established for Neanderthals relative to AMH. For Neanderthals, therefore, the energy available to be allotted to subsistence tasks is expected to be a lower amount than that available to AMH. A lower cost threshold is therefore expected for Neanderthal carcass processing. Thus, in Middle Paleolithic faunal assemblages, we expect to find evidence for less intensive carcass processing than in Upper Paleolithic assemblages. Greater access to lipids in restrictive climatic conditions may have led to increased adaptive fitness and overall survival for AMH, with evolutionary implications. A comparison of skeletal element representation and bone fragmentation from five Paleolithic faunal assemblages from southwest France tests for differences in intensiveness of bone fat processing in Quina Mousterian, early Aurignacian, and Magdalenian glacial contexts.

Goldstein, Lynne (Michigan State University)  
Thinking Differently? How Digital Engagement, Teaching, and Research Have Influenced My Archaeological Knowledge  
Having been a professional archaeologist for a very long time, I have used a variety of different tools. Since 1988, I have actively employed digital tools for archaeological research, teaching, and public engagement. This work has primarily been based in the Midwestern United States, and has included both prehistoric and historic sites. In this paper, I highlight three examples and discuss the epistemological implications of the digital tools. The first is a Wisconsin projectile point book prepared almost completely from a digital database I created. The second is a flipped classroom whose focus was a report jointly written by the students in the class, as well as their own separate projects. The final example examines the extensive social media work done as creator and Director of the Michigan State University Campus Archaeology Program. In each example, the work could certainly have been accomplished without digital tools, but the tools significantly changed the way that I and the other participants thought about and conducted the archaeological work. These epistemological shifts in thinking have had significant, and I argue positive, impacts on archaeological research, teaching, and engagement.

Goldstein, David (National Park Service) and Jon Hageman (Northeastern Illinois University)  
From Quelites to Crop Indices: Thinking Through Maya Chenopods  
While chenopod cultivation has been documented extensively in North and South America, evidence for similar practices in the Maya area is lacking. Macrobotanical evidence of Chenopodium recovered from prehispanic Maya archaeological sites is limited to a few seeds. In contrast, the palynological record suggests widespread tolerance across the entirety of the Maya area, if not intensive management or even cultivation of Chenopod genera in some contexts. It is likely that chenopods are an integral part in the successional agroecology of fallowing and milpa agriculture. Typically, archaeologists consider such data as evidence of food production, but our work in documenting the ubiquity and uses of plant among ethnographic Maya populations strongly suggests that the primary use of chenopods among the Maya is as a source of greens and medicine.

Goldstein, Paul (UC San Diego)  
Tiwanku Colonization and the Great Reach West: Preliminary Results of the Locumba Archaeological Survey 2015–2016  
Locumba represents a key intermediate location for consideration of the timing and affiliation of Tiwanaku colonization of the Moquegua, Sama, Capilina and Azapa valleys. Models of Tiwanaku state colonization, diasporic enclaves, and a "daisy chain" of secondary and tertiary colonization from initial provinces in Moquegua are considered. Ongoing systematic regional survey in the 2015 and 2016 seasons of the Locumba Archaeological Project has defined 74 site sectors, including 16 sectors of Tiwanaku affiliation, in the Cinto and Salado tributaries (600–1000 masl). 2016 fieldwork delineated the three Tiwanaku residential sectors of the multicomponent site of Cerro San Antonio (L1 with systematic surface collection and test excavations. Excavations suggests a typical Tiwanaku V occupation with functional distinctions between Tiwanaku and one small ceremonial structure. Ceramics connect to other Tiwanaku V assemblages of the western valleys, with a majority presence resembling Moquegua’s Chen Chen style, along with local and other Tiwanaku regional variants (Tumilaca, Cabuza). Comparison suggests contemporaneity and a degree of social relationship with the Moquegua colony, leaving open the possibility of the daisy chain model. However, differences in motif distribution also suggest independent social, stylistic and exchange ties to both the altiplano and the Norte Grande.

Goldstein, Steven (Washington University in St. Louis), Michael Storozum (Washington University in St. Louis), Fiona Marshall (Washington University in St. Louis), Rachel Reid (Washington University in St. Louis) and Stanley Ambrose (University of Illinois at Urbana-Champaign) [154] Herder Land Use and Nutrient Hotspots in Southern Kenya: Geochemical Analysis of Anthropogenic Soil Enrichment Mobile herding societies are often considered to leave behind few traces in the archaeological record, however pastoral settlements may have helped shape the broader landscape. Herders relying on domesticated cattle, sheep and goat arrived in the most productive grasslands of East Africa >3600 cal BP years ago. Our collaborative research investigates the legacies of their land use through geoarchaeological analyses. We present results of analyses of five Pastoral Neolithic era archaeological sites and offsite controls from southern Kenya dating to between 3300 and 1800 BP. Particle size, loss on ignition, magnetic susceptibility and ICP-MS elemental analyses demonstrate that sediments derive from comparable lithologies. Livestock-dung-derived deposits at these archaeological sites are significantly enriched in Ca, K, Mg, Na, P, Sr, compared to controls. These are important micro-nutrients for plant growth. In some samples, these elements are elevated in archaeological layers by 10–80%, but sometimes 1000%, over background values. This research demonstrates that small scale pastoralist land use over three millennia leaves an enduring imprint on the landscape that is inextricable from the natural history and ecology of East African savannas. This pilot study illustrates the role of mobile herders in promoting ecological resilience and biodiversity in African savannas by creating nutrient “hotspots.”

Golitko, Mark (University of Notre Dame) [178] How Social are Archaeological Social Network Analyses? Archaeometric studies of archaeological materials by their nature examine social process—for instance learned technological traditions, socially mediated access to raw materials, or the social act of exchange. Models and methods drawn from social network analysis have gained popularity as a means of more formally modeling social relationships, and hold promise as a missing link between laboratory data and the social dynamics archaeologists wish to understand. However, archaeological applications to date have in many cases lacked detailed discussion of the underlying social processes and behaviors that produce the archaeological record, or rely on network principles conceived at the level of the individual and apply them to aggregate social behavior. Here, I discuss some of the potentials and shortcomings of network analysis in archaeology as practiced to date, and suggest that archaeologists need to become more involved in the production of underlying social network theory if such methods are to achieve lasting relevance to studying the past.

Golubiewski-Davis, Kristina (Middlebury College) [189] Reconstructing Social Networks: Using 3D Scans to Infer Networks of Shared Manufacture Knowledge in Late Bronze Age Central Europe This project is a case study using 3D scans of Late Bronze Age swords (~1200–800 BC) to re-create community networks of knowledge. Measurements from 111 3D scans of bronze sword hilts were taken based on characteristics related to manufacture and style, including cross sections. Fourier analysis was used to represent the curvature of cross sections numerically. The measurements taken and the results of the Fourier analyses were then processed using principal component analysis to combine related shape data. From there, several cluster analyses on the different types of data were used to group blades by morphological similarities. These cluster analyses formed the basis of links in a network graph. While nodes were defined in various ways, treating individual swords as nodes provided the most interesting results. Finally, a community detection algorithm was run on the networks to examine potential communities of bronze smiths, as represented by the swords. In this paper, I will present the general workflow and statistical methods used alongside my conclusions discussing the networks I detected and how those affect our understanding of LBA bronze smith communities.

Goman, Michelle (Sonoma State University), Arthur Joyce (University Colorado, Boulder) and Jessica Hedgepeth Balkin (University Colorado, Boulder) [82] Formative to Postclassic Land-Use Changes in the Lower Río Verde Valley, Oaxaca We provide a summary of the past ~15 years of paleoecological and paleoenvironmental analysis in the Lower Río Verde Valley. Ten lacustrine, wetland and estuarine sites throughout the valley and coastal zone were selected for sediment coring. The sediments were intensively sampled for a suite of biological and sedimentary analyses chosen to provide insight into changes in local and regional land use. Our findings indicate initial land clearance and incipient agriculture occurred during the Archaic in the coastal zone. Agricultural activity, with the planting of maize, first occurred in the floodplain during the Late Formative. A spatial analysis of agricultural activity at the sites indicates a preference for areas throughout the western floodplain; however, the focus of regional land use changed with regional political developments. The southern and southwestern sections of the valley were avoided during the Early Classic when archaeological evidence suggests the decline of the Río Viejo polity and a demographic shift into the more western Piedmont. Ongoing analysis of two floodplain lakes indicate significant dry conditions occurred at the end of the Classic and through the Postclassic with archaeological data indicating the collapse of the Río Viejo polity and a shift of settlement into the piedmont.

The central topic of this poster focus on the conversion of archaeological survey data to a GIS format for the identification of settlement patterns by communities that inhabited the Elephant River region, a tributary of the Limpopo River (southern Mozambique), from c. 300,000 to c. 20,000 years ago. Specifically, we tried to identify and characterize the settlement dynamics of each cultural phase (MSA and LSA), in order to understand the choices related to the selection of site location in connection to natural/landscape-related factors, visual prominence in the landscape, among others. Using data collected during archaeological field survey conducted in the Elephants river valley in 2015 and 2016 and GIS techniques we explore a series of simple but important issues in relation to visibility and patterning of archaeological data. The GIS analysis were conducted using ESRI’s ArcGIS 10.3 software leveraging a variety of standard geoprocessing tools and custom geoprocessing models.

Gonlin, Nan (Bellevue College) [80] Luminosity in the Ancient Maya World

It is only through light that darkness is visible. The anthropology of luminosity as put forth by Bille and Serensen (2007) regards light as something to be manipulated, matter which is used in cultural practices. In what ways did the ancient Maya light up the night and illuminate dark places? Evidence for ancient lighting is contained in artifacts and features, epigraphy, iconography, language, ethnolinguistic, and history, as well as the ethnographic record. Some of the major topics that we will address are how ancient cities were lit at night, variation in lighting from city to countryside, status differences in illumination, and the role of bioluminescent insects in adding glow to the dark. We question whether the modern desire for abundant night lighting is a cultural universal; humans perform without the brightness of day as other senses come to dominate the nightscape. In many circumstances, however, lower lighting is preferable for the performance of a variety of activities that were best conducted under the cover of dark. Apart from the material evidence for lighting, the metaphorical place of light and dark in the Classic Maya worldview will be examined.

Gonzalez, Lissandra (Instituto Nacional de Antropologia e Historia—Centro Regional Michoacán), José Luis Punzo (INAH-Michoacán), Mijaely Castañón (INAH-Michoacán) and Alejandro Valdes (INAH-Michoacán) [12] Ritualism and Metal Objects in Michoacán

The area of the current state of Michoacán has been considered one of the most important producers of metal objects during the Prehispanic period. These objects are always related to various rituals because of its peculiar characteristics of color, sound, shape and even smell. From the analysis of more than 1,800 metal objects from extensive collections, particularly at the Regional Museum of Michoacán and the State Museum of Michoacán, by the Project Archaeology and Landscape of the Center—South Area of Michoacán, we could deepen into various and important rituals in which the characteristics of the metal objects played fundamental roles in the interagency relationships between practitioners and ritual specialists, and the phenomenon of metal objects as another factor which interact as minimum unit of symbolism underlying the Tarascan world view. In that sense, we investigate the agential abilities of metal objects in the Tarascan world through archaeological contexts, but especially through the study of historical sources.

Gonzalez, Sara L. (University of Washington, Seattle) [108] Architecting the Underworld: What Is a Southern Maya Lowland Chultun?
Chultunes, man-made subterranean chambers excavated into limestone bedrock, are ubiquitous features encountered throughout the Maya cultural region. Although studies in the Northern Lowlands have demonstrated that chultunes in that locale functioned as water cisterns, the ascription of them as purely utilitarian within the Southern Lowlands is under much debate. One issue that hinders dialogue is lack of a commonly accepted understanding of what constitutes a chultun. The first aim of this paper is therefore to elaborate on specific characteristics that can be used to identify these subterranean features. The second is to couple a ritual landscape approach with the theoretical paradigm utilized by cave archaeologists to begin to frame questions about what the morphology and spatial distribution of chultunes within and between sites can tell us about their importance to and utilization by the ancient Maya.

Societies against the Chief? Reassessing the Value of “Heterarchy” as a Concept for Describing European Iron Age Societies

As a reaction against the dominant warrior chieftdom model of European Iron Age society, much of recent scholarship has emphasized the negotiated nature of power in these societies. Such approaches frequently characterize these societies as ‘heterarchical’ yet the dynamics of how communities operated above the level of the household remain relatively under-theorized. This paper reassesses the value of concepts of heterarchy for two regions of Europe, southern Britain and North-western Iberia. It will explore the extent to which the social organization of these regions share any similarities which makes this overarching term useful and, through exploration of the work of the likes of Pierre Clastres, discuss the underpinning mechanisms which might explain these heterarchical social forms. A better understanding of the social dynamics of these communities will also allow for a more nuanced assessment of the apparent emergence of more centralized, hierarchical societies at the end of the Iron Age. Was this really the emergence of proto-states as so often argued? Or does the apparently fluid nature of Kingship in the Late Iron Age suggest these power structures were more heterarchical than we imagine and owe a greater debt to the social systems of earlier centuries than is normally suggested?

Gonzalez Carretero, Lara (University College London) and Dorian Q. Fuller (University College London) [21]

9,000-Year-Old Cereal Meals: New Methods for the Analysis of Charred Food Remains from Çatalhöyük East (Turkey)

Remains of archaeological cereal preparations are often recovered from archaeological Neolithic sites across the Near East and Europe through flotation. These are recognizable as seemingly amorphous charred fragments of plant material. The study of these charred fragments of ancient meals is of considerable importance because the identification of their components allows the characterization of the nature of the food types represented, and their preparation, provides insights into past culinary traditions. Within this paper a new methodology for the investigation of these charred fragments of cereal preparations is presented, which utilizes Scanning Electronic Microscopy (SEM) analyses of microstructures present within them by which the processes leading to their formation can be scrutinized. We will concentrate on three aspects: (1) the composition of these charred fragments; (2) the characterization and classification of their microstructure according to possible methods of processing, preparation and cooking; (3) their comparison with experimentally prepared charred reference material. These techniques were applied to material recovered from Neolithic Çatalhöyük (Turkey), and the first results are presented here.

[267] The Archaeological Collections of the Gulf Coast Cultures at the National Museum of Anthropology

The National Museum of Anthropology in Mexico City holds the largest collection of archaeological artifacts in the country. A recent survey and inventory of the objects that form the Gulf Coast cultures section has revealed a more comprehensive and detailed view of the composition of it. This paper will present an overview of this collection providing information on the site provenience of the artifacts; what private collections were incorporated into it; the types of artifacts, as well as their chronology, among other kinds of data. I will also talk about the challenges of the individual documentation of the objects and of making this information available to the wider public.

Gonzalez Lauck, Rebecca B. [3] see Dobereiner, Jeffrey

González López, Angel (UC Riverside) and Andrew D. Turner (Yale University) [119] The Personification of Sacrificial Fire: An Undescribed Deity in Imperial Mexico Sculpture

A recurring theme in H. B. Nicholson’s groundbreaking analysis of Central Mexican deities is the application of a holistic approach to the analysis of Mexico stone sculpture, which includes visual and iconographic analysis, and comparison to early colonial texts. This paper will analyze a poorly understood deity that appears in late Mexico stone sculpture based on Nicholson’s innovative methodology. This fanged being appears only in stone sculpture from the imperial capital, and has previously been interpreted as an earth goddess, Tlaltecuhltli, or the fire god, Xiuhtecuhltli. We argue that this deity is indeed a being of fire and earth, although not the aforementioned deities. Rather, this deity appears as a personified brazier and as a burning bundle of wood, and was likely associated with cremation, sacrifice, and fire ceremonies.

Gonzalez Macqueen, Felipe (Western University), Giles Spence-Morrow (University of Toronto), Peter Bikoulis (University of Toronto), Willy Yépez Álvarez (Royal Ontario Museum) and Justin Jennings (Royal Ontario Museum) [233] Spatial Analysis of Geoglyphs in the Sihuas Valley, Peru

Geoglyphs are large features frequently created by removing rocks and surface dirt in order to create a large scale designs. Although often studied in isolation, much can be learned from the position of geoglyphs relative to other features on the landscape. As part of the Quilcapampa Archaeological Project, a reconnaissance survey guided by remotely sensed imagery was performed in order to document and map geoglyph iconography found on the pampa of the Sihuas Valley, Peru. To date, over 100 geoglyphs have been identified. We performed a variety of spatial analyses in order to determine what their location can potentially tell us about their original creation and purpose. In particular, the close proximity of these geoglyphs to ancient trails and roadways on the open pampa speaks to the importance they may have had marking routes and connectivity during the Middle Horizon and Late Intermediate periods.

Gonzalez Omaña, Diana (Diana Gonzalez Omaña) [328] San Marcos Jilotezongo: Heritage Issues after 900 Years of Continuous Occupancy

In September 2015, the second season of The Northern Basin of Mexico Sites Verification Project was made. During fieldwork, we had the chance of visit San Marcos Jilotezongo, a little town in the Mexican state of Mexico, and realize that the current village lay over the remains of prehispanic Xilotzingo, in which they share the same agricultural terraces, the tuff carved streets and building materials. But surprisingly there were no structures, since the current inhabitants of Jilotezongo dismantled prehispanic constructions in order to solve their daily needs, such as: raise the fences of their homes, to dam the river, or building tombs in the local cemetery. The viceregal Xilotzingo, use to bring limestone to Hueypoxtla, to produce lime to sell to the Spaniards. Later, this area was incorporated into the encomienda given by Cortes to Isabel de Moctezuma. But all this is ignored by the modern inhabitants of
Provided diverse natural resources for the Preceramic cultures at Huaca Prieta and Paredones. The archaeological site of Huaca Prieta is situated on the southern tip of a Pleistocene terrace along the shore, ~3 km north of the Chicama River mouth and floodplain system. Paredones is located 0.6 km to the north on the eastern edge of the terrace. Here we present the results of a geological investigation of sediment cores, outcrops, and surface morphology from the coastal plain and lower Chicama River valley. From these data we reconstruct the Holocene paleoenvironmental history of the area.

Gooderham, Ellie (Simon Fraser University), Luisa Marinho (Simon Fraser University), Laure Spake (Simon Fraser University), Shera Fisk (Simon Fraser University) and Ana Luisa Santos (University of Coimbra) [235] Severe Skeletal Lesions and Loss of Bone Mass in a Child Associated with a Case of Spinal Tuberculosis and Prolonged Immobilization

This paper describes the lesions identified in the skeletal remains of a nine-year-old girl who died of pulmonary tuberculosis in Lisbon, Portugal, in the 1940s. This individual is housed in the skeletal collection at the National Museum of Natural History and Science, Lisbon. These remains show a variety of lytic lesions on the ribs and thoracic vertebrae, with complete destruction of the bodies and fusion of the vertebral arches of four vertebrae at a 60° angle. The individual was likely bedridden for a prolonged period, which is reflected by abnormal size and shape changes to the pelvis and leg, including loss of bone mass, stunting of the long bones, premature fusion of epiphyses, and bone erosion. This clinically diagnosed case is one of the few examples of confirmed juvenile skeletal tuberculosis prior to the antibiotic era. As such, it provides a reference for the skeletal modifications which may be expected in archaeological tuberculosis cases.

Goodwin, Rebecca (University of Western Ontario) and Lisa Hodgetts (University of Western Ontario) [35] Foxy Ladies: Investigating Human-Animal Interactions at Agvik, Banks Island

Outstanding organic preservation at many Arctic sites gives archaeologists access to large artifactual and faunal assemblages through which to examine human-animal interactions. However, much of the research focused on these interactions conceives them not only in ecological/economic terms, but also examines them at the level of entire communities (e.g., zooarchaeological studies of subsistence) or focuses on the predominantly male realm of hunting. The Arctic ethnographic record reflects a strongly gendered division of labor. We therefore suggest that at least some elements of human social interactions with nonhuman animals were strongly gendered as well. In a case study from a 500-year-old Inuit dwelling at Agvik (OkRn-1) on Banks Island, we examine the material evidence for the ways in which women and men engaged with a range of animal species in their daily lives. One dwelling at Agvik contains a number of unusual features suggesting that the preparation of fox skins was an important activity at the site. Over 90 slate uluit (women’s knives) were recovered in addition to a possible symbolic cluster of fox crania. We go on to consider the implications for human social relationships with these animals.

Goralski, Craig T. (Cypress College) [14] Is There Strength in Numbers? An Evaluation of the Complementary Roles of Archaeologists and Anthropologists in Forensic Contexts

This paper explores the training and education that forensic anthropologists and forensic archaeologists have traditionally received, and how it is put into practice in forensic contexts. The substantial differences in theory, method, and practice between the two subdisciplines will be summarized and how these differences shape what each can contribute in the field will be discussed. This paper will argue that although some overlap between the two subdisciplines exists, contemporary anthropology contributes in forensic contexts best when forensic anthropologists collaborate with forensic archaeologists and vice versa. Whether a more integrated model merging forensic anthropology/archaeology education and training is tenable will be assessed using previous field schools conducted by the author and colleagues as test cases.

[202] Results preliminares del Proyecto Moqi (Peru): Explorando la administracion inkaica en el departamento de Tacna

Moqi es un asentamiento Inca ubicado entre las cuencas de los ríos Cambaya y Borogueña, a 2,8000 msnm, en la cabecera del río Locumba (Tacna, Peru). Las investigaciones (2012–2014) buscaron ampliar el conocimiento de las características arquitectónicas de Moqi Alto y Moqi Bajo, la producción del sitio arqueológico, las relaciones entre su población y el vínculo económico, social y cultural con el Estado Inca. Los primeros resultados, en el contexto de la hipótesis planteada (que propone que Moqi parece representar un clásico modelo de “centro de control administrativo” de los espacios productivos instalado por una élite demandante de las políticas del Estado Inca), nos revela un conjunto de rasgos que aseveran la complejidad de la producción del sitio arqueológico, diseño arquitectónico y espacial de Moqi Alto frente a la arquitectura más modesta de Moqi Bajo, y la producción del sitio arqueológico que nos hace pensar en una función diferente y probablemente complementaria de sus sectores. También se buscó conocer las características estructurales del sitio, los elementos arquitectónicos constructivos (tipos de roca y argamasa) y el sistema de circulación a través del análisis de la composición arquitectónica.

Excavations at the locus of Tongle Huayuen in the Late Shang Dynasty (ca. 1250–1046 BCE) capital site of Yinwu, near the modern city of Anyang, uncovered the remains of a small aboveground earthen structure (2015ALNF1). The recovery of wall and ceiling remains, much of which displayed considerable fire-reddening, from refuse pits associated with building foundations provided the opportunity to examine nonelite, non-palatial architecture in greater detail than has generally been possible at Shang Dynasty sites, due to the frequently poor preservation of earthen building materials. Comparison of these remains with those recovered from the palatial courtyard buildings at the Middle Shang city site of Huanbei, as well as the published descriptions of the remarkably preserved Early Shang structures at Gaogeng Taixi, provides valuable insight into the variation that existed within Shang Dynasty building practices and draws attention to avenues for future research. In addition, heating sediments dating to the Shang Dynasty under controlled conditions allows exploration of the conditions under which 2015ALNF1, and the palatial structures from Huanbei were abandoned and destroyed, which may have involved some kind of ritual closing activity.

Gore, Angela (Center for the Study of the First Americans, Texas A&M University)

Investigating prehistoric landscape use is significant in understanding adaptive strategies in the Late Pleistocene and early Holocene. One way to begin to address landscape use is through lithic procurement and selection studies; these are significant in understanding prehistoric human behavior because procurement and selection behaviors shape tool kits, mobile strategies and settlement patterns. An initial step in addressing these problems is attempted through examining lithic artifacts from Dry Creek and Little Panguingue Creek, two Nenana Valley sites dating from the Late Pleistocene to Holocene containing artifacts produced on volcanic materials such as basalts, rhyolites and dacites. We can geochemically characterize these toolstones through portable X-ray fluorescence (pXRF) analysis to explore toolstone use in the valley. This presentation reports preliminary results of my 2016 dissertation research and compares geochemical data from Nenana Valley sites (Dry Creek and Little Panguingue Creek) with geochemical signatures obtained from both primary outcrops and local alluvium sources to establish how local volcanic materials were utilized by prehistoric Alaskans in the Nenana Valley through time.

[308] A Ceramic Investigation into the Relationship between Emergent Complexity and Religion on the South Coast of Peru

This paper investigates negotiations of power on the south coast of Peru through ceramic attribute analysis. The ceramic sample comes from the site of Cerro Tortolita, which contains both ceremonial and habitation zones. This site’s emergence in the upper Ica Valley during the third century AD coincided with a broader increase in local settlement hierarchy. The timing of Cerro Tortolita’s rise and its religious nature provide a unique opportunity to isolate and investigate the relationship between religion and emergent inequality. Although inequality was once thought to be an inevitable transition on the road to progress to Western civilization-like complexity, it is now recognized that societies have social norms and leveling mechanisms that actively maintain distributions of power. For inequality to arise, social norms and limitations maintaining equality must first be overcome, and religion is one means of doing so. The hypotheses tested through this work concern use of space within the ceremonial zone of the site, and what this can tell us about elite strategies for power and how regular people shaped those strategies. By studying the power dynamics at Cerro Tortolita, we can better understand the potential of religion in emergent inequality.

[166] Mining, Migration, and Movement in Roman Iberia

The Iberian Peninsula was a rich source of metals in antiquity, and indigenous people practiced mining in many areas from at least 4000 BCE. Following Roman conquest of the region in the late third century BCE, the scale of mining increased dramatically to accommodate the growing needs of the Roman Empire from the production of coins to the creation of urban water infrastructure. This growth catalyzed episodes of migration of people and movement of materials in ways that stimulated both regional and empire-wide connectivity. In this paper, I explore these changing patterns of movement—both of people and goods—in and out of major mining districts in southern Iberia. I argue that the migration of Italians into Iberia soon after Roman conquest contributed to the diversification of communities in the countryside, and the development of lasting connections between these areas and other parts of the empire. By contrast, in later centuries, increased movement of people and goods within the peninsula stimulated connectivity.
regionally, increasing provincial ties. Understanding connectivity brought about by the demands of mining ultimately sheds light on the relationship between natural resources, the formation of diverse communities, and the creation of empire in Roman Iberia.

[377] Seeding Colonialism: European Trade Beads within Native American Contexts

The typological and scientific study of trade beads in Native American contexts has contributed a great deal to understanding contact period sites (ca. 1607–1783). The Cape Creek site, NC, is a perfect example of British-indigenous connectivity in the contact period and is important for understanding interaction in the Southeast. Unlike other studies of this type that mostly focus on mortuary sites, Cape Creek is a village settlement and will therefore provide a different view of day-to-day bead usage in a domestic context. This paper will discuss the change of field methodologies that allowed for increased detection of beads within the complicated strata of Cape Creek, and will also apply previous methodologies to analyze the beads and discuss possibilities for dating and sourcing.

[174] Ashes to Ashes, Dust to Dust: The Role of Wood in Ancient Maya Funerary Sequences

From 2014 to 2016, the intensive excavation of the residential unit SN6 in Naachten (Guatemala) has yielded 13 burials intricately linked with the evolution of the architecture. Put together, these funerary contexts allow for a fine-scale reconstruction of the local dynamics and everyday life in the unit. However, funerary archaeologists often fail to consider the burial itself as a micro-context, a combination of significant gestures and actions that can be analyzed using the same principles as those used in a larger scale. The presence of layers of ashes and charcoal in the ancient Maya burials is a very well-known fact. Spatial analysis adapted to the dimensions of single burials demonstrate the existence of ritualized, cultural selection of the woods rather than random deposits. When combined with archaeoethnology, this fine-scale analysis gives us a new insight on ancient Maya funerary practices as a whole.

Value and Impact: The New Philanthropy and Funding Archaeology

In an era of globally declining government funding for culture, including archaeology and heritage, the philanthropic sector will loom increasingly important to funding this discipline. Major philanthropic organizations and individual philanthropists increasingly are seeking to define and measure the impact of the causes they fund. That “impact” may be social, economic, political, or cultural, but in all cases the essential element is a set of clearly defined impact metrics. This change in perspective is compelling those seeking funds to define in a measurable and meaningful way the difference that their work makes in the world. Increasingly, causes and projects that have relied on donor enthusiasm or emotional attachment to the activity will encounter resistance from a new generation of mission- and impact-focused donors. This paper will explore this emerging terrain and consider both alternative approaches to evaluating the impact of archaeology and the implications of these trends for those seeking funding for archaeology-related projects. Examples will be drawn from a number of different sectors in order to illuminate both the nature of impact philanthropy and the variety of approaches available to address donors’ emerging requirements for impact data.

[260] An Archaeology of Illegal Garbage Dumping in the Twenty-First Century

A boon to the archaeological study of American lifeways in the past and present, the massive assemblages of discarded objects at landfills poignantly speak to an era of unrivaled consumption and waste. Aggregated through municipally sanctioned collection services, these assemblages, however, are rarely representative of the full range of household-level discard behaviors. Illegal dump sites, in contrast, comprise assemblages that cannot be easily or quickly discarded through regular garbage collection utilities. As such, illegal dump sites implicate economies of garbage that are otherwise not evident or, at best, poorly represented at municipal landfills. In this poster, we present data generated with the application of archaeological methods to the study of recent illegal garbage dump sites in southeastern Connecticut. We argue these sites represent discard decisions that are undergirded by ideologies of elusion and, sometimes, subversion. Some dump sites afford analyses of small social group behavior, such as household life cycling. Others permit the study of individual histories and modern processes of loss and “accidental” deposition. All provide opportunity to evaluate the ways that broader structures shape expressions of nonconformity and the ways that nonconformity is materialized in the archaeological record.

[47] Investigations of Late Glacial Occupations at the McDonald Creek Site, Central Alaska

In 2013 our team began testing the recently-discovered McDonald Creek archaeological site, located in the Tanana Flats, Central Alaska. To date we have excavated a total of 15 m². The site contains evidence of a set of living floors dating to the Middle Holocene, Younger Dryas, and early Allerød. Our tests have revealed thousands of archaeological materials, including lithics and faunal and floral remains, associated with domestic features such as hearths and possible dwellings. We are analyzing materials collected thus far and preparing for full-scale excavations beginning summer 2017. This paper reports initial results of geochronological, lithic, zooarchaeological, and paleoethnobotanical analyses and places the site in the context of eastern Beringian prehistory.

[21] Phrygian Cuisine at Kerkenes: A Synthesis of Ceramic and Botanical Evidence for Food Storage and Cooking

At the Iron Age site of Kerkenes in Central Turkey, researchers are using different analytical methods to study cooking and food preparation. Evidence for cooking pots and other ceramic containers used for preparing, storing, and cooking food are found together with a variety of botanical remains. A new project at the site initiated the complementary analysis of ceramic container production and use with plant preparation, storage, and consumption. Situating these data in context, taking advantage of a site-wide destruction preserving features related to cooking, tools related to food preparation, and
faunal remains, this project is able to discover new and complementary information on cooking and food preparation. These complementary analyses will make it possible to learn more about the choices people made in the past and discover insights about the different social practices at this large urban center.

[103] Copper and Bone: Craft Labor and Aesthetics in the Early Creole Faubourgs of New Orleans, 1790–1865
The early residents of the Creole faubourgs have long been recognized as contributors to the development of New Orleans’s unique aesthetic traditions. Indeed many of the city’s most iconic architectural forms and cultural practices were forged in these neighborhoods—semi-urban spaces where people from a variety of local and trans-Atlantic backgrounds came together to redefine and embody the meaning of “Creole” in the nineteenth century. But much of the details about the labor that built these physical and social communities—the physical work of enslaved laborers and free people of color—has been eclipsed by dominant narratives that privilege more recent developments in the city’s history. This is particularly true of Faubourg Tremé, the neighborhood that gave birth to jazz but was also the location of the city’s earliest plantations. This paper employs recent archaeological findings from one of these early plantations to examine the physical traces of the labor that built the Creole city. From buttons to furniture hardware, it asks, What are some of the material traces of Creole aesthetic traditions? and How did craft labor assist in the building and making of new urban communities at the turn of the nineteenth century?

[232] Preliminary Compositional Analysis of Raw Clays and Ceramic Pastes from the Callejón de Huaylas, Highland Ancash, Peru (ca. 200–800 CE)
Located in north-central Peru, the highland Ancash region sits at an important geographic and scholarly intersection. Despite its position as a main thoroughfare between the northern and southern sierra, it is often neglected during discussions of the increased interregional interaction of the Middle Horizon (ca. 700–1000 CE). This period is characterized by the expansion of the Wari state out of the south highlands. There remains much to be known about the Middle Horizon in highland Ancash, particularly the involvement of local groups in trade networks. Here we present the preliminary results of compositional analysis of ceramic pastes and raw clays undertaken at the Field Museum's Elemental Analysis Facility in order to shed light on the organization of production and the movement of pottery prior to and during Wari expansion. Our ceramic samples span the Early Intermediate Period (ca. 1–700 CE), including Recuay style fancy kaolinite wares, and the Middle Horizon, and were obtained from eight different sites in the Callejón de Huaylas region. By including such a broad sample, we tentatively identify zones of production and propose further testable hypotheses about the nature of interaction during the Middle Horizon.

[38] Using ABM to Evaluate the Impact of Topography and Climate Change on Social Networks
Anthropological research suggests that climate and environmental resources influence the lifestyle of hunter-gatherers. My research uses an agent-based model to generate test expectations related to the impact of different geographical and social environments on the social networks formed therein. It focuses on Magdalenian social networks created in the Cantabrian and Dordogne region, and visible through similarities of portable art representations. The regional resources and climate of the period are re-created through ecological models and downscaled paleoclimatic data, respectively. The model also uses realistic DEMs and a human-informed version of least-cost path to reproduce possible traveling routes between fake archaeological sites. The expectations generated are tested through a stylistic study of Magdalenian portable art objects. This presentation will demonstrate the potential of combining computer models with empirical data to increase our understanding of prehistoric social dynamics.

[302] Integrating Archaeological and Historical Information to Identify Agricultural Features and Reconstruct Traditional Hawaiian Irrigation Networks in Windward Kohala, Hawai'i Island
Where landscapes have been modified by recent development, identifying surface archaeological features requires a different analytical approach. In windward Kohala, Hawai'i Island, after more than 150 years of land conversion to commercial agriculture features that comprised traditional Hawaiian irrigation agriculture have been mostly obscured. To address this, several sources of information were collected including historic documents and maps, previous and recent archaeological surveys, and remote sensing. These were georeferenced, converted to GIS files, and combined. From this it was possible to reconstruct not only the locations and extent of former fields and irrigation ditches, but also to identify the spatial linkages among them. Agricultural networks were formed that linked water sources from streams in the uplands with ditches and natural drainages to deliver irrigation to a series of plots and fields at lower elevations. Water was transported out of its stream drainage onto neighboring ridge lands where plots were

[129] Household and Political Economy in Ancient Hohokam Society
Examining household-level economic behaviors has long been a means for archaeologists to explore social and political organization in ancient Hohokam society. In this presentation, I reflect on the training and influence of Katherine Spielmann in my thinking about the economic roots of inequality in small-scale societies and begin to outline an explicitly political-economic framework to explore the structure and bases of power among the Hohokam of southern Arizona. The Hohokam household was the locus of crucial relations of production and it was households who controlled both the means of production and productive labor. I argue that Hohokam households exploited production and labor to compete with one another for political power. Inequality was created and experienced through a relative ranking of households based on control, exploitation, and competition. Understanding changes in the relations of production and how production and labor may have been controlled can help us model changes in the nature of power and the experience of inequality throughout Hohokam history.

[326] A Seriation of Local Ceramics from Cosmapa Oriental, Department of Chinandega, Nicaragua
Many local ceramic wares in northwestern Nicaragua are, as of yet, undescribed. Excavations at the site of Cosmapa Oriental in the municipality of Chichigalpa, Department of Chinandega, Nicaragua were conducted by Dr. Clifford Brown of Florida Atlantic University in 2013. Analysis of the ceramic sample in 2015 revealed two occupational periods at the site: a Late Preclassic occupation related to cultures in El Salvador; and a Classic to Early Postclassic occupation, which include Las Vegas and Ulúa Polychromes. This paper will introduce a seriation and description of the Classic to Early Postclassic local ceramic wares recovered from the site of Cosmapa Oriental. The Cosmapa seriation was constructed using the Type: Variety-Mode system, however, emphasis was maintained on paste characteristics. The main local paste is soft and friable, brown to buff, with medium sub-angular volcanic grit temper. Cosmapa wares include an unslipped type and a few types with buff, red, and black slips. Incision and punctuation are common ceramic decorations on both unslipped and slipped variations, while we have noted appliquéd and the use of stucco on unslipped varieties. This seriation will be the first description of local ceramics from the Department of Chinandega, Nicaragua.

Gray Jones, Amy (University of Chester)

[139] Manipulation of the Body in the Mesolithic of North-West Europe
This paper seeks to situate the phenomena of “loose” human bones in the Mesolithic of north-west Europe within a wider understanding of the role of post-mortem manipulation of the body in the mortuary practices of these Mesolithic hunter-gatherers. While originally interpreted as the remains of disturbed burials, assemblages of disarticulated human remains have begun to be accepted as evidence for alternative mortuary practices, though their specific nature has so far received little critical attention. Recent doctoral research, based on detailed osteological analysis, has identified the specific processes and practices that were undertaken at a number of sites across Europe. This material is considered against the background of evidence for Mesolithic mortuary practice which displays enormous variation in the treatment of the body after death. While “loose” human bones may seem isolated to us, I argue that the practices and processes that produced these remains, and their deposition in the landscape, involved them in relationships with other objects, places and (living) people, revealing Mesolithic attitudes to persons, bodies and death.

[44] Ethnoarchaeology of Natural Solution Cavities as Water Sources Affecting Settlement and Economic Activities in a Yucatec Maya Community, Mexico
Ethnoarchaeological investigations in the Yucatec Maya community of Xcoloc recently included inventorying the location and uses of a range of small-large water sources. This karst landscape has no surface rivers, ponds, or lakes. Currently, the community uses a deep well at the former hacienda in rainfall. All of the identified water sources (sartenejas, aguadas, and cenotes) are maintained and still used at least periodically for apiaries, incidental agricultural use, laundry washing, drinking water sources for groups working away from the village, and as locations to check for game during hunting trips. Our research addresses how these sartenejas and aguadas can be used to study past settlement in the region of Xcoloc, as well as past and present economic activities. Present economic activities.

Green, Kirsten (University of Montana)

Mortuary practices are created to convey something about the deceased individual, as well as their surviving relatives, but can also give insight into the religious, social, and political structure of the community. This paper focuses on Maya mortuary practices in Belize, and how/why those practices changed over the transition from the Formative period (2000 BC–AD 300) to the Classic Maya florescence (AD 300–800). Comparing differences of mortuary characteristics within and between communities, time periods, and/or geographic regions can tell us about the differing political systems, social stresses, population movement, kinship relationships, and ecological changes that may have effected change to a religious structure. Mortuary practices are consistently used as a proxy that reflects the complexity of the sociopolitical structure and distribution of the population allowing for bioarchaeologists and mortuary archaeologists to infer social structure, religious beliefs, population demographics, and political or ecological shifts. The Classic Maya were known for their complex ritual, social, and political structures and this chapter will identify trends in Maya mortuary practices and discuss reasons for those trends. Specifically, questions of how the complex mortuary ritual came about and how social, political, and environmental stresses were reflected in the treatment of their dead.

Wedded to Privilege? Archaeology and Academic Capital
If archaeology is by definition strongly attached to certain academic ideals (or “scholastic fallacies”), to a particular secular, rationalist way of looking at the world, and to ever-proliferating specializations that require scarce technological resources and expertise; and if, moreover, academic symbolic and cultural capital is constantly and increasingly measured by membership in the correct status groups and by access to these scarce resources, can academic initiation of, or even participation in, community-based heritage and memory work ever be more than lip-service? On the other hand, if the basis for archaeology is, ultimately, field-work, i.e., a physical presence in, and impact on, real, inhabited places, does academic archaeology have a future without recourse to communities? What is the political, ethical and scientific cost of an archaeology that is wedded to privilege?

Greene, Lance (Wright State University)

Cherokee Participation in the Southern Slave Society
On the eve of the Removal during the Early Republic era, most Cherokees still practiced traditional modes of subsistence farming and participated in local economies. At the same time, a small but influential segment of the Cherokee Nation was completely entrenched in the capitalist economy, operating large-scale plantations, businesses, and other ventures. These Cherokees were participants in the slave society of the southeastern United States in two ways; they owned African-American slaves, and they produced surplus crops, livestock, and goods that were sold to white plantation owners in the Lowcountry South. Most of these wealthy Cherokees lived in northern Georgia, which held the most extensive agricultural lands of the Cherokee Nation. However, small numbers of Cherokees also participated in the market economy in other parts of the Cherokee Nation. Documentary research on and archaeological investigations at the plantation site of a Cherokee family in the mountainous region of western North Carolina reveal how this family used their wealth to avoid forced Removal, to assist other Cherokees to remain in the area, and, ironically, to maintain some traditional aspects of Cherokee life. Their story reveals local complexities of capitalism, race, and class in the antebellum South.

Greene, Alan (New York University)

Regional Political Economies in the South Caucasus: Tracing Social Boundaries in an Eurasian Context
After more than a century of Russian Imperial and Soviet research dominated by the excavation of tumulus burials, researchers in the South Caucasus have now spent two decades investigating exactly how settlement archaeology sheds light on the inhabitants of the region’s earliest polities (ca. 1500–1150 BC). Most of this data has emerged from the sites of the Tsaghkahovit Plain, which have served as a micro-regional laboratory for Bronze and Iron Age studies since 1998. But how exactly do these local models of political organization and economic life articulate with the broader dynamics of circulation, boundaries, and human movement that tied the residents of the South Caucasus into a regional ecumene with a common sociopolitical vocabulary? What relates our understandings of site-based devotion, bodily adornment, and commodity stockpiling to the flows of people and products that traversed political communities? Data from the Kasakh Valley Archaeological Survey of Project ArAGATS are now providing access points to these regional aspects of society and economy. At the same time, they are illuminating the paths and stakes of geographically extensive political archaeology more generally.

The Historical Ecology of Laxgalts’ap: A Cultural Keystone Place of the Gitga’at of Northern British Columbia
For many Indigenous Peoples, their traditional lands are archives of their histories, from the deepest of time to recent memories and actions. These histories are written in the landscapes’ geological features, the plant and animal communities, and associated archaeological and paleoecological records. Some of these landscapes, recently termed “Cultural Keystone Places” (CKPs), are iconic for these groups and have become symbols of the connections between the past and the future, and between people and place. Using an historical ecological approach, we describe our novel methods and initial results for documenting the history of Laxgalts’ap (Old Town) in the territory of the Gitga’at. We combine data and knowledge from diverse disciplines and communities to tell the deep and recent histories of Laxgalts’ap. This CKP encompasses expansive landscapes and diverse habitats transformed by generations of people interacting with their surrounding environments. Documenting the “softer” footprints of past human-environmental interactions can be elusive and requires using diverse approaches and novel techniques.

Fertility in Ancient California: Life History Strategies and Implications for Demographics, Resource Intensification, and Social Organization
Child behavior ecology predicts that individuals alter reproductive strategies in response to environmental and social conditions. Consider stable isotope measures (δ15N and δ13C) of weaning age, parental provisioning, and child foraging derived from human tissues as proxies for the reproductive strategies employed by prehistoric hunter-gatherer populations from Central California over a 6,000-year period. Shifts in weaning age and childhood diet over time suggest reduced parental investment associated with the Medieval Climatic Anomaly (MCA) (1100–700 BP), a period noted for severe episodic droughts and global environmental and social disruption. The decline in mean weaning age and associated shortening of inter-birth intervals during the MCA is consistent with the hypothesized offspring quantity-quality trade-off. This change in life history strategy initiated a cycle of population growth and resource intensification that drove adaptive shifts in settlement patterns and sociopolitical structure, ultimately resulting in native California’s high population density and unique tribal organization.

Signage Effectiveness as Rock Art Protection

Site signage has long been used to inform people of the importance and fragile nature of rock art and consequences of damaging the images and related cultural remains. Many styles of signs, with variable content, amount of information, and degrees of threatened legal action, have been used around the world, and their effectiveness may be evaluated by damage to the sign, associated rock art, and surrounding landscape. Other factors, such as fences, walkways, distance from roads, and presence of site overseers, may also influence a sign's effectiveness. Recommendations are made as to the most effective sign styles, placement, and contents.

Gregory, Andrea (Archaeological Consulting Services, Ltd.) and Alanna Ossa (State University of New York at Oswego)

Life between Two Rivers: A Study of the Sedentary to Early Classic Transition on the Queen Creek Delta, Arizona

Disruption of exchange networks and settlement patterns during the late Sedentary to early Classic period transition has been well documented along the middle Gila River Valley. Previous research has suggested a trend in population relocation from downstream Gila River sites such as Snaketown in favor of sites upstream such as the Grewe-Casa Grande complex during this time. Based on evidence recovered from residential contexts identified during the PVR FRS project, outlying areas situated along the Queen Creek delta and bajada show a continued occupation well into the Classic period, maintaining contact with middle Gila River communities throughout this transitional period. The PVR FRS project findings bridge the Sedentary and Classic occupation, offering a unique opportunity to analyze both continuity and fluctuations in exchange networks between the Hohokam settlements in Queen Creek and communities in the middle Gila and lower Salt Rivers during this time. The settlements identified from the PVR FRS project also show increasing involvement with ceramic production and potentially botanical resources into the early Classic period, supporting their importance in helping us understand the circumstances of increasingly localized production identified during that era.

Tracking Dogs Across the Pacific Using Ancient Mitogenomes

Dogs were introduced to the islands of Australasia and the Pacific during human migrations and colonizations, but the timing and dispersal routes are unclear. To investigate these Oceanic dog introductions and movements, we generated complete or near complete ancient mitochondrial genomes from archaeological dog specimens from Thailand, Island Southeast Asia and Pacific islands, and from modern dingoes. When combined with additional published complete mitogenome sequences from modern dogs from Southeast Asia and New Guinea, and Australian dingoes, a complex history of dog-human interactions and multiple introductions into the region is revealed. This complexity is also mirrored in archaeological and linguistic evidence.

In Search of Camps’ Warner: Tracking U.S. Military Presence in the Warner Valley, Oregon 1866–1874

Following the discovery of gold and growing reports of trouble in eastern Oregon, the U.S. Military established a series of four forts to protect settlers and miners flocking to this part of the state and to insure continued use of local military roads. One of these forts, Camp Warner, served as the primary military fort in the Warner Valley from 1866 to 1874. Camp Warner actually consisted of two separate fort locations; old Camp Warner in use from 1866–
1867, and new Camp Warner in use from 1867–1874. In its heyday, Camp Warner consisted of over 80 structures that housed over 270 men along with some officers’ families and served as an important military outpost during both the Snake (1866–1868) and Modoc (1873) Wars. This paper outlines recent attempts to relocate both fort sites, now located on both private and federal lands, and to determine their state of preservation. To facilitate the abandonment of Old Camp Warner to its new location to the west, a stone bridge was constructed across wetlands that were part of the Warner Lakes. The site of this bridge was also relocated and evaluated.

Griffith, Cameron S. (Texas Tech University), Adam Spring and Brent Woodfill [386] Comparisons and Contrasts of Digital Imaging Technologies in Subterranean Mesoamerica
Over a period of just a few short years there have been dramatic advancements in digital imaging and scanning technologies. Increasingly, cave archaeologists around the world are utilizing many of these new platforms and techniques to document subterranean artwork. This paper outlines two different approaches to digital imaging of ancient Maya cave art. In Guatemala, a Z+F IMAGER 5010C 3D Laser scanner, mounted on a tripod, was employed in Cueva San Juan and Hun Nal Ye to document both painted and carved artwork. In Belize, an Occipital Structure Sensor 3D scanner, mounted on an iPhone 6, was used to document monumental modified speleothem sculptures in Actun Halal. In addition to comparing and contrasting the methodologies, results, costs, time, and logistics involved in these two different archaeological endeavors, we provide suggestions for those who may be interested in carrying out similar initiatives in the future.

Griffiths, Seren (University of Central Lancashire) [81] New Romantic Archaeology: Radiocarbon Revolutions and Revolutions in Understanding
This presentation will reflect on the so called four Radiocarbon Revolutions and their implications on archaeological narratives and theory generally, and Neolithic studies in Britain specifically. The timing of this reflection is critical given the implications of recent Bayesian analysis in order to produce precise, robust and probabilistic chronologies for parts of European prehistory. This paper will revisit the reactions to the initial radiocarbon revolutions by important theorists such as Colin Renfrew and David Clarke. Beyond this work there has been a marked lack of discussion of the implication that scientific dating has had and continues to have on archaeological theory as a whole. This paper will return to the considerations of the earlier radiocarbon revolutions by Clarke and Renfrew, as well as Wheeler, Childe and Sherratt to examine the implications for contemporary practice. Chiefly it will argue that the implications of earlier revolutions that Clarke identified have not been integrated with the newly available chronologies in archaeological practice. It will argue that glossing approaches as ordered “New” science, and relativist Romanticism is misleading, and will return to Wylie’s emphasis on the importance of “tacking” between data and interpretation, which is especially relevant with our newly precise chronologies.

Grimes, Vaughan (Memorial University), Alison J T Harris (Memorial University), Ana T. Duggan (McMaster University), Stephanie Marciniak (McMaster University) and Hendrik Poinar (McMaster University) [245] Strontium and Oxygen Isotope Evidence for Maritime Archaic Mobility Patterns at the Site of Port au Choix-3, Newfoundland
Recent archaeological and biomolecular investigations of the burial assemblage from the Maritime Archaic cemetery at Port au Choix-3, Newfoundland, reveal intriguing patterns of variability. New bone collagen stable isotope evidence supports significant dietary variation between individuals, and artifact-based analyses appear to indicate the site functioned as a meeting ground for different Maritime Archaic ethnic groups from within Newfoundland and the Atlantic region. When combined with previous osteological research on this burial assemblage that suggested nonspecific exogamy, these new data may reflect human mobility that potentially ranged across Newfoundland and into the mainland of Atlantic Canada. To test these ideas, we measured strontium and phosphate oxygen isotopes in tooth enamel from individuals representing all burial loci at Port au Choix-3. Our strontium and oxygen data suggests a differential pattern of mobility within the burial assemblage that appears to lend support to these new theories. Here we will present these results and discuss the implications for interpreting this important Maritime Archaic site.

Grinstead, Deanna (Ohio State University), Jay Quade (University of Arizona) and Mary Stiner (University of Arizona) [284] Isotopic Evidence for Long-Distance Mammal Procurement, Chaco Canyon, New Mexico, USA
Previous research on the prehistoric communities of Chaco Canyon, New Mexico (ca. AD 800–1250) provides evidence of an extensive procurement system of nonlocal food and economic goods. In this paper we use oxygen, carbon, and strontium isotope analyses to establish whether animal protein followed a similar pattern. We contextualized our analyses of the archaeofaunas from recent excavations at Pueblo Bonito with data on modern faunas across an area of ~100,000 km² around the site. Our results show that most archaeological deer, rabbits, and prairie dogs were obtained from >40 km away from Pueblo Bonito with the latter two likely being garden hunted. The Chuska Mountains west of Chaco Canyon and more distant San Juan Mountains to the north were the main source areas. These results closely align with previous results on architectural wood, corn, and other resources. The importation of small game animals suggests that the local supplies could not meet the needs of the community. Long distance meat procurement
may have been embedded within a more complex network of ritual-goods exchange or tribute that helped to offset the transport costs. Resource depletion may have contributed to the eventual abandonment of the region during the Medieval Warm Period.

“Ashes to ashes, dust to dust”: Natufian Cemeteries and Human Perceptions of Nature

A chief source of information on archaeological cultures is gathered from excavated cemeteries. Burial location and treatment provide insight into many aspects of the daily life, social organization, and ideology of past human populations. In particular, the location and organization of human interments can reveal how past cultures perceived their natural surroundings and their place within them. Through burial, an individual returns to the soil of their homeland symbolizing the connections between nature, the living and the dead. We explore this connection by investigating the burial locations of the Natufians, the last Paleolithic culture in the southern Levant prior to the transition to early Neolithic entities. The unique cultural dynamics of the Natufian, shifts in subsistence strategies and the environmental setting of various sites are key for understanding the emergence of early agricultural communities. New insights into how this Natufian population perceived nature will be presented by investigating two very Late Natufian burial locations in Israel—Hilazon Tachtit cave in the western Galilee and Nahal Ein Gev II in the Jordan Valley, Israel.

Early Metallurgy from Waywaka in the South-Central Highlands of Andahuaylas, Apurimac, Peru: New AMS Dates and XRF Analysis

This presentation will discuss the results of processing eight high-resolution Accelerator Mass Spectrometry (AMS) radiocarbon determinations on charcoal found in association with poorly dated ceramics and copper-alloy artifacts recovered from an important pre-Inca site, Waywaka, in the south-central highlands of Andahuaylas, Apurimac, Peru. Excavations at Waywaka revealed a naturally stratified series of deposits of Pre-Inca cultures spanning nearly four millennia. In the bottom-most layers was evidence of early pottery making and gold working in the Andes which included an actual gold worker’s tool kit. Higher in the stratified sequence the excavation yielded a subsequent culture, the Qasawirka style, which produced a range of small (2–5 cm) copper-alloy artifacts. It is the antiquity of this early copper-alloy technology that is in question. It is the proposition of this AMS testing strategy that the Qasawirka style copper-alloy artifacts from the site of Waywaka could conceivably date to a significantly earlier period in Andean prehistory, possibly EI—Early Intermediate Period. The presentation will also discuss these Qasawirka copper-alloy artifacts in terms of their constituent, non-copper, trace-elements using new portable XRF (X-ray fluorescence) scanning equipment at the Lamont-Doherty Earth Observatory (LDEO)/NASA laboratory of Columbia University.

Animals and Urbanization in Northern Mesopotamia: Late Chalcolithic Faunal Remains from Hamoukar, Syria

This paper presents the results of a five year zooarchaeological study at the site of Hamoukar, a major Late Chalcolithic (fourth millennium BC) site in northeastern Syria. The Late Chalcolithic occupation at Hamoukar presents an excellent opportunity to study the social impact of foodways at an early urban site in northern Mesopotamia. When the site was destroyed by fire during the late fourth millennium BC, the occupants fled, leaving their goods and garbage behind in a well-preserved building complex. Excavations within these Late Chalcolithic buildings recovered intact floor assemblages that included many kinds of evidence for food management and consumption, including animal bones, ceramic vessels, and administrative devices for the control of access to stored goods. Excavations in exterior spaces also produced interesting data regarding food preparation and disposal, including numerous ovens and a dumping ground for animal carcasses. In this paper, faunal remains will be integrated with other classes of evidence to produce a multidimensional analysis of foodways and their role in social and political life at the site.

UAV-Based 3D Modeling of Excavations in Mayapán’s Periphery

During our 2015 and 2016 field seasons, we mapped and created 3D models of numerous excavation sites in the region surrounding Mayapán in the Northern Yucatán. Complete horizontal excavations of several rural house groups were conducted. We used unmanned aerial vehicles (UAVs/drones) to carry photographic equipment to collect both vertical and oblique photos as well as videos. The resulting images were processed in photogrammetric software to generate orthorectified airphoto mosaics and 3D models of each fieldwork location. These products were integrated into a Geographical Information System (GIS) to evaluate their accuracy and precision, and ultimately to facilitate analysis. In this poster, we outline the technology and data processing workflow used, display resulting 3D models, and report results of tests of product quality. The horizontally excavated sites include small groups of residential architecture in rural areas in Mayapán’s periphery. The sites vary in size and types of architecture as well as status of preservation of features.

Grund, Brigid (University of Wyoming) [186] Radiocarbon Dating of Technological Transitions: From Atlatl to Bow in Northwestern Subarctic Canada
Prehistoric archaeologists traditionally focus on periods of stability rather than change when constructing regional cultural chronologies, even though explaining periods of change is equally if not more important than explaining periods of stability. The advent of large radiocarbon date databases and the proliferation of open-source computing programs such as program R have recently provided archaeologists with the tools necessary to begin understanding prehistoric transitions with high chronological precision. In this study, I employ Markov-Chain Monte Carlo procedures, Bayesian statistical theory, Program R, R’s Bchron package, and IntCal13 to calculate the optimal number of dates required on atlatl and bow technology to adequately date this transition. Further analysis compares a subset of previously published radiocarbon dates on diagnostic atlatl and bow technologies collected from ice patches in the northwestern Canadian subarctic to thousands of runs of computer generated models in order to determine whether bow and atlatl technology overlapped for a significant amount of time in prehistory, and for how many years of actual calendric time they overlapped. Analyses such as this one open the door to explaining why and how technological transitions occurred within and between prehistoric groups.

Guanghui, Dong (Lanzhou University) and Fahu Chen (Lanzhou University) [26] Trans-Continental Cultural Exchange in Hexi Corridor, Northwest China during Bronze Age
The Hexi Corridor of Northwest China was an important area for cultural exchange between west and east parts of the Eurasia during both historical and prehistoric times. Here we present new dataset of archaeobotanic, zooarchaeological and bone isotopic analysis, and radiocarbon dating from late Neolithic and Bronze sites in Hexi Corridor, and discuss the history of trans-continental cultural exchange in Hexi Corridor before Han Dynasty (202 BC–AD 220). Our results revealed the chronology of Neolithic and Bronze Age cultures, the accurate timing of the introduction of millet crops domestication in north China, and wheat and barley domesticated in west Asia, the transition of subsistence strategies, the impact of climate change on culture evolution, and human metal-smelting activities during Bronze period in Hexi Corridor. These works provide valuable insights to understand the pattern of prehistoric culture exchange across Eurasia in key region of the ancient Silk Road, and its impact on cultural development during that period.

Guarino, Michael (University of Kansas) [344] Weaponry Standardization and the Potential for Sharing at the Agate Basin Site
This study explores the potential for sharing of weaponry elements during communal hunts, and the implications of sharing pertaining to the overall technological organization of Agate Basin hunting groups. K-means cluster analysis was utilized to determine whether hafted-area morphologies on Agate Basin points were standardized and displayed properties consistent with expectations we might have if sharing of weaponry elements incorporated into the preparation for a communal hunt. I argue two standardized haft-area sizes are present in the complete Agate Basin point assemblage, and weaponry sharing could have been a reliable organizational technique employed by Paleoindian hunters during seasonal aggregation, serving to secure critical resources during a time when failure during a hunt would prove catastrophic.

Guderjan, Thomas Harold (University of Texas at Tyler), Sara Eshleman (University of Texas at Austin), Justin Telepak (Maya Research Program), Samantha Krause (University of Texas at Austin) and Timothy Beach (University of Texas at Austin) [243] Que Linda Vista! The First Glance at Lidar from Northwestern Belize
In this paper, we offer a first look at the results of a lidar survey of northwestern Belize performed by the National Center for Aerial Laser Mapping in July, 2016. Three survey blocks were defined—one centered on the site of Xnoha near the Mexican border and another along the Rio Hondo corridor from near its headwaters to Chetumal Bay. The third and largest, covers the sites of La Milpa and Blue Creek as well as numerous ditched agricultural areas. At the time of submission, only the first was available to us and will be the focus of this discussion. In this 40 sq. mile area, we clarified the relationships among known sites such as Xnoha, Grey Fox and Nojol Nah. We also discovered two new plaza-pyramid complexes and enigmatic linear and rectangular features which may relate to land tenure in the Classic period.

[176] "We lived there for the food": Archaeologies of Dal̓k Gyilakyaw, Home of the Gitsm'geelm (Kitsumkalum) Tsimshian

The Gitsm'geelm are a gal̓ts'ap (community) of the Tsimshian Nation. Today, Kitsumkalum is located at the confluence of the Kalum and Skeena Rivers. There are a number of documented archaeology sites in the core territorial lands, down the Skeena River to the coast where Gitsm'geelm people hold various types of resource use sites. Dal̓k Gyilakyaw (Robin Town), a large terraced village site replete with evidence of maintained gardens, orchards and distinct archaeological features, is located at the canyon on the Kalum River. A variety of external influences led to the eventual abandonment of Dal̓k Gyilakyaw in the 1870s. Population loss and the introduction of a Western market economy, exacerbated by a devastating fire, led most of the community to move down the Skeena River to (primarily) Port Essington to engage in the fishing industry. Although a rich ethnographic history of the social and cultural importance of Dal̓k Gyilakyaw to the Gitsm'geelm remains, little knowledge has been produced by the archaeology conducted since the 1940s. This paper reviews the range and scope of the more “classic” archaeological work conducted at this site from the mid-twentieth century, and will discuss the present “noninvasive” archaeology overseen by the community today.

[391] Hand-Modeled Preclassic Figurines and Early Expression of Concepts of Replication

This paper concentrates on the vast corpus of hand modeled ceramic figurines from Preclassic Pacific slope of Mesoamerica, in particular those from Middle Preclassic La Blanca, Guatemala. We argue that, within this collection of figurines and related ones from elsewhere in Middle Preclassic Mesoamerica, one can find evidence for the concept of replication—or an emphasis on a recurring “type” or “character”—that predates the invention of the mold. Although Preclassic figurine assemblages are invariably marked by any number of unique examples that attest to the creative potential of these miniature objects, they are also characterized by recurring human characters whose “sameness” warrants consideration, especially with regard to questions of personhood, social identities, social norms, and concepts of destiny. While these Preclassic examples are not identical, nor produced en masse through a technology of replication, we argue that they do shed insight into the potential conceptual precursors for later technologies, especially those engaged in (re)production of the human form.

[394] Empowering Tribal Youth in Cultural Heritage Management

We examine a multiyear cultural heritage training program developed by Elders, youth and archaeologists in the Kenai Peninsula of Alaska. The program aims to embed cultural protocols and knowledge into methods of cultural heritage management (CHM). The program demonstrates the benefits of collaborative approaches that provide the foundation for more effective CHM, while at the same time providing direct social outcomes. We examine how this was established via a case study of one of the projects. The conclusion provides a brief assessment of how this model assists with the education of anthropologists and archaeologists toward a more culturally-embedded practice, and how the model is now being applied to a Cultural Resource Management (commercial) framework.

Guindon, Amelie (Université de Montréal)

[178] Bonding Pots: Ceramics from the Midi Toulousain (Southwest France) and their Transatlantic Journeys to New France (Seventeenth–Eighteenth Centuries)

The Midi Toulousain area shows a distinctive organization of its rural ceramic crafts during the early modern period. Three production centers made pottery, imitating each other’s decorative styles and techniques. Distribution patterns are keys to understanding the social and economic factors that underlie regional competition in production and marketing. We believe that Midi Toulousain pottery production fits into the much larger socioeconomic sphere of the French Atlantic. This pottery was especially distributed downstream of the Garonne River toward the oceanic port of Bordeaux. Community of merchants as several New France Intendants who originated in the Garonne hinterland probably controlled ceramic exports across the Atlantic. Their networks may explain the transatlantic pottery trade from this region. Thereby, Midi Toulousain pottery in the colonial trade may be explained by the social nature of this trade. Through archaeometry aimed at determining provenance (ICP-MS/OES) we have examined ceramic diffusion paths along the Garonne River and toward New France in the seventeenth and eighteenth centuries. Our goal is to perceive social or familial trade networks within the supplying of French colonies using the example of Midi Toulousain pottery from Canadian sites. We will present results for the Fortress of Louisbourg and Place-Royale (Québec).

[284] Isotopic Analyses of Predatory Pelagic Fishes Show Significant Environmental Change in Lake Ontario Following European Settlement

Isotopic analyses of archaeological faunal remains can add significant temporal depth to modern and historical baseline data, which play an important role in understanding present and future environmental change. In this paper, we use stable nitrogen isotope analyses of archaeological (AD 1000–1900) bone collagen of pelagic predators, such as lake trout (Salvelinus namaycush) and whitefishes (Coregonus sp.), as a proxy measure for environmental changes in Lake Ontario over time. Results show a significant enrichment in heavy 15N in the freshwater nitrogen cycle of Lake Ontario during the nineteenth century, likely linked to human-induced changes in the lake’s nutrient and trophic structures. These findings provide a new baseline for modern ecological restoration work and give fresh insights into the broader environmental context for the impact of European settlement on the Great Lakes region.

Guiterman, Christopher (Tree-Ring Lab, University of Arizona)

[130] The Origins of Chaco Timbers by Tree-Ring Based Sourcing

The regional integration of Chaco Society includes the procurement of goods and materials from distant landscapes. Wood incorporated as roof beams, door and window lintels, and other building elements is no exception. Hundreds of thousands of trees were felled and hand-carried from mountain
ranges over 50 km from Chaco Canyon. Using tree-ring width patterns of beams compared to tree-ring chronologies from potential harvesting areas, we have begun to reconstruct the dynamics of timber procurement for the great houses. Our results corroborate previous efforts to source Chacoan beams by strontium isotope comparisons. Now, with hundreds of sourced beams, we show that prior to AD 1020, nearly all beams came from south of Chaco Canyon in the Zuni and San Mateo Mountains. At the onset of major great house construction in the eleventh century, timber began to arrive from the Chuska Mountains. By AD 1060, the Chuskas had eclipsed the southern areas in total wood importation. This shift coincides with a major influx of Chuskan pottery and Narbona Pass Chert, each unique to the Chuskas. Our results thus far demonstrate that the eleventh century florescence of Chaco culture was directly tied to, and supported by, outlier communities in the Chuska Mountains.

Land Rituals for Heaven: The Soft Cultural Power of an Early Nomadic Kingdom and the Begin of Silk Road

Early nomadic kingdoms appeared during the early period of the first millennium BC. Those objects or art theme symbolized the ideology of the ruling class embodied on the prestige goods, the imperial kinsmen’s cemetery, the large seasonal ritual center. The formation and expansion of the Aldy bel/Sandaohaizi culture reflected this process. Standing gold deer, curled up or standing snow leopard, the implements of the boar or patterns, and the conical gold earrings, widely spread with along the expansion. Kurgans of Arzhan Valley in Tuva in Russia is the imperial kinsmen’s cemetery and the land of Sandaohaizi is the ritual center in summer. Those early nomads were likely to be Arimaspians in west historical text and Single Eye People in Chinese text. They were the key people to open the Silk Road in the Eurasian Steppes.

Fishers and Farmers in Northern Kerala: Preliminary Results from the Northern Kerala Archaeological Project (NorKAP)

Conventional narratives of Indian history tend to focus on agricultural communities and have typically underestimated the role of fishing and fishers. With over 7,500 km of coastline along present day India, there is great potential for examining how fishing traditions changed and continued through time, and how they might have facilitated social complexification typically associated with agricultural communities. This paper will present preliminary survey results from the Northern Kerala Archaeological Project (NorKAP). Located between the Arabian Sea and the Western Ghats mountain range, the Bharathapuzha River Valley is characterized by slightly rolling uplands and plateaus that descend sometimes dramatically to the coastal plains. NorKAP’s field survey begins to shed light on the changing relationship between coastal communities and those in the upland.

Keepers of Tradition, Harbingers of Change: Tracing Communities of Practice through Archaeological Ceramics

Traditions are transmitted through teaching and learning. The manner in which knowledge relating to craft production gets transmitted can help us in understanding the causes behind cultural continuity and change. In this paper, I use an anthropological approach to discern teaching and learning patterns. I investigate the role of potters in modern-day pottery workshops of Egypt and India in the transmission of knowledge relating to pottery production. Employing video footage using a video annotation research tool, I discern subtle gestures and postures of potters engaged in the process of pottery production and statistically examine these to reveal patterns specific to each workshop. I transpose the method and understanding gained from the study of modern potters to the archaeological context in Karanis, Egypt. Teaching and learning of pottery making leaves recognizable markers on the vessel that can be traced metrically. My research suggests that one can trace ancient communities of practice, knowledge transfer and interpret continuity or change in material culture as part of an ongoing learning tradition.

A Wake of Change: Investigating Biocultural Interaction during the Early Colonial Period in the Central Andes, Peru

Burial practice in the Central Andes was transmitted continuously from the Middle Horizon (AD 700–1000) onward, if not earlier in some areas, reflecting an agreed-upon understanding of Andean social identity throughout time. However, when the Spanish colonized the Andes, they drastically altered this continuity, forcing indigenous populations to bury their dead under the Church in idealized Catholic tradition. This sudden change in burial practice ruptured Andean identity as indigenous populations conformed, resisted or attempted to both maintain Andean identity while still act as good Catholics under Spanish control. At Igiesiachayqo (Ayacucho), an Inka settlement in the Chicha-Soras Valley of Peru, Andeans resisted this rupture of social identity through a subversive revitalization of traditional Andean landscape deities: a movement known as Taki Onqoy, (Quechua: Dancing Sickness). Using church burials excavated at Igiesiachayqo, we use mortuary and isotope analysis to address the question of changing social identities and the relationship between indigenous and imperial actors at the moment of contact. We find that participation in Taki Onqoy was likely fragmentary, and that church burials reflect both patterns of indigenous and Spanish cultural and religious tradition, indicating the negotiated and improvised nature of interaction and identity in the Early Colonial Period.

Of Mummies and Guinea Pigs: An Analysis of Burial Contexts at Chiribaya Alta

[231]
In the Pre-Incan site of Chiribaya Alta, animals were often included in the graves of the deceased. Cuy, or Guinea pig, are among the most common type of animal found in these contexts, signaling the significance of these animals for the Chiribaya peoples in life and in death. Among traditional peoples in the Andes documented ethnohistorically and ethnographically, guinea pigs are consumed as food and are also used for divination and other religious practices. At Chiribaya Alta, a site in southern Peru near the city of Ilo, cuy have frequently been recovered from graves. This project explores the relationship between cuy and the Chiribaya beyond diet, as the frequent inclusion of cuy in graves at Chiribaya Alta suggest these animals possessed significant spiritual importance for Chiribaya peoples. Here, we use statistical analyses of burial goods to explore the significance of cuy to the Chiribaya people. These data allow us to infer the meaning of animal sacrifices to the Chiribaya and related views about death and identity. Thus, we use cuy to infer aspects of Chiribaya belief systems.

Above and Below the Waves: Advances in the Search for a Late Pleistocene Colonization of California’s Islands

Methodological advances are reshaping our understanding of island colonization. Refinements in dating methods, paleoenvironmental reconstructions, and search techniques have resulted in discoveries that challenge outdated theories of islands as marginal to human migration, settlement, and subsistence. This is particularly true for research related to the initial peopling of the New World via a Pacific Coast route. Once considered irrelevant to the story of New World colonization, California’s Northern Channel Islands have become a focal point in the search for evidence of Late Pleistocene migrations to North America. Integral to this search is identification of Pleistocene landforms that may harbor cultural material. Our search efforts have focused on the terrestrial and submerged portions of the island landscape that were intact and subaerial during the Late Pleistocene. By integrating paleoenvironmental reconstructions, archaeology, historical ecology, and terrestrial and marine geology, researchers are advancing methods that aid in understanding early island colonization and the search for the first Americans.

Gust, John [280]

Comparing Labor Regimes: Debt Peons in the Northeastern Yucatán versus Free Laborers in British Honduras

In this paper I compare the working conditions and cultural material found at a cluster of three sites in the northeast corner of the Mexican Yucatán Peninsula, to those at San Pedro Siris in the Cayo District of then British Honduras. The people in both areas contended with more militant Maya groups that were unhappy with improved relations with Mexican and British Honduran authorities respectively. Similar workplace dangers confronted both the lumber workers at San Pedro Siris and the sugar/rum workers in northeastern Yucatán. What was not shared by the two areas was how labor was organized. At the sites in the northeastern Yucatán, sugar/rum workers often had little to no land of their own, and it was common elsewhere in the Mexican Yucatán for laborers to accept becoming debt peons to gain access to farmland. The San Pedro Maya, including the inhabitants of San Pedro Siris, lived in free villages. They held, and jealously guarded, their own lands against interests of British logging companies. Thus, the sites in these two areas, the northeastern Yucatán and western British Honduras, provide a great opportunity for exploring similar groups of people with different levels of freedom to do as they chose.

Least Cost Analysis of Maritime Movement in Prince Rupert Harbour during the Holocene and Late Pleistocene

Spatial modeling of prehistoric maritime movement on the Pacific Northwest Coast is important in contemporary archaeology because it can help reveal previously unseen patterns and trends in movement through a landscape that has radically changed over time. GIS analysis has the potential to reveal new sites that have been hidden by changing sea levels. Here we present models of maritime movement using least cost path analysis (LCA) to determine the area’s most likely to have been traveled through by the Tsimshian of Prince Rupert Harbour over the last 15,000 cal. yr BP. Using targeted origin points, high resolution lidar and bathymetry, new cost movement metrics, and more accurate sea level curves possible migration routes were derived for the Harbour. For time periods that lie within Prince Rupert Harbour’s archaeological record calculated routes were systematically compared against known site locations to determine their predictive accuracy. Additionally, we provide estimations of where undiscovered sites from latter periods may exist within this environment. This work refines the application of LCA to seascapes and increases our ability to predict the location of submerged sites on the Northwest Coast, which is an important step in furthering our understanding of this area’s human history.

Gutiérrez, Gerardo (University of Colorado at Boulder, Department of Anthropology) [306]

Who Are the Olmec in Eastern Guerrero? From Graffiti to Monuments in the Caves of Guerrero

The caves of Cauadzidziqui and Techan offer contrasting views of how Olmec style appears in eastern Guerrero. Cauadzidziqui presents large-scale paintings of individuals with Olmec style symbols and objects plastered over what is believed to be local late Archaic paintings—essentially graffiti placed in a sacred locale along a primary route between the highlands and coast. The Cave of the Governors presents three or possibly four jaguar sculptures carved out of living rock, flanking the interior opening to the cave. The cave opening offers a view of the rising sun on the summer solstice highlighting the cave’s importance as conduit to the underworld and water mountain. Surrounding the cave opening were smaller niches recalling the cerro of Chalcatzingo and the origin of Chicomoztoc. This paper explores the significance of the iconography of these caves in eastern Guerrero and its relationship to broader Formative period iconography in Mesoamerica.

Spatial Signatures of Ceremony and Social Interaction: GIS Exploratory Analysis and Spatial Modeling at Tule Creek Village (CA-SNI-25), San Nicolas Island, California

The spatial patterning of artifacts and features excavated from the Tule Creek site (CA-SNI-25), San Nicolas Island, provides an opportunity to analyze the intrasite correlations between artifact types, materials, and features. Excavations at East Locus at CA-SNI-25 have yielded evidence of trade with other islands as well as evidence suggesting complex ceremonial activity, such as dog and bird burials, large hearths, stacked stone features, and multiple discrete pits. Here we use GIS exploratory analysis to examine the intrasite spatial distributions of artifact types and materials in context with ceremonial features. The clustering of artifact and material types are evaluated using spatial autocorrelation and hot-spot analysis. Our analysis includes circular and j-shaped shell fishhooks, sandstone saw abraders, local and extra-local lithic debitage, red ochre, quartz and calcite crystals, and chipped and ground stone tools of exotic stone. We utilize GIS exploratory methods to isolate distributions of formal artifacts and features, and to examine the organization of space in both ceremonial and utilitarian contexts. Ultimately, spatial analysis using intrasite GIS reveals possible linkages of artifacts, as well as patterns of spatial and temporal variability in technology, subsistence, and behavior at a village on San Nicolas just prior to European contact.

Guzman, Benito (NAU) Northern Arizona University

Mapping Prehistoric Behavior Patterns at Lithic Toolstone Source in the Colorado Desert

This pilot study examines lithic artifact scatters recorded in the Colorado Desert of California. The dataset used in this research was compiled from several Cultural Resource Management (CRM) projects that have taken place in the study area. Tierra Environmental Services of San Diego collected large portions of data located on cobblestone terraces in Imperial County, California between 2011 and 2013 (smaller sections have been recorded by various environmental consulting firms since the mid-1930s). Research goals include: understanding prehistoric settlement, mobility, and subsistence practices on the cobblestone terraces that rest a short distance from the Western margin of prehistoric Lake Cahuilla. The study will develop inferences regarding behavior through the geospatial mapping of lithic reduction locations. In addition, least cost path analysis is applied (through Geographic Information Systems) to examine the most efficient travel paths within the environment. Optimal foraging theory supports the use of analysis of least cost travel paths in the distributions of lithic reduction, as such events are predicted when examining small-scale societies and their focus on procurement of the least costly lithic resources. Cost, in this study, is determined and assessed based on energy expenditure and potential routes to quarry sites.

From Beads to Biographies: A Microwear Study of Late Precolonial Ornaments from the Dominican Republic

Body adornments are found throughout the Greater Antilles and have been generally regarded as items belonging to high-status individuals. Many studies have focused on their iconographic designs, meaning, and exchange among so-called Taíno societies (AD 1200–1500). However, much of the biography of stone and shell ornaments is poorly known, as raw materials, technologies of production, systems of attachment, and modes of deposition have not received comparable attention. This is partially because only recently such artifacts have been recovered from secure archaeological contexts. The present paper focuses on the biography of ornaments, as part of a larger research project that aims to generate a more dynamic and plural picture of the societies that occupied the Dominican Republic during the colonial encounter. Emphasis is given to the site of El Flaco in the northwestern region where almost 200 ornaments were found. Each ornament is studied through microwear analysis in order to reconstruct its production sequence and use life. Raw material availability and properties, as well as contexts of deposition are also taken into account. The systematic study of ornaments from recently excavated sites will generate for the first time an understanding of how these objects operated within and also between different settlements.

From Beads to Biographies: A Microwear Study of Late Precolonial Ornaments from the Dominican Republic

Archaeological material, for example engraved ochre and bone, shell beads, bone tools, and bifacial points recovered from the Middle Stone Age levels (c. 101–70 ka BP) at Blombos Cave (BBC), South Africa, is central to our current understanding of the technological and cultural development of early modern humans in southern Africa during the Late Pleistocene. While these artifacts have attracted much attention for their behavioral implications, the sedimentary context in which they were recovered has not yet been studied in detail. Here we present the results of a micro-contextual approach to the BBC cave deposits, including a geoarchaeological study of the complete sedimentary sequence of the site. We have applied and combined a range of methods during both field work (photogrammetry and micromorphological sampling) and laboratory analysis (FTIR, micro-FTIR, micro-GIS, and optical petrology). Our geoarchaeological investigation of BBC enables us for the first time to identify and interpret the major site formation processes responsible for the accumulation of anthropogenic and geogenic deposit within this important cave site. It also enables us to investigate human aspects of the BBC context that hitherto have been overlooked, such as overall site structure, intrasite spatial variability, prehistoric pyrogenic activity, and site modification and maintenance.

Integrating Site Formation Processes, Spatial Analysis, and Local Statistics to Assess Archaeological Site Structure: A Case Study from a Multicomponent Site in the Western Great Lakes

This paper presents a method to delineate discrete temporal occupations at open-air multicomponent sites by integrating site formation processes, spatial analysis, and local statistics. Open-air multicomponent sites, formed on stable surfaces but lacking strong vertical integrity, pose many challenges for the delineation and interpretation of temporally discrete occupations. Such sites often lack vertical stratigraphy, so defining the horizontal spatial structure of components represents a critical first step in analysis and a prerequisite for further interpretation. The case study reviewed here focuses on the Finch site (47JE902) in southeastern Wisconsin. Finch harbors prehistoric occupations that span circa 8300 BC to AD 1400. Recent excavations generated over 200,000 artifacts and a high density of in situ cultural features including living floors, hearths, and cooking, processing, and refuse pits. Site formation processes are used to determine temporally sensitive factors such as the origination depth of cultural features. A GIS-aided analysis using descriptive statistics and kernel density maps are used to explore the patterning of diagnostic material culture and guide the selection of weighting measures for the local statistics. Local statistics are then used to delineate areas within the site that are the focus of activities associated with each cultural-temporal component.

The Signalling and Inheritance of Cooperation: Artificial Cranial Modification among Altiplano Foragers

This paper presents a method to delineate discrete temporal occupations at open-air multicomponent sites by integrating site formation processes, spatial analysis, and local statistics. Open-air multicomponent sites, formed on stable surfaces but lacking strong vertical integrity, pose many challenges for the delineation and interpretation of temporally discrete occupations. Such sites often lack vertical stratigraphy, so defining the horizontal spatial structure of components represents a critical first step in analysis and a prerequisite for further interpretation. The case study reviewed here focuses on the Finch site (47JE902) in southeastern Wisconsin. Finch harbors prehistoric occupations that span circa 8300 BC to AD 1400. Recent excavations generated over 200,000 artifacts and a high density of in situ cultural features including living floors, hearths, and cooking, processing, and refuse pits. Site formation processes are used to determine temporally sensitive factors such as the origination depth of cultural features. A GIS-aided analysis using descriptive statistics and kernel density maps are used to explore the patterning of diagnostic material culture and guide the selection of weighting measures for the local statistics. Local statistics are then used to delineate areas within the site that are the focus of activities associated with each cultural-temporal component.
We report on the recent archaeological discovery of a 7,000-year-old population of hunter-gatherer burials and discuss the key insights they offer into how hunter-gatherer societies may have maintained cooperative structure against evolutionary odds. Sixteen human burials interred at the site of Soro Mik’aya Patjxa in the Andean Altiplano of Peru consistently exhibit intentional artificial cranial modification (ACM)—the irreversible shaping of human crania during infancy. Our analysis of cranial form, burial context, and skeletal properties indicates that the ACM existed among a relatively egalitarian hunter-gatherer population and cannot be linked to hierarchical social structure. These observations in conjunction with fundamental properties of ACM—its unfakability, visibility, and vertical inheritance—suggest that ACM served as an honest visual index of an individual’s enculturation including their understanding of moral codes that mitigated the inherent risks of non-kin cooperation. Groups that engaged in ACM would have enjoyed competitive advantages over those that did not, and offspring who received ACM from their parents would have inherited those group advantages. The entailed mechanism of kin and non-kin cooperation helps resolve the question of how a seemingly trivial form of human body modification persisted for more than seven millennia and radiated throughout South America.

Ancient Crops, Modern Possibilities: A Study on the Potential for Millet Agriculture in the United States

Millets are among the world’s oldest crops. Unique characteristics such as their adaptation to high temperatures, drought conditions, marginal environments and low-input farming systems, make millets promising rotational in diverse agro-environments across the United States. Millets could play a vital role in the diversification of cropping systems and provides a regionally available source of highly nutritious cereal grain. Despite being a very early domesticated cereal crop, and a major food source in East Asia, South Asia, and Africa, millets now play a relatively minor role in most human diets and agricultural systems. In order to fully examine their potential role as alternative crops in the United States, new and expanded research is needed in the fields of millet agronomy, breeding, nutrition, and food science. This paper presents the archaeological background of millet domestication and spread as well as lessons learned from field and greenhouse trials. Crop niche models evaluate how millets could be adaptive in the arid regions across the United States.

Magnetic Susceptibility of Soils: Tephra, Erosion, and Fire on Columbia Plateau Landscapes

Sedimentation and soil formation on uplands of the Columbia Plateau are strongly influenced by climate, tephras, erosion of arid lands, and fire regimes. Magnetic susceptibility of in situ strata, and laboratory samples from arroyo profiles of the Yakima Upland Fold Belt can help untangle the interactions of these processes in shaping natural and cultural landscapes. Records from four profiles of overlapping age (500–9000 BP) are compared. Data for mass specific magnetic susceptibility are cross-evaluated between these four sites. The graphed results are compared for profiles with and without artifact bearing cultural strata. Several working hypotheses are outlined. High magnetism in these profiles appears to correspond with Mazama tephra and erosion during the arid post glacial maximum (8000–4000 BP). However, magnetism also peaks in buried A horizons during moist intervals (4000–3000 BP). Some of these signatures can be attributed to the presence of Mount St. Helens tephra, and/or burn layers as a result of natural and cultural fire episodes related to Native American management of sage-grass steppe communities.

Plant Analysis of an Eighteenth-Century Slave Quarter: Incorporating Macrobotanical and Pollen Analysis at Monticello to Improve our Understanding of Enslaved African-American Lifeways

This research emphasizes the value of studying plant remains recovered from archaeological contexts while contributing to our understanding of the lifeways of enslaved African-Americans from late eighteenth-century Virginia. The primary objective of this research is to identify plants selected by enslaved field laborers living on the Home Farm Quarter of Thomas Jefferson’s Monticello plantation. This study incorporates both macrobotanical and pollen analysis and presents a wide variety of useful plant species uncovered from the subfloor pits found at Site 8, one of the housing quarters for enslaved field laborers. These results expand our understanding of the methods employed by the occupants of Site 8 to improve their conditions. Additionally, this research addresses how Monticello’s agricultural shift from tobacco to wheat production altered subsistence strategies of enslaved field laborers over time. The botanical data reveal that the enslaved occupants of Site 8 actively improved their circumstances by producing domesticated plants in nearby gardens and procuring wild plant species by traveling across the Monticello landscape.

(Re)new(ed) Perspectives on Mortuary Practices at Neolithic Çatalhöyük

At Çatalhöyük, as elsewhere in the Neolithic Near East, there is an emphasis on the manipulation and redistribution of human body parts, with particular attention paid to the skull. Evidence for this practice occurs with the observation of 'headless' primary burials and the secondary re-deposition of disarticulated crania and mandibles within primary and secondary burial contexts. The manner in which these practices were carried out and the motivations for such behavior have been the subject of much debate since the site was first excavated in the 1960s. In recent years, our understanding of the mortuary customs practiced by the Neolithic inhabitants of Çatalhöyük has changed considerably, largely as a result of new insights and new personnel, but also by revisiting previously discounted interpretations which had long been ignored. As the Çatalhöyük Research Project nears the end of its 25 year remit, I will discuss the most recent interpretations of the mortuary practices, while also providing a critical appraisal of the ways in which these interpretations have evolved over the years.

[139] The Afterlife of the Charnel Chapel at Rothwell (Northamptonshire, UK)

The practice of cremating human remains has recently been revealed to have been widespread in medieval England, with chapels specially built for this purpose. However, this practice ceased at the time of the early sixteenth-century Protestant Reformation, and the charnel chapels were emptied and in some cases demolished. A rare exception is at Rothwell (Northamptonshire, UK), which survived the Reformation intact, apparently because it was closed up at this time with the charnel in situ. The chapel was rediscovered in the early eighteenth century, by a—presumably shocked—grave digger, who fell into it! By this time, charnel chapels no longer had any formal liturgical function, but the site became a place of local fascination and folklore, recounted by antiquarians and reflected in graffiti scratched on to the walls of the chapel. New radiocarbon dating evidence, reveals that some human remains were added to the chapel in the eighteenth and nineteenth centuries, possibly medical specimens. This paper explores the post-medieval history of the Rothwell charnel chapel, and examines the interactions of the local community with the chapel and the human remains it contained, to throw new light on how a fundamentally medieval practice was appropriated in later periods.

[388] From Quelites to Crop Indices: Thinking Through Maya Chenopods

While chenopod cultivation has been documented extensively in North and South America, evidence for similar practices in the Maya area is lacking. Macrobotanical evidence of Chenopodium recovered from prehispanic Maya archaeological sites is limited to a few seeds. In contrast, the palynological record minimally suggests widespread tolerance across the entirety of the Maya area, if not intensive management or in some contexts even cultivation of Cheno-am genera. It is likely that chenopods were an integral part of the successional agroecology of fallowing and milpa agriculture. Typically, archaeologists consider such data as evidence of food production, but our work in documenting the ubiquity and uses of plant among ethnographic Maya populations strongly suggests that the primary use of chenopods among the Maya is as a source of medicine and greens.

[337] Investigations of Peri-Urban Settlement and Domestic Reservoirs: Research from Yaxnohcah, Campeche, Mexico

Peri-urban zones of settlement are unique localities among the urban-rural continuum that form due to dispersed urban growth, creating hybrid landscapes of fragmented urban and rural characteristics. Within these zones, domestic-scale reservoirs that the ancient Maya modified and maintained to manage their seasonally-scarce water resources are an important component. This study focuses on processes of multiple nuclei urban development and associated peri-urban formation at the site of Yaxnohcah in southern Campeche, Mexico, with particular emphasis on the collaborative research on residential and small water reservoirs situated between the Alba and Fidelia complex groups. Yaxnohcah is located in the middle of the Central Karstic Uplands, a region in the Yucatán Peninsula known for its large, early urban centers. The extended period of occupation at the site (c. 1000 BCE–850 CE) combined with a distinct, dispersed, multiple nuclei settlement pattern provide an excellent opportunity to investigate questions concerning early urban development and its dynamic connections to local environmental and integrative processes. Our research to-date (2011– ) adopts both higher and lower scale approaches—using lidar-derived imagery and investigating massive platforms, smaller urban house lots, and household tanks—to advance our awareness of early urban development in this area of the central Maya lowlands.

Haines, Helen (Trent University) and Kerry Sagebiel (Northern Illinois University)

Jade has been long recognized by archaeologists as an important trade item among ancient Mesoamerican cultures. This is particularly true for ancient Olmec and Maya cultures where it also is seen as an indicator of social status. Unfortunately, the precocious development of Olmec society, lead many early archaeologists to an over-emphasis of Olmec influence on the Maya during the Formative Period (ca. 1000–400 BC). This is particularly noteworthy in the attribution of jade “spoons” to the Olmec, despite the lack of archaeological evidence. This paper focuses on the discovery of a jade spoon excavated at Ka’akabish, an ancient Maya site in North-Central Belize. This is one of two spoons recovered from a secure archaeological context and as such it helps further our understanding of the use and history of these objects. Based on this discovery, coupled with the limited number of other spoons that can be linked to a known site, this paper argues that these pieces should not be unquestionably attributed to the Olmec.

[378] Native American Whaling and Porpoise Hunting Techniques along the East Coast of North America

Native Americans were the first people to exploit the cetacean fauna found in the coastal waters of the western North Atlantic. Most of these animals were drift whales found washed up along the shoreline, but there is historiographical evidence indicating that some Native Americans actively pursued whales, porpoises and dolphins from small craft offshore. In this paper I discuss various tools and techniques utilized by the indigenous inhabitants of North America to pursue, harvest and process whales in the Atlantic, examining early accounts from the coast of Florida north through the Carolinas to New England and the Canadian Maritimes. I also discuss the results of experiments made with my colleagues at the North Carolina Maritime Museum in Beaufort replicating the process of oil extraction from odontocete blubber as well as porpoise jaw oil.

[193] To Guard or Not to Guard? Variations in Territoriality within Hunter-Gatherer Societies

Variation in territory size, population density, and residential mobility among small scale hunting and gathering societies tends to co-vary with territorial behaviors. Specifically, groups living in larger areas, at lower population densities with higher mobility are less likely to exhibit territorial behavior than their counterparts in smaller areas. Based on models from behavioral ecology, we suggest that this variation is due to underlying levels of environmental productivity: where productivity is high, resources are abundant, allowing for dense populations that do not need to move as much, which creates smaller territories that can be defended. Here we compile and evaluate a global dataset of ethnographic and ethnohistoric hunter-gatherers linked to remotely sensed data on environmental productivity to test this hypothesis.

An Application of Geospatial Technology to the Collection and Analysis of Human Skeletal Remains

Documenting the spatial distribution of scattered and commingled skeletal elements is an important aspect of forensic anthropology and bioarchaeology. While existing methods of documentation may effectively represent scattered and commingled human skeletal remains, they do not facilitate further spatial analysis that may be useful in reconstructing taphonomic processes. Geographic Information Systems (GIS) have recently been leveraged as a method of inventoring human remains, but their capacity for detailed spatial analysis is underutilized. In the spring of 2016, graduate students from Texas Tech University explored GIS as a tool for the documentation and analysis of human skeletal remains. The remains of eight individuals—previously deposited at the Southeast Texas Applied Forensic Science facility within a 15 m² area over a four-year period—were mapped in situ with a Total Data Station. Geospatial analyses were then performed in ArcGIS to assess patterns in the spatial distribution of remains. This paper presents a comprehensive method for the efficient mapping of human remains using GIS and details potential uses of geospatial software in the reconstruction of taphonomic events. It further discusses the benefits and shortcomings of a geospatial method of documentation and analysis in forensic anthropology and bioarchaeology.

Diet and Adaptations in a High-Altitude Rockshelter of Southern Peru, Based on Stable Carbon and Nitrogen Isotopes

We present the results of stable carbon and nitrogen isotope analyses made on well-preserved collagen of four Early and one Middle Holocene adult humans together with coeval faunal remains of Cuncaicha rockshelter in the Peruvian puna to determine paleodiet. In addition, we reconstruct important aspects of the ecology of the Pucuncho Basin, in which Cuncaicha is located, using new as well as already available and secured values for stable carbon and nitrogen of archaeological and modern fauna and plants. This work addresses issues of aridity and altitude in paleodietary reconstructions and contributes to the development of ecological models for the interpretation of archaeological remains in the high altitude and arid Andes. Comparing archaeological and modern material offers higher resolution on chronological variation of the productivity of the basin. The results for paleoecology confirm the presence of a distinct local signal, and the results for human collagen indicate a consumption of protein from local animal and plant resources. As one of the oldest archaeological sites in South America, the apparent prolonged occupation of Cuncaicha has significance for early Paleoindian settlement strategies and resource exploitation as behavioral adaptations to puna ecosystems, and thus for the onset of adaptations to high altitude.

Halliday, Jennifer [258]  
Assessing Age Related Changes in the Strength of Relationship for Dental, Skeletal, and Chronological Age using Bivariate Correlations

This study examines the changes in the strength of relationship between dental and skeletal ages against chronological age in a sample of known sex and age skeletons using bivariate correlations and linear regression models. The sample is selected from the Electronic Encyclopedia on Maxillo-Facial, Dental, and Skeletal Development by Dr. Arto Demirjian, and consists of 483 observations from 78 individuals aged 6 to 19 years. The results indicate that while dental maturity has a stronger correlation with chronological age in younger individuals, as they get older this strength decreases and the relationship between skeletal maturity and chronological age gets stronger.

Halligan, Jessi (Florida State University) [226]  
Pre-Clovis Archaeology in the Frontiers of Research: Page-Ladson and the Importance of Submerged Sites to Understanding the First Americans

Dr. Gruhn has spent her career working in locations that most Paleoindian archaeologists consider to be inaccessible and difficult, maintaining that the story of the First Americans can best be found in well-preserved localities on the geographical and chronological frontiers. Our recent work at the Page-Ladson site in Florida fits well within the spirit of her investigations. Page-Ladson is an inundated terrestrial site with sediments containing lithic artifacts associated with a butchered mastodon radiocarbon dated to 14,450 years ago. Page-Ladson is more than a thousand years older than Clovis, and demonstrates that people were in the Southeast well before the opening of the ice-free corridor, providing indirect support for coastal colonization models. Further, this submerged cultural component is buried within a well-preserved Late Pleistocene-Early Holocene geological sequence spanning the period from 16,000–8,500 years ago that has provided proxy evidence for major climatic changes and the extinction of megafauna in the Southeast. Propane Illuminations: Molded Maya Figurines in Comparative Context
In many ways, simple molded Maya figurines during the Late Classic period become ordinary objects, aided in part by the technological capability of reproduction through molds. Nonetheless, molds do not automatically create ordinary, accessible, everyday objects, and, in turn, ordinary objects are not without their ability to delight and affect the senses. This paper draws on newly collected ceramic production evidence from the site of Ucanal, Guatemala, as well as a compilation of research on figurines from elsewhere in Petén, Guatemala, to explore the technological, spiritual, and sensual aspects of ceramic figurines. In comparing molded figurines from the Late/Terminal Classic period with figurines from the Preclassic and Postclassic periods, the paper explores how the value of mold technologies—and concepts of the ordinary—change over the longue durée.

Hamilton, Derek (Scottish Universities Environmental Research Centre) [81] The Dating Game: The Dialogue between Absolute and Relative Techniques in the British Iron Age

The traditional approach to the Iron Age (c. 800 cal BC–cal AD 43) has been to construct complex chronologies based on artifact typologies. Historically, radiocarbon dating was eschewed in this period, because it was thought to offer less precision than artifact dating. Such views are becoming increasingly untenable, and recent Iron Age research is showing that typological dating produces sequences that are regularly too late. This paper will draw upon British Iron Age research from across the last decade to explore how chronologies based in scientific-dating and developed within a Bayesian framework can allow us to explore events and investigate processes. Furthermore, it will argue that by maintaining an open dialogue with the ‘traditional’ dating techniques, it often is possible to come to a reconciliation and thus new forms of understanding.

Hamilton, Marian (University of New Mexico), Lee Drake (University of New Mexico), Wirt Wills (University of New Mexico) and Emily Lena Jones (University of New Mexico) [130] Stable Isotope Ratios from Modern and Archaeological Fauna from Chaco Canyon, New Mexico

Stable isotope analysis of archaeological material can reveal aspects of diet, mobility, resource exchange, and social structure in ancient civilizations. Chaco Canyon, New Mexico is a World Heritage site in northwestern New Mexico with peak activity and habitation around AD 1000. The nature of resource management by those inhabiting the Canyon has been long debated. Here, we present carbon, oxygen, nitrogen, and strontium isotope data from archaeological faunal remains collected from multiple time intervals throughout the habitation of Chaco Canyon. We also include a robust comparable dataset of modern fauna from the same region to provide context and quantify expected isotopic variation under known parameters. We use these isotopic systems to test hypotheses regarding long-distance animal resource procurement, small mammal domestication, and shifting ecological niches of nondomesticated fauna as human activity intensified. We also discuss limitations in the application of isotopic data to such questions and suggest methodologies to accurately quantify variation and uncertainty when using this type of data.

Hamilton, Marcus (University of Missouri) and Robert Walker (University of Missouri) [277] Population-Area Scaling in Contacted and Uncontacted Amazonian Indigenous Groups

Sublinear population-area scaling relations have been documented across a range of human societies, from hunter-gatherers to both ancient and modern cities. As such, these scaling patterns seem to capture a common statistical feature of human spatial ecology. In this talk we examine the spatial ecology of both recently-contacted and uncontacted groups in the Amazon Basin. Using a combination of census data, government estimates and imagery we find sublinear scaling between the size of villages and their populations in both contacted and uncontacted groups. We discuss these results and show how scaling-based research may be useful in assessing the demographic health of uncontacted populations and their future viability.

Hammer, Ben (PaleoWest Archaeology), James Potter (PaleoWest Archaeology), Terry Knight (Ute Mountain Ute Tribe) and Lynn Hartman (Ute Mountain Ute Tribe) [366] West Mancos Survey and Site Preservation Project, Southwest Colorado

The Ute Mountain Reservation in the Four Corners region of the American Southwest contains some of the most spectacular and numerous prehistoric archaeological sites containing standing architecture in the country. Combining research and preservation efforts at these sites is a priority of the Ute Mountain Ute Tribal Historic Preservation Office. The West Mancos Project focused on three sites along the Mancos River containing the remnants of circular towers. Preservation and research efforts consisted of site recording and mapping, infield pottery analysis to acquire dates of occupation, GIS analysis, and conducting photogrammetry both from pole-mounted cameras and unmanned aerial vehicles (UAVs). The results include a greater understanding of the chronology and function of these sites, 3D models of the standing architecture, and broader contextualization within an extensive cultural landscape.

Hammer, Emily (University of Chicago) and Dan Lawrence (Durham University) [118] Sites, Landscapes, and Survey Intensity in the South Caucasus: the Evolution of Landscape Archaeology Approaches in Armenia, Azerbaijan, and Georgia

In the last decade, the number of landscape archaeology projects in South Caucasus has dramatically increased. South Caucasia geographically and disciplinarily sits between two early centers of survey archaeology (Near East and Mediterranean), each with its own methodologies and primary approaches to archaeological data. The increased interest in landscape archaeology in the region has led to the publication of several books and numerous articles on numerous topics. As such, the focus of this paper is to discuss the evolution of landscape archaeology in South Caucasus and summarize the most important approaches.
questions. The mountainous landscapes of South Caucasia, the high degree of population mobility in many periods, and the extent of Soviet land
engineering challenge archaeologists to develop hybrid survey strategies, new definitions of “sites,” and new satellite imagery interpretation methods, as
well as to question conventional ways of interregional settlement data comparison. This paper illustrates several promising approaches carrying
landscape archaeology forward in the region.

How to Enact Reconciliation in British Columbia CRM

[17]

Righting the balance between Indigenous and non-Indigenous populations is the defining challenge of twenty-first century nationhood in Canada.
Archaeology, as a discipline and an industry, has specific responsibilities and opportunities in this reconciliation. Despite recent attention brought to the
social injustices of colonization, reconciliation is still scantily considered and spottily applied by heritage practitioners, governments and businesses. I
discuss how we can and must enact reconciliation in the heritage resource management industry in BC, and consider its actual and potential effects on
the practice of archaeology in general and CRM in particular. I set the challenges of decolonizing BC CRM in wider legal, political, and economic
discourses, including how archaeology interacts with case law big and small, treaty processes, UNDRIP, the work of the Truth and Reconciliation
Commission of Canada, and evolving government-to-government relationships. I propose a “republic of archaeology” as unifying philosophy through
which reconciliation can be pursued through specific kinds of engagements with the primary constituencies of CRM: Indigenous groups, professional
practitioners, regulatory bodies and the non-Indigenous public. I suggest concrete steps we can take as individuals and organizations to support
reconciliation, and evaluate some of the potential barriers to this shift in heritage practice.

[28]  Embodied Rock Art Motifs in Far West Texas and Northern South Africa

In this paper, I consider embodied rock art motifs in two rock art regions: far west Texas and northern South Africa. By employing the tools of
embodiment theory, certain motifs in both regions can usefully be seen as expressions of how indigenous ontologies were perceived, how things were,
and how identities were tied to physical beings and manifestations of physical beings. As with research on ritualistic ontologies and the process of
making rock art, embodiment theory can help us overcome the tendency in rock art studies to treat the original image-makers as reactive viewers of their
own handiwork. A key point is that, once created, pictographs and petroglyphs are symbolic manifestations and powerful things in themselves; they are
not mere ‘reflections’ of either natural or supernatural phenomena.

[286]  The Evolution of Cooperative Labor within a Long-Lived Housepit at the Bridge River site in British Columbia

At the Bridge River site, British Columbia, evidence for intra-household cooperation appears to center within a time of village growth during late Bridge
River 2 (ca. 1500–1300 cal. BP) before collapsing into familial-based competitive behavior during Bridge River 3 (ca. 1300–1100 cal. BP). This shift from
cooperation to competition occurs in tandem with a rise in inequality as the community experienced a Mathusian ceiling. Building on previous
multivariate statistical approaches, further analysis of the association of household-based cooperative labor and variation in activity areas is performed.
This analysis focuses on teasing out shifting patterns of cooperation over time along with subtle changes in gendered work that such patterns may belie.
Excavations at Housepit 54 have uncovered a series of 17 anthropogenic floors. By examining this household floor-sequence, we can interrogate the
underlying factors that function to reinforce or negate cooperative social interaction. Keeping in mind that such “micro-interactions” are also reflective of
individualized embodiments of socially understood distinctions (sex, age, kinship) a more thorough understanding of past social lives is revealed.
Through such analysis we provide more nuanced interpretations of cooperative labor patterns within the Mid-Fraser region and highlight the potential of
quantitative and qualitative methodologies in household archaeology.

[115]  Dental Microwear Analysis and Diets of Dacaozi Ancient Population in Qinghai, China

Dental microwear analysis (DMA) focuses on the microscopic scratches and pits that formed on a tooth’s surface as the result of chewing which is a
useful approach to reconstruct the diets of animal species and human ancestors. The aim of this study is to use this new method to reconstruct the diets
of the Dacaozi ancient population, whom lived in the ancient interactive region of agricultural and nomadic economy in Qinghai Province, northwest
China. Different microwear patterns of scratches on the buccal surface indicate different dietary composition. All samples from 17 individuals have been
observed at 200X magnification by utilizing the 3D deep field microscope. After scanning and measuring buccal surface microwear features, the ratio
between the average length of the horizontal scratches and the average length of the vertical scratches (LH/LV) can be calculated. Comparing with other
researches, Dacaozi population have a LH/LV ratio of 96.93%, which is similar to Veddas with a LH/LV ratio of 95.78%, who are originally hunter-
gatherers living in a tropical forest environment. The results obtained show that people of the Dacaozi cemetery ingested both plant products and animal products which is in accordance with the archaeological researches, historical records and lifestyle in Qinghai nowadays.

Han, Yu [116]  
**Analysis of the Faunal Remains at Shangjing City Site, Inner Mongolia (2013 Excavation)**

The Shangjing city site is located on the boundary between agricultural and herding subsistence economies in the Western Liao River Basin, eastern Inner Mongolia. The site was used as the Upper capital in the Liao Dynasty (AD 916–1125) and the Northern capital city in the Jin Dynasty (AD 1115–1234). In 2013, several burials in the Liao and Jin Periods were unearthed, and more than 36,000 faunal remains, including bones and teeth, were collected systematically. Although Liao and Jin are regarded as very important Iron Age dynasties in Northern China, there have only been a few zooarchaeological studies of the two periods; and their subsistence patterns are still unclear. This study explores the faunal remains excavated at Shangjing city in 2013 using morphological, isotopic and ancient DNA analyses to increase the zooarchaeological data in this area as well as to address the relationships between humans and animals in the Liao and Jin Dynasties.

Hankins, Sharon, Yarely Meza (University of Texas Rio Grande Valley) and Cristina Gonzales (University of Texas at Austin) [11]  
**Firing Strategies: Experimental Pottery Technology Programme for Belize**

This report is a continuation of the Experimental Pottery Research Program I began in Belize in 2000 (Hankins 2009:177–186). The scarcity of material evidence of pottery manufacture and firing signatures contributes to the relevance of different research strategies to expand our understanding of this technology. Firing pottery is challenging. The technology of constructing pottery is difficult, stressful, and requires constant attention. All the labor, skill, and planning can be lost in the final accumulation of effort. Mastering pyrotechnology and the knowledge of pottery manufacture can be extremely variable. All the additive processes of creating are subject to possible destruction in the fire. Experimenting with different methods of firing teaches us what different firing strategies can produce, and the signatures they deposit (or not) in the archaeological record. Kilns are somewhat more predictable. Bonfire firings, pit firings and other open firings challenge our quest for evidence. This poster will focus on our experiences with different types of bonfire firings we have undertaken in Belize. Every location has so many different environmental issues to consider. In Belize there are seasonal differences to consider, atmospheric conditions, temperature fluctuations (hourly), and of course, time and labor.

Hanks, Bryan (University of Pittsburgh, Department of Anthropology) [323]  
**Geophysical and Geochemical Spatial Approaches to Early Copper Metal Production among Bronze Age Communities in the Southern Urals, Russia**

The combination of social, economic, and political variables that led to greater levels of sedentism and demographic growth in human societies has long been a key topic within the study of world prehistory. Indeed, the comparative study of such dynamics has been at the very core of anthropological archaeology with numerous classic case studies stemming from fieldwork in the Americas, Africa, Europe, the Near East, and China. The Eurasian steppes, a vast region stretching half way around the world, has contributed much less to such comparative understandings of early human communities and the forces underpinning the emergence and development of greater levels of complexity in social organization and craft specialization. This paper examines such dynamics within the context of what has been perceived as an exceptionally rapid development in socioeconomic organization connected with the Middle Bronze Age of the Southern Ural Mountains region of Russia. Starting at around 2100 BCE, this region of the Eurasian steppes witnessed dynamic shifts in demography, settlement patterning, conflict, and metal production. This paper will examine recent studies utilizing multi-method geophysical surveys combined with HHpXRF and focused excavation to identify the spatial organization of copper working within and around Bronze Age settlements.

Hanks, Michele [212]  
**“That Box is Haunted!” English Paranormal Investigating and the Immateriality of the Past**

Since the late 1990s, paranormal investigating has emerged as a popular means of seeking knowledge of the ghostly or paranormal in England. Paranormal investigators are self-fashioned experts who aim to balance scientific and spiritual perspectives in hopes of proving or disproving the existence of ghosts from an objective perspective. They dedicate significant amounts of their leisure time to reading about, talking about, and researching ghosts or the paranormal. English paranormal investigators ground many of their research practices in engagements with the material remains of the past, including historical artifacts and architectural ruins. Some paranormal investigators believe that these physical objects can act as repositories of or triggers for spirits from the past. Drawing on my long term ethnographic research in the North of England, this paper examines paranormal researchers’ epistemological and practical engagement with these physical remains and shows how they produce narratives of the past. Here, I argue that juxtaposing the immateriality of spirits with the materiality of the physical remains of the past opens up an intellectual space in which paranormal investigators reimagine the past while challenging the expertise of orthodox researchers of the past, including historians and archaeologists.

Hanlon, Julie (University of Chicago) [167]  
**Carving a Space for Jainism: Jain Rock-Cut Caves in Early Historic to Medieval Tamil Nadu, South India**

The ancient temple city of Madurai, Tamil Nadu is flanked on the east and west by a series of granitic hill ranges and inselbergs. Upon many of these hills are caves containing rock-cut beds and inscriptions that record donations to Jain mendicants. Until recently, interest in these caves has been primarily epigraphical with exiguous analysis of their architectural features and use as Jain residences. In fact, the role of Jains in the history of Tamil Nadu, where they currently represent 0.1% of the population, has been notably marginalized. This paper draws on archaeological evidence and geospatial analysis to situate these cave sites within a broader archaeological context and examine their occupational history and use by Jain monastic communities, beginning c. third century BCE. I suggest that Jain mendicants chose particular hills and caves as the sites of their religious retreats due to their topographic features and close proximity to trade routes and economic and political centers. Moreover, the proximity and inter-visibility of these cave sites poses interesting questions about the organization of early Jain monasticism and the significance of these sites for itinerant merchants, who appear prominently in the donative inscriptions.

Multidisciplinary Analyses of a Paleoindian Bison Butchering Event in Eagle Cave

From its inception, a major objective of the Ancient Southwest Texas (ASWT) project has been to investigate the potential for Paleoindian-age deposits in Eagle Cave. Previously, the oldest dated deposit in the shelter was a zone of dense charcoal and decomposing fiber designated “Lens 14” and dated to about 8500 RCYBP by University of Texas investigations in the 1960s. These excavations terminated beneath Lens 14 at “Zone 6,” a stratum described as “sterile yellow cave dust.” During the 2016 ASWT field season, excavations through and beyond Zone 6 shortly exposed a discrete layer of scattered, fractured, cut, and burned bison bones. Decomposing plant remains, debitage, and chipped stone tools were interspersed among the bones, and an associated surface hearth contained charcoal, ash, and charred bone. Collectively these materials appear to represent an isolated bison processing event, possibly related to Paleoindian-age bison jump events at Bonfire Shelter, upstream in the same box canyon. We discuss this unique Paleoindian assemblage and interpretations gleaned from ongoing spatial, faunal, macrobotanical, and chipped stone analyses.

Hansel, Patricia (Temple University)

High-Resolution Imaging of Stone Tools from the First Millennium BC, Grand Cocle Region of Panama: A Digital Archive Initiative

Archaeological investigations often result in large quantities of stone and ceramic artifacts which, after being catalogued and analyzed, are stored in accessible places and rarely used for further research, student training or public education. Digital technology is changing this. It is revolutionizing the way we do research, archive our results and communicate with others. Based on a sample of time- or functionally-sensitive stone tools from the first millennium BC component at the archaeological site of La Mula-Sarigua in the Grand Cocle Region of Panama, this poster will describe the results of my initiative to (1) digitally photograph and/or scan each object to produce high resolution 3D images, and (2) place them in a publicly accessible web-based repository. The incorporation of high resolution 3D scanned artifacts in digital databases will allow users to manipulate, make observations and take measurements similar to handling the actual artifact. That such databases will be an important tool for analyses in the future is certain as it allows for extensive research independent of the physical objects and institution, the latter of which are often continents apart.

The Origins of Complex Maya Societies: The Middle Preclassic Period in the Mirador-Calakmul Basin

Recent multidisciplinary investigations in the Mirador-Calakmul Basin have provided evidence of human sedentary occupation by about 2600 BC. Data from coring of shallow lakes and from small residential structures with postholes in bedrock below Middle Preclassic platforms show evidence of corn pollen, isopotes, and human presence by this early period. Archaeological investigations at sites such as Nakbe, El Mirador, Xulnal, Wakna and El Pesqueiro, among others, have identified architectural constructions dating to the Middle Preclassic period between 1000 and 400 BC, indicating a rapid and sophisticated cultural ascent. The results indicate that the origins of the first Maya state begins by the early Middle Preclassic period, resulting in the construction of some of the largest structures in the ancient world, as well as architectural systems for the collection and distribution of water, architectural art, agricultural systems, murals, platforms, dikes, terraces, palaces, dams, causeways, and sophisticated commerce and trading systems centuries before Christ.

Arukhlo: Neolithic Settlement and Ritual Place in Georgia, Southern Caucasus

The Neolithic way of life arrived in the Caucasus at the beginning of the sixth millennium BC. Recent excavations in Arukhlo in the Republic of Georgia, not far away from the capital Tblisis, shed light on the occupation of the place between 5800 and 5400 BC. The building activities on the site were several times interrupted by digging deep ditches through the village. In the presentation it will be argued that Arukhlo and probably other places were centers of ritual activities.

Hanson, John

Settlement Scaling Theory, Specialization, and the Greek and Roman World

In the last decade, there has been increasing interest in using urbanism as a means of investigating the economy of the Greek and Roman world. The most recent research on the relationship between urbanization and economic growth suggests that the correlation between them is not as straightforward as once thought. There is a growing corpus of theory, however, that suggests that modern settlements act as ‘social reactors,’ which increase the number of opportunities for interactions between individuals, and therefore encourage division of labor and economies of scale, stimulating economic growth. In this talk, I will examine whether the settlements of the Greek and Roman world had a similar effect. To do this, I will estimate the number of professional associations, known as collegia, in a number of sites and use them as a proxy for the number and variety of crafts and trades. This demonstrates that there was a direct relationship between the scale of these settlements and the occupations within them, which is consistent with the models discussed above. This suggests that these settlements might well have made an important contribution to economic growth, which raises important questions about the links between urbanism and the economy over time.

Acorn Oil Rendering in the Upper Great Lakes

Recent research in the Upper Great Lakes region has demonstrated the importance of acorns as a dietary staple. As a plentiful and easily storable source of carbohydrates and fats, acorns provide an excellent dietary complement. Organic residue analysis of pottery sherds and fire-cracked rock from Grand Island, Michigan, yielded lipid profiles consistent with nut oil, suggesting that the vessels may have been used to process acorns through boiling or simmering. In order to make many species of acorns palatable, regionally-specific methods for removing harmful tannic acid are documented throughout North America. Because tannic acid is water soluble, rendering oil from acorns through boiling may have been an effective means of producing a storable, high-fat product free of tannins. While ethnographic descriptions of rendering oil from acorns exist, the mechanics and
archaeological signatures remain poorly understood. In order to evaluate the hypothesis that ceramic vessels were a crucial component of nut oil rendering, we test a variety of techniques to render acorn oil. The results of these experiments will not only inform the rationale behind changing cooking technologies in the Upper Great Lakes, but may also provide a means for identifying alternative acorn-derived products in the archaeological record.

Hanson, Sydney and Jade d’Alpoim Guedes (Washington State University) [177] Millets and Rice on the Move: Adaptive Strategies in the Past and Future
A growing tradition of archaeobotanical research, one that was pioneered by Steven Weber, is allowing us to form a picture of how millets and rice spread into Southeast Asia. Although rice continues to play an important role in the diet in this area, the use of millet has been slowly forgotten. These two different crops have both been alternatively seen as a “cultural package” that coincided with the spread of farmer populations from Southern China, or adaptations to different ecological or climatic conditions. Using crop niche modeling, and new archaeobotanical data, this paper examines these two differing but complimentary perspectives on their adoption and potential futures across Southern China and Southeast Asia.

Hanson, Sydney [260] see Downey, Caitlin

Hanten, Nicholas (University of California, Davis) [381] Settlement Patterning and the Ideal Free Distribution in the Ethnographic and Prehistoric Sierra Nevada of California
The ideal free distribution, which predicts that individuals will assort themselves across habitats of varying quality such that all individuals receive equal fitness benefits, can be an important model in the analysis of human settlement patterning. Despite its simplicity, the ideal free distribution can be difficult to apply to archaeological problems because, in addition to often requiring estimates of population size, the model necessitates a definition of habitat "suitability" in the context of past environments and subsistence systems. The current study attempts to overcome these problems by combining ethnographic data on population size and location with environmental resource distribution data to define habitat suitability using the distribution of resources across the landscape and their effect on settlement patterning during the ethnographic period. These results are then compared with prehistoric datasets in an effort to explain settlement and subsistence patterns in the late prehistoric Sierra Nevada.

Hard, Robert (University of Texas at San Antonio), Raymond Mauldin (University of Texas at San Antonio), Kristin Corl (University of Texas at San Antonio), Deborah Bolnick (University of Texas at Austin) and Jacob Freeman (Utah State University) [344] Isotope and Hunter-Gatherer Ecology at the Morhiss Site on the Texas Coastal Plain
We analyze radiocarbon, stable carbon, and nitrogen isotope data from the Morhiss Site (41VT1) located on the Texas Coastal Plain. In 1939–1940, personnel with the Works Progress Administration excavated deep deposits at this large hunter-gatherer site but they lacked adequate chronological control and results were never fully reported. From this location on the Guadalupe River and only 35 km from the Gulf of Mexico, hunter-gatherers could access a variety of habitats. In fact they returned to this productive setting from 5000 BC to at least AD 1000. With National Science Foundation funding we are developing a radiocarbon, stable isotope, and ancient DNA database from curated collections to evaluate the long-term ecological and population dynamics at the site. Site use reoccurred despite climate change, sea level rise, and population growth and the site may have served as an important node in changing patterns of hunter-gatherer land use and territoriality from the Archaic to the Late Prehistoric periods. With preliminary data we analyze the role of estuarine, riverine, and terrestrial resources thru time while considering models of land use.

Hare, P. Gregory (Government of Yukon, Cultural Services Branch) and Christian D. Thomas (Government of Yukon, Cultural Services Branch) [339] Fragile, Organic Artifacts from Alpine Ice in the Athapaskan Homeland, Southern Yukon, Canada
Since the late 1990s, a significant collection of fragile, organic artifacts has been collected from melting alpine ice patches in southern Yukon, Canada. The ice patch study area is in the Athapaskan homeland, and was an area strongly impacted by the White River Ash event, ca. 1200 yr BP, which possibly triggered southward migrations of some Athapaskan speakers. This paper will present an overview of the Yukon ice patch project and will include a description of organic hunting artifacts providing new insights into the design of traditional Athapaskan technologies that are relevant to the discussion of Apachean origins. We will focus on the construction of Athapaskan bows, arrows and an ice patch moccasin.

Hare, Timothy (Morehead State University), Rebekah Vermillion (Morehead State University) and Madison Cissell (Morehead State University) [336] Mapping and 3D Modeling of Excavations Using UAVs, Photogrammetry, and Lidar
Using unmanned aerial vehicles (UAVs/drones) to carry photographic equipment and photogrammetric processing of resulting data simplifies and accelerates mapping, 3D modeling, and environmental reconstruction. Construction and expansion of highways through Mayapan and the surrounding region are destroying valuable archaeological remains and environmental features. The 2016 field season targeted these areas for rapid recording and depended on UAV photography and photogrammetric processing for site and excavation photos as well as production of 3D modeling of archaeological remains and excavation units. In this presentation, I outline the technology used, the data processing workflow, and the resulting products including oblique photos, orthorectified aerial photo mosaics, digital elevation models, 3D models, and data layers for use in geographical information systems. I conclude with an example of implementing UAV-borne lidar and multispectral cameras into archaeological mapping and modeling.

Harke, Ryan [223] Sclerochronology of the Tiger Lucine Clam (Codakia orbicularis): Implications for Florida Keys and Northern Caribbean Archaeological Site Seasonality
The Tiger Lucine (Codakia orbicularis) is a large bivalve native to the West Indies. This tropical species is a common constituent of late prehistoric (AD 800–1500) shell middens in the Florida Keys, the Lucayan Archipelago, and the Greater Antilles (e.g., Jamaica). C. orbicularis’ prominence in the archaeological deposits of these regions is the predictable result of its abundance, relative ease of access, and widespread efficacy as both a subsistence resource and raw material for tools (e.g., fish-net sinker). For the present study, I constructed stable isotope profiles (δ18O and δ13C) for modern and archaeological (≈AD 1250) C. orbicularis specimens from the Lower Florida Keys to determine growth rates and seasonality, and season(s) of collection, respectively. Preliminary results align well with published data from the Bahamas, providing further support that this species precipitates shell throughout most of the year, ceasing growth only at or near winter minima temperatures. The archaeological specimen yielded three annual temperature (δ18O) cycles, ending on the most negative value observed in the dataset (−2.1%), suggesting it was collected during the summer. These stable isotope data form a solid foundation from which prehistoric season of habitation can be ascertained for the Florida Keys and western North Atlantic.

Challenges of Using NGS to Detect T. cruzi in Human Remains from Precolumbian South America

The trypanosomatid parasites are responsible for devastating human disease worldwide. In the Americas, Trypanosoma cruzi is the causative agent of Chagas Disease (CD), the most epidemic zoonosis in Latin America today. The clinical manifestations of CD, however, have been recognized in archaeological human remains from South America as early as 9,000 years ago. We present preliminary results of a project that applies paleogenomic methods, including targeted enrichment and next-generation sequencing (NGS), to capture T. cruzi in precolombian human remains, incorporating material with and without signs of infection. To date, the molecular detection of T. cruzi via PCR has been reported for a number of cases, but PCR products have limited power to address evolutionary questions. If successful, reconstructed NGS data from ancient parasites will be used test hypotheses regarding the origins, timing and dispersal of human-adapted lineages in ways that PCR products cannot. NGS methods, especially products have limited power to address evolutionary questions. If successful, reconstructed NGS data from ancient parasites will be used test hypotheses regarding the origins, timing and dispersal of human-adapted lineages in ways that PCR products cannot. NGS methods, especially

A Ticking Clock? Considerations for Preservation, Valuation and Site Management of Greenland’s Coastal Archaeology in the Twenty-First Century

Documenting and evaluating the rate of deterioration at coastal archaeological sites presents a number of fundamental challenges in the Arctic. In Greenland for example, increasing soil temperatures, perennial thaws, coastal erosion, storm surges and pioneer plant species such as dwarf willow and dwarf birch are observed as increasingly detrimental to the long-term preservation of archaeological deposits and features found scattered along the country’s west coast and extensive inner fjord systems. Since 2009 several projects, including the ongoing REMAINS (REsearch and Management of Archaeological sites IN a changing environment and Society) project, have explored the variable factors that currently threaten Greenland’s heritage landscape in the twenty-first century. This paper specifically addresses the threats immediate to house middens located in the littoral zones of Greenland west coast and reviews results from a workshop in 2016. The workshop gathered provides a baseline for “ground-truthing” predictive models of preservation and deterioration of material such as bone, antler and wood frequently observed in varying states of decay in these coastal middens. Knowledge derived from the project will assist heritage managers, conservationists and local people with new tools to actively document annual changes observed at archaeological sites at both the local and regional scale.

“First Fruits” Household Foodways at the ca. 1638 Waterman Site House, Marshfield, Plymouth Colony, Massachusetts

In New England’s First Fruits published in 1643 in London, an anonymous author addressed various questions and misconceptions prospective colonists often had related to life in the colonies. The author assured readers there was an abundance of food that was “farre more faire pleasant and wholesome than here.” While early chroniclers provide clues to the hardships of the early years of Plymouth Colony, very little detail about First Period foodways is known from documentary data and archaeological evidence in eastern Massachusetts. The Waterman Site in Marshfield is associated with Robert and Elizabeth (Bourne) Waterman, who married in Plymouth in 1638 and were related to the Winslow and Bradford families. Archaeological evidence indicates that the house was a modest earthfast structure that burned down only after a few years of occupation and was never rebuilt. An integrated research approach, including study of faunal and botanical remains, ceramics, cooking implements, and food storage features, along with associated historical documentation, is providing the first detailed information on the material culture, subsistence strategies, and general lifeways of a Pilgrim family. Ongoing analyses indicate that the Watermans practiced a dynamic household economy that thoroughly integrated Old World and New World plants, dairying, fishing, and hunting.

[144] Lithics and the Late Prehistoric: Changing Adaptive Strategies on the Southeastern Columbia Plateau

Port au Choix-3 (4800–3600 BP) is a large Maritime Archaic mortuary site in northwestern Newfoundland. Since the 1940s, archaeological excavations have yielded thousands of artifacts and the skeletal remains of over 100 individuals. This site has been instrumental for defining the Maritime Archaic tradition, and for understanding human-environment interactions during the Archaic occupation of Newfoundland and Labrador. As such, it is currently the focus of a multi-isotope and ancient DNA project exploring the lifeways and biocultural relationships of the Maritime Archaic people. This paper presents the results of our investigation into diet and resource use through stable isotope analysis of bulk bone collagen and collagen amino acids. Our analyses have revealed considerable isotopic variation within the sample, indicating the presence of several distinct dietary patterns. While the variation may in part be attributed to sex-based dietary differences, it also indicates that Maritime Archaic subsistence in Newfoundland can no longer be generalized as a single adaptation. We will examine the results in relation to site distribution data, and in light of recent interpretations of Maritime Archaic social organization and settlement patterns in Newfoundland and the Strait of Belle Isle region.

[343] A Yard and Its Belongin’s: Archaeological Research of Laborer Houseyords on the Morne Patat Estate, Dominica

Caribbean ‘yards’ and their associated structures have long been of interest to archaeologists determined to understand how the domestic spaces of enslaved laborers both embodied and reflected kinship ties, labor arrangements, and sociopolitical shifts. Often regarded as an elemental feature of Caribbean society, houseyards are the spaces where the repeated acts of daily life took place, as a result, understanding how enslaved laborers utilized and altered their domestic space over generations, offers key insight into the conditions of enslavement and subsequent freedom. In this presentation, I explore and discuss the defining characteristics of houseyords, using archaeological evidence from the Morne Patat Estate in Dominica. First, I situate each houseyard within a plantation-wide chronology using ceramic and other diagnostic data. Then, I discuss the shifts in material and spatial practices that occurred, linking the actions and choices of the enslaved to wider trends in plantation archaeology.

Harris, Khadene (Northwestern University)

[317] Interior Salish Organizational Principles: Recasting the Dynamics of Sociopolitical Change in Aggregated Village Archaeology on the Northern Plateau

The Middle Fraser Canyon of south-central British Columbia is well-known for the large Late Prehistoric aggregated pithouse villages that line the terraces of the region's major rivers and tributaries. These villages represent a dynamic period in the history of Northern Interior Salish societies. Our understanding of the cultural dynamics underlying the formation and breakup of these large villages has been limited by reliance on theories that are rooted in uniquely Western concepts of individuality and the naturalized state of self-determination. In short, the theories misunderstand the dynamics of culture change associated with the aggregated village period precisely because they draw on insights that are external and alien to the system they are invoked to explain. In this paper I introduce a model of Interior Salish Secwepemc sociopolitical dynamics proposed by cultural anthropologist Elizabeth Furniss and briefly discuss the application of that model to the archaeology of the aggregated villages. Finally, I demonstrate the ethnographically documented relationship between sociopolitical organization and settlement patterning. I propose that relationship be used as a means of further refining understanding of sociopolitical dynamics during the aggregated village period.

[387] Ground Stone Disk Bead Distribution and Frequency in Katzie Territory, British Columbia

Inquiries into ground stone disk beads in the Salish Sea region have focused on frequency counts at one particular archaeological site, regional syntheses of distribution, or the use of beads as a means to explore Coast Salish expressions of wealth and status. Although these studies provide important information relating to the social role of these beads, they are either too broad in focus or ignore the interplay of beads between neighboring sites. This presentation examines the inter site variability of beads recovered from archaeological sites within Katzie territory. Using the Katzie territory as an example focuses on the idiosyncratic uses of beads and the role that they may have had for the Katzie people. The meaning of beads for particular groups of people is often overlooked in both large regional syntheses and myopic frequency examinations of individual archaeological sites.

[90] Neolithic Landscapes of Southern Germany: Insights from Regional Survey

Landscape archaeology in Central Europe has historically built on a foundation of high-resolution excavations of village structures. In this poster, we combine results of systematic plow zone survey carried out by two research groups to explore and reflect on the contributions of regional survey for understanding Neolithic land use in southern Germany. Surveys were conducted in two areas with contrasting archaeological records and geographic characteristics. On the southeastern Swabian Alb plateau, active work by avocational archaeologists provides a foundation for systematic landscape archaeology spanning the Early/Middle, Upper, and Final Neolithic. To the south, in the Alpine Foreland, exceptional preservation and detailed
excavations of Upper and Final Neolithic sites in lakes and bogs raise questions about the presence, intensity, and type of Neolithic activities that might have occurred outside the intensively-studied wetlands. We analyze the distribution of Neolithic materials in lithic scatters and compare their location and density between regions and across time periods to consider questions of settlement continuity, nonresidential activities, and effects of factors such as site visibility and modern land use on known site distributions.

**Skuggi and Siglunes: Two Icelandic Settlement Sites**

This paper presents results from multidisciplinary investigations at two Icelandic sites from the same region: Skuggi and Siglunes. The small subsidiary farm at Skuggi was likely settled during the earliest stages of Icelandic colonization and was located on a steep mountain slope, about 150 m above the valley bottom. Ideas on its occupation history and causes of abandonment will be discussed, as well as the possibility that the decision to abandon the settlement was heavily influenced by landslides in that particular area. Siglunes, located in the outer fjords of the same region, was also settled early during the island’s colonization. There, well-preserved faunal remains were recovered from several midden deposits infilling the remains of structures such as dwellings and boat houses. From ongoing faunal analysis, we know now that this site may have been one of the fishing sites providing the region called Eyjafjord with various preserved fish products. Possible impacts on the landscape as well as on both these sites will be discussed.

**Virtualization as a Method for Heritage Preservation: A Case Study from Seyitömer Höyük, Turkey**

In Turkey, rapid industrialization is one of the most prescient concerns facing the country’s natural and cultural heritage. Increasingly, archaeologists are expanding their traditional tool kit to incorporate methods of virtualization, to create 3D models of sites, structures, and artifacts. This paper offers a case study of digital heritage preservation at Seyitömer Höyük, an Early Bronze Age (ca. 3000–2000 BCE) urban center that is located within an active coal mine, and is under direct threat from industrialization. This paper reveals how Information and Communication Technologies (ICT) were used to create a photorealistic 3D model of this endangered site, and produce a valuable interpretable and educational tool available in an open access format on the Internet. It is argued that the use of such digitization strategies is a valuable component of site management planning, particularly in cases where archaeological resources face imminent danger from external threats.

**It's the Journey, Not the Destination: Maya New Year’s Pilgrimage as Circumambulatory Movement and Regenerative Power**

Maya ethnohistory suggests that burning incense, erecting monuments, penis bloodletting, and pilgrimage were all activities associated with New Year ceremonies. These annual rites were calendrically inked and aimed at ensuring agricultural renewal and earthly regeneration. Today, Maya New Year ceremonies involve initiation of young men prior to marriage and sexual relations, requiring self-sacrifice and long-distance pilgrimage with male elders. Cross-examining these data alongside archaeological evidence, I suggest similar New Year traditions existed in Postclassic and Terminal Classic times (AD 800–1500). Maya pilgrimage was not about acquiring a particular thing or venerating a specific place or destination. It was about the journey or what Tim Ingold (2010) calls “ambulatory knowing.” The Maya gained cosmological knowledge, linking the movement of their body to the annual path of the sun and their sexuality and human regenerative power to earthly renewal. New Year circumambulatory rituals express a core ontological principle of dualistic transformation that the Tzutujil Maya call Jaloj-k’ejox, demarcating physical change (jal) from youth to adulthood and transference or replacement (k’ejox) of power in official leadership roles. This distinct way of knowing the world emphasizes one’s reciprocal relationship with it, constituting mutual interdependency in both same-sex and cross-sex relationships (sensu Strathern 1988).

**Beyond Broken Bones: The Value of Creating an Osteobiography when Analyzing Violence in the Past**

Population level analyses of violence that are focused on quantifying and comparing traumatic injuries on human skeletal remains recovered from an archaeological context are crucial for understanding violent interactions through time and across regions. However, these types of studies are also limited because, by design, they place less emphasis on individuals and their lived experience. In contrast, when researchers create what Frank and Julie Saul called an osteobiography for each set of remains, they are attempting to reconstruct as much about each person as possible. An osteobiography tells a story about who the skeletal remains represent using an array of different osteological methods, which include age-at-death, biological sex, indicators of diet and nutrition, markers of activity, pathological conditions, and traumatic injuries. The result is that in addition to counting and describing trauma it is possible to place the individual into a larger sociopolitical context and begin to potentially understand why they were at risk of violent altercations, what the consequence of the resulting injury would have been, and how the culture viewed violence.

The Empire of Aksum was one of the earliest and most influential African complex polities, yet remains one of the world’s most scantily documented ancient civilizations. The Eastern Tigrai Archaeological Project (ETAP) surveyed a 196 km² area between the ancient capital city of Aksum and the Red Sea over four field seasons from 2005–2008. This work documented 137 archaeological sites, including seven ancient towns larger than 6 hectares, and contributes a substantial body of data on geographies of Aksumite and Pre-Aksumite polities. Spatial analysis of this dataset yields substantial insights regarding site hierarchies, site clustering, trade routes, and associations among sites and environmental variables, including landforms and hydrology. Collectively, ETAP archaeological survey clarifies key issues, and raises a wide range of new questions poised to be addressed by a steadily increasing number of international teams and local scholars working in the region.

**Lithic Artifact Production at the Large-Scale Pharaonic Period Chert Quarries of Wadi el-Sheikh, Egypt**

Recent research into quarrying and lithic production in Wadi el-Sheikh, Egypt by the University of Vienna has identified activities extending from the Middle Paleolithic to modern times. These include Middle Paleolithic use of surface materials, Neolithic chert quarrying, Pharaonic gypsum extraction, quarrying and production of groundstone, ochre collection, and small-scale independent modern salt quarrying. However, the most striking activities are the large-scale Pharaonic period chert quarries. These massive works stretched for 8 km in one section of the wadi alone. Mining strategies included...
surface pits, trenches, vertical shafts, and deep horizontal galleries. The surfaces are carpeted in lithic debitage, and stratified deposits over 1 m deep have been identified. Surface collection and analysis of materials from four 1 × 1 m test units has revealed evidence for the manufacture of prismatic blades, bifacial knives, and bifacial bangles. Analysis of the distribution of tool fragments, cores, debitage, and debris indicates that production was likely segmented, with different types and stages of production taking place across the site. This evidence combined with finds of barrack-like structures, and the sheer scale of the activities, indicate that these quarrying expeditions were likely organized by the state—a rare case for chert quarrying worldwide.

[159] Stories from North of Main: Neighborhood Heritage Story Mapping
This paper discusses the use of GIS Story Map applications for discerning shared values and community capacity building in a small, diverse, deindustrialized urban neighborhood in Binghamton, New York. Most local sustainability and revitalization projects focus on homogenous communities that have shared stories and understandings about the neighborhood’s past and present. But in the economically marginalized and diverse neighborhoods of America smaller rust belt cities, narratives of decline dominate and shape perceptions of the place and its residents, perpetuating race and class-based divisions. The Neighborhood Heritage and Sustainability Project is a community-based effort to understand neighborhood change and create an alternative to elite-driven heritage. Through interviews with residents, business owners, activists, and city officials we are working to identify shared values, aspirations, and experiences that can be the basis for new neighborhood stories. Using the GIS Story Map Application, we are mapping the multiple meanings attached to different neighborhood places, layering audio, images, and text to create stories of work, home, and community life. Here, we report on the results of this project and evaluate the effectiveness of digital mapping and storytelling for a marginalized urban neighborhood.

[366] New Contributions to Black Mesa Archaeology
Between 1967 and 1983 the Black Mesa Archaeological Project (BMAP) conducted extensive survey and excavations on Peabody Western Coal Company lease area on Hopi and Navajo tribal lands on northern Black Mesa, Arizona. The project contributed immensely to our collective understanding of the Kayenta Branch of Ancestral Pueblo and prehistory in northern Arizona. In support of a current environmental impact statement, Logan Simpson recently completed a Class III pedestrian survey of nearly 4,000 acres of Peabody-leased lands on Black Mesa owned by the Navajo Nation and Hopi Tribe. This poster presents an overview of the current archaeological project on Black Mesa and details how the collaborative and innovative approach that included working with Navajo and Hopi archaeologists and communities; and the use of modern technology, such as aerial drone photography and 3D site and artifact modeling, has contributed to our understanding of the prehistory and history on northern Black Mesa.

[83] Ecological and Paleoethnobotanical Research at the Programme for Belize Archaeological Project
Archaeological research requires interdisciplinary scholarship to answer broad questions relating to resilience, social complexity, climate, and environmental impacts in Mesoamerica throughout ancient Maya times and into the present. RBCM A, PIBAP, plant ecology, and paleoethnobotany have provided a platform to reconstruct ancient Maya landscapes, which delves into the nuances of human-environmental relationships in northwestern Belize. Ecological studies of the impacts of ancient Maya on soils, and studies on present soil-tree species relationships, suggest that the ancient Maya have greatly affected the present distribution and abundance of tree species. The present heterogeneity of soil characteristics over the landscape also suggests the opportunities the ancient Maya had for varied agriculture. Paleoethnobotanical studies at PIBAP have demonstrated that it is possible to recover preserved archaeological plant remains from harsh tropical conditions and that these types of studies hold the potential to advance understanding of ancient Maya agriculture and land use beyond simple maize, bean, and squash subsistence strategies. This paper is a synthesis of research on the articulation among botany, ecology, and human populations at the RBCM A over the last 25 years, as well as of current and future research projects.

[9] UAV-Based Mapping and 3D Modeling of Maya Sites in the Northern Yucatán
During our 2015 and 2016 field seasons, we mapped and created 3D models of numerous excavation sites in the Northern Yucatán. Several of these sites are located in Mayapán’s periphery and many were scheduled for destruction due to highway expansion. We used unmanned aerial vehicles (UAVs/drones) to carry photographic equipment to collect both vertical and oblique photos as well as videos. In several areas we used both visible light and a near-infrared (NIR) cameras. The resulting images were processed in photogrammetric software to generate orthorectified airphoto mosaics and 3D models. The various sites include small groups of residential and public architecture, different sizes of platforms, and some monumental architecture. Fieldwork at mapped locations range from minimal clearing of vegetation with test excavations to completely cleared with broad horizontal excavations.

Despotism and Territorial Behavior: Low Population Density Foragers and Territorial Maintenance
Habitat distribution theory has been applied to a variety of archaeological research programs. The success of the framework has been largely demonstrated through the use of the ideal free distribution (IFD) model to elucidate the nature of colonization and settlement of insular environments. However, territorial maintenance, especially in the face of resource competition, may require the occupation of less suitable habitats as a means of controlling access to resources and land. This paper focuses on the less utilized ideal despotic distribution (IDD) model and the role of territorial maintenance among low population density groups. I present a model of territorial establishment and maintenance for the Tubatulabal of the far southern Sierra Nevada that posits an IDD strategy is best suited for territorial maintenance among low population density foragers. Recent archaeological investigations aimed at testing the model suggest that a shift from an IFD to an IDD strategy in the region began when the Tubatulabal were circumscribed by larger population density groups ca. 1500 BP.

Hasaki, Eleni (University of Arizona)
Space, Workforce, and Scale of Production: Ethnoarchaeological Approaches to Craft Workshops in Ancient Mediterranean
More than dots on a map, the craft production loci need to be examined for the space they occupy: their size, organization, and capacity. Spatial analysis can put constraints on workforce size and scale of production, allowing us therefore to reconstruct more accurate models of craft economy. We can also attempt to correlate space occupancy with scales of craft specialization. The “chaîne opératoire” can be examined parallel to the “espace opératoire” to establish what the spatial requirements use flexibility, and archaeological visibility are for different stages of craft production. Furthermore, the study of workshop space impacts discussions of structure and length of apprenticeships and ability to stockpile, to name a few. The paper will examine archaeological and ethnoarchaeological cases of craft workshops in the Mediterranean.

Hasenstab, Robert
The Use of Geographic Information Systems in the Analysis of Prehistoric Social Dynamics
Geographic Information Systems (GIS) are typically used in Archaeology to analyze the patterning of sites in a region. Part of this patterning is the result of past human social behavior. Such patterns are manifested in the spatial arrangement of sites on the landscape. These patterns and arrangements can be analyzed using certain GIS methods. This paper presents GIS methods sensitive to analyzing prehistoric social dynamics. Demonstration of the methods is shown by way of example as well as through review of extant literature.

Presentation of the Past: Interaction and Storytelling; How We Grow through Dialogue
While archaeobotanist’s work hard at interpreting botanical data, one way to improve our interpretations is to interact about our material, tacking between raw and adjusted data to better understand those transformations with others, bring us closer to the past. Like a gear change, presenting material and hearing responses make a big difference in our explanations and perspectives. I stress this here because of Steve’s crucial initiation of the Society for Ethnobiology some years ago, which has allowed many of us in the United States to learn about the importance of presenting and listening to colleagues. Discussing data in the context of current methods and theories applied to paleoethnobotany launched the meetings and continues to allow us to advance our interpretations.

Hatch, Mallorie (Arizona State University)
Warfare in the Mississippian World: Comparing Variation in War across Small and Multi-Mound Centers
Warfare during the Mississippian Period (ca. AD 1000–1500) of the U.S. midcontinent and southeast has been hypothesized as an important political and social practice throughout the region. This paper will explore diachronic and synchronic evidence of warfare, comparing and contrasting evidence between large and small sites. Particular emphasis will be placed on observations of warfare patterns in the Central Illinois Valley of west-central Illinois. Skeletal remains with warfare-trauma have been infrequently recovered from large multi-mound centers like Moundville and Cahokia. While skeletal trauma is found in low frequencies at these sites, large-scale fortifications and warrior iconography on portable art objects represent important evidence of war’s importance. In contrast, warfare-related skeletal trauma has been recovered in the highest frequencies from small and medium-sized Mississippian villages and towns. Available evidence indicates that war may have functioned differently between the periphery and mound centers. The large size of and fortifications surrounding mound centers may have dissuaded ambushing enemies, creating more coordinated attacks. Warfare also served as a coercive threat, curbing the aspirations of loosely consolidated chiefs and reinforcing ideological dominance at large centers. Ambush warfare may have been more endemic at smaller sites due to a reduced defensive capacity.

Cooking Up a Storm  
Food is not only essential for survival but also an important element of any culture. Artifacts for the storage, preparation and serving of food and drink form a large proportion of archaeological assemblages demonstrating that this has always been the case. Understanding how these artifacts were used gives us valuable insight into our past. Organic residue analysis allows us to more accurately determine how a vessel was, in fact, used. My research looked at several vessels sourced from Thailand to determine if it was possible to undertake residue analysis in the changeable climate and conditions found in Southeast Asia. Residues were successfully extracted and preliminary interpretations were made of the results. Since this work was undertaken a number of successful organic residue analyses have been carried out in Southeast Asia. Using the new data these analyses afford, and through comparison with modern subsistence practices in Thailand, I aim to provide a more in-depth interpretation of my results and a fuller picture of what people were storing, cooking and serving in their ceramic vessels in the Bronze and Iron Ages of Thailand.

Archaeological Survey of Colonial Dominica  
The Archaeological Survey of Colonial Dominica centered household production, provisioning, and consumption in the relationship between colonies and metropoles. This paper introduces this session, which develops an approach that considers the political economy of colonial empires at the human scale. As a site of imperial contention between Britain and France, Dominica's material record can help examine the similarities and differences in how land, labor and commerce was imagined in the homeland and practiced on the frontier. Because slaves were not only producers of export goods but consumers of manufactured items, it is possible to examine the ways in which household consumption was regulated by functional demands, competition or social solidarity.

Making a Case for Large-Scale Seasonality Studies: Preliminary Results from the ACCELERATE Project  
The chemical composition of carbonate shell from paleoecological and archaeological assemblages is laborious to analyze, yet the information that is locked within shell deposits worldwide contains valuable insights on past environments and human ecology. At present, studies struggle with the acquisition of sufficient amounts of data to make robust interpretations. Large amounts of information are inaccessible due to costly and time-intensive techniques. Here we aim to develop the technique of Laser Induced Breakdown Spectroscopy (LIBS), which will allow rapid chemical analyses of carbonates, increasing the cost efficiency and making datasets more comprehensive. We apply the technique to various molluskan species around the world, to develop a rapid and affordable method and to globally advance the reconstruction of climate change, exploitation of coastal resources and human-landscape interactions. Furthermore, we argue for an increase in sample numbers within archaeological shell accumulations, to use spatially grouped seasonality data as temporal scaffolding of the archaeological deposit. By making use of the shell matrix in this way, it is possible to answer questions regarding, seasonal context of burials and artifacts, identification of single episodes of mollusk consumption (feasting), and to enhance chaîne-opératoire studies by adding a temporal component.

Diagnostic Elements and Interobserver Variation in the Identification of Fish Bones  
Research by us and others has demonstrated that the taxonomic identification of fish bones from archaeological sites varies between analysts. While rarely acknowledged, this variation may be significant enough to result in different interpretations of site function and seasonality. The level of specificity of identifications and the elements considered identifiable are two important sources of variation. Other factors include the nature of the reference collection used and the experience of the analyst. Using samples from the lower Great Lakes region, in this poster we consider whether use of a select suite of diagnostic elements would improve reliability of identifications.

On Point-Cloud 9: A Replicable Protocol to Model 3D Point Clouds of Artifacts as 3D Surfaces  
The comparative study of artifact-form across time and space is fundamental to archaeological inquiry. Increasingly accessible 3D-scanning technology has allowed digital models of artifacts to have a prominent role in archaeological analyses. With this technology, researchers can generate digital 3D models and point clouds representing scanned artifacts to be later analyzed and distributed to other scientists through open-source repositories. However, because comparative morphometric analyses of 3D digital artifacts are recent, common protocols to model point-cloud data have not been established. This makes research replication difficult. Here, we provide a replicable protocol to model 3D surfaces from point cloud data using Meshlab. We show how to import text files containing the raw 3D point-cloud coordinates acquired using any scanning instrument. We proceed to model these point clouds as surfaces by creating, cleaning, and optimizing a triangular mesh, removing outliers and noise generated by the instrument. Finally, the 3D mesh model can be exported as several common 3D-file formats. As a case study, we apply this protocol to 3D point-clouds of experimental marks on bone, and conduct a comparative morphometric analysis to discriminate between bone-marks. This protocol is simple, replicable, and applicable to any point cloud data representing artifacts.

The Middle-Upper Paleolithic Transition in Southern Iberia: New Dates from Lapa do Picareiro, Portugal  
The transition from Middle to Upper Paleolithic in western Eurasia remains a hotly debated and intensely researched archaeological problem. Recent developments in radiocarbon dating and genetics have permitted some refinements to our understanding of the spatiotemporal process but many issues...
remains unresolved. For the Iberian Peninsula, Zilhão’s “Ebro Frontier” model of late Neanderthal survival and subsequent replacement by anatomically modern humans has held sway for over two decades. Unfortunately, this and other models remain open to debate because of persistent problems with stratigraphic integrity, depositional hiatuses, and dating uncertainties at the relevant Middle-Upper Paleolithic transitional sites. New radiocarbon results from these sites have overturned their status and some have questioned the idea of late Neanderthal survival after 40 kya. Here we present new radiocarbon dates from Lapa do Picareiro, a cave with about 10m of sediments spanning 50,000 years of the Late Pleistocene. The sequence includes almost 2m of deposits dated between 30–42k cal BP, making it an ideal locale to track the Middle-Upper Paleolithic transition. Level FF, dated 36–38k cal BP, contains diagnostic Middle Paleolithic discoidal core technology, supporting models of late Neanderthal survival in southern Iberia.

Hawthorne, Paige (Washington State University) and Colin Grier (Washington State University) [181] Put a Bird on It! A Multi-analytical Approach to Avian Analysis in Southwestern British Columbia

Zooarchaeological identifications provide important data related to subsistence changes and the exploitation of past environments. Previous faunal analyses at Shingle Point (DgRv-2), Dionisio Point (DgRv-3), and the Coon Bay/Perry Lagoon (DgRv-6) sites have indicated multiple occupations with important variation in archaeofaunal representation. These locales exhibit a variety of avian fauna, which are not frequently explored in detail within zooarchaeological analyses. We present new osteological data to understand the exploitation of avian species at these sites, which include plankhouse and midden contexts that span the Marpole and Late periods. Through analyzing the avian faunal assemblage, we can understand change over time in resource exploitation across a variety of microenvironments. The results also illustrate how settlement patterns and food acquisition in the southern Gulf Islands involved aspects of landscape construction and modification to enhance resource diversity and abundance.

Hayden, Brian (Simon Fraser University) [68] The Secrets in Caves: Use of Caves by Secret Societies

Caves have been recognized as important prehistoric ritual sites for well over a century. Yet, archaeological discussion of the rituals conducted in caves has rarely gone beyond the platitude that they were locations for contacting the spirits, invoking powers of fertility, or burying the dead. This paper attempts to place the ritual use of many caves in a more specific ritual context by documenting the ethnographic ritual use of caves by secret society members and relating this to some prehistoric examples, beginning with the painted caves in Upper Paleolithic Europe. Caves provided ideal locations and environments for special types of secret society rituals. The linking of cave use to secret societies opens up a new dimension of inferences about rituals and the nature of the cultures that supported such organizations.

Hayne, Jeremy (Independent researcher) [166] The Missing Link? Sardinia, Corsica, and Italy and Their Connections in the Late Bronze and Early Iron Age

The late Bronze and early Iron Age were periods of population movement and change and recent scholarship has highlighted the multidirectional interactions and networks involving the various communities across the whole of the west Mediterranean, as opposed to more static core-periphery models. In Sardinia, for example, this has emphasized the binary relationships between Phoenicians and the local Nuragic communities. With a greater awareness of local networks and connections the regional differences in the island have become more apparent that has come under scrutiny is between Sardinia and central Italy, where scholars have convincingly argued for the active role of Sardinia in these exchanges. However, despite being part of the route between the two locations the role of Corsica remains less well understood. How far did it play a part in the exchanges and how far can ‘network thinking’ help explain the dynamics of the interactions in this area of the Mediterranean? This paper focuses on the exchanges between north Sardinia and the Italian peninsula, specifically examining the role that Corsica may have played in them, examining the local connectivities at the start of the first Millennium BC.

Haynes, Gary (University of Nevada-Reno) and Janis Klimowicz (Desert Research Institute) [140] Clovis-Killed Mammals

Published opinion pieces about Clovis prey choices are unintentionally misleading. Over 120 individual animals from 8 extinct megafaunal species (or 12, depending upon taxonomy) were killed by Clovis people in a relatively short time span, according to conservative estimates—and the number is even higher in some lists. The 11 Clovis sites said to have acceptable evidence for human predation on mammoths actually contain 50–53 separate individuals, some being discrete kills that should be counted independently; and some are probably also equivalent to discrete short-term camps. In the cold reversals of the Bølling-Allerød warming phase, both extinct and non-extinct megafaunal genera suffered through periods of population fragmentation and reduced genetic diversity, making them more sensitive to environmental stress, but these taxa had also recovered from earlier such periods, suggesting that loss of genetic diversity was not necessarily a precursor of extinction. If Clovis hunting contributed to any extinctions, it was likely through the localized hunting of juvenile and young adult individuals in fragmented populations with low fecundity.

Hayward, Michele (Panamerican Consultants), Frank Schieppati (Panamerican Consultants) and Michael Cinquino (Panamerican Consultants) [175] Lesser Antillean Windward Island Rock Art and Prehistoric Cultural Systems

Two datasets-Jonsson Marquet’s proposed chronological framework for rock art of the Windward Islands and Alistair Bright’s reconstruction of settlement, sociopolitical and exchange networks within the same region-provide a context for examining the interrelationships among the material cultural correlates (petroglyphs, settlement types, pottery) of various aspects of the area’s, as well as inter-area prehistoric cultural components.

[123] **Microfossil Analysis of Sediments from a Qaraqara Terrace Site, Viti Levu, Fiji**

Microfossils in archaeology are defined as the floral and faunal-derived microscopic biogenic particles that preserve long after the original organism has died and decayed. Some such examples are silica phytoliths, starches, pollens and spores, cellulose microfibers, and plant cellular tissue like trichomes and stomata. This type of analysis is a valuable proxy for inferring prehistoric environmental conditions and landscape change over time, as well as direct evidence for the presence of certain agricultural domesticates and other important subsistence cultigens. In this paper we report some preliminary results of the microfossil analysis performed on sediment samples collected during two excavation field seasons at a site in the Qaraqara drainage, located in the Sigatoka Valley of Viti Levu, Fiji. As part of a collaborative multiyear project, the research presented here seeks to provide vegetation-based evidence surrounding the prehistoric Post-Lapita subsistence transition from foraging to agriculture in the Sigatoka Valley. Specifically, we are interested in addressing questions related to when and how agriculture become the main mode of subsistence at this site, especially in the context of similar research performed at other sites in Fiji and other islands in the South Pacific.

[288] **The Afterlife in Exile: Butterfly Imagery on Teotihuacán-Style Censers from the Pacific Coast of Guatemala**

The Teotihuacán-style censers from Guatemala have received relatively little attention since the 1980s. Following upon earlier suggestions for a merchant-warrior presence in the Escuintla region, this study examines the butterfly imagery on a group of Teotihuacán-style censers in the national collections of Guatemala. This group of unprovenanced artifacts has research value because (1) its original imagery is intact, and (2) all have been sampled for paste analysis (instrumental neutron activation analysis–INAA). The paste chemistry, combined with archaeological data and stylistic analyses, allow us to recontextualize the censers in terms of interaction among the Pacic Coast sites as well as their external connections. Focused analyses of their intact imagery seek to better understand their social and funerary functions. The censers’ emphasis on Teotihuacános living far from home. Yet their prominent three-mountain motif intimates a connection to mythologized landscapes of both the southern Guatemalan Mayas and their Teotihuacán homeland.

[74] **An Intersectional Study of Authorship and Citation in American Antiquity, Latin American Antiquity, and Advances in Archaeological Practice**

Over the last thirty years, archaeologists studying identity in the past have also examined archaeologists in the present. Feminist archaeologists of the 1990s examined gender inequities among archaeologists using a wide variety of metrics. Since NAGPRA passed in 1991, many have written about the roles of Native Americans and other people of color in archaeological research. Yet there are no studies of how sexism, racism, and heterosexism work together in our field. I will examine patterns of authorship and citation in the SAA’s peer-reviewed journals in order to show the demographic composition of Americanist archaeologists producing publishable research. I will test several working hypotheses: that men are overrepresented as compared to women, that white people are overrepresented as compared to people of color, and that straight cisgender people are overrepresented as compared to queer and transgender people. Furthermore, I will test the hypothesis that archaeologists who face multiple forms of systemic oppression (i.e., women of color, queer women, queer people of color) are even less represented in these publications than their counterparts who only face one form of oppression. By using an intersectional feminist lens, I will be able to clearly show the effects of systemic oppression in our discipline.
Hechler, Ryan (Tulane University) [220] Beyond Monumentality: Looking Past the Pyramids of Cochasquí, Ecuador

The northern highland Ecuadorian site of Cochasquí is one of the country’s most respected archaeological resources. Investigations by archaeologists Jacinto Jijón y Caamaño (1910s), Max Uhle (1932), and Udo Oberem (1964–65) had principally focused on this Late Period site’s highly visible quadrangular earthen pyramids, which can reach heights of approximately 20 m. The archaeological and public fascination with the visibly monumental has long diverted attention away from between and beyond the pyramids. To ameliorate this research deficiency, the Proyecto Arqueológico Cochasquí-Mojanda was reestablished in the summer of 2016. Long prior to the 1979 creation of a provincial government-administered park to protect the site’s pyramids, the earliest archaeological mentions of Cochasquí were about ceramics looted from the site area in the nineteenth century. With the introduction of controlled archaeological investigations, ceramics recovered from the site and surrounding area have demonstrated a regionally diverse political economy, with pottery having origins from the Ecuadorian montañas, Amazon, southern Colombian highlands, and even Inka ceramics as well as Inka-influenced ceramics. Additionally, examples of allochthonous obsidian artifacts have been recovered. Aside from such material, recent research has discovered unique spaces in between and just beyond the pyramids that challenges the previously perceived nature of the site.

Heckel, Claire (American Museum of Natural History) [138] Tracing the Emergence of Pan-Indian Conventions of Dress in the Collections of the American Museum of Natural History

During the late nineteenth and early twentieth centuries, professional ethnographers/archaeologists and amateur collectors amassed more than 3,000 artifacts of dress and adornment from 17 cultural groups that are now part of the “Plains” collections at the American Museum of Natural History. These objects constitute a material record of conventions of dress that were inconsistently recorded at the time of artifact collection. Drawing on archaeological and ethnographic records, historical documents, and photographic archives, the present study is part of an ongoing effort to recontextualize these objects and to reexamine conventional narratives of culture change and cultural resilience in Great Plains tribes of roughly the 1840s–1930s. This paper presents results of case studies of materials from the Omaha Tribe, the Three Affiliated Tribes (Mandan, Hidatsa, Arikara) and the Cheyenne and Arapaho Tribes. One of the central themes that has emerged in this study is the significance of intertribal exchange and the emergence of a Pan-Indian style of formal dress in the late 1800s. Selected results demonstrate the potential that reanalyses of museum collections have to emphasize native agency and resilience in narratives of culture change, and provide examples of the evidence that emerges with shifting research priorities and renewed approaches to artifacts.

Hedden, John (University of Iowa) and Daniel Horgen (University of Iowa) [188] The Strange and Terrible Tale of the Davenport Iowa Danish Hall Site: A Lesson in Urban Archaeology from the Farm State

The Davenport Danish Hall was considered eligible for the NRHP under Criterion A for its “association with the Danish ethnic population in Davenport, and with the history of city politics, specifically the impact of the Socialist Party in the 1920s.” This structure was scheduled for demolition to allow for the construction of a new apartment complex as part of the redevelopment of downtown Davenport. As part of the mitigation, a small 30 × 50 ft. parcel behind the structure was scheduled for architectural inspection. This inspection identified site 13ST323. Though the site contained an intact mid-nineteenth century artifact deposit and features associated with the early settlement of Davenport, the archaeological consultant determined the site not eligible for the National Register. What followed was an unfortunate series of events that occurred prior to review comments being issued by the Iowa SHPO, including the demolition of the structure and construction activities commencing on the site. An after-the-fact mitigation of the site yielded what may be the largest intact deposit of mid-nineteenth-century urban artifacts excavated in Iowa. An amazing turn of events that provides new insight into the economics and lifeways of the mid-nineteenth-century working class of urban Iowa.

Hedenstierna-Jonson, Charlotte (Uppsala University/Swedish History Museum, Sweden) [15] Entering the Viking Age

Often depicted as a time of local but powerful chieftains, mounted elite warriors and spectacular boat inhumation burials, the Vendel period preceded the Viking Age in Swedish history writing. While contacts with Central Europe and beyond were extensive the societal structure in Scandinavia was still small scale, spread out and based on personal relations. But times were changing and from the mid-eighth century several new features evolve: the emergence of town like structures, changes in scale and organization of the martial aspects of society and most famously the introduction of campaigns outside the Scandinavian homelands; warfare, raids and trade. It is the start of a new phenomenon that we have come to know as the Viking Age. But what do we know about the people that took part in this development and change? Where did they come from? How did they move? By combining archaeological evidence with DNA and isotopic data a more complex image is starting to emerge. This presentation aims at presenting and discussing some of the individuals that took an active part in the process of the eighth century that could be described as entering the Viking Age.

Hedgepeth Balkin, Jessica (University of Colorado, Boulder), Arthur Joyce (University of Colorado at Boulder) and Raymond Mueller (Stockton University) [82] Settlement beyond the Alluvial Plains: Recent Findings from the 2016 Río Verde Settlement Project (RVSP), Coastal Oaxaca, Mexico

From January–June of 2016, an interdisciplinary dissertation study was conducted in the lower Río Verde Valley, Oaxaca, Mexico which was designed to investigate how prehispanic settlement patterning was affected by environmental productivity. The Río Verde Settlement Project (RVSP) included a continuation of the regional full-cover survey as well as a systematic sedimentological sampling program to examine regional variation in soil fertility. This paper focuses on the initial results of the survey, which includes promising information for answering two major research questions. First, after environmental changes led to floodplain expansion and estuary formation (c.a. 1800–150 BCE), did settlement concentrate around these resource-rich areas? Second, if people did indeed congregate around the floodplain and estuaries, was there a time lag between the ecological changes and settlement shifts? Preliminary evidence suggests that: 1) more people were attracted to the less productive piedmont and secondary valleys than previously surmised; and 2) a time lag occurred in some resource-rich habitats of the valley before a settlement increase took place. We will explore potential factors behind settlement outside these productive areas, ranging from historical memory of landscapes to variation in agricultural productivity across the lower Verde region.

A Colorful Past: Assessing Motivations for the Acquisition of Turquoise in the Ancient U.S. Southwest

Turquoise is an icon of the U.S. Southwest, long drawing value as a metaphor for moisture in the arid region. As color and material, turquoise is fundamental to the worldviews of many indigenous groups. For the Hopi and Zuni people, the importance and use of turquoise dates back countless generations, to “time immemorial.” Continuities in use (e.g., ornamental style and placement in offerings) suggest deep epistemological and ideological affinities; contemporary values are clearly visible in the archaeological record. Our work examines the social uses of turquoise and other blue-green minerals in the late prehispanic Western Pueblo region of the U.S. Southwest. Informed by interviews with Hopi and Zuni consultants, we discuss how contemporary Pueblo uses of turquoise compare to (and oftentimes clarify) archaeological patterns. We assess the geologic provenance of archaeological specimens using measurements of lead and strontium isotopes. With these data, and inspired by social network analysis, we explore the social implications of turquoise exchange in the region by comparing inferred procurement patterns to those of other sourceable materials (e.g., ceramics and obsidian). We hope to provide a more comprehensive and humanistic interpretation of the factors that motivated the circulation and use of turquoise in the ancient Southwest.

Heeb, Bernhard (Museum für Vor- und Frühgeschichte), Alexandru Szentmiklosi (Muzeul National al Banatului Timisoara) and Rüdiger Krause (Johann Wolfgang Goethe-Universität Frankfurt am Main) [76]

The Museum für Vor- und Frühgeschichte der Staatlichen Museen zu Berlin, the Muzeul Național al Banatului Timișoara and the Johann Wolfgang Goethe-Universität Frankfurt am Main, have been investigating the archaeology as well as the landscape context of the Late Bronze Age settlement of larcuri in the Romanian Banat region with the support of the Deutsches Forschungsgemeinschaft for the last 10 years. The site is composed of four walled earth and timber enclosures. Its size alone makes the site unique: The total length of all four enclosures is 33 km, and the area encompassed by the walls is about 17.7 km². The investigations of the last 10 years have brought to light completely new insights into the defensive structures and the organization of settlements during the southeastern European Late Bronze Age (ca.1500 to 1200 BC). However, each new insight throws up a whole variety of new questions, which means that the research is really only in its early stages.

Space Is the Place: Integrating Context through GIS and Geophysical Surveys at Santa Cruz de Tuti, Peru

The reducción of Santa Cruz de Tuti (AKA Espinar de Tuti) in the Colca Valley is a complex archaeological site in the high Andes with occupational phases representing the Inka, colonial, and republican periods. Multiple geophysical instrument surveys conducted during planning phases, as well as concurrently with a large-scale excavation program in 2016, provided critical information on site use and depositional environment. Spatial, pattern and visual analyses reveal how domestic, public, and ceremonial spaces each suggest differing patterns of site use diachronically and synchronically. Subsurface anomalies of similar character in domestic spaces reveals a cultural pattern that is consistent with ethnographic data and suggests that pre-Spanish traditions were carried on long after Spanish occupation, while public spaces show multiple episodes of landscape modification and re-modification. Both GPR and gradiometer survey were successful for noninvasively locating subsurface cultural features, and test excavations during the 2016 season provided important clues for assessing geophysical survey results across the site. Volcanic sediments and massive fill episodes, however, create a heterogeneous subsurface particularly in the public and ceremonial spaces that impedes anomaly characterization. Integrating geophysical results with the spatial database and ethnographic data contextualizes the geophysical surveys, and provides additional data for spatial analysis.

Forecasting Climate Change Impacts and Resource Values to Set Preservation and Research Priorities

Globally, climate change represents one of the largest impending threats to archaeological research and heritage preservation. Rising sea levels and increased storm intensity cause inundation and erosion of coastal and island resources across the globe. Climate change impacts will increase in their frequency and severity in the coming decades, resulting in compromised integrity or outright destruction of thousands of heritage resources, many of which may never be identified before they are gone. Efforts are needed now to understand the extent of the problem; to identify, record, and save what can be rescued; and to study important resources that will be lost. To set research and preservation priorities, the vulnerability of resources to specific climate change impacts and their relative importance to scientific research, preservation, and other resource values needs to be understood. To this end, we advocate a modeling approach that predicts the location, timing, and severity of climate change impacts, identifies resources at risk, their resource values, and opportunity costs; and prioritizes research and preservation options based on these assessments. We highlight our work with two case studies, one from the Atlantic coast of the United States and one from the Baltic Sea region.

Soil, Hands, and Heads: An Ethnoarchaeological Study on Local Preconditions of Pottery Production in the Wei River Valley (Northern China)

This paper approaches ceramic production by combining four aspects of data: geographic background, archaeological find, ethnoarchaeological work, and material analysis. Taking the middle Neolithic site of Yangguanzi in Shaanxi as a case study, this paper examined the preconditions and processes of pottery making in northern China during the Yangshao Period (5000–3000 BC). Materials from over ten years of excavation and survey at Yangguanzi and the results of ethnoarchaeological studies in the same region were compared and samples were analyzed using ED-XRF. The results show that potters, both past and present, systematically sought out suitable raw materials, and preferred to work and settle close to clay and...
water sources as well as major routes of distribution. A larger scale of production may cause modern potters to use more than one type of clay and include less ideal material, a process which is also visible in the archaeological record. Both ancient and modern potters were specialized, and Yangguanzhai may even have been a specialized production center and not a normal settlement as previously assumed. As this preliminary study shows, such research could go further toward understanding the scale and organization of ceramic production in prehistoric northern China.

Helmer, Matthew (SWCA Environmental Consultants)

Social memory and ancestor veneration are recurring themes throughout Andean belief systems. Yet, the relationship between ancient Andeans and the archaeological ruins they encountered remains an underexplored research topic. Recent fieldwork at Samanco, an Early Horizon coastal settlement in Peru ca. 1470–1534 CE, has for larger issues within Maya studies. Excavations conducted during the Actuncan Archaeological Project 2015/2016 field seasons examined GPR anomalies in the Northern Neighborhood region of the Actuncan, Belize site; the proposed poster will discuss evidence of terracing obtained from these excavations, including how these probable terraces were built, their arrangement within the larger landscape, and their possible role in water drainage and agricultural production. Excavations revealed multiple possible terracing and water drainage systems, including: 1) terraforming to create berms made of yeso, a soil comprised of gypsum; 2) a traditional stone terrace made of limestone and chert cobbles with domestic fill on its western side, reinforcing the terrace from water draining downslope; and 3) short, plastered, sloping walls that appear heavily eroded by water drainage and may have provided water drain channels. These systems may reflect the different ways in which the ancient Maya at Actuncan managed water and agricultural production, as well as address larger issues regarding site spatial distribution and the role of state institutions in the creation and maintenance of agricultural production and landholding.

Heindel, Theresa (University of California—Riverside)

Recent studies on ancient Maya agriculture address differences in farming methods used within the Maya area, and the implications these differences have for larger issues within Maya studies. Excavations conducted during the Actuncan Archaeological Project 2015/2016 field seasons examined GPR anomalies in the Northern Neighborhood region of the Actuncan, Belize site; the proposed poster will discuss evidence of terracing obtained from these excavations, including how these probable terraces were built, their arrangement within the larger landscape, and their possible role in water drainage and agricultural production. Excavations revealed multiple possible terracing and water drainage systems, including: 1) terraforming to create berms made of yeso, a soil comprised of gypsum; 2) a traditional stone terrace made of limestone and chert cobbles with domestic fill on its western side, reinforcing the terrace from water draining downslope; and 3) short, plastered, sloping walls that appear heavily eroded by water drainage and may have provided water drain channels. These systems may reflect the different ways in which the ancient Maya at Actuncan managed water and agricultural production, as well as address larger issues regarding site spatial distribution and the role of state institutions in the creation and maintenance of agricultural production and landholding.

A “Color” Test: Subsistence Practices among Racially Integrated Communities between 1839 and 1890 in the Midwest Region

Sitting one quarter of a mile from the banks of the Ohio River in New Richmond, Ohio, are the foundational remnants of a nineteenth-century schoolhouse and associated dormitory. The historical and archaeological work of this site are part of an ongoing transdisciplinary project, named for the school, The Parker Academy Project. The college preparatory academy, opened in 1839 by Reverend Daniel Parker and his wife, Priscilla Parker, is the first known documented school in Ohio to accept anyone regardless of race, gender, or religion. Archaeological evidence uncovered at the site, and archival records indicate that residents of the academy lived together in unison sharing daily chores and activities. Foodways during the antebellum and postbellum periods have been well documented on both black and white communities, however, less research has been conducted to discern if foodways continued to reflect individual sociocultural behaviors upon convergence, or if each culture adapted to one another’s practices. The methodology in this research is preliminary, but it includes compiling a comparative literature analysis using historic documents, Parker Academy archives, and that from other racially integrated sites between 1839 and 1890. Furthermore, text analysis will be supplemented by cultural materials uncovered from all sites researched.

Heinzel, Danielle

Built on Sand: The Historical Roots of Modern Queerphobia within Christianity

Homosexuality’s place within the church has been a topic of considerable debate among modern theologians. However, most theologians have only focused on homosexuality, disregarding the presence of all other alternative sexual identities and have used only Biblical textual evidence to justify their views on homosexuality. This text contributes a broader scope to the sexuality debate. It considers all queer sexualities, archaeological artifacts, and uses a queer theoretical lens to deconstruct the normalization of queerphobia within Christianity and to propose a new way for understanding the Bible as a source. Because the beginning of queerphobia in Christianity is difficult to trace using the archaeological record, a parallel study in which archaeology can be used to understand the foundation of another prejudice has been considered. This work argues that the emergence of queerphobia parallels the emergence of “false monotheism,” including prejudice against polytheism, since both are rooted in misogyny, individual biases, and function to ensure the continuity of the church, unified under one god, Yahweh. Rather than suggesting that these prejudices are justified by God, this article shows how human biases have worked to wrongfully shape Christianity and cause discrimination toward others.

Desperate Times, Distinctive Places: Human Landscape Interaction at Tzak Naab, Belize

Located in northwestern Belize, the ancient Maya site of Tzak Naab lay at the intersection of an urban polity and vital agricultural space during the Terminal Classic, a period of considerable ecological and economic stress. The monumental architecture of the site strays from regional grammars with an atypical spatial syntax that emphasizes a connection to an adjacent bajo, a seasonally inundated wetland significant to the regional political economy. Attention to site planning and experiential aspects of place suggest that Tzak Naab served as a nexus for community ritual practices related to agricultural fecundity. By contextualizing the site within the greater political landscape—and critically evaluating the degrees of difference in built environments as well as the object assemblages—this paper demonstrates that localized cosmology is capable of permeating the material milieu. We argue that the idiosyncrasies present at Tzak Naab constitute meaningful and distinctive choices that represent a transformation in the religious and ritual priorities of a community negotiating the anxieties of changing environmental conditions.

Social Memory and the Reuse of Archaeological Ruins: Preliminary Insights from a Chimú-Inka Elite Gravesite at Samanco, Nepeña Valley, Peru ca. 1470–1534 CE

Social memory and ancestor veneration are recurring themes throughout Andean belief systems. Yet, the relationship between ancient Andeans and the archaeological ruins they encountered remains an underexplored research topic. Recent fieldwork at Samanco, an Early Horizon coastal settlement in
the Nepeña Valley, shows intriguing mortuary practices of reutilizing site ruins as cemeteries. After an abandonment hiatus over several centuries, Samanco’s ruins of stone enclosures were reutilized as a cemetery for local groups. Eventually, site ruins became a burial ground for high ranking members of society, showcased in a spectacular multi-room grave complex excavated in the heart of Samanco. The grave complex dates to provincial Inka rule during the Late Horizon. I will be presenting the rich material contents of the grave, and preliminary evidence suggesting usage of coastal archaeological ruins as venues of social memory associated with ancestor veneration. I suggest the possibility of ‘deep’ ancestor veneration, linking later coastal populations to apical ancestors through mortuary practices at site ruins. Such practices may have been vital to Late Horizon leadership and coastal identities, after the imposition of the Inkas.

Henao, Julian (Simon Fraser University) and Suzanne Villeneuve (Simon Fraser University) [258] Advancing the Analysis of Complex Stratigraphy and House Life Histories at Keatley Creek on the Northwestern Canadian Plateau

Digital methods have led to a new research paradigm in archaeology and have transformed the way in which archaeologists can engage with archaeological contexts or materials and ultimately understand the past. This paper discusses a few highlights resulting from implementing digital oriented methods and combined new conceptual approaches in the research at Keatley Creek on the Northwestern Canadian Plateau. Two primary objectives for digital methods have included improving resolution and understanding of complex stratigraphy, especially in large housepit rim deposits, and correlating various results to help advance stratigraphic interpretations. Primary focus has been on a combination of high resolution imaging and image processing, photogrammetry and GIS techniques for rectifying imagery and spatially analyzing various excavation data. The results emerging from Keatley Creek are helping to demonstrate how significantly different field interpretations can be for complex stratigraphy when a combination of digital approaches are applied in comparison to traditional methods. This has important implications for understanding the formation processes of houses, monitoring changes over time, interpretations of house life histories and extending this to reconstructing entire site or regional chronologies. These new developments are providing significant advantages in how we understand early cultural developments and hunter-gatherer adaptations on the Canadian Plateau.

Henderson, A. Gwynn (Kentucky Archaeological Survey) and Linda Levstik (University of Kentucky) [97] Investigating a Shotgun House: Piloting a new Project Archaeology Shelter Investigation

"Investigating a Shotgun House" draws on diverse data sources to examine the lives of poor, mid-twentieth-century working-class people in Davis Bottom, a historically integrated neighborhood near downtown Lexington, Kentucky. Piloting drafts of the investigation were integral elements in its development. A weeklong teachers’ academy provided revisions to the draft, which was then piloted by four 5th–7th grade teachers who had attended the academy. Feedback from interviews with both teachers and students shows that the investigation provides a rich, inquiry-based learning experience. Teachers could make clear links to their mandated curriculum, and students enthusiastically embraced the unit. Unanticipated outcomes included the lack of time which prevented most teachers from teaching the preservation thread of the unit, the way the students identified with the Davis Bottom residents and aspired to live in a racially diverse neighborhood, and the unit’s relevance for challenging students to consider broader themes such as civil rights, economic inequalities, and the uses and abuses of power.

Henderson, Cory A. (Department of Anthropology, University of North Carolina at Greensboro), Ryan M. Byerly (Far Western Anthropological Research Group), Cynthia M. Fadem (Department of Geology, Earlham College), Curran Fitzgerald (Department of Anthropology, University of North Ca) and Charles P. Egeland (Department of Anthropology, University of North Ca) [305] Patterns of Hominin Land Use and Raw Material Procurement in the Paleo-Olduvai Basin, Tanzania

Suitable toolstone was a key affordance for Early Stone Age (ESA) populations across Africa. Northern Tanzania’s Olduvai Basin, because it contains numerous ESA archaeological localities and a variety of quartzitic outcrops, offers an excellent opportunity to evaluate the effect of raw material distribution on hominin land use. While the lithology and mineralogy of these outcrops have been well described, their macroscopic similarities confound efforts to reliably determine the exact source of quartzite artifacts. Here, we provide quantitative geochemical data that (1) statistically distinguish three of the Basin’s quartzite outcrops, and (2) probabilistically identify the origin of a sample of artifacts from several of the Basin’s important ESA lithic assemblages.

Henderson, Lucia (Denver Art Museum) [182] Changing Faces: Evolutions in Art at Kaminaljuyu, Guatemala

The site of Kaminaljuyu experienced intensive ideological and material cultural change from the Preclassic through the early Classic period. Certain artistic forms and ideological precepts, however, simultaneously demonstrate remarkable continuity. This talk focuses specifically on public messages communicated through stone sculpture as well as, to a lesser degree, messages communicated by elite and royal funerary contexts in order to access continuity and change in Kaminaljuyu’s archaeological and art historical record. This talk argues that shifts in elite material culture and public art reflect efforts by the Kaminaljuyu elite to communicate their participation in shifting ideological, political, and economic marketplaces over time. While many underlying ideologies remain consistent, one finds dramatic changes in how these messages are communicated through public art and elite funerary contexts through the centuries. One of the most important factors in recognizing and analyzing these developments is the recent identification of an indigenous structural tradition, native to the Southern Region, which arose after the Olmec style fell out of favor. Since this locally developed style articulated locally relevant messages, it provides scholars with a baseline, highlighting the ways in which these messages and the format of their presentation changed through time.

Hendon, Julia (Gettysburg College) [5] Fine Dining and Social Position among the Classic Period Maya and Their Neighbors in Honduras

Drawing on the substantial body of information that has accumulated over decades of research on the kingdom of Copan and its southern and eastern neighbors, I address the question, What were the key components of Maya meals that turned dining into an important, flexible, and subtle way to embody status? This paper draws together information from a range of methods and bodies of data including ethnobotanical and archaeozoological studies, chemical analyses, research on human skeletal remains, visual imagery, text, artifacts, and architecture. No one approach can answer the question posed in this abstract but collating the many specific studies may provide a way to construct a more complete picture of the relationship between Maya cuisine (including such topics as what was served, how, and when) and social identity, including class and gender, as well as political authority.
The Resurgence of Geometric-Patterned Regalia on the Northern Northwest Coast

Hendrickson, Steve and Janice Criswell (Weaver)

In the late 1980s, weaver and scholar Cheryl Samuel studied these survivals, documented them in great detail, and developed curriculum to teach these traditions. Only a dozen of these early robes (or archaeological fragments thereof) remain in museums. In Regalia woven using the “Chilkat” technique appeared on the northern Northwest Coast in the early nineteenth century, apparently replacing an older tradition of regalia decorated with geometric patterns. This resource colonization is suggested to be of major economic importance and fundamental for the understanding of social development during the Viking age.

Hendrickson, Mitch [29] see Fischer, Christian

Viking Age Tar Production and the Exploitation of the Outlands

Hennius, Andreas (Department of Archaeology and Ancient History, Uppsala, Sweden)

In Sweden, recent excavations have revealed how the production of tar evolved from a small scale, household operation situated within the settlements of the Roman Iron Age, to a large-scale activity in the forests during the Vendel and Viking periods. The resulting quantities of tar far exceeded ordinary household requirements. This change in production coincides with the introduction of the sail, characteristic for the Viking Age, with extensive need for large amounts of tar. The change in character of tar production follows a pattern seen in many other handicrafts during the same period, with an intensification of production beyond the farmsteads and exploitation of areas such as forests, coastal zones or mountains—what in Swedish is termed “Utmark”—the Outlands. In addition to reviewing this tar production, the paper will discuss the exploitation of the outlands, with their vast reserves of raw materials. I argue that the increased outland use can be seen as a new way of organizing society, managing labor, the landscape and its natural resources. This resource colonization is suggested to be of major economic importance and fundamental for the understanding of social development during the Viking age.

There and Back Again: Dick Jefferies, Winchester Farm, and Middle Woodland Interaction across Central Kentucky

Henry, Edward (Washington University in St. Louis), George Milner (Pennsylvania State University) and Natalie Mueller (Washington University in St. Louis)

Adena-Hopewell enclosures complexes have inspired much conjecture and some well-supported inferences concerning the rise of Middle Woodland ceremonialism, interaction, and social organization in the Eastern Woodlands. After examining Hopewellian interaction at Tunacuratee in Northeastern Georgia, Dick Jefferies turned his focus to Adena-Hopewell mound and enclosure sites in Central Kentucky. Dick’s examination of the Winchester Farm Enclosure in the early 1980s with George Milner was the first research on this little-known earthen enclosure within the Mount Horeb complex. His direction of a geophysical survey with Edward Henry at the site in 2009 led to its discovery as the only known “squircle” in Kentucky, an enclosure form common in the Ohio Hopewell heartland and elsewhere. Recent excavations at Winchester Farm included a trench through its ditch and embankment, as well as an area inside the enclosure. Construction methods are comparable with other enclosures in the Mount Horeb complex, but the site was used differently. Here we put the construction, use, and abandonment of this enclosure in a larger cultural and temporal context. The chronology of Winchester Farm calls into question culture historical constructs like “Adena” and “Hopewell,” and suggests Middle Woodland interaction in the Kentucky Bluegrass occurred longer than previously thought.

[395] Contact and Colonial Impact in Jamaica: Comparative Material Culture and Diet at Sevilla la Nueva and the Taino Village of Maima  
In June 1503, Columbus and his two battered ships were run aground in the sheltered harbor of St. Anns Bay Jamaica, 1.4 km from the Taino village of Maima. After spending a year marooned there, the Spanish left with the knowledge of the people and resources of the area. Six years later, in 1509, the Spanish returned to found the Jamaican colonial capital of Sevilla la Nueva. By the time Sevilla la Nueva was abandoned in 1534, Maima was deserted. Historical records kept by the colonists indicate that the villagers were brought to the colony and made into laborers and wives. The material culture and dietary practices at Sevilla la Nueva reflect this through the presence of colonoware and Taino adapted European goods. At Maima, very few adapted European goods and remains of domesticate animals were found. This, and the presence of traditional material culture and diet throughout the site, indicates continuity of a traditional way of life until their final act of resistance, abandoning Maima. This paper will discuss the adapted European/Taino material culture and faunal remains found at both Sevilla la Nueva and Maima, illuminated, in some way, the ultimately devastating impact of contact and colonialism.

Hensler, Rachel (University of Kentucky)  
[163] Native American Interaction during the Spanish Contact and Mission Period on the Central Coastal Plain of Georgia, USA, AD 1540–1700  
This paper examines how interaction between Native American groups living in areas of indirect contact changed during the Spanish colonization of the southeastern United States. The project area, the Big Bend Region of the Ocmulgee River Valley in the central coastal plain of Georgia, had ties to the Spanish mission region in both prehistoric and historic periods, though there was little direct interaction between Spanish missionaries and Native Americans. Using technological style as a theoretical backdrop, I demonstrate how interaction changed through time by defining the step-by-step sequence of ceramic production, from clay selection to final decorative attributes. Results show that the production sequence changed through time in the region and decorative attributes suggest increasing contact with groups living in coastal Georgia, where there was a string of Spanish missions. Though interaction with other groups may have changed, the potters of Ocmulgee Big Bend remains a relatively cohesive potting group despite the changing world around them, as the effects of European colonization spread through the southeastern United States.

Heo, Jina (University of Wisconsin-Madison)  
[333] Early Urban Configurations in Mahan, Korea: Local and Regional Approaches to Settlements dated to 100 BCE–CE 300  
Mahan, composed of 54 polities in central and southwestern Korea, grew rapidly from 100 BCE to CE 300, by which time it covered about 40,000 km², with a population of roughly 500,000. During much of this time, urban zones became the dominant residential mode at both local and regional levels, but without suggesting a strong central authority. No unequivocal capital cities have been identified. At the same time, there is evidence of a dual-urban organization with distinctive functions in terms of social networks, economic activities, and political opportunities led by socioeconomic diversity between the Mahan polities. The local urban centers surrounded by elites’ cemeteries, which were bounded with identical forms of pottery and houses, were mostly formed in agricultural sustaining areas. On the other hand, the regional urban centers represented different social groups and craft activities of iron and bead working, concentrated in the location of possible nodes in wider regional and transregional transportation networks with relatively dense population and prolonged persistence. Urban centers in Mahan may have developed at both local and regional levels, serving different functions because of a high level of economic interdependence between a variety of economic and social groups.

Hepburn, Joseph (Simon Fraser University), Brian Chisholm (University of British Columbia) and Michael P. Richards (Simon Fraser University)  
[258] Isotopic Perspectives on Spatial and Temporal Variability in British Columbia Paleodiet  
This study aggregates and reevaluates all available stable isotope data from archaeological human remains in British Columbia. Isotope signatures for coastal individuals correspond well with the heavy marine specialization attested to by archaeological and ethnographic studies of traditional Northwest Coast diets. Within this marine specialization, the data for coastal BC demonstrate a high degree of regional dietary variability, although high trophic level marine species are of ubiquitous importance. No large-scale temporal shifts are present in coastal diets, with consistent carbon and nitrogen δ-values across the entire timespan represented. Despite the near universal marine specialization, notable outliers exist throughout the coast, with three individuals’ fully terrestrial diets contrasting significantly with regional dietary patterns. In the BC interior diets are much more variable, representing a range between purely terrestrial to mixed marine (anadromous fish) and terrestrial. Along salmon-bearing rivers, the apparent marine component of diet is positively correlated with downstream proximity to the ocean.

Hepp, Guy (California State University, San Bernardino)  
[357] Evidence for the Emergence of Social Complexity in Early Formative Period Coastal Oaxaca, Mexico  
The emergence of sociopolitical complexity, and its connections to other developments such as changing subsistence and domestic mobility, has been a central theme of archaeology for over a century. Mesoamerica has been no exception to this trend, and scholars of pre columbian Mexico and Central America have scrutinized socioeconomic correlates of changing political integration and centralization. One concept central to this research has been that of hereditary hierarchical inequality. In fact, ancient societies are often considered complex on the basis of producing evidence for such hierarchies. Even as incipient inequality has been traced further back in time in parts of Mesoamerica (to the Early Formative period [2000–1000 BCE]), questions remain regarding how ostensibly “egalitarian” groups became “transegalitarian,” or began shifting toward permanent inequalities. In this paper, I join a few other researchers in arguing that hierarchical distinctions were foundational to Mesoamerican complexity. I present iconographic and mortuary evidence from the Oaxacan site of La Consentida, one of the earliest known villages on Mexico’s Pacific coast. I conclude that distinctions in attire and in specialized knowledge evinced at La Consentida suggest one avenue through which egalitarian peoples laid the foundation for the famous complex civilizations of later Mesoamerican history.

[360] Navigating Global and Local Attitudes Toward Heritage Initiatives in Southern Costa Rica

This paper explores the dynamic between local and foreign perceptions toward cultural and environmental exploitation and stewardship, presenting recent reactions to medium to long term initiatives that have been started by national and international institutions in southern Costa Rica. It reviews how
researchers are attempting to better integrate themselves with local communities and national organizations in a more sustainable and responsible manner, presenting the current challenges encountered while trying to implement a bio-cultural tourism and education model in the Osa Peninsula of Costa Rica. The variable acknowledgement of precontact cultural resources and environmental corridors, tension between what is often perceived as foreign versus local priorities, and differing attitudes within Costa Rican society are central to understanding the range of meaning among multiple stakeholders. Using the Osa region as a case study, the paper reviews the multivocal definitions of heritage, identity and landscape that have produced varying levels of cooperation, collaboration as well as tension and resistance. Addressed within a general historical ecological approach, it summarizes the evolving nature of research and conservation methodologies and its implications for global and local economic and cultural interactions.

[158] Contrasting Worldviews in Hispaniola: Places and Taskspaces at the Age of Colonial Encounter

Landscape has been a useful analytical tool for archaeologists for a long time. Its definition since its first uses in the discipline has grown and diversified to the point that it has been called a “usefully ambiguous” concept. However, this broad definition should not be applied everywhere and in every temporal/historical context. This concept should not be used as a straightforward analytical tool but requires a critical contextual revision. For an alternative approach in the area of this research, I am using Ingold’s concept of taskspace and place to analyze and interpret the conflicting relations between the indigenous population of Hispaniola island and the Spaniards as a result of the beginning of colonization after 1492. Moreover, when relating Ingold’s concept of taskspace with Descola’s symbolic ecology with particular reference to his notion of mode of identification, the resulting theoretical frame allowed to compare the different worldviews from these groups at this specific historical period. This paper will present the first results of this theoretical exploration, particularly the indigenous and Spaniard intentionality behind their own spatial patterning in relation as well with material culture and the environmental context.

[124] Building at Bac: Chronological Challenges in Conservation at Mission San Xavier

Traces of early modern European presence in the Sonoran Desert endure today as plaster-white mission churches dotted across the arid landscape. Established by Jesuits as early as AD 1691, Mission San Xavier del Bac in Tucson, Arizona is unique in its continued usage as a modern Catholic church. Its long-standing occupation necessitates nearly-constant conservation practices, which must be complementary to the church’s original construction. However, the absence of nearly two-hundred years’ (AD 1691–1864) worth of church records consigns the information regarding the mission’s early building and repair history to a few oblique textual references and sporadic, modern archaeological sampling. Coupled with multiple building phases and sometimes ambiguous construction methods, assumed biographies of the structures seen today are incredibly convoluted. As recently as January 2015 and August 2016, foundations near the East Tower exposed during routine restoration have revealed inconsistencies with the fragmented early historical records. Solidifying a building chronology for this beautiful, historic mission church has become paramount in addressing difficulties in conservation practice, especially as restorative work on the mission foundations becomes more necessary. In particular, dendrochronological analysis of reused timber in the southern convento wing may attach the church’s early history to a calendar date.

[220] Tabuchila Ceramics of the Jama River Valley, Manabi, Ecuador

Archaeological excavations by the Proyecto-Paleoetnobotánico Río Jama (PAPRJ) in the Jama River Valley of northern Manabi, Ecuador, have established a cultural chronology spanning over three millennia of prehispanic occupation. One of these occupations, the Tabuchila Complex of the Late Formative Period (1000—500 BC), remains poorly understood. Excavations at three sites in the Jama Valley in the 1990s recovered ceramic, lithic, obsidian, paleobotanical, archaeofaunal, and human skeletal remains from Late Formative Tabuchila contexts, with the goal of orienting Late Formative occupation of the northern Manabi region to its contemporaries in western lowland Ecuador. This study employs a methodology of modal ceramic analysis to recognize and catalogue formal and stylistic variation within the recovered Tabuchila ceramic assemblage. Through this analysis the Tabuchila assemblage is compared to other studies of Middle and Late Formative culture, to understand how Tabuchila represented a regional variant of and contributor to the formation of the Chorrera ceramic tradition.

[338] Manot 1 Brain Characteristics

Manot is a nearly-sealed, active karstic cave located in the hilly landscape of the western Galilee, Israel. It contains abundant archaeological accumulations attributed to the early phase of the Upper Paleolithic (UP) period as well as evidence for the Middle Paleolithic (MP). During the initial survey of the cave (2008), a nearly complete calvaria (Manot 1) was found. The specimen was dated to ~55 ky by the U-Th method. In an earlier study, Hershkovitz et al 2015 described the morphometrical characteristics of the calvaria and discussed its possible taxonomy and populations’ affinity. The present study focuses on the Manot 1 endcranial features and the brain endocast traits and compares them to contemporaneous and modern brains in order to shed light on brain evolution during the last 50 ky.

[301] A Spatial and Predictive Model of Archaeological Sites on the Lincoln National Forest

The Lincoln National Forest has produced a wealth of GIS data on archaeological sites in Southeastern New Mexico. This data has not yet been analyzed. This poster presents a predictive spatial model of archaeological sites on the Lincoln National Forest to provide information on the interaction between people and the environment and the changing use of the landscape over time. In this project, I have developed a predictive model of archaeological sites based on a statistical analysis of environmental variables and test it by withholding a sample of sites. I also examined the distribution and density of archaeological sites relative to geographic and environmental factors, site distribution and density over time, as well as the
changing use of the landscape of the Lincoln National Forest. As southeast New Mexico is a region often overlooked in archaeological research, this project represents an important preliminary exploration of spatial data in the region.

[351] Mitigation of the Alder Creek Mining District, Sacramento County, California
The mission of the U.S. Army Corps of Engineers’ (Corps) Regulatory Program is to protect the Nation’s aquatic resources while allowing reasonable development through fair and balanced permit decisions. The Corps consults with federal agencies and other consulting parties, in a collaborative effort, to develop appropriate mitigation measures when adverse effects to historic properties cannot be avoided. A new development was proposed that would adversely affect the National Register of Historic Places-eligible Alder Creek Corridor Mining District (ACCMD), a historic district containing early placer mining, drift mining, and ground-sluicing features, as well as low-pressure hydraulic, dragline, bucket line, and mechanical dry-land dredging tailings and features, located in Sacramento County, California. The Corps worked with the California State Historic Preservation Officer and the permit applicant to develop a mitigation strategy to address the proposed adverse effects to the ACCMD. The mitigation strategy includes LIDAR mapping, archaeological excavation, data analysis, installation of public interpretive displays at recreational areas located within the ACCMD, and the long-term preservation and management of a portion of the ACCMD. This presentation discusses the mitigation strategy, results to date, and ongoing work to complete meaningful mitigation with tangible results for the benefit of the public.

[77] Grassroots Modernization: Pastoral Economies, Climate, and Political Change in Iceland’s Eighteenth through Twentieth Centuries
The intersecting tensions among Iceland’s hay cultivation, livestock productivity, and climate have a long history and a significant influence on both political discourse and local knowledge production. In the eighteenth century, Iceland was assessed by its Danish colonial government as being a marginally productive region in terms of its significant rural surpluses. Even in spite of producing some surplus, the country struggled with periodic famines until the late nineteenth century. These events and perspectives were produced in the context of a highly variable climate which at times severely impacted grass growth and the hay harvest. However, in our study area, the Mývatn region, farmers ecologically restructured their upland, wetland landscape and surpassed perceived limitations on grass and livestock productivity. These shifts were enmeshed with significant social change; a transition away from feudal style governance and toward participation in capitalist free markets. This collaborative interdisciplinary research synthesizes archaeological data, historical documentary evidence, primary sources of ecological information, and climate data in order to understand these deliberate cultural and ecological changes.

[137] Motherhood at Majatepec: A Hypothesis Based on an Early Colonial Period Cemetery in the Sierras Sur of Oaxaca
In 2011 and 2013, the Nejapa/Tavela Archaeological Project explored a possible Early Colonial period cemetery (AD 1550–1650) at the site of Majatepec. The excavated portion of the cemetery included eight individuals from five burials, wherein four were subadults, at least one of which is likely a woman, and four were children. In spite of the overall poor preservation, it is clear that the children and subadults were buried together, without accompanying household members of older ages and both sexes. By bringing together ethnohistorical and archaeological information from Oaxaca on marriage and child-rearing, we argue that the Majatepec funerary rituals represent cultural hybridization of indigenous and Spanish practices connected with the social and cultural construction of motherhood and mothering. In particular, we argue that the close bond between young mothers and children attested in ethnohistorical accounts from the 1800s and 1900s extended from life into death, impacting funerary rituals during the Early Colonial period.

Higgins, Howard (TRC Environmental Corp.)
Most consultation occurs as part of NEPA and/or Section 106 compliance. That is, there is a predefined, location specific undertaking that concerns traditional communities, such as Native American entities, who are contacted and with whom consultation occurs. This is not, however, the only, or even the best, process by which traditional peoples may be included in consultations with land managers. Some land managing agencies have recently been adopting more proactive approaches. One example of such an approach is that recently followed by Santa Fe National Forest staff. This approach was designed to create and foster ongoing communication with traditional communities concerning projects within those portions of their traditional lands under management by the Forest Service in the Jemez Mountains of central New Mexico. This approach included the initiation of consultation with both Native American tribes and traditional Hispanic organizations well in advance of the federal actions. This paper examines the original concept of the consultation, how it was implemented, and results. Difficulties and drawbacks (as well as strengths and benefits) of the approach are discussed.

[124] Reformulating Cultural Heritage Management Strategies in the Post-Soviet Caucasus region
The inheritance of Soviet-molded approaches to cultural heritage has seen slow changes in the last two decades in ex-Soviet South Caucasian countries. This is not surprising: if the same specialists continue to run and manage heritage change is expected to be slow; new generations are just starting to work in state agencies. The exposure of the systems to new approaches and its practical application is a difficult task. To compound the problems, the heritage of Georgia, Azerbaijan and Armenia is very mixed. These three countries, of distinct religious majorities, have a mix of the majority, hence overlooking the heritage of minorities even when the latter populations are still thriving. This complex population and heritage mix is a consequence of Soviet population movements. These will continue to mark the diversity of these countries, as populations are, for the time being
staying put. In this paper I will describe two cases in the realm of heritage management: a long-term documentation project in Azerbaijan and a case for seeking the private management of an archaeological site in Georgia.

**[57] Drones in the Desert: Unpiloted Aerial Vehicle (UAV) Survey in the Black Desert, Jordan**

Unpiloted Aerial Vehicles (UAVs) and photogrammetry provide a precise tool for high resolution surveys of arid landscapes. In 2016, as part of the Eastern Badia Archaeological Project, we undertook a large survey (32 km²) in the remote Black Desert of eastern Jordan. Although excavation has been ongoing in the survey area for several years, many extant Neolithic structures have not been properly mapped or identified because of the large number of structures and the large scale of the area. For the most part, these stone structures are too small to be effectively mapped by satellite imagery and too spread out to be effectively mapped using traditional terrestrial survey tools. Our survey provides important documentation of the archaeological landscape and a tool for decision making on future work in the region.

**Hill, Christopher L.**

**[87] Late Quaternary Radiocarbon Geochronology and Stratigraphy on the Northern Plains: Silts, Mammoths, and Buried Soils in the Lower Yellowstone Valley, Montana**

Within the Yellowstone River basin, in eastern Montana, upland landscapes contain silts with buried soils. Radiocarbon measurements from bone and the paleosols provide a basis for proposing a regional chronostratigraphic model. At the Lindsay locality, north of the Yellowstone River, mammoth remains were recovered within silts overlain by a buried soil A-horizon. Samples from the mammoth have been analyzed by six laboratories, using beta decay or AMS. If the radiocarbon determinations older than 12,000 RCYBP provide the most accurate age estimates, then the mammoth is older than the Younger Dryas and possibly associated with the Bølling climatic event. Radiocarbon measurements of buried soils at OUL Ridge, in the uplands south of the Yellowstone River, suggest the soils may range in age from about 11,415–9,330 years RCYBP. These silt and paleosol sequences are similar to Oahe Formation (the Aggie Brown member within the Leonard Paleosol) as well as sequences associated with the Brady Paleosol. For the most part, these stone structures are too small to be effectively mapped by satellite imagery and too spread out to be effectively mapped using traditional terrestrial survey tools. Our survey provides important documentation of the archaeological landscape and a tool for decision making on future work in the region.

**Hill, Erica (University of Alaska Southeast)**

The use of personal amulets appears to have been a common practice among northern hunting peoples of Alaska, Canada, and Greenland. Many of these amulets were intended to facilitate individual relations with sea mammals. Cooperative whaling, however, required the development of an amulet that mediated group relations with prey. This paper describes a set of Alaska Eskimo whaling “charms” dated to the late nineteenth century and identified in museum collections from across the United States. The charms, actually seats for umiat (large skin boats), represented idealized whales and were intended to flatten, attract, and secure this key prey species. As part of the material culture of whaling, umiaq amulets materialized social relations among the whaling crew, the whale, and the umiaq itself.

**[247] Archaeological Repositories in British Columbia**

This paper will begin examining the historical context for the development of archaeological repositories in BC, and the changing role they have played. Commercial archaeologists have, of late, regarded repositories in British Columbia as an afterthought, though this was not always the case. A review of the original stakeholders, and goals of archaeological bodies in BC’s past will shed light on where we find ourselves and where we should be headed. The second half of the paper will examine the changing role of repositories in light of their various responsibilities, obligations, and goals. Recent calls by the provincial government for repatriation of archaeological and cultural material to their home communities have begun to influence repository practice in BC. What might BC’s archaeological repositories look like in the future? And how can repositories, First Nations, and archaeologists work effectively together to achieve these new goals?

**[364] Reconstructing the Culture-History of Squires Ridge (31ED365)**

Until recently, the prehistoric culture-history of the coastal plain has remained the least understood in North Carolina due to a lack of known sites with stratified context and dateable components. Sites, such as Barber Creek (31PT259) and Squires Ridge (31ED365) situated along the Tar River, have archaeological data that can test the previous model (Moore and Daniel 2011; Phelps 1983). The excavations at these two sites have established the presence of archaeological sequences of four occupation zones dating from the Early Archaic to the Early/Middle Woodland. Previous studies (Daniel et al. 2013; Barbour 2014) have analyzed part of the stratigraphic sequence at Squires Ridge. Through the use of backplot, frequency, and artifact refitting analyses of the material recovered from the 2011–2012 field seasons, I have explored the stratigraphic sequence of the northern end of the site. Through the continued analysis of Squires Ridge, the culture history of the site as well as the North Carolina coastal plain as a region can be better understood.

**Hill, Mark (Ball State University)**

**[4] Elemental Analysis of Late Archaic Copper from the McQueen Shell Ring, St. Catherines Island, Georgia**

Excavations conducted at the McQueen Shell Ring site on St Catherines Island off the coast of Georgia recovered several fragments of a copper artifact. These fragments represent an artifact made from a thin sheet of copper, and were recovered from a Late Archaic feature with calibrated radiocarbon dates placing its use between 2300 and 1800 BC. Seven of these fragments were analyzed at the Elemental Analysis Facility of the Chicago Field Museum of Natural History to determine elemental composition with the intent of identifying probable sources for the copper from which the artifact was manufactured. Laser Ablation Inductively Coupled Plasma Mass Spectrometry (LA-ICP-MS) was used to collect elemental composition data for these seven fragments as well as from geological source samples representing Lake Superior, the southern and central Appalachians, and the Canadian
Maritimes. Two independent statistical analyses were performed on the resulting data. Both analyses place the most likely source for this artifact in the Lake Superior region far to the north rather than in the closer sources of the Appalachians, requiring a more complex explanatory framework to account for this long distance interaction or acquisition.

Hill, Matthew E., Jr. (University of Iowa), Sarah Trabert (University of Oklahoma) and Margaret Beck (University of Iowa) [339] The Dismal River Complex and the Continuing Debate of Early Apachen Presence on the Central Great Plains

Great Plains Apachen groups have a strong documentary presence between the mid-1500s to the early 1700s, but the archaeological record of these groups is poorly understood. Early researchers such as James Gunnerson and Waldo Wedel argued strongly that Dismal River sites represented the earliest expression for Apachen groups in the Central Great Plains. These claims are still widely accepted, in part because there is little recent work to contradict them. The exciting research on early Navajo and Promontory sites in the last decade addresses larger questions about Proto-Apachen population movements, highlighting a possible role for Dismal River archaeology in reconstructing movements to the south. So far, efforts to include Dismal River data in the larger Proto-Apachen picture often rely on outdated information. Here we synthesize current views of the Dismal River complex, focusing on new data for site chronology and ceramic technology that help us reevaluate older ideas about Dismal River identity and interactions with neighboring groups. We highlight how the Dismal River complex can contribute to broader discussions of Apachen community formation across North America.

Hill, Matthew G. (Iowa State University), Thomas Loebel (Illinois State Archaeological Survey) and John Lambert (University of California—Davis) [342] Synthesis and Assessment of the Folsom Record in Illinois and Wisconsin

Census of avocational and public collections for Folsom and Midland artifacts from Illinois and Wisconsin signals a substantial Folsom occupation in the Upper Midwest. Over 200 points and preforms demonstrate a southwest–northeast pattern of point manufacture, use, discard, and loss across much of Illinois and the southern third of Wisconsin. The distribution of these artifacts overlaps to a large extent; however, most Midland points occur in Wisconsin. This non-fluted weaponry is interpreted as a techno-situational response to the intrinsic properties and distribution of regional toolstones, combined with the relatively high cost of fluting failed during periods of focused hunting. Folsom mobility and land use are structured along major rivers, with southern Wisconsin most often functioning as a main destination of group movement. Woodland caribou (Rangifer tarandus) are the inferred focal prey and organizational driver of Folsom adaptations in the Upper Midwest.

Hilmerd, Charlotta (University of Aberdeen, Scotland), Kate Britton (University of Aberdeen, UK), Warren Jones (Qanirtuq Inc., AK, USA) and Rick Knecht (University of Aberdeen, UK) [144] Nunalleq: Archaeologies of Climate Change and Community in Coastal Western Alaska

Northern sea ice levels are at an historical and millennial low, and nowhere are the effects of recent climate change more pronounced or destructive than in the Western Arctic, with the erosion and subsequent loss of coastal archaeological sites in this area being yet another casualty. Based in the community of Quinhagak, and at the well-preserved precontact Yup’ik site of Nunalleq, our project examines the complex relationship between past cultures and ecosystems change, and the interplay between modern climate change, archaeology and heritage. Organic and inorganic artifacts and bioarchaeological material from Nunalleq allows for the examination of diverse but complementary interdisciplinarian studies of diet, population genetics, zooarchaeology, paleoentomology, climate change and culture history in the region. Using the processes, as well as the products of archaeological research, our community-based project is illuminating the impact of the Little Ice Age on precontact Yup’ik in the Yukon-Kuskokwim Delta; building sustainable frameworks for documenting local sites under threat; and providing new contexts for encountering and documenting the past.

Hills, Kendall (University of Illinois at Chicago) [214] Investigating the Socio-Ecological Entanglement of Integrative Mechanisms among the Charter States of South and Southeast Asia

The prime objective of the Socio-Ecological Entanglement in Tropical Societies (SETS) project is to produce a comparative study of socio-ecological dynamics in a variety of low-density tropical urban civilizations through cross-cultural and transdisciplinary investigations. This paper highlights the contribution of the SETS’s integrative mechanisms sub-project, whose primary goals are to examine, evaluate, and compare the integrative mechanisms evident within a sample of charter states in South Asia, Southeast Asia, and Mesoamerica. Although anthropologists and archaeologists have identified various methods of state integration, this research concentrates on the monumental public architecture and spaces of the built landscape which foster integration. Such integrative mechanisms include, but are not necessarily limited to roads, temples, monasteries, markets, administrative nodes, hospitals, rest houses, and storage facilities. The construction and subsequent maintenance of these integrative mechanisms would have been an important factor in the consolidation and stability of early tropical states. Through their construction and continual maintenance states often become highly entangled in a web of reliance and resource input with their integrative mechanisms. This form of entrapment may then lead to lower levels of resiliency, and the vulnerability of the state in general.

[151] Comparing Bone Structure and Domestic Sheep Management Strategies Using Microcomputed Tomography (microCT)  
Bone structure is known to reflect behavioral differences related to locomotion, diet, and activity patterns. We present new data using microcomputed tomography (microCT) to analyze cortical and trabecular bone structure on samples of modern domestic sheep bones from individuals with known biogeographies and life histories. Indicators of skeletal robusticity, such as thicker cortical bone, higher trabecular bone volume fraction, and thicker trabeculae, reflect consistently higher bone strain and therefore should be found in sheep that are moved frequently and/or over long distances. In contrast, penned sheep will have relatively gracile skeletons, reflecting lower activity levels and less movement. By comparing penned and transhumant modern sheep, we assess the viability of this approach to identify domestic animal management strategies in the past.

[306] Applications of Photogrammetry in Understanding Spatial and Ritual Contexts of Caves in the La Montaña Region, Eastern Guerrero  
Mapping caves has always been a daunting task, given the complexity of its forms and the usually difficult access for surveyors and their equipment. 3D modeling of the exterior and interior of some caves is now possible using photogrammetry. Here, we present how we captured the complexity of the Mesoaamerican underworld using both drones and digital photography in the caves of Guerrero.

Hirahara, Nobutaka (Waseda University)  
[211] Feasting and Concentrated Pottery Production in East Cape, Papua New Guinea  
East Cape, the southeastern tip of Papua New Guinea mainland, is one of the pottery production areas in southern Massim. Domestic pottery production has continued to the present day, mainly made by female potters to supply their own needs. However, more extensive pottery production beyond the household level occasionally occurs, especially when funerals (toleha) are held. Toleha are organized by the matrilineal descent group (gguni) of a dead person; the potters who belong the descent group get together and make the large amount of pottery used for feasting. In addition, any surplus pottery is traded with people of surrounding islands for foods served in the feast through local exchange called kidoko. The feast-associated pottery production for toleha, and local exchange are complementary. On the other hand, the pottery produced for toleha have strong stylistic similarity caused by the same technique shared with the potters. Here, I focus on the toleha pottery production system, and discuss the social linkage between stylistic similarity and the structure.

Hirasawa, Yu (Center for Ainu and Indigenous Studies, Hokkaido University), Ren Iwanami (Department of Natural History Sciences, Hokkaido U), Masaki Naganuma (Center for Ainu and Indigenous Studies, Hokkaido U), Andrzej Weber (Department of Anthropology, University of Alberta) and Hiroyumi Kato (Center for Ainu and Indigenous Studies, Hokkaido U)  
Since 2011, BHAP and JSPS Core to Core program have been conducted the joint archaeological investigation at Hamanaka 2 site on Rebun Island, Northern Japan. This site has been recognized as important sand dune site that provided well-preserved archaeological materials date back to middle Jomon period (ca. 5500–4500 cal BP). Interdisciplinary studies conducted by participating scholars produced significant outcomes in archaeology, physical anthropology, molecular biology, paleobotany and radiocarbon dating. Until today, we gradually gained our knowledge of the site structure. Hamanaka 2 has five major archaeological periods in the same area. On the one hand, broadly distributing shell midden layers formed during Okhotsk cultural periods (ca. 1500–900 cal BP) contained rich fish and sea mammal remains with a few human remains. On the other hand, other Jomon (late—final), Epi-Jomon and Historical Ainu layers represent different site function because of less fish and shell remains. Despite of these differences, there are marine-related ritualistic evidences from different cultural components that suggest physical and mental connection between people and marine resources. In this paper, authors report current results of research on Hamanaka 2 and discuss differences and similarities of in-site activity with excavated evidence.

[212] Digging into the Supernatural World. Cinema’s Intrinsically Religious Depiction of Archaeology  
Over the last half century film makers have created hundreds of movies about archaeologists. Many of these films present narratives that are located in supernatural worlds and explicitly religious in character. Within these supernatural and extraterrestrial stories, archaeologists are positioned as mage or priest, the individuals with the knowledge to release magic into the world or to prevent release. These fictional representations of archaeologists as active participants in supernatural dramas advocate pseudoarchaeological and religious views that reflect nonscientific beliefs popular in film studios as well as with audiences across the globe. This paper explores the ways in which film-makers have created a concept of archaeologist that has helped them pursue mythic imperatives.

[152] Patterns in Amino Acid Delta 15N Values of Lemurs Are Inconsistent with Aridity Driving Megafaunal Extinction in Southwestern Madagascar  
Early human colonists of Madagascar encountered a diverse endemic fauna during the late Holocene that included elephant birds, pygmy hippos, and giant lemurs. All fauna >10 kg went extinct in the past 1,000–2,000 years. Direct human predation and anthropogenic landscape change help explain
aspects of the extinction pattern. Increasing aridity may have also played a role in some regions, but its contribution remains controversial. We track changes in aridity during the past 4,000 years in southwestern Madagascar using nitrogen isotope (delta 15N) values of individual amino acids preserved in bones from extinct Pachylemur and extant Propithecus from two subfossil sites: Tsimarv and Taolambiby. We use the delta 15N values of source amino acids as a proxy for aridity and the spacing of delta 15N values between source and trophic amino acids to quantify the trophic position of these lemurs. Despite paleohydrological evidence for a lowering water table and paleoecological evidence for the expansion of relatively arid savanna between 4,000 and 1,000 years ago, the isotopic data indicate that extinct lemurs did not live in increasingly arid habitats. Thus, aridity cannot be the primary driver of lemur extinction in southwestern Madagascar.

[74] An Intersectional Archaeology of Colonial White Male Privilege?  
I suggest that it is worth pursuing an archaeology of white male privilege through the contextual study of white privileged males. Among many outcomes, this project can de-naturalize “maleness” and “whiteness” as nomothetic and unmarked—thereby advantaged—social categories and reveal systematized advantage/oppression. Historical gendering was a nuanced process. Masculinity had multiple practiced and experienced forms. They persisted even within a tightly controlled environment, such as colonial Harvard College in Cambridge, Massachusetts. There, enfranchisement was shaped by gender, which was itself realized through age race, ethnicity, spirituality, and status; by physical and intellectual capacity, education, and personhood; by consumer and sexual desires; and by the material things and physical settings through which social reproduction took place. A study of intersecting identities may offer special insight into the invention of masculinities and their association with authority in colonial America. Intersectionality is even embedded in the now-familiar phrase “white male privilege,” which presumes an essential relationship between race, gender, and power. But the experiences of young, well-connected, educated Englishmen are not a typical subject for an intersectional approach. This paper asks if an archaeology of colonial white male privilege can, or should, benefit from Intersectional Theory and considers possible paths forward.

Hodges, Charles (Pacific Geoarchaeological Services)  
[51] Late Pleistocene-Holocene (LPH) Paleogeography of the Bear Creek Site (45KI832), Puget Lowland, Western Washington  
Stratigraphic and soil horizon sequences within the boundaries of archaeological sites are remnants of formerly more extensive paleolandscapes. Since these fragments have both spatial and temporal boundaries extending beyond the site boundaries, the sedimentary and soil bodies defined within an archaeological site represent segments of past landscapes and reflect, sometimes indirectly, relationships with the broader surrounding paleosystem. In order to further our understanding of LPH human-land interaction, we develop here a preliminary model of the landscape elements in the vicinity of the site utilizing offsite legacy geotechnical data coupled with retrieval of additional core data to document the dynamics of the changing LPH landscape surrounding the Bear Creek site. During the LPH, the site vicinity experienced numerous landscape changes including inundation from Glacial Lake Bretz, ending about 15,000 cal B.P.; high-energy recessional channeling; significant fan-delta formation; multiple post-Bretz lake-level changes; and early to mid-Holocene alluvial flooding and channel migration during emergence of the Bear Creek and Sammamish River fluvial systems. As a result of this study, we can begin to correlate the Bear Creek site depositional history to major postglacial events in the surrounding Lake Sammamish basin, and begin assessing local buried landforms for potential to contain archaeological materials.

Hodgetts, Lisa (University of Western Ontario) and Laura Kelvin (Independent Researcher/University of Western Ontar)  
[172] At the Heart of the Ikaahuk Archaeology Project  
For several years, we have been working with Inuvialuit community members from Sachs Harbour in Canada’s Northwest Territories, developing a research partnership called the Ikaahuk Archaeology Project (IAP). Many Inuvialuit connect with the past through “doing”; engaging in a range of traditional and nontraditional activities. Through them, they come to know the past physically, intellectually, emotionally, and spiritually. While archaeologists primarily engage with the past intellectually, many of us also engage with the past in these other ways. Here, we outline how our own multifaceted experiences over the course of the project, and within archaeology more broadly, inform our thinking about future research directions for the IAP. These experiences have led us to recognize our own limitations and fostered our desire to work toward social justice alongside our Inuvialuit partners. Beyond the IAP, we suggest that more explicitly framing archaeology as an act of the body, the heart, and the soul, as much as the mind, would help to move it beyond its colonial history. This reframing will mean building on existing trends in Indigenous archaeology, activist archaeology and co-creation to broaden the kinds of “doing” that constitute archaeology.

[333] Sex and Gender in Southeast Asian Rock Art: Case Studies from Borneo  
Multiple indigenous and intrusive Borneo rock art (the additive or reductive human modification of naturally fixed-in-place stone) traditions depict figures and abstract designs that can be interpreted as sexed/gendered. Dating from the terminal Pleistocene through modern period, these images are an untapped source of archaeological information regarding the roles and interactions of the biological sexes and culturally constructed and ascribed genders. This paper uses rock art to identify and examine sex and gender in groups indigenous and intrusive to Borneo. It treats rock art through formal analysis and employs archaeological and ethnohistoric information on iconography and ideology to delineate sexed/gendered rock art images and the prehistoric roles, relationships, values and structures of power they possibly represent. Results reveal chronologically and culturally distinct depictions of sex and gender both restricted to Borneo Island and found regionally that can be associated with hunter-gatherers as well as later “Neolithic” and historic
groups. This research generates insights into sex and gender in ancient and historic societies on and beyond Borneo. It also underscores the informative potential of rock art and gender archaeology in Southeast Asia.

Archaeology of the Port des Morts Lighthouse Ruins (47DR497): A Mid-Nineteenth-Century Lighthouse Site

The Port des Morts ruins (47DR497) are from a Great Lakes lighthouse in operation for a brief nine years from 1849 to 1858. Located on Plum Island off the tip of Wisconsin’s Door Peninsula, this hastily constructed and poorly positioned lighthouse was home to William Riggins his wife Phebe and their growing family for all but the lighthouse’s final year. Historic documents suggest they lived a difficult frontier existence, but otherwise little is known about their time on the island. Now part of the Green Bay National Wildlife Refuge, in 2013 the U.S. Fish and Wildlife Service and Hamline University began investigating the ruins prior to the island being opened to visitors. Three seasons of excavations uncovered intriguing architectural evidence of desperate attempts to stabilize walls and keep the lighthouse functioning. The recovery of a robust assemblage of over 15,000 artifacts and faunal remains paints a picture of their daily lives from troubles with lanterns, to teaching writing skills, to feeding the family dog.

Place, Practice, and Pathology: Dental Pathology in Medieval Iceland

This study focuses on the cultural, political, and biological factors that led to the formation of a unique pattern of dental pathology within an Icelandic population at Haffjarðarøy, Iceland between the thirteenth and sixteenth centuries. The Haffjarðarøy church and cemetery clearly served as an important meeting place and burial site for the surrounding region during this period. A paleopathological analysis of the population reveals a high rate of ante-mortem tooth loss, severe tooth wear, and alveolar bone resorption. This project incorporates analysis of the human skeletal remains from the Haffjarðarøy church cemetery, interpretations of community attachment (topophilia) and subsequent fear (topophobia) of this once revered location and later feared location. It is argued that a combination of cultural practices specifically food preparation and the spinning of wool, political and economic upheaval associated with the imposition of Norwegian authority in the thirteenth century, and a lack of sufficient nutritional intake resulted in widespread periodontal disease within the population of Haffjarðarøy. The abandonment and transformation of Haffjarðarøy may have reinforced long held Icelandic folklore beliefs in the power of the dead and their space on the living.

“We ask only that you come to us with an open heart and an open mind”: The Transformative Power of an Archaeology of Heart

Indigenous scholars propose that the outside researchers most useful to indigenous communities are those willing to engage in a process of self-discovery and transformation. These researchers are willing to learn from, not just about, the people they work with. This paper contemplates the challenges and opportunities that arise when archaeologists embark on this transformative journey. I use personal examples drawn from two decades of conducting archaeology with and for indigenous communities to suggest ways in which heart-centered archaeology can transform our discipline. I close with examples of the transformative power of heart-centered interpretations of the past.

Ancient Networks of the Caribbean: Interaction and Exchange across the Historical Divide

In this paper, we present multiple lines of evidence for the existence of interwoven and dynamic ancient networks in the Caribbean. This region is characterized by a long and unique history of social relationships between communities and peoples at various temporal and spatial scales. Through time, Caribbean networks of human mobility and the exchange of goods and ideas were shaped by expanding and contracting group territories, fission and fusion of local communities, and variable degrees of sociopolitical integration, all of which were important in defining forms of interaction. With the aid of interdisciplinary approaches and new methods and techniques grand scale interaction networks have been revealed that were in place between 6000 BC and the time of colonial encounters from AD 1492 when they were exploited by the European colonizers. These enigmatic networks of the Caribbean were fundamental in the shaping of modern global society.

Biomolecular Archaeology: New Insights from the Past

The field of biomolecular archaeology has been transformed in recent years by new technological and methodological approaches, including DNA, protein and small molecule characterization. At the Laboratories of Molecular Anthropology and Microbiome Research (LMAMR) at the University of Oklahoma, we have successfully expanded these approaches to study past populations, for example through the investigation of: 1) ancient animal use, translocations, and domestication, 2) human dietary adaptations, and 3) the coevolution of humans and their microbes. Specifically, the resolution offered by some of these techniques permits testing a multitude of hypotheses with only small amounts of archaeological material, including those from traditionally underutilized sources, such as dental calculus. While these sample sources and methods have the potential to make substantial contributions to archaeology, fostering strong interdisciplinary collaborations with archaeologists, anthropologists, and other natural scientists is critical to advancing this field. Only by integrating the archaeological and cultural context with biomolecular data, can meaningful conclusions be derived. Together these datasets can address important anthropological questions about human health and evolution, human-environmental interactions, and broad scale cultural change.

Archaeological Assessment of Land Claims

The 2014 Tsilhqot’in Decision in the Supreme Court of Canada reaffirms the relevance of archaeological research in the adjudication of Indigenous land and title claims. The evidentiary standards adopted by the Court, that occupation must be sufficient, continuous, and exclusive, invite comparisons with previous archaeological contributions to land claim settlements, refresh inquiry into current applications of archaeological data and perspectives to argue for (and against) affinities between present and past social groups, and create a template for future efforts to assess the strength of historical claims to territory.

Hollenback, Kacy (Southern Methodist University) and Abigail Fisher (Southern Methodist University)

Chien Opératoire: Dogs as Technological Systems in the Northern Great Plains
In the past, like today, dogs (Canis familiaris) were not only human companions, they were also tools, beasts of burden, alarm systems, sources of food, and ritual elements. Since first domesticated, humans have shaped dogs physically and behaviorally, and they have, in turn, shaped our societies. As such, domesticated canines can be treated as a form of technology, regardless of their own forms of agency. By technology we refer to objects (i.e., dogs and linked artifacts), related practices, and associated knowledge. In this paper, we use concepts developed in technological theory to explore canid technological systems of the Northern Plains over time. Using data derived from ethnohistory, early ethnographies, and archaeology, we situate human-canine relationships within the context of other technological systems embedded in Plains cultures.

Mount Rainier's Oldest Artifact: Temporally and Geographically Contextualizing Early Microblade Technology

The temporal distribution of archaeological sites bearing differing microblade technologies in North America suggests that microblade technology spread from what is today central Alaska onto the Alaskan Panhandle and the British Columbia coast before extending across the continent's western territory. By the end of the early Holocene, microblade technology had reached present-day Southern California. In 2007, excavations at the Buck Lake open-air site in Mount Rainier National Park revealed a microblade core located in pre-Mount Mazama strata and several microblades located in younger stratigraphic layers. These artifacts provide new data on the southern temporal and geographic scope of microblade technology, but they have yet to be included in major considerations of the distribution of this technology. This paper examines similarities between the Buck Lake microblade core and other lithic artifacts in the Buck Lake assemblage, particularly those which are associated with the earliest occupation of the site, as well as how the technological and stratigraphic characteristics of the Buck Lake core compare to microblade technology at other southerly located sites.

Speed Mapping: Using Drones to Construct Imagery and Elevation Models of Cultural Intertidal Landscapes

Unmanned aerial systems (UAS) have been used extensively in remote sensing in recent years because of their low cost and ease of implementation. Mapping cultural sites in intertidal areas is challenging because of the short time window in which features are exposed. UAS provide an efficient and high spatial resolution method of capturing imagery and elevation data for a variety of cultural landscapes. We have used UAS at sites along the coastal margin of British Columbia to map clam gardens, fish traps, tidal pools, and exposed archaeological sites. Our study areas are in coastal British Columbia, including the West Coast of Vancouver Island intertidal cultural sites, the Discovery Islands clam gardens, and Central Coast village site and fish traps. The data collected can be processed in the field to provide near-real-time imagery and elevation data that researchers can use to better locate
and understand complex cultural sites. The data can also be integrated into geographic information systems for further spatial analysis both during and after archaeological field campaigns.

Holst, Melissa (University of Louisville) and Jonathan Haws (University of Louisville) [90] Late Magdalenian Lithic Technology at Lapa do Picareiro, Central Portugal

Lapa do Picareiro, a cave located in Portuguese Estremadura, contains continuous deposits dated to the Late Pleistocene. As one of the highest elevation Upper Paleolithic sites currently known in Portugal, questions are raised about the function of the site during this time. The high resolution datasets generated from the ongoing excavation allow for various types of analysis to help shed light on a broader understanding of the site’s function. This poster presents a comprehensive analysis of the lithic assemblage recovered from the Late Magdalenian layer of F/G (12,300 and 11,800 BP). The data generated from this study, when looked at in conjunction with the previously analyzed faunal assemblage, helps to provide a broader understanding of the site’s function during the Late Magdalenian. The analysis focuses on raw material preference and use, representation of reduction phases, and typologies present in the assemblage. These data are then compared with other contemporaneous sites in the region to see what, if any, inferences can be drawn about location and site function. This work ultimately contextualizes the observed patterns found in the lithic assemblage in the broader context of the Late Magdalenian in southern Iberia.

Holyoke, Kenneth (Stantec Consulting Ltd.), Susan Blair (University of New Brunswick “1st author”) and Ramona Nicholas (Green Eagle Services Inc.) [17] Toponymical Indices to the Past Landscape and Resource Extraction along the Wolastoq and Its Environs

Previous studies in New Brunswick have described traditional terminologies and place-names (Blair, nd.; Ganong 1896; Rayburn 1975) as well as traditional lifeways and practice (Perley et al. 2000) along the Saint John River, or, the Wolastoq. These studies recognize the intimate relationship between the river and its people, and the language that describes the connection to the river and its dynamic landscape. Certainly, this applies to a perception of resource locales along the river, from where to catch fish, to sourcing wood for a wigwam, to locations for quality toolstone resources. Drawing on these toponymical indices in comparison to the distribution of known archaeological sites presents an opportunity to reflect on the interpretations we have about site function and location, as well as the memory of these places through time and the importance of certain resources and resource extraction locales.

Hoogland, Menno (Leiden University) and Corinna L. Hofman (Leiden University) [395] Colonial Encounters in the Southern Lesser Antilles

During the colonization processes, vast webs of social relationships emerged between Amerindians, Europeans, and Africans in the Lesser Antilles. The intercultural dynamics that materialized during this period were likely contingent on local and regional networks of peoples, goods and ideas which had developed in the Caribbean over the previous 5,000 years. This paper focuses on the impacts of colonial encounters on indigenous Carib societies by studying transformations in settlement pattern and organization, material culture, and network strategies. Recent excavations at the early colonial sites of Argyle, St. Vincent and La Poterie, Grenada have revealed the remains of indigenous villages and a set of material culture evidencing the first Amerindian, European and African interactions in the southern Lesser Antilles. In this paper we will advance novel perspectives on intercultural dynamics in colonial encounter situations and contribute to discussions of indigenous resistance, cultural transformations, and cultural diversity in an ever globalizing world.

Hoover, Corey (University of Wisconsin–Milwaukee), Patrick Mullins (University of Pittsburgh) and Brian Billman (University of North Carolina at Chapel Hill) [231] GIS and Drones in the Middle Moche Valley: An Analysis of Huaca Menocucho

Huaca Menocucho is a prehistoric monumental center located in the middle Moche Valley on the northern coast of Peru. The site shows evidence of several construction and occupation phases of the Moche Valley cultural sequence (Prieto and Maquera, 2015). Huaca Menocucho and the surrounding area have faced looting and destruction from several sources. In July 2016, MOCHE, Inc. conducted a drone survey combined with a systematic surface artifact survey to record information about activities and taphonomy of the site’s occupation. With the use of photogrammetry software, drone technology, geospatial analysis, and interpolation of surface artifact densities, this study outlines the spatial extents and densities of several of the site’s occupational phases. Additionally, this study explores how an integration of high-resolution site DEMs and systematic surface collections may assist archaeologists in investigating sites that have been heavily looted.

Hopkins, Maren (Anthropological Research, L.L.C.) and Octavius Seowtewa (Pueblo of Zuni) [34] Anshe Ky’an’a and Zuni Traditions of Movement

After the Zuni people emerged into this present world from Ribbon Falls in the Grand Canyon, they set out on a centuries-long journey in search of their spiritual and physical destination, Idiwana. During their travels, the Zuni people split into groups and moved in different directions, forming medicine
societies, acquiring song and prayers, and gaining knowledge about the environment that would become the core of their cultural practices into the present. As such, the places of Zuni’s past remain a tangible part of Zuni cultural memory. Recent work conducted on the Fort Wingate Depot Activity, an area known to Zunis as Anshe Ky’an’a, exemplifies the greater concepts that underlie Zuni traditions of movement. Anshe Ky’an’a, located part way between Chaco Canyon and Zuni Pueblo, was established as a Zuni cultural landscape in the ancient past. Through songs, pilgrimages, the procurement of ceremonial items, and reciprocal offerings made to the ancestors in exchange for spiritual blessings, Zunis literally and figuratively continue to bring Anshe Ky’an’a into their daily lives. In our paper, we draw on the research conducted at Anshe Ky’an’a to further explore how Zuni’s history of migrations led to the ongoing values that incorporate movement across their ancestral homeland.

Horn, Sherman (Tulane University) and Anabel Ford (University of California, Santa Barbara/MARC) [204] Putting El Pilar back on the Middle Preclassic Map: Assessment and Synthesis of the Architectural Data Analyses of early settlement in the eastern Maya Lowlands have benefited from nearly thirty years of research targeting Middle Preclassic (900–350 BC) occupations in the Belize Valley. Frequently overlooked in these settlement pattern reconstructions is the site of El Pilar, which is situated in the limestone hills to the northwest of the Belize River headwaters. Excavations at El Pilar have primarily focused on the impressive Classic-period architectural remains that comprise the site epicenter, but intact Middle Preclassic structures and deposits beneath these constructions suggest the site was home to a vibrant community from at least 800 BC. This paper synthesizes Middle Preclassic architectural data from previous excavations at El Pilar to examine the development of the early community through changes in its built environment. We examine the forms and spatial configurations of Middle Preclassic structures as well as the materials used to build them, and we compare these sequences to more extensively excavated examples to contextualize and interpret architectural developments. Early ceremonial structures, including a possible E-Group assemblage, suggest El Pilar was an important sociopolitical center during the Middle Preclassic and must be accounted for in settlement models of the Belize Valley and its surroundings.

Hornak, Johnathon [99] see Deibel, Corinne

Hornig, Audrey (Queen’s University Belfast) [141] Collaboration, Collaborators, and Conflict: Ethics, Engagement, and Archaeological Practice Collaboration in contemporary archaeological parlance principally refers to active engagement with one or more selected groups of stakeholders and coproducers of knowledge. But knowledge is always produced for a purpose, and collaboration, or to be a ‘collaborator’ in conflict settings implies an allegiance, often deceitful, to one cause or another. When embedding archaeology in conflict transformation activities, being seen as a ‘collaborator,’ or partisan, can actively work against the aims of peacebuilding. Drawing upon experience in conflict transformation within post-Troubles Northern Ireland (where the term collaborator has very negative connotations), issues of ethics and positionality are considered, and an alternative terminology for embedding archaeology in peacebuilding activity is posited.

Horowitz, Mara (Purchase College SUNY) [240] You Are How You Eat: Changes in Dining Style and Society at Late Bronze I Alalakh Ceramics are intimately tied to both foodways and normative behavior within a culture. The appearance of a new shape or the long-term persistence of an old shape must be contextualized by first investigating the use to which the vessel was put, a use that can be inferred through multiple lines of evidence and explored using a variety of approaches. Recent excavations at Alalakh have illuminated the site’s Late Bronze I period, especially the troubled seventeenth-sixteenth century BC transition from the Middle Bronze II. Striking continuity exists alongside major new introductions. Cups, craters, and pitchers with matching decorations form ‘drinking sets’ and persist though time even as the specific forms and decorations change in response to foreign aesthetics, suggesting continuity in drinking practices. On the other hand, the introduction of the large and very shallow ‘plate’ and the loss of Middle Bronze open forms may indicate a dramatic change in the way serving and dining was carried out. This paper examines what the style of dining may say about major social and cultural changes in the transition to the LB I period.

Horowitz, Rachel (Tulane University) [79] Technological Organization Approaches to Lithic Analysis: Case Studies from the Late Classic Maya and Magdalenian Spain Technological organization approaches to studying lithic technology provide a framework through which to view relationships between people and their technology. Such approaches help us address a wide variety of subjects including mobility, access to raw materials, risk, and time and energy costs. We will address the impact of Beck and Jones’ research on organizational approaches to lithic technology, in particular on the study of mobility and resource acquisition using two case studies: Late Classic Maya lithic raw material acquisition in western Belize and mobility and resource acquisition of Magdalenian hunter-gatherers in the Cantabrian region of Spain. These two widely disparate case studies, of sedentary and mobile peoples, highlight the versatility of organizational approaches and the wide-reaching influence of Beck and Jones on lithic scholarship.

Horsley, Timothy (Horsley Archaeological Prospection, LLC), Casey Barrier (Bryn Mawr College), Robin Beck (University of Michigan) and John Kelly (Washington University in St. Louis) [283] New Views of Cahokia’s Urban Landscape: Multi-instrument Geophysical Survey at the Ramey Field In this paper we report on new collaborative research that seeks to investigate the history of pre columbian urbanism and Mississippian culture in the greater American Bottom region of eastern North America. Our research is being designed to take advantage of a wide range of archaeological methods, technologies, and analyses to produce information for Cahokia and other sites in the region. Here, we present initial results from our first season of work at Cahokia. In July 2016, project members conducted a multi-instrument geophysical survey covering around 9 hectares in the Ramey Field portion of the site, an area extending along Canteen Creek north and east of Monks Mound. Our preliminary results are being used to develop research questions that include understanding the history of occupation of this area, monument and plaza construction, and pre columbian landscape modifications and management. Other regional sites that figure into our long-term research designs may also be discussed, including new surveys at the Pulcher site, a large and early mound-town that continued to expand into the mid-twelfth century, overlapping with Cahokia’s major transformations.

[62] Recovering the Iconography of the One Snuff Tray Ever Collected in Tiahuanaco (Bolivia)

The Musée du Quai Branly holds a snuff tray allegedly from Tiahuanaco. It was collected by the geologist Georges Courty during the archaeological excavations conducted on the site by the French Scientific Mission to South America in 1903. The wooden artifact, with inlays of turquiose and metal, is delicately sculpted in low relief, perforated and engraved. Its fragmentary condition has restricted its analysis. A study and conservation plan enabled the recovery of its shape (trapezoidal) and iconographic details. The latter show a supernatural camelled, known as a Waruqilaca, standing on a pedestal. The radio-carbon dating of the tray places it at the end of the Middle period (AD 600–1000), which matches the 14C ages obtained for the other five similar specimens excavated in Coyo Oriente, Solcor 3, and Quitor 5, in the San Pedro de Atacama Desert. The Waruqilaca figure is also represented on metal votive plaques recovered in Lake Titicaca, as well as on Tiahuanaco ceramic incense burners and stone sculptures. The presence of the tray at Tiahuanaco supports the hypothesis of this type of ritual object being directly imported from the Altiplano center to San Pedro de Atacama, both regions sharing a precise set of ritual practices.

Hosek, Lauren (Syracuse University)

[31] From Life History to Large Scale: Osteobiography as Microhistory

Osteobiography, like other types of biographies, extends beyond the individual through entanglements with objects, landscapes, and social phenomena. The approach requires a multi-scalar analysis to understand how bodies both emerge from and create historical process. Osteobiographies are developed by tacking between an individual’s remains and the wider skeletal population to establish a contextualized life history. Conceptualizing osteobiography as a microhistory of human remains is one way in which bioarchaeologists may go beyond detailed descriptions of individual life histories recorded in bone. Microhistory, which has been variously defined and employed by historians and archaeologists alike, is here envisioned as the intersections between biography and large-scale and long-term phenomena. In this way, the body is viewed as a node conjoining overlapping temporalities, materials, and biographies, thereby combining the lived experience of an individual with other emergent temporalities and scales. By way of illustration, I present an osteobiography of an early medieval individual from the Czech Republic. The body becomes a site for the coalescence of scales, but also of different forms of evidence, as textual, archaeological, and osteological data inform the analysis. In emphasizing the relational, the historical, and the contingent, a microhistorical approach extends osteobiography beyond the case study.

Hosoya, Leo Aoi (Ochanomizu University, Tokyo)

[211] Feast as a Farming “Technique”: Ethnohistorical Case Studies from Amami and Yaeyama Islands, Japan

Since the role of feast as a calendar marker for farming communities was proposed by Bender in 1970s, ‘practical’ roles of feasts in production systems have been debated. In this paper, I argue that feasts can also considered as a farming “technique” because they can substantially enable regular and continuous farming production by motivating and obliging people for the production, particularly in settings unfavorable for cultivation. In Japan, the southern Amami and Yaeyama Islands were governed by rulers since the Medieval period, and the history shows that when the ruling body well understood the local feasting culture and tactfully used it, its farming management went well, but when the ruling body failed to that, the management failed. The significance of feasting is so strong in local culture that people today still annually hold large-scale rice fertility festivals although their rice production practically stopped several decades ago due to environmental factors. Furthermore there are recent community movements to revive rice paddies to show their great cultural attachments to the practice. Based on those ethnohistorical case studies, I discuss the fundamental role of feasts.

[321] The Role of Offerings in Interpreting Maya Mortuary Ritual: Bioarchaeological Analysis at Xultun

Bioarchaeological analyses in the past have worked to investigate and contextualize human remains in the broader realm of ancient Maya mortuary practices. Offerings are a common component of Maya ritual; however, the role of human offerings is still not understood in its entirety. In the 2014 field season at Xultun, Petén, Guatemala, three sets of human remains were excavated within the Los Arboles structure, a pyramid complex to the north of the site. In this paper, I discuss the results of bioarchaeological analyses of these three individuals in an attempt to further explore the significance of these interments, their relationship to the associated architecture, and the pertinence of women and children in Maya worldviews regarding the afterlife. This paper provides further insight into the maintenance of ritual and ancestral obligations of the Maya at Los Arboles, and more broadly aims to answer questions surrounding the supposedly characteristic nature of mortuary practice in the Maya realm.

[37] The Digital Evolution at Chan Chich, Belize

In 2012, the Chan Chich Archaeological Project transitioned from paper field forms to a relational database on iPads in the field and an iMac in the laboratory. Since then, the database has evolved each season, becoming more powerful and more useful with each modification. The project has also adopted Structure from Motion as a standard method for documenting excavations over the past three seasons. The digital revolution has not been without its difficulties, but the evolution of the database and attendant technologies has moved the suite of methods from a novelty to be discussed to a powerful set of tool to be employed. This paper discusses the CCAP database and reflects on the ways it has changed how the project approaches data collection and analysis and how those changes, in turn, have transformed how we interpret the ancient past. The digital data and models allow excavators to reconstruct and consider cultural contexts across multiple excavation units much more easily than traditional paper-based systems do.

[114] Climate Amelioration and the Rise of the Xiongnu Empire
Climate has been debated by historians and archaeologists as one possible contributing factor for the emergence and collapse of complex societies. Recently, connections have been proposed between an ameliorating environment, surplus resources, energy, and the rise of Chinggis Khan’s thirteenth-century Mongol Empire. If favorable climate and increased rangeland productivity do indeed play a critical role in the politics of pastoral nomads, then we should be able to observe this in other cases too. This poster presentation evaluates the role that climate might have played in the rise and expansion of the Xiongnu Empire (third century BC to second century AD), using regional-scale archaeological data and climate reconstructions in Mongolia. Our data show a dramatic change in temperature and precipitation in central Mongolia during the Xiongnu period and enhanced productivity in the heartland of the empire. Climatic amelioration could thus have provided ample resources for strengthening the new unified leadership, although the picture is more complex.

[391] Molded Meaning
Since the time of Walter Benjamin, scholarship has posed important questions about replication and meaning: what is an “original,” what does this imply for “aura”—the particular resonance of unique productions—and are such concepts and concerns solely applicable to industrial production in capitalist society? This session converses with Benjamin, long after his death, by addressing the meaning of replication in precapitalist societies, indeed, outside a Marxian framework altogether. The virtuosity of imagery and texts, their tightly controlled circumstances of reception, and the very meaning of “originals” are studied here, in a session ranging across precolombian America.

[169] Are Lithics and Fauna a Match Made in Prehistoric Heaven?
Lithic artifacts and animal bones form the bulk of the material remains of the Paleolithic. This has led archaeologists to interpret these two types of finds as tethered components of subsistence systems. Differences observed through time and space in the lithic repertoire were considered as functional adjustments, designed to maximize gains from a diverse faunal resource base. While we do not challenge the general notion that lithic artifacts were used (also) for exploiting faunal (and other) resources, we note that significant lithic technological breakthroughs, clearly directed toward higher efficiency of procurement of faunal resources (e.g., hafting, projectile weapons) are few and far-apart in the evolution of material culture. Based on case studies from the Levantine Middle Paleolithic, we question the degree to which fauna-based subsistence determined lithic variability. Current research focus on functional relationship between lithics and fauna may preclude consideration of other causes for lithic typo-technological diversity. These may include technological traditions, differences in cultural transmission processes, or the level of within- and between-group connectivity, various combinations of which may have operated already in the Middle Paleolithic.

[335] Mesa Grande and Its World: An Analysis of Intrusive Pottery Types Recovered from Mesa Grande and Their Social Implications
Mesa Grande, one of the two largest Hohokam platform mound villages in the lower Salt River Valley, Arizona, contains an exceptionally large and diverse excavated sample of intrusive, diagnostic pottery types that have been cross-dated with tree-ring dates in other regions. Complexes of these intrusive types in a stratigraphically defined sequence at the site provide new insight into calendrical age of the mound and its associated compounds, allowing us to test recent suggestions that Mesa Grande was one of the first sites within the valley to be depopulated before the end of the Hohokam sequence. These data can also be used to address whether and when it was reoccupied. Finally, we use the intrusive ceramic dataset to investigate ideological and exchange connections among Mesa Grande and its Hohokam and regional neighbors, providing a basis for reconstructing aspects of the changing social order in the late prehistory of the southern Southwest.

[257] Cutmarks on Prehistoric Alcidae Tibiotarsi in the Rat Islands, Aleutian Islands, Alaska
The Rat Islands Research Project (2009–2014) examined precontact era Aleut/Unangan archaeological sites on Hawadax and Kiska Islands to test hypotheses about Aleut impacts on and intersections with the environment. The 2003 test excavations at RAT-081 on Hawadax Islands resulted in the recovery of more than 6,000 remarkably well-preserved faunal specimens, which date from 2,500 to 250 years ago and include fish, sea mammal, and bird species. The 2104 test excavation at KIS-050 on Kiska Island resulted in the recovery of more than 10,000 specimens, also dating from about 2,500 to 250 years ago. More than 50% of the faunal materials are avian. Within the avian portion, many of the Alcidae tibiotarsi exhibit cutmarks resulting from...
The Uses of Photomicroscopy for Specimens in Museums

Howard, Nicola
[191]

Do you have a collection of tiny teeth, bones or seeds?? Photomicroscopy might be for you! This poster demonstrates the results of a four month contract position to digitize a small section of the Quaternary Paleontology’s collections at the Royal Alberta Museum in 2013/2014. Photomicroscopy is an effective, noninvasive digitization technique for museums and educational institutions to be able to expand the accessibility of collections for display and education purposes. Taking several photos of specimens using a DSLR camera and microscope at multiple focal ranges followed by stacking a small number of photos produces a high resolution photo. The stacking process revealed details not easily noticed when taking a single shot. Later versions of Photoshop or free, open access photo stacking software allows for a high quality photo with minimal time spent in postproduction. Many different types of microscopic specimens and artifacts can be digitized using this technique. This technique allows a museums’ professional or volunteer to be able to take thousands of photos and then process them for a clear and detailed photo.

The Karl Site: New Insights on Archaeology in the Upper Allegheny Valley and Life during the Archaic Period

Howard, Steven
[52]

Most archaeological sites within the upper Allegheny Valley of Northwestern Pennsylvania and Southwestern New York have been heavily damaged by decades of plowing. The Karl Site, while no exception, has revealed that a precious few undisturbed features can exist beneath the ravages of the plow zone. Investigations at the site, involving geophysical survey, controlled surface survey, and limited excavations, have revealed some insights into the function of the site within the broader landscape. Although the majority of the site had been compromised, this study shows that data from such sites can still be useful, and such sites should not be overlooked in academic research. The work has also provided a practical methodology for investigation of heavily plow-damaged sites that provides multiple lines of data collection, and provides a less-intrusive, less time-consuming alternative to plow-zone stripping. Such an approach can be favorable in sensitive areas, and where preservation is the desired outcome.

Projectile Dysfunction: A Controlled Archery Experiment to Determine the Presence and Replacement of the Bow and Atlatl Technologies in Prehistoric North America

Howe, David
[287]

There is an undeniable trend of a gradual decrease in projectile point size over time in prehistoric North America. About 1,000 years ago (1kya), this morphologic decrease seems to plateau at a very small size, until projectile points were no longer used. Most archaeologists today posit that this sudden change has to do with the invention or adoption of the bow and arrow; however, without a large sample of preserved wooden bows, arrows, or darts, it is difficult to say for certain that this notion is correct. Via a controlled archery experiment, projectile point performance and function will be tested to determine if there is a variable threshold at which large projectile points are no longer functional when fired from a bow, or small projectile points are no longer functional when thrown from an atlatl. Or simply: is there a specific point size or weight that can tell the difference between these point types? A simple analysis as to whether large lithic projectile points can be fired efficiently from a bow was also conducted. These performance characteristics will be tested through use of a mounted bow rig, stone-tipped arrows, high-speed cameras, and ballistics gel.

The Red Bluff Dam Project: A 1930s New Deal Construction Project

Howe, Mark (U.S. State Department—USIBWC)
[103]

The Red Bluff Project is an earthen dam in Texas on the Pecos River near the New Mexico border. A preliminary geological report of the originally named Angeles Dam Site in Texas by Geologist Kirk Bryan in 1929 found the dam site favorable but he made no conclusion on feasibility. This discussion will talk about the work Dr. Bryan contributed to the later construction of this dam and the later name change to the Red Bluff Project. Emphasis will include the construction of the dam from 1934 to 1936 based on original photos recently found in the IBWC archives. This trove of photos shows the area as it was before the construction of the dam and the region in the 1930s. An historical approach of the archaeology of the now historical dam is examined based on the sites lost with the dam construction.

Principles of Cherokee Regionalization and Material Practices of the Pisgah Phase in the Trans-Appalachian Area

Howe, Tyler (University of Tennessee) and Kathryn Sampeck (Illinois State University)
[160]

This paper presents ethnohistoric accounts, ethnographic commentary, early colonial cartography, and archaeological evidence to investigate factors affecting processes of regionalization in the southeastern Appalachians. Returning to ethnohistorical theoretical and methodological roots of multisourced data and community co-construction to understand ethno-landscapes, we explore how central tenets of the Kituwah Way, the ethical and cultural principles guiding Cherokee practices, have observable material effects and appear to be of much greater antiquity than has been considered in scholarly literature. Integrating ongoing research in ethno-landscapes, through regionality, highlights principles of the Kituwah Way, including tohi (steady fluidity in life), osi (neutral or normal state of life), and gadugi (town or community) which contributed to a flexible, resilient, yet integrated network of communities that made initial colonial encounters of a different tenor than other regional Native American communities. We suggest that many social aspects of the Kituwah Way are later interpretations of earlier cultural foundations, much in the same way the material culture transitions of Connestee-Pisgah-Qualla show transformations that hearken to precedents. The regionalization that Mississippianization usually involves is often superfluous, and in other ways, a poor fit for Cherokees. Ethno-landscape approaches show material practices of affiliation, distinction, and regionalization that could be termed meta-Mississippian.

Removing the Present to Model the Past: DEM and Paths in the Sandhills of South Carolina

Howell, Cameron (ERM)
[377]

Modern infrastructure and development have created problems for reconstructing prehistoric landscapes which adversely affects the accuracy of tools designed to determine trail networks. The attempts to reconstruct prehistoric networks and trail systems between Mississippian period mound sites along different river valleys in the Sandhills region of South Carolina is hampered by even low amounts of development of the landscape. This paper employs some common methods of removing modern disturbances and provides a way of judging the accuracy of the method by comparing paths on adjusted to prehistoric condition landscapes to existing modern infrastructure.

Howie, Linda (University of Western Ontario), Heather McKillop (Louisiana State University) and E. Cory Sills (University of Texas at Tyler) [281] The Provenance and Technology of Paynes Creek Salt Works Pottery and Briquetage
The pottery recovered from Late Classic Maya salt works sites can reveal important information about both the production and distribution of this highly valued trade item. Determination of the geographic origin of the serving vessels and storage jars recovered from salt works, for example, provides direct evidence of trade connections to other areas, as well as the geographic extent of the exchange networks through which salt was distributed. From local perspective, the technological characteristics of briquetage offers insight into materials investments in salt production and production strategies. In this paper we present the results of a petrographic characterization study of serving vessels, storage jars and salt-making implements recovered from different salt works sites in the Paynes Creek area. The objectives of this study were to: 1) investigate the geographic origins of different functional categories of pottery, 2) identify locally made pottery and 3) to examine the technological characteristics of ceramic salt production implements from a mechanical performance perspective, thereby generating insight into processing strategies. Here we focus on the nature of briquetage technology and the ceramic evidence of trade connections to different areas of the Maya Lowland region.

Howse, Lesley (McGill University) [144] Late Dorset and Thule Inuit Hunting Technologies and Archaeofaunas: Implications for Societal Differences
This paper investigates human and animal interaction in two very different hunter-gatherer societies, Late Dorset and Thule Inuit, who once occupied the eastern Arctic. To access cultural differences I focus on how disparate hunting technologies impacted each society’s archaeofaunas, and describe what appear to be culturally distinct trends in the faunal remains. In light of these findings, differences between Late Dorset and Thule Inuit hunting strategies, and other societal aspects including labor organization, hierarchy, and prestige are considered. How generalized versus specialized hunting technologies impacted the trajectory of each society is also discussed.

Hruby, Zachary (Northern Kentucky University) [39] The Stromsvik Macroblade Cache from Copan, Honduras: A Symbolic Analysis
Among the myriad types of votive offerings created by the Classic Maya, many contain chipped-stone obsidian and flint materials. These caches often consist of debitage, cores, flakes, blades, and sometimes so-called eccentrics, which are elaborately chipped ceremonial items that sometimes take the form of god effigies. The contexts of these deposits can include the stairways, centerlines, and corners of important structures, below stelae and other monuments, and in the center of royal or elite plazas. Classic Maya caches mark sacred space associated with the five directions as well as celestial bodies, especially the sun at equinoxes and solstices. The cache discussed here was one such cache of obsidian macroblades, flakes, sacrificial knives, and eccentrics. It also happens to be one of the largest obsidian caches in the Maya Lowlands, consisting of over 500 obsidians and weighing over 166 kilograms. This presentation reviews the symbolic aspects of this unique ceremonial deposit from the Grand Plaza of Copan, which was excavated by Gustav Stromsvik.
