In the context of rapid social or environmental change, foodways offer a way to track how identities are negotiated amid new realities. The Protohistoric period (550–350 BP) in the Northeast was an early site of sporadic and often indirect Indigenous-European contact in North America and the Wabanaki of Maine and the Maritime Provinces were early participants in the world economic system. Analyses of the Devil’s Head and Birch Cove sites in Passamaquoddy Bay indicate that Wabanaki diets were becoming increasingly specialized during the Protohistoric period and that Wabanaki people were shifting the seasonality of their occupations, likely to adapt to a new social seascape. Published accounts of peri-contemporaneous faunal remains from the initial French settlement at Saint Croix Island suggest an unwillingness or inability to integrate local foods into Old World foodways despite dietary stress. Yet subsequent French settlers incorporated some Wabanaki foods into their diet, which eventually became a blended and distinct Acadian cuisine. In both cases, foodways may comprise an ongoing way in which people set themselves apart, offering us a window onto the nature of the contact experience in Passamaquoddy Bay.

Hsieh, Ellen (Cotsen Institute of Archaeology, UCLA) [36] Placing Intramuros in Global History: Insights from the Ceramic Consumption in Spanish Manila
Manila was a critical link between Asia, Europe, and the New World during a pivotal period in world history; however, little attention has been paid to its colonial live. This paper aims to fill this void by reexamining consumption patterns of various types of ceramics excavated from sites in the Spanish walled city. The result shows that the Spanish colonists consumed better products than other subordinate groups and demonstrated their power by using customized Chinese goods rather than their home products, which was a traditional political strategy in Southeast Asia. Ironically, these Chinese products were initially developed due to the demand of these colonists’ Muslim enemy. Combining the artifacts mentioned above with the indigenous traditional cooking ware and the innovative colonial style tableware, the material culture of Intramuros reveals the hybridity process of Spanish Manila during its early colonial period. This paper enhances the postcolonial discussion in the archaeological study by providing a case that neither the colonists nor the indigenous people, but rather the trade diaspora that dominated trading activities and material culture. It places a local colonial episode to a global framework, where the longue durée of each tradition is considered while evaluating the contemporary cultural change.

Hu, Baohua (Shaanxi Normal University) [113] A Kind of Broad-Leave Bronze Spears in North China That Are Similar to the Seima-Turbino Ones
Through type division of a kind of barbed broad-leave bronze spearheads discovered in North China and analogy analysis with the similar artifacts widely discovered in the Eurasia steppes, we consider they are results of the Qijia (齐家) People in the Gansu-Qinghai area (甘青地区) engaging with the further north Seima-Turbino People. However, based on the feature differences on many aspects between them, we consider the former is not a kind of exotic object, but imitations from the latter. The Gansu-Qinghai area might be its producing area in China; and the four newly excavated bronze spearheads in pit H181 of Xiawanggang (下王岗) site in Xichuan (淅川) County are possible to be objects imported from the Qijia culture and then handed down as a kind of foreign assimilated element in the Erlitou (二里头) culture.

Hu, Songmei (Shaanxi Provincial Institute of Archaeology, Xi’an, Shaanxi, China), Miaomiao Yang (Shaanxi Provincial Institute of Archaeology, Xi’an), Zhouyong Sun (Shaanxi Provincial Institute of Archaeology, Xi’an) and Jing Sun (Shaanxi Provincial Institute of Archaeology, Xi’an) [116] Research on Faunal Remains from the 2012–2013 Season Excavation at the Shimao Site in Shenmu, Shaanxi
In 2012–2013, a large number of faunal remains were unearthed from the Shimao site in Shenmu county, northern Shaanxi Province, China. All of these faunal remains were collected scientifically according to archaeological units and were carefully classified, measured and identified. The results of sorting and analysis indicates that there are at least 15 species including the Yangtze alligator, pheasant, rat, Myospalax fontanieri, Myospalax census, rabbit, dog, horse, domestic pig, goat, sheep and cattle. The identified goats are the oldest known cases in China. The identifications of these faunal remains suggest that the climate of the site was damper than at present, associated with large square grasslands, some forests and wetland areas. The economic pattern was semi-farming and semi-pasturing. Domestic animals were the main source for humans to obtain meat, with hunting wild animals only serving as a supplementary source of meat.

Hu, YaoWu (University of Chinese Academy of Sciences) [117] Isotopic Evidence of Affinity and Social Classes of Mongolian Noble Family during Yuan Dynasty
So far, the relationship among Mongolian noble families is scarce due to little findings of Mongolian burials. In this study, isotopic analysis of Mongolian noble tombs was undertaken, aiming to understand the dietary affinity and social classes within Mongolian families. The isotopic similarity and difference was discerned among the population and the reason to account for that was also discussed.

Hu, Yue, Ben Marwick, Weiwen Huang, Jiafu Zhang and Bo Li [113] The Lithic Assemblage of Guanyindong: Implications of Technological Cognition of Hominids in Southwest China in Middle-Late Pleistocene
The Guanyindong site, discovered in 1964, is located in Guizhou Province, Southwest China, dated back to 80–115 ka and 40–190 ka based on two U-series dating (fossil and carbonate samples) results. The 2,323 stone artifacts and numerous fauna fossils were yielded during three main excavation seasons. Here we present the study of 2,272 stone artifacts, which consist of untouched flakes (N = 161) and retouched flakes (N = 1,077), cores (N = 176), chunks and debris (N = 804). The principle raw materials are chert (77%) and limestone (22%). Compared with other sites in south China, Guanyindong is distinctive because of the appearance of the Levallois technique. In the lithic assemblage, we found 59 Levallois flakes and 11 Levallois cores with characteristics that differ slightly from European and African assemblages. In the Guanyindong assemblage, Levallois products have fewer dorsal scars and simpler platform preparation than classical western Levallois artifacts. We use a demographic model to explain why Levallois techniques in Southeast Asia are different from the western. China and Southeast Asia is geographically distant from East Africa where the Levallois technique originated. As hominids dispersed from west to east, progressively smaller populations and drastic differences in environments have influenced the style of the Levallois technique, such as what was observed at Guanyindong.

Huang, Tsuimei (Professor at Tainan National University of the Arts) [26] Contacts between Chinese Regional Cultures and Northern Grasslands during the Early Bronze Age: A Case Study of Turquoise-Inlaid Ornaments
The turquoise-inlaid bronze plaques with animal motifs excavated from the Erlitou sites are among the most conspicuous artifacts ever discovered in the Culture. This work explores issues regarding the function and origin of these items, which were worn as ornamental objects at the wrists of the deceased at the time of excavation. Through an analysis of the deposition and placement of these artifacts in the graves, it is speculated that this unique artifact type could be traced all the way back to late Neolithic period. On the basis of available data, this research reviewed the change of these turquoise-inlaid wrast ornaments in relation to turquoise-inlaid body ornaments from prehistoric China dated to periods prior to the second millennium BC, to explore possible interactions between Chinese regional and Grassland cultures.

Huashi, Liu [333] The Neolithic of the Middle Dadu River Valley in Southwest China: Recent Discoveries and New Insights
In recent years, a large number of Neolithic remains have been found in the middle reaches of the Dadu River in Southwest China, most importantly in the valleys of Hanyuan and Shimian. Excavations conducted at the settlement cluster around Maiping site have led to the discovery of numerous features and object finds displaying strong local characteristics. This paper introduces these finds, highlighting their importance for understanding of local prehistoric developments. The middle Dadu River region forms an independent geographic unit whose early archaeological remains display strong local characteristics, combining a large number of microliths with local-style Neolithic ceramics including jars with decorated lips carrying shallow saw-tooth indentations, appliqué points, and fine corded-ware impressions on the vessel bottom. Considering the strong local characteristics of the assemblages and the dense distribution of similar finds within the region, this facies can be ascribed to the same “Maiping Culture.” Based on these recent discoveries of a large number of sites, features, and objects combined with a scientific analysis of the archaeological material, this paper sketches the local cultural development during the middle and late Neolithic.

Huckell, Bruce (University of New Mexico), Christopher Merriman (University of New Mexico) and Matthew O’Brien (California State University-Chico)  

**Boca Negra Wash: Investigating Activity Organization at a Shallowly Buried Folsom Camp in the Middle Rio Grande Valley of New Mexico**  
Shallow open-air Folsom sites in central New Mexico have been known for six decades, but have received little investigation; most are known only from surface collection. Their post-occupational geomorphic histories of erosional exposure and reburial, coupled with limited archaeological investigation, pose significant challenges to efforts to examine and interpret Folsom intrasite activity organization. We report on our efforts to detect and make sense of patterning in the distribution of artifacts and bison remains at Locus B of the Boca Negra Wash Folsom site, a substantial portion of which was excavated in 2001–2004. The Locus B artifact assemblage is indicative of a short-term residential camp at which both resource processing and weaponry repair and replacement tasks were carried out. We describe the geomorphic and soil stratigraphic history of Locus B, and then present distributional data on various classes of flaked stone artifacts, point production debris, tool manufacture and repair debitage, and poorly preserved bison remains. These data are analyzed using spatial statistical methods to discern whether traces of cultural patterning in the locations of particular tasks have survived the impact of post-occupational geomorphic processes.

**Paleoclimate Data and Behavioral Change in the Highlands of Papua New Guinea**  
Climate variability generates both opportunities and limitations for subsistence strategies, as well as related settlement patterns and technologies. While not the only driver of behavioral change, climate is a critical force in shaping patterns of past behavior. This paper presents the results of lithic analysis of three sites from the Eastern Highlands of Papua New Guinea that span 20,000 years of occupation. Additionally, the findings from a summed probability distribution analysis of radiocarbon dates and site types are presented. These lines of archaeological evidence are combined with paleoclimate data to construct a robust explanation linking changes in precipitation to changes in site use, subsistence strategies, and related technologies in the highlands of New Guinea from the terminal Pleistocene through the Holocene. Changes in precipitation in the form of general climate trends or changes in the intensity and frequency of ENSO are found to be more closely linked to changes in the archaeological record than ecological changes recorded in the palynological record, or a generic demic expansion model.

Huffer, Damien (Research Associate, Smithsonian Museum Conservation Institute), Duncan Chappell (Faculty of Law, University of Sydney), Lâm Thị Mỹ Dung (Vietnam National University, Hanoi, Vietnam) and Hoàng Long Nguyen (Universität Bayreuth, Germany)  

**From the Ground Up: The Looting of Vườn Chuỗi in Archaeological and Criminological Context**
The nature of the illicit antiquities trade from ground to market in Southeast Asia remains poorly known outside of Thailand and Cambodia, where most research has been focused. This paper helps to address this imbalance by documenting and contextualizing looting activities at the Bronze and Iron Age site of Vườn Chuối, located within urban Hanoi. We provide a brief excavation history so as to place looting into archaeological and bioarchaeological contexts, and discuss current and future research on salvaged burials. The methods used to document the recent looting are then discussed, followed by a summation of what little is known about the Vietnamese antiquities trade in general and its relationship to regional trade networks. Finally, we briefly discuss the current regulatory landscape and conclude by discussing how best to protect Vườn Chuối and similar sites in and around Hanoi and continue to raise public awareness of the archaeological repercussions of the trade itself.

Huffman, Thomas (University of the Witwatersrand) and Frank Earley (University of the Witwatersrand) [175] Apishapa Rock Art and Soul Capture

Rather than a western extension of the Plains Village tradition, the Apishapa phase was more likely an eastern extension of the Great Basin Desert culture. Among other things, Great Basin origins explain the Apishapa foraging economy that focused on small mammals, antelope and deer, and meager horticulture. Insusufficient structures and temporary rockshelter habitations attest to residential mobility. As others have noted, Archaic rock art in the Great Basin and Apishapa areas are remarkably similar. Abstract curvilinear and rectilinear styles in both areas share several motifs and combinations. We use Great Basin ethnography to discuss abstract rock art at the mouth of the Apishapa canyon in southeast Colorado. Pilgrimages and the Great Basin version of shamanism, especially the concept of soul capture, help to explain Apishapa ‘maps.’

Huggett, Jeremy (University of Glasgow) [37] Archaeology’s Digital Interfaces

Computing devices have been increasingly used by archaeologists since the 1950s, their adoption accelerating significantly since the 1980s with the availability of personal computers. What is the nature of this changing relationship and what are the implications for archaeology (and computing)? These questions will be addressed through the metaphor of the interface. We are accustomed to the textual and graphical user interfaces as a means of negotiation between archaeologist and computer, but how else does an interface operate beyond the visual and the obvious? An interface separates and brings together. It limits and reveals. It restricts and enables. It excludes and includes (Hookway 2014:4). An interface operates simultaneously in the technical, social, and political realms. What does a consideration of digital interfaces expose about the consequences of archaeology’s relationship with the computer, an association which has developed across barely a generation?

Hull, Bryna (University of California, Davis), Jelmer Eerkens (University of California, Davis) and Reba Fuller (Tuolumne Me-Wuk) [381] Adaptive Dietary Response to Long-Term Drought: Diachronic Stable Isotope Evidence from the Central Sierra Nevada, California

This study examines human dietary responses to the Medieval Climatic Anomaly (MCA), an extended period of warmer and drier environmental conditions from AD 900–1300, in the Central Sierra Nevada Mountains of California. Stable isotope and radiocarbon analyses of human remains attributable to the Tuolumne Me-Wuk reveal individual-level dietary behaviors. Results show a region-specific “Central Sierran” pattern of resource use in the form of a distinctive isotopic signature relative to other areas of California. Radiocarbon dates reveal gradually changing diets over time, but with a marked decrease in trophic level, decreased use of pine nuts, and interindividual homogenization coinciding with the MCA, suggesting significant dietary stress and resource intensification. Further stable isotope analyses of serial sections of teeth from individuals who lived before, during, and after the MCA are used to examine more fine scale dietary changes over individuals’ lifetimes. The data illuminate broad-scale human behavioral adaptation to changing climatic conditions, particularly interindividual variation and differences between age groups and the sexes.

Hull, Emily (Hamilton College), Nathan Goodale (Hamilton College), Alissa Nauman (Hamilton College) and David G. Bailey (Hamilton College) [343] Microwear Analysis of Mica Lamented Quartzite Scrapers from Slocan Narrows, Upper Columbia River Area

Ethnographic evidence suggests that semi-sedentary hunter-gatherers in the interior Pacific Northwest inhabited aggregated winter villages on a multi-season basis and specific times throughout the year much of the group made long distance forays for resource procurement, trade, and exchange. Extensive excavation efforts at the Slocan Narrows Pithouse Village has produced an assemblage of mica lamented quartzite scrapers. This study presents findings from analysis and characterization of microwear on these tools in order to infer their potential function. We also conducted experimental studies using the same quartzite on several contact materials. The experimental tools were used in blind tests. This analysis allows for a better understanding of why aboriginal peoples would transport quartzite scrapers over 200 km up the Columbia River from Kettle Falls, WA, to Slocan Narrows, BC.

Hull, Kathleen (University of California, Merced) [42] Splitting and Lumping: Decision-Making and Meaning in Intentional Artifact Fragmentation and Deposition

Drawing on archaeological data from the greater Los Angeles Basin, this paper examines sequences of intentional ground-stone artifact fragmentation and singular or multiple-recombined fragment placement within various feature contexts. Recent studies of putative communal mourning features have indicated an initial suite of intentional artifact fragmentation and treatment practices including pigmentation or burning, but ongoing study of these and other types of features has revealed additional practices that suggest acts designed to produce fragments of particular types (e.g., specific portions of tools) and/or a desired number of pieces that could be distributed individually or recombined in particular configurations for placement within one or more features. The potential significance and meaning of such splitting and lumping with respect to certain feature types is explored.

Hulme-Beaman, Arderne [85] see Ameen, Carly

Hulse, Eva (Archaeological Investigations Northwest) and Sarah L. Dubois (Archaeological Investigations Northwest) [387] Head for the Hills: Resource Specialization in the Prehistoric Portland Basin

In the Portland Basin north of the Columbia River, the oldest sites (5000 years BP and older) tend to be larger than younger sites, have a more diverse array of artifacts, and lie in upland areas. Sites post-dating 5000 years BP vary in size, tend to have specialized artifact types, and are found at a wide
range of elevations. We hypothesize that the lack of older sites at lower elevations is due to changes in subsistence strategies, rather than differential preservation of older materials. We approach the question using archaeological and paleoenvironmental data collected primarily from the Camas/Washougal area in Washington, supplemented by data from other parts of the Portland Basin.

Humes, Cynthia (Claremont McKenna College)

[212] Hindutva’s Rediscovery/Appropriation of Its Ancient Past
Religious proponents are increasingly challenging academic research on India and its religious past. Book burnings, petitions, and even riots, have resulted when religious adherents have felt maligned by the scholarship of academic archaeologists and historians. In my presentation, I will introduce and clarify the complicated history and major debates regarding key archaeological finds in South Asia. In particular, I will discuss debates regarding the history of the “Aryan” and the Indus Valley Civilization. I will elucidate ideologically-inspired interpretations of the South Asian archaeological record, particularly by those called Hindutvādins, and those who write, blog, and speak about (and against) them. I next describe some of the major controversies that in the past several decades have flared into increasingly virulent interactions between Hindutva proponents, indigenist theorists, and academic interpreters. I then highlight major accusations by academics of partisan pseudoarchaeology and pseudoscience, and close with comments regarding what these debates foretell of the future of Indus Valley archaeological scholarship.

Humphreys, Stephen (Durham University) and Clarissa DiSantis Humphreys (Durham University)

The potential archaeological fieldwork holds for facilitating positive change among disabled military veterans has only recently begun to be explored. Since 2012 three dedicated veterans’ archaeology programs have been developed within the United Kingdom (Breaking Ground Heritage, Operation Nightingale, and Waterloo: Uncovered), and one has been created within the United States (Operation Nightingale USA). These programs share an interest in integrating disabled serving and ex-service personnel into a supportive new community, providing them with transferable skills that may or may not lead to a career in archaeology, and increasing wellbeing by providing a sense of purpose. They draw upon methods developed and refined in veteran support organizations over the last decade, emphasizing in particular the value of formal and informal peer support. At the same time, veterans’ archaeology programs provide an opportunity to expose a new demographic to the value of cultural heritage. This paper will discuss the application of best practices derived from veteran support organizations to archaeological project organization and field practice, focusing specifically upon the joint Operation Nightingale/Operation Nightingale USA 2016 field season at Malton, North Yorkshire.

[203] Early Iron Production in Sudan
Since 2012 archaeometallurgical investigations have been undertaken at the Royal City of Meroe, a capital of the Kingdom of Kush situated c. 250 km north of modern day Khartoum, Sudan. During the research, a chronological history of iron production at this site has been generated that spans at least one thousand years. Insights into various stages of the chaîne opératoire of iron production have also been revealed, including the location and techniques of iron ore extraction, the procurement of charcoal, the production of technical ceramics, and insights into the smelting parameters such as furnace design. This paper presents new data concerning the earliest remains of iron production found so far at the site. The material has recently been excavated toward the lowest levels of the largest slag mound at Meroe, and includes iron slag, charcoal and tuyere fragments. This material may date back to the Napatan period or earlier; new radiocarbon dates will also be presented. The results of laboratory analysis of the excavated material are contextualized within the framework of Kushite history as well as African ferrous metallurgy.

[42] Three Dimensional Aggregate Flake Scar Analysis on Experimental Lithics, and Archaeological Lithics from Tabun Cave, Israel
Dorsal flake scar directionality is used in lithic analysis to infer methods of core reduction and flake production. This has been done in two dimensions. This study analyzes flake scars at the assemblage level in three dimensions. I use both experimental assemblages (bifacial, blade, discoidal, and levallois) as well as archaeological samples from Tabun Cave, Israel, an important reference sequence (partly defined by scar patterning) for the Levantine Paleolithic. Experimental samples provide a comparative baseline with known production methods. The samples from Tabun Cave represent Units I and IX, respectively Tabun C-type and Tabun D-type, and some of their respective beds. Results from the experimental samples’ scar analysis suggest different methods of reduction are distinguishable in some cases. Results from the archaeological assemblages suggest some assemblages are indistinguishable, e.g., the two Beds from Unit I, while other comparisons, e.g., between Units I and IX as well as between some of the Beds within Unit IX, suggest the utility of the new method to differentiate archaeological samples by their 3D scar pattern variables. In particular, the ability of the method to distinguish between individual beds within Unit IX calls into question the legitimacy of treating Tabun “types” as monolithic categories.

Hunt, Alice (University of Georgia)

[79] Social Function, Semiotic Meaning, and Community Identity, or Sometimes a Pot Is Not Just a Pot
The spread of “Palace Ware,” an eighth–seventh century BCE drabware, across the Neo-Assyrian imperial landscape coincides with the annexation of territory and establishment of vassal states and buffer zones throughout the ancient Near East. Consequently, Palace Ware has been considered ‘imperial’ material culture and equated with imperial identity. This unilateral, top-down interpretation reduces material expression of complex interregional, intercultural interaction into either imposition or emulation. In this paper, we take a more nuanced approach to the transmission of Palace Ware. Imperial interactions are context specific, recursive relationships negotiated through material culture and symbols of identity and power. If Palace Ware served as a medium through which Neo-Assyrian imperial relationships were established, justified and maintained, it is important to understand (a) how it was transported across the empire; and (b) who consumed Palace Ware both inside and outside the Neo-Assyrian heartland. In the process of answering these questions, using morphometric, petrographic and geochemical data, we are able to evaluate subtle changes in the social function and semiotic meaning of Palace Ware across the Neo-Assyrian imperial landscape and better understand the nature of these relationships.

Hunt, David, Marcos Llobera (University of Washington) and Jacob Deppen (University of Washington)

[118] Getting More from Survey: A Case Study from the Western Mediterranean (Mallorca, Spain)
In this paper we present preliminary results of three campaigns of intensive survey carried out as part of the ongoing Landscape, Encounters and Identity project being undertaken in the NE of the island of Mallorca (Spain). The project is uniquely situated to explore the confluence of various
archaeological evidence (surface scatters, lidar, 3D photogrammetric models) and the interpretative challenges these pose. Our paper here will focus primarily on the results recovered through intensive field walking, and the impact that technology has had on these. At a broader theoretical level, we seek to reflect on the nature of information recovered through this type of practice, the challenges and potentials that it offers to study people and their surroundings, and the role that technology plays to promote and/or overcome these. We view this as part of a larger conversation on the interpretative perspectives that different types of material evidence bring to the study of past landscapes.

Hunt, Garett [4] see Cooper, H. Kory

Hunter, Raymond (University of Chicago) and Steve Kosiba (University of Minnesota) [331] Land, Labor, and Status: A Perspective from Colonial Cusco, Peru

Access to land is an important marker of status in agrarian societies. During the Andean Late Horizon (c.1400–1532), land differences grounded status distinctions, notably in the most monumental estate farms and kin-oriented communities communitarily farmed or mistread patchwork fields. Under the Spanish colonial system (1532–1824) access to land and labor came to differentiate status in new ways. Spaniards appropriated labor and property, while indigenous nobility contested Spanish rule and staked new claims to authority by advocating for control of lands that had been Inca estates. During these decades of social crisis, many Andeans detached themselves from traditional lands, becoming itinerant outsiders (forasteros), or landless laborers (yanakuna). Little is known about these new categories of subjectivity and their impact on the Andean social landscape. In this paper we treat land as a category of material culture that can render status legible to archaeologists. We consider the circumstances under which social actors might severe ties to land, a political tactic to create an inconspicuous way of life beneath the scrutiny of state authorities. Archaeological survey data, GIS analysis, and historical documents provide evidence of how Andean people sought to define their land and their identity in early colonial Cusco, Peru.

Huntington, Yumi (Jackson State University) and John Warner (University of South Florida, Sarasota-Manatee) [359] Jequetepeque-Jatanca Acropolis as a Mesocosm: The Role of Architecture during the Late Formative Period

Jequetepeque-Jatanca, located on 3 km away from Cerro Cañoncillo, was occupied during the late Formative period by several successive cultures suggesting that it was a site of consistent religious and political importance to many different societies. The Jatanca archaeological complex consists of an Acropolis, the oldest and only elevated structure, along with five compounds that are distinguished by their sizes and dates of construction. Among all, the Acropolis itself becomes the center of power, namely as an astronomical observation point. Viewed from the Acropolis, Cerro Cañoncillo serves as a calendrical mountain, marking the summer and winter solstices with sunrises at the left and right extremities of the mountain. As the viewing point, the Acropolis itself becomes the nexus where natural cosmic cycles are translated into the mundane realm of human life, a kind of mesocosm that re-creates the structure of the sacred mountain mimetically even as it takes command of that power for human use. Using Starry Night Pro 7, I show illustrations of the calendrical functions of Cerro Cañoncillo and the mediating role of the Acropolis in the context of the Jatanca site.

Huntley, Deborah (Tetra Tech, Inc.) and Cynthia Herhahn (Bureau of Land Management) [129] Rio Grande Glaze Ware Knowledgescapes

Research by Katherine Spielmann and many of her students highlights the economic and social significance of glaze-decorated ware vessels during the fourteenth through sixteenth centuries AD. We take a new approach to Rio Grande Glaze Ware in this paper, examining the role of knowledgescapes in structuring economy in Ancestral Pueblo middle-range societies. Knowledgescapes encompass economic, social, technological, and ritual aspects of glaze ware production, use and exchange. We explore the origins and development of glaze ware knowledgescapes from the initial creation of the technology, its subsequent spread through networks of information exchange, to the eventual regionalization and standardization of glaze paint recipes. The locations of lead ores and temper sources and their social contexts provide the physical tie between spheres of knowledge and the landscape itself. We emphasize variability in age, gender, skill, and social identity that characterized glaze ware knowledgescapes.

Huntley, Jillian (Place, Evolution and Rock Art Heritage Unit Griffith University), Steven George (Earth Sciences, Macquarie University, NSW, Australia), Mary-Jean Sutton (Virtus Heritage, Pottsville, NSW, Australia) and Paul Tacon (1. Place, Evolution, Rock Art Heritage Unit, Griff) [375] Second-hand? Paint Chemistry and the Age, Authenticity, and Conservation/ Management of Hand Stencils from the Sunshine Coast, Queensland, Australia

The materials used to created rock art preserve information regarding how, and in some instances when, it was made. Here we outline the field based, geochemical study of three white hand stencils on the Sunshine Coast of Queensland, Australia. Portable X-ray fluorescence analysis determined that the stencils were made using a titanium dioxide pigment, almost certainly commercially produced white paint. Significantly, this helped us assign a chronology as the rock art must have been produced after the European colonization of Australia. The amount of titanium in the paint reflects a twentieth century recipe (specifically >1960) rather than a modern, twenty-first-century paint. The manner in which the stencils were made are consistent with Aboriginal rock art across the continent. Rather than a paste of Aboriginal art made by European Australians, we conclude that these stencils provide rare insight into the continuing cultural traditions of Indigenous peoples during the mid-1900s. We conclude by outlining the implications of the materiality of these hand stencils for their preservation and ongoing site management.

Hurst, Heather (Skidmore College) [392] The Black, The Red: A Study of Two Maya Mural Pigments from the Petén Region

Black and red are foundational colors in Mesoamerican painting and scribal arts, often derived from easily accessible raw materials. Although their presence is ubiquitous, variations in chemistry and microscopic properties are data that tell a more nuanced story. This paper summarizes analysis of black and red colorants used in Maya wall paintings that contribute to observations regarding local traditions in manufacture, as well as individual variation in artistic practice. Reported results focus on the characterization of materials and methods used in mural manufacture at Cival, La Sufricaya, San Bartolo and Xultun (Guatemala), over a period of 1,000 years. Multiple lines of evidence including stylistic, chemical and materials science analyses considered within the context of current preservation and observed degradation are integrated in order to understand raw materials used to produce colorants, as well as the methods of preparing wall substrates including plaster and paint application and/or finishing. Collaborative and inter-disciplinary research provided insight into artistic attribution, workshop practice and decision-making (raw material selection and processing, time allocation, etc.) in Maya mural painting from the Petén region.

Enslaved Christians in Early Modern North Africa: Resolving Historical Contentions through Archaeology

Establishing estimates of European Christians enslaved in North Africa during the Early Modern Period (1500–1800) is highly contested among scholars. On one hand, historian Robert Davis argues that more than a million Europeans were captured, enslaved, and left unransomed in North Africa in the Early Modern period. On the other hand, Nabil Matar suggests that both the historical accounts and Davis’ estimates are exaggerated, in part because of a lack of physical evidence and the ambiguous characteristics of known and remaining prisons for Christian slaves in North Africa. During historical archaeological research into enslaved Christians in North Africa, I excavated a separate sealed subterranean dungeon associated with Christian slavery in Morocco, the Mazmorras of Tétouan, Morocco. My archaeological research corroborates historical accounts of Christian slavery through archaeological evidence. Building on these links allowed me to situate the Mazmorras’ within local networks of capture and ransom between Spain and Morocco. In establishing a strong association of archaeological evidence with archival sources and primary texts, this research helps to resolve a decade-long historical debate about enslaved Christians and orienting Tétouan within a larger system of ecclesiastical and royal power as well as interfaith relations in the Early Modern Mediterranean.

Huster, Angela (Arizona State University)

Characterization of Local and Aztec Rule at Calixtlahuaca

The Aztec Empire has been characterized as both an example of relatively indirect rule and as a case of relatively collective rule, positions which are least superficially opposed. In this paper, I use ceramic data (INAA, petrography, and type classification) from multiple contemporaneous households at the provincial capital of Calixtlahuaca in the Toluca Valley to evaluate these two positions. I compare data from the time periods during which the site was under local rule and when it was incorporated into the Aztec Empire. I find that the preexisting local rule was likely relatively collective. Aztec imperial rule, while relatively indirect, did result in some reduction in the collectiveness of rule. This study illustrates the importance of separating local governance traditions from imperial rulership strategies.

Huston, Melyssa (Petrified Forest National Park), Christine Mikeska (Boston University) and Catherine F. West (Boston University)

Food or Fur: Dog Butchery on Kodiak Island, Alaska

Archaeological evidence suggests that domesticated dogs (Canis familiaris) have been in the Kodiak Archipelago of Alaska for at least 7,000 years. Despite their lengthy presence, little is known about their relationship with Kodiak’s human inhabitants. Based on both western assumption and the limited ethnohistoric record for this region, it is commonly assumed that people simply kept dogs as pets. However, previous studies of dog remains from the Uyak site on Kodiak Island note the presence of cutmarks on many of the bones. These observations suggest that the role of dogs in the lives of people may be far more complicated than previously assumed. Even more, cutmarks suggest that dogs may have been used for their fur or meat. Through systematic analysis of cutmarks found on these bones, we demonstrate that some dogs were dismembered and defleshed. Based on these results, we argue that these dogs were likely butchered for meat consumption.

Hutchinson, Ian, Sarah L. Sterling (Anthropology, Portland State University), Virginia L. Butler (Anthropology, Portland State University) and Carrie Garrison-Laney (Earth and Space Sciences, University of Washington)

Washed Away? Was Tse-whit-zen Deserted in the Aftermath of Cascadian Earthquakes?

The northern segment of the Cascadia subduction zone has ruptured at least four times in the last 2,000 years. Each of these giant earthquakes triggered a tsunami that potentially inundated the Tse-whit-zen village site to depths of 3–6 m and exposed it to currents of ~10 m/s. We compare the timing of these tsunamis, as recorded by wash-over deposits at Tse-whit-zen and sand sheets in the marshes at Discovery Bay, some 50 km to the east of Tse-whit-zen, with the paleodemographic history of the village. The latter is modeled using the probability density of AMS radiocarbon ages as a population proxy, and tested against a null model derived from the IntCal13 calibration database. The results suggest that the size of the population at Tse-whit-zen oscillated wildly in the 1,500 years before European contact, with minima in the wake of each of these natural disasters.

Investigating the Modeling of Neanderthal Population Size

Developing some understanding of how many hominins occupied the landscape at any one point in prehistory can provide important insights into basic behavioral patterns, how these differed between hominin species, and how they changed over the course of the Pleistocene. Population density is an important factor in subsistence behaviors, mobility patterns, and the nature of group interaction. A number of approaches have been used by researchers to provide estimates for effective Neanderthal population size across Eurasia: quantifying the Middle Paleolithic archaeological record, quantifying genetic variability, and paleodemographic modeling. Given the huge area that the species occupied and compared to other top carnivore species, all published estimates for Neanderthal population size and density are surprisingly low. This suggests that this topic should be explored in more depth. Here we focus on the paleodemographic modeling approach, which relies on developing effective birth and death rate values for an extinct hominin species. In order to put these numbers into perspective, data from modern hunter-gatherers and other top carnivore species living in similar regions were used as points of comparison. It was found that Neanderthals are commonly estimated to have had populations over twenty times less dense than these modern analogs.

Let’s Hear It for the Boy: Masculinity, Manhood, and Archaeologies of Gender

This paper will seek to explore how archaeological investigations of masculinity and manhood can contribute to contemporary theory on gender and sexuality. Drawing on material from a nineteenth century industrial work camp in Coastal California, I will argue that intersectionality provides promising avenues as both a theoretical paradigm and as a way to articulate archaeological work within a wider, multidisciplinary discourse on gender. Methodological implications for archaeological engagements with masculinity and intersectionality will also be explored.

Hyde, David M. (Western State Colorado University) and Michael Stowe (U.S. Department of Defense)

Settlement Pattern Analysis at a Hinterland Community in Northwestern Belize: Results of the medicinal Trail Reconnaissance and Mapping Project
The Medicinal Trail Reconnaissance and Mapping Project (MTRAMP) began in 2013 and just completed its fourth season in 2016. Those four seasons, plus the integration of previous mapping endeavors, has refined our understanding of the size and distribution of households and numerous landscape features that have been, or continue to be, the focus of excavations. Intensive survey and mapping of the Medicinal Trail locality has revealed, (a) that the largest, and most complex architectural groups are associated with ridge tops, (b) artificial drainages and reservoirs are associated with dense settlement, and (c) numerous terraces are located on the slopes of the ridges, near drainage features. In this paper we will present the results of the MTRAMP and provide a discussion as to their function and relation to the sociopolitical dynamics of the community.

Weaving the Strands of Evidence: Multifaceted Confirmation of Textile Production and Use at Mission Santa Clara de Asís

Mission Santa Clara de Asís, founded in 1777, is one in a chain of 21 Spanish Colonial missions established along the coastal region of Alta California. Recent excavations within Santa Clara’s Native American Rancheria have revealed a plethora of objects directly and indirectly associated with textile production and use within the colonial setting. Indigenous practices from ethnic regions of California and Mexico are reflected within the assemblage of sewing/weaving tools, adornments, faunal remains, and the remnants of fabric, fibers, basketry and cordage themselves. Our paper aims to highlight the persistence of native textile traditions that clearly played an important role in the domestic and economic success of Mission Santa Clara.

Merit Making at Ancient Bagan, Myanmar: A Consideration of Socioreligious Entanglements and the Rise and Fall of a Classical Southeast Asian State

Much of the recent discourse surrounding the collapse of archaic states is centered on the impacts of ecoside or climate change. Driven by natural scientists and increasingly sophisticated data generation and analysis methods, such environmentally-based approaches to collapse have tended to gloss over the myriad cultural factors also involved in such severe transformations, thus inhibiting our ability to fully grasp the complexities of the collapse process in the various case studies currently under archaeological scrutiny. This presentation underscores the importance of including considerations of both religion and ritual in our interpretations of sociopolitical collapse, using insights from the rise and fall of Bagan, Myanmar’s “classical period” capital. The focus of the discussion will be on the roles that Buddhist merit making played in Bagan’s development and denouement, with specific attention to the various ecological, economic, social, and political entanglements that resulted from ideologically charged donations to temples and monasteries.

Los microrrestos botánicos (polen) en ofrendas y rellenos constructivos del área de Tlaltecuhtli

Dentro de la gran cantidad de material arqueológico recuperado en la Séptima Temporada del Proyecto Templo Mayor se encuentran los microrrestos botánicos, elementos que al reflejar la flora regional nos permiten inferir sobre las actividades de tipo rituales y sagradas realizadas en torno a Tlaltecuhtli al pie del Templo Mayor. Esto cobra importancia si recordamos que para el pueblo Mexica, las plantas jugaban un papel importante en su cosmovisión, relacionándose no sólo con elementos como la guerra, la fertilidad, el sol, sino también en varios casos, se asociaban con deidades específicas, como en el caso de Tlátoc y el yauhtli. Para determinar qué tipo de plantas eran utilizadas y el por qué de su presencia, se realizó el análisis del polen, siendo de relevancia su presencia tanto en las ofrendas como en los rellenos, puesto que estos últimos, al informarnos sobre la flora común en la época prehispánica, nos permite establecer un margen de comparación para detectar elementos atípicos y exóticos en las ofrendas.

Thread Production in Late Postclassic Tepeticpac, Tlaxcala: A Technological and Experimental Study of Archaeological Spindle Whorls

Textile production was one of the most valuable social and economic activities in prehispanic Mesoamerica. In this study, we inquire into thread production in the site of Tepeticpac, Tlaxcala, one of the main altepemeh of Late Postclassic Tlaxcallan, using a technological, ethnoarchaeological and experimental analysis. In particular, we evaluate key attributes of archaeological spindle whorls in the spinning process, including weight, shape and moment of inertia. With the collaboration of three craftswomen ( zapotec and otomi), we performed an experimental study of thread production using replicas of archaeological spindle whorls and different types of fibers. Preliminary results show that although there is a certain correlation between the size of the spindle whorl and the quality of thread produced, it is the ability of the craftswoman and the spinning technique that determines its final quality.

Use and Symbolism of Copper Axes in Tarascan Society during the Late Postclassic Period in Modern-Day Michoacán, Mexico

The cultural core of the Tarascan society settled in the region of what is now Michoacán, western Mexico. For the Tarascans, gathering firewood was a sacred activity, and the maintenance of a never-ending fire within their temples or “cues” was an essential part of their religion. This sacred element was an offering for their most venerated god, Curicaueri. Collecting wood was an activity so sacred that even the tools used to retrieve it were transformed into consecrated objects sharing the same taboos as the sacred firewood itself. This work is about how copper axes became depositories of status in Tarascan society. Through an analysis of the specific use of the ax, the individuals who used them, and the different raw materials used for manufacture, I will analyze how each factor contributed to the significance of copper axes and shaped their role within Tarascan society and their vision of the world.

A Paleopathological Analysis of Skeletal Remains Uncovered in La Cueva de los Hacheros, Turicato, Michoacán

[12]
This poster deals with the study of skeletal remains belonging to eighteen individuals deposited within La Cueva de los Hacheros, a site located in the municipality of Turicato, Michoacán. Unfortunately, as a result of looting by landowners, the site has an altered context. Despite that fact, a salvage excavation and a comprehensive analysis of the remains yielded valuable data for interpreting the site and learning more about the individuals buried within. The skeletal analysis made it possible to recognize various pathologies including antemortem trauma, diseases, and developmental anomalies, some of which were represented in various individuals. This investigation also provided us with sufficient data to register the total number of individuals and differentiate them by age and sex. This investigation will provide a better understanding of those whose final resting place was at La Cueva de los Hacheros and the diseases that afflicted them.

Ibarrola, Mary Elizabeth (University of Florida)

[74] Resistance and Intersectionality in Maroon Archaeology

We define Maroons by their overt resistance; theirs was one of the most extreme forms of anti-slavery opposition in the Americas and for many scholars is representative of the human desire to be free. However, defining Maroons by the act of marronage is isolating and limits attempts to study cultural continuities and ethnogenesis among the wider African Diaspora. This paper will look at the potential for, and advantages of, an intersectional maroon archaeology. Through the lens of marronage in Florida, and comparative analysis of the three Florida sites—a slave cabin at Butow Plantation in east-central Florida, an urban slave site at 71 Park Place in St. Augustine, and the Maroon settlement of Pelikilikaha in central Florida, all of which date from the late Second Spanish Period—the paper will address the ability of intersectionality to both challenge our understanding of marronage and to build more complex comparisons of Maroon, slave, and free black societies in the colonial world.

Ichikawa, Akira

[235] A Revised Chronology of the Southeastern Maya Area: an Evaluation of New and Existing Radiocarbon Dates from the Preclassic to Postclassic period

The establishment and refinement of chronology is a critical issue in archaeological practice worldwide. In the archaeology of the southern Maya area, Inomata et al. (2014) have currently proposed a new revised chronology for Kaminaljuyu, Guatemala, especially for the Preclassic period, using several calibrated radiocarbon dates and Bayesian statistics. They also highlight a new interpretation of the social process in southern Maya area. However, the dataset for the southeastern Maya area, especially that located in the western part of present-day El Salvador, has not been updated since the 1970s and 1980s. This paper shows the latest updated radiocarbon dates for the southeastern Maya area. These include more than 100 dates collected from Chalchuapa, which is a key site in the region, and other sites by applying Bayesian statistics to further better the chronology. Based on this data, I present an enhanced local chronology from the Middle Preclassic to the Late Postclassic period. Furthermore, although it requires minor revisions, I support the validity of the chronology proposed by Inomata et al.

Iles, Louise (University of Sheffield)

Theories of the origin(s) of iron production and the spread of ferrous technology have provoked many decades of lively and enduring debate. The notion that iron production developed in one core location—from where knowledge of it spread—has been challenged by claims of early, independent inventions of iron production in Africa, India and China. However, it has proved problematic to verify the timing and contexts of these multi-origin hypotheses without placing undue emphasis on isolated radiocarbon dates. This research reopens the discussion of the origins and spread of iron production using summed probability distributions of published radiocarbon dates as a proxy for technological activity. It aims to investigate the broad-scale dynamics of the spread of iron metallurgy through the whole of the Old World, exploring some of the socioeconomic factors that influenced the movement of knowledge, and considering the impact of iron production on the environments where it flourished. The research began in 2016 with the collection of published radiocarbon dates from Africa, and this presentation introduces and considers the results of the initial analysis of the African dataset.

[369] A Place for the Living, A Place for the Dead: Social Memory at the Ancient Maya Hinterland Community of San Lorenzo, Belize

Public structures across the Maya lowlands functioned as materializations of ideology, memory, and identity. However, documentation of public ritual structures is typically limited to formal ceremonial centers. Little is known about public spaces within hinterland communities. Excavations at the site of San Lorenzo offer insight into the use and transformation of ritual space within a hinterland community. Recent excavations of a public structure group have uncovered multiple construction phases beginning in the Preclassic and culminating in the Terminal Classic. The Preclassic phase of these structures is a round platform resting on a tamped molar surface. Due to its size and form, comparative data suggests that this platform may have functioned as a space for public ritual. Excavations have further uncovered seven interred individuals within the patio space of the Late Classic construction phases. Thus, by the Late and Terminal Classic periods, this site became a burial ground. The transformation in use and the continual reconstruction of ritual space over centuries suggests that this site served as a space of social remembrance and identity on the landscape of the San Lorenzo community.

[217] Maya Palaces at Aguateca and Ceibal, Guatemala

Royal palaces at the medium-sized centers of Aguateca and Ceibal appear to represent a basic template for the spatial and functional configurations of Maya palaces. They exhibit simple square forms resembling smaller residential groups of lower status, indicating their primary function as residential complexes of the royal families. Administrative and ceremonial functions were likely merged with domestic ones. These palaces also provide information on the degree of spatial mobility. While the Maya were generally attached to fixed residential localities, they allowed a certain level of residential mobility. The royal palaces of these dynasties moved through their history, depending on administrative and strategic needs and the idiosyncrasies of individual rulers.

[31] Being Male in al-Andalus: A Comparative Osteobiographical Approach to Reconstructing Islamic Identities in Medieval Spain

In AD 711 the influx of Arabs and Berbers into Iberia culminated in the formation of the only Islamic state in medieval Western Europe. The uptake of new religious ideology and cultural practices by the inhabitants, which when applied in their unique sociohistorical context, resulted in an Iberian Islamic identity. While much research has explored variation in the lives of women, including debates on their freedom of movement and activity, less is
postulated about the lives of men and what it meant to be Muslim and male in al-Andalus. Fortunately, due to the reflective relationship that exists between the body and society, the analysis of human skeletal and funerary remains offers an opportunity to address this lacuna. An osteobiographical approach, which explores both cumulative and individual life histories, can inform about shifts in male practices and lifeways when data are compared between groups. Furthermore, as the practice of certain behaviors is key in identity (re)construction, interpretation of these changes in the relevant social, political and historical context informs about important factors affecting the lives of men in Iberia. This is demonstrated through an analysis of markers of activity, disease, stature and burial rites from Medieval Écija and Coracho, Spain.

Evaluating the Effect of Force and Duration on Lithic Use Wear Using a Force- and Impedance-Controlled Robot  

Use-wear analysis relies on the strength of the analogy between microscopic wear patterns produced in laboratory experiments and those present on archaeological tools. Unfortunately, the physical processes that control the production of these patterns, both in the lab and in the past, are subject to complex interactions. One approach to reducing this complexity is to isolate factors (duration, material properties, or dynamics) that influence wear patterns and try to identify their contribution. An important issue concerns the possibility that wear on tools thought to have been used for a long time may in fact reflect use with a higher force, as both factors should, in theory, affect wear (e.g., Key et al. 2014, JAMT). We present results from experiments using a KUKA LWR-iiwa force- and impedance-controlled robot to scrape beech plates. The input data for controlling the robot (force, torque, velocity, position) were obtained from a dynamically monitored scraping experiment performed by humans (Pfleging et al. 2015, PLoS One). Because of the high level of control, we are able to systematically vary the duration and force and investigate their effect on the wear patterns, which are quantified via 3D surface metrological methods using a focus-variation instrument from Alicona.

Historical Archaeology in Downtown Mexico City: The Case of "La Casa del Mayorazgo de Nava Chávez"  

The historical center of Mexico City is a canvas of superimposed maps in which we can perceive history through the streets and architectural diversity. In this territory the Mexica Empire was settled as well as the colonial city. Later, this area was essential for the independence conflict and revolution. Nowadays is the political and cultural center of Mexico. The historic heart of the city has been the setting of outstanding incidental discoveries, of great significance for Mexican archaeology. The latest major finding was the monolith of the Earth Goddess, Tláloc, discovered on October 2, 2016, inside the Mayorazgo of Nava Chávez, premises popularly known as "La Casa de las Ajaracas." Although this site was the scenario of an intensive religious and ritual activity during prehispanic times, it has been continuously occupied for five centuries, since the Conquest. The aim of this paper is to present the history of this place and their inhabitants, as well as the results of the analysis of colonial ceramic materials recovered during the excavations of the seventh field season of the Templo Mayor Project.

Issavi, Justine (Stanford University) (Chair)

Trash Talk: (Re)evaluating External Spaces at Çatalhöyük, Turkey  

The Neolithic tell site of Çatalhöyük is composed of clusters of structures interspersed with open or external areas that contain extensive deposits of midden, as well as evidence for several other activities. James Mellaart (1967) initially identified these areas as courtyards while the current project has variously evaluated these spaces through frameworks of discard, food, and sharing practices. A general understanding of external spaces at Çatalhöyük sees them transformed from relatively informal and communal spaces into spaces that were used by individual houses or households as they became more autonomous and insulated, mirroring a wider social transformation noted elsewhere in the Near Eastern Neolithic. External spaces at Çatalhöyük, however, tend to be varied and complex and analyses often rely on comparisons between broad spatiotemporal categories. A multipronged approach including archaeological excavation, archival research, and spatial and statistical analyses has been deployed to provide a deeper understanding of these dynamic spaces and their long-term development. This paper will provide a brief synthesis of previous results, as well as present preliminary insights from recent research and the excavation of a large external space at Çatalhöyük in order to reevaluate external spaces as integrated parts of the Neolithic social and architectural landscape.

Iverson, Shannon (Rice University) (Chair)

Resignification as a Way In and a Way Out: Power and the Colonial Religious Experience in Tula, Hidalgo  

Archaeological assemblages from two early colonial religious sites at Tula, Hidalgo, are nearly indistinguishable from precolombian assemblages at the same sites. These findings indicate that colonial changes in material culture were much more gradual than we expected, and driven to a surprising degree by Indigenous traditions and aesthetic prerogatives. These data led us to reconsider various models of social change that would adequately account for the observations of material culture at Spanish religious sites. Clearly, we know from documentary sources that the so-called colonial encounter was not an equal exchange of ideas. However, models of top-down power alone could not account for the data in Tula. Conversely, models
that posited cultural continuity—an Indigenous “core” with a Spanish colonial “veneer”—seemed inadequate to account for genuine Indigenous relationships with the Church. This paper explores the legacies and problems of several models, including acculturation and syncretism, before positing Judith Butler’s concept of resignification as an appropriate model of colonial power and religious change.

Ives, John W. (University of Alberta)

Seeking Congruency: Search Images, Archaeological Records, and Apachean Origins

Apachean prehistory presents a significant conundrum: remarkably resilient and pragmatic people, Athapaskan speakers consistently adopted many elements of the ceremonial life and material culture of their neighbors, making for profound archaeological challenges. How do we truly know when an archaeological record was created by Proto-Apachean ancestors? The best response to this challenge is to draw upon the independent strengths of anthropological, linguistic and genetic studies to develop a series of “search images” pertinent to various stages of Apachean migration from Subarctic Canada to the American Southwest. These fields have provided clear targets we should anticipate in Apachean prehistory. The founding Apachean population was small, and undoubtedly grew through fissioning of small populations creating further founder effects. Yet, Proto-Apachean populations did not remain small; many people (especially women from neighboring societies) joined nascent Apache and Navajo groups. With new data emerging from Promontory culture, Franktown Cave and Dismal River sites, specific search images can be evaluated against the rich perishable, demographic, and isotopic data as well as evidence of societal interactions now available, in the context of high-precision chronologies. This paper will offer a synthesis of the status of archaeological research into Apachean prehistory arising from the symposium contributions.

Networking: Digital Archaeology Repositories in Argentina

The digitization of primary data in social sciences and humanities, including archaeology, has been a central issue in the management of science in Argentina by federal agencies, public universities and private foundations. About this topic, Argentina’s National Research Council (CONICET) created the Interactive Platform for Social Science Research, an interdisciplinary space, that over six years has generated protocols related to digitization and ways to share these results under the concept of open science. In this framework, a program focused on archaeology (Digital Archaeology Program—PAD) became an instance of theoretical reflexivity on the digital turn in the discipline and the social sciences and the humanities. Based on that experience we present some results from the PAD digital repository, which integrates archaeological collections, databases, gray literature, and publications. We will discuss relevant topics such as repository laws and digitalization criteria in Argentina, limitation of software and hardware, methodological issues and the training of human resources.

Jackley, Julia, Dana Lepofsky (Simon Fraser University), Nancy J. Turner (University of Victoria) and Jennifer Carpenter (Heiltsuk Integrated Resource Management Department)

Mountain Top to Ocean Floor: The Eco-Cultural History of Hauyat

The Mountain Top to Ocean Floor Project is a collaborative undertaking by the Heiltsuk First Nation, Simon Fraser University, and the University of Victoria that seeks to document and explore the unique cultural and ecological history of Hauyat, a landscape in Heiltsuk traditional territory on the Central Coast of British Columbia. Over millennia, Hauyat has been transformed by a complex web of relationships among people, plants, animals and ecosystems. The rich and deep history of this place is known through Heiltsuk oral history and is also reflected in the number and diversity of archaeological sites and eco-cultural features. Ranging from the lower intertidal to the subalpine, the landscape has been modified to include clam gardens, fish traps, root gardens, berry patches, orchards, settlements, rock art, and defensive sites. These features are suggestive of long-term resource management systems that likely worked together to provide food, materials, and medicines for past communities.

The Ernic, the Eltc, and the Electronic: Digital Documentation in Northwestern Belize

Twenty-five years of archaeological research in northwestern Belize have yielded a robust regional database, allowing a rich and diverse picture of ancient Maya life to emerge. As part of this research, multiple projects have recently adopted innovative digital technologies using new methods to record and envision ancient sites in novel ways. This paper presents some of the ways in which researchers have engaged with digital technologies that allow for the collection of new types of data, as well as renewed engagement with traditional archaeological data, with the overall goal of highlighting the array of methods used in this region and how they might be translatable to other Maya sites. In particular, our paper focuses on digital approaches used by the Say Kah and Chan Chich Archaeological Projects. Both projects use tablet-based paperless recording systems to streamline data collection. At Say Kah, the relational database is unique as it provides interpretive transformations by recording artifacts and features according to two cultural perspectives: archaeological and Classic Maya. The project at Chan Chich employs drones to map vast cleared areas and includes Structure from Motion documentation of excavations as a standard recording practice.

Between Control and Influence: Early Globalization Processes in Bronze Age China

The traditional narrative of the Zhou expansion (1046–771 BCE, roughly 800 before the formation of the first Chinese empire in 221 BCE), has been to view it as a military enlargement and conquest and as leading, consequently, to the establishment of a polity controlling a large territorial state. To date, most studies have viewed the finding of Zhou artifacts in a given region as indicating Zhou political control over that area or even that actual Zhou people inhabited the region. This paper argues that the Zhou expansion must be investigated in a contextual manner to evaluate the regional-specific cases of cultural exchange and the process through which it created new forms of localized social identities. Globalization offers a model that focuses less on an
all-powerful center dominating a periphery. Instead, it is the natural process by which the creation of new forms of connectivity, entanglements and cultural practices emerge from supra local interaction. This approach not only gets away from problematic models that identify material culture with specific ethnic groups, but also renounces power dynamics that conflate control with material assemblages.

Jafr, Nazim (Aligarh Muslim University, Aligarh India) [167] Cultural Change in Funerary Practices from Harappan to Post-Harappan Phases in Protohistoric India Various archaeological sites in the Indian subcontinent namely, Harappa, Kalibangan, Surkotada, Lothal, Daimabad, Bhagwanpura, Navadatoli and Nevasa have been identified as settlements dated to roughly 3000 to 1000 BC. These archaeological sites present evidences of urn burials, which have generally been overlooked in favor of extended burials and cremations, not unlike contemporary funerary practices. In this paper, I examine the distribution pattern of burials and cremations at the above sites, to shed light on cultural changes with respect to funerary practices in protohistoric India. The results suggest a dramatic cultural change in the practice of burials from the north Indian sites to the cremations on the sites in central and Eastern India. This suggests the Harappan Civilization was confined to the northern Indian continent, and its extension toward central and southern India was Post-Harappan expansion with remarkable cultural or religious change.

Jaimes Vences, Gustavo (Doctorado en Estudios Mesoamericanos. Universidad Nacional Autónoma de México) [145] Caracterización química (MEB-EDS) y cristalográfica (DRX) de cerámica local del sitio arqueológico Santa Cruz Atizapán En el sitio arqueológico de Santa Cruz Atizapán (con ocupación desde el Clásico tardío ca. 500–650 dc hasta el Epítasisca ca. 650–900 dc), han sido detectadas maestrosadamente una serie de pastas, que por sus atributos de textura, compatibilidad e inclusiones, fueron agrupadas en nueve conjuntos (inclusiones café, blancas, naranjas, de varios colores, pseudo anaranjado delgado, fina, intermedia, burda y con mica). Lo anterior refleja una diversidad en los posibles centros de producción cerámica que abastecían de vasijas a Santa Cruz Atizapán durante la época prehispánica. Con el objetivo de corroborar dicho planteamiento, se obtuvo la composición química de esos conjuntos mediante Microscopía Electrónica de Barrido y Escopetiloscopía por Dispersión de Energía (MEB-EDS), además se adquirieron diversas imágenes de la estructura microscópica de la pasta. Así mismo, para complementar la caracterización, se empleó la Difracción de Rayos X (DRX), lo cual permitió identificar las fases cristalinas de las arcillas usadas para la elaboración del utilaje cerámico. Los resultados preliminares permitieron la identificación de diatomeas en arcillas pertenecientes, en su mayoría, al Epítasisca, así como en aquellos correspondientes al Pseudo Anaranjado Delgado. Por su parte, las predominantes del Clásico (inclusiones café, naranjas, de varios colores) no las presentan.

Jakob, Tina, Joe W. Walser III (University of Iceland and the National Museum), Donatella Usai (Centro Studi Sudanesi e Sub-Sahariani, Trevio, Ita) and Sandro Salvatori (Centro Studi Sudanesi e Sub-Sahariani, Trevio, Ita) [219] A View from the Periphery: Bioarchaeology and Funerary Archaeology at Al Khiday, Central Sudan Archaeological sites south of Khartoum are much scarcer compared to those further to the north and this presentation aims to report on a multi-phase cemetery that is situated at the periphery of our archaeological knowledge. At present, burials dating to three chronological periods have been recovered at Al Khiday. The site is located on the left bank of the White Nile, approximately 20 km south of Omdurman (Khartoum). Forty-two individuals are dated to the Classic/Late Meroitic period (end of the first millennium BCE/beginning of the first millennium CE), while 25 early Neolithic burials date to the mid-fifth millennium BCE. Bioarchaeological parameters (age and sex distribution) are analyzed in conjunction with funerary rites (body placement, orientation and grave goods) and compared to Neolithic and Meroitic cemeteries in Nubia to evaluate whether the Al Khiday populations adhered to the same burial customs as those further north. Furthermore, the oldest burials, dated to the pre-Mesolithic period (>12.700–11.100 BCE), by using a combination of stratigraphic observations, mineral deposition and stable isotope analyses are the most exceptional. Most of the 94 individuals are buried in an extended, prone position, attesting to a unique funerary rite that is unparalleled on such a large scale.

Jalbert, Catherine (Memorial University of Newfoundland/Moore Archeological Consulting, Inc.) [258] Archaeology and the Social Sciences and Humanities Research Council (SSHRC): A Gendered Analysis of Federal Funding in Canada, Fiscal Years 1994–2014 Research conducted over the past twenty years on gender politics in archaeology has addressed both how the past is investigated, and has examined the presence of equity issues in the archaeological workplace. It has been suggested that multiple barriers exist for women’s advancement, however, funding for archaeological research has received little attention in the literature. Although studies in the United States and Australia have highlighted the presence of funding disparities between women and men, the situation in Canada is less understood. Specifically, I will present analyzed data from SSHRC’s Standard Research Grant and Insight Grant programs to examine if similar disparities are seen in Canada. Results from SSHRC show that although women and men had similar success rates, submissions from women were less than half that of men, and women listed as principal investigator received less funding on average. These results will then be compared to extant data from the United States and Australia. Providing contextualization in this way will aid in determining if global trends in gender disparities in archaeological funding are present and why they might be occurring.

James, Nathaniel (Washington State University) [177] Revisiting Harappa: A Reevaluation of Macrobotanical Evidence Harappa is a key site in understanding of the plant-human relationships that defined the increasing urbanization and eventual regionalization of the Indus Valley from 3300–1700 cal. BC. This paper presents a reevaluation of macrobotanical evidence excavated at Harappa from 1990–2000. It charts how the archaeobotanical record reflects changing social organization at the site.

Jamieson, Elaine (University of Reading) [168] Wizards, Dragons, and Giants: Creating Motte Castles in an English Landscape Medieval motte castles are large flat-topped earth and stone mounds, often coupled with an enclosure or bailey, and represent a characteristic component of the British landscape. Motte castles often dominate their immediate surroundings, with many remaining visually impressive monuments to this day. Although their creation often involved substantial landscape change, it is becoming increasingly clear that continuity could also be maintained. Many mottes were placed at points in the landscape with preexisting ritual significance, as seen through the adaptation of extant Saxon town defenses,
the reuse of Iron-Age hillforts, and the reappraisal of prehistoric mounds. The transformation of such sites would have reshaped peoples’ perception of place, serving not only to create continuities with the past, but also to facilitate a reordering of the broader social and symbolic world. A ritual dimension may also have been ascribed to the creation of the motte castle, with levels of significance attached to the processes surrounding its construction. This paper will draw on results from the Leverhulme Trust funded project Extending Histories: From Medieval Motte to Prehistoric Round Mounds, which is investigating the archaeology and history of monumental mounds in the English landscape.

[270] **Tokens of Oppression: Coinage at a Nineteenth-Century Galapagos Sugar Plantation**  
In the 1870s Manuel J. Cobos founded the El Progreso plantation agricultural operation on the Island of San Cristóbal in the Galapagos. It is known that he used “scrip,” or company-issued cash, to force workers to only spend their wages at the company store. Archaeological recovery of hard rubber tokens from several plantation contexts brings up many questions of economics and labor relations surrounding this remote location that was also tied to the global economy through steam power, commodity agriculture, and ideas of modernity.

[92] **Woodland Period Occupations along the Savannah River: An Update of the Late Prehistoric Investigations at the Topper Site (38AL23), Allendale, South Carolina**  
The Topper Site (38AL23) is a multicomponent prehistoric site located along the eastern bank of the Savannah River in South Carolina. The focus of ongoing University of Tennessee, Knoxville excavations at the Topper Site are the extensive Woodland and Mississippian occupations that have until recently gone unexamined. To date, two block excavations and a dispersed 1 × 1 m unit survey have been completed to better define these later occupations. Excavations have also resulted in the mapping, excavation, and processing of 357 features representing possible pits, post-holes, and other signs of past human activity. Utilizing the open-source software QGIS, site-level distributional analyses of recovered materials and features, and regional-level comparisons have shed new light on the peoples inhabiting and utilizing the Savannah River and surrounding areas. This paper presents a synthesis of these analyses as well as highlights the unique artifacts and features that have been excavated and will discuss the future directions of the project.

[344] **Before and After Mazama at the Billy Big Spring Site: Landscape Evolution during Altithermal Times and Reoccupation after the Eruption**  
How did the ash fall from the Mount Mazama eruption (7682–7584 cal. yr BP [Egan et al. 2015]) affect the people on the Northwestern Plains who experienced it? Data from 24GL304 (the Billy Big Spring Site) in north-central Montana is used to investigate this question. Excavations conducted in 1952, 1954, 1971 by Thomas Kehoe and in 2016 by our team all found extensive Middle and Late Plains Archaic deposits, but in 2016 we discovered a ~10 cm thick layer of ash from this eruption. This poster addresses four research questions through the lens of geomorphology and soil science: (1) How did the landscape evolve before and after the Mazama ash fall? (2) How did the paleoenvironment evolve after the eruption? (3) How does this landscape setting correspond to what archaeologists know about the Altithermal (9400–6000 cal. yr BP [Barnosky 1989]) on the Northwestern Plains? (4) How long did it take for people to reoccupy this site after it was covered with Mazama ash, and what did this occupation look like? Archaeologists have long hypothesized about the impacts of the Altithermal on the Northwestern Plains, and I hope to contribute to this discussion with data from these recent excavations.

[99] **Expanding Frontier and Building the Sphere in the Western Deserts**  
During the early and middle Holocene the deserts of Mongolia and northern China were characterized by arid grasslands and numerous lakes and wetlands. Specialized wetland exploitation defined land use during this period, but more detailed data on subsistence is not clear. The prevalent use of microlithic technology and the lack of architectural structures underscores the presumption that these groups were highly mobile hunter-gatherers, but increasing evidence reveals that pastoralism spread widely across the steppes of Northeast Asia during the third millennium BC. There has been no clear discussion of how desert groups were impacted by these changes. Here I examined the extent of climatic amelioration and present evidence to...
suggest that inhabitants of the western deserts were numerous and influential, and that they played a substantial role in the spread of pastoralist technologies—such as herding and bronze—into and across China.

Janzen, Anneke (Cotsen Institute of Archaeology, UCLA), Patrick Roberts (Max Planck Institute for the Science of Human Hist) and Nicole Boivin (Max Planck Institute for the Science of Human Hist) [224] Using Stable Isotopes to Explore Ancient Wildebeest Mobility in the Context of Pastoral Expansion

The spread of pastoralism through Kenya may have been slowed by novel disease challenges presented to livestock by wild taxa. In particular, wildebeest-derived malignant catarrhal fever (WD-MCF), which is extremely fatal to cattle, would have been encountered by pastoralists for the first time as they moved south of the Lake Turkana Basin into the native range of East African wildebeest (Connochaetes taurinus). Today, migratory wildebeest have well-known annual migration patterns. However, while they are currently not found north of Kenya’s Loita or Athi-Kapiti Plains, nor did early explorers describe them there, archaeological sites document their presence as far north as Lake Baringo until the second millennium BP. Pastoral extirpation of wildebeest populations from the prime grazing areas of the Central Rift Valley is one likely cause of their shifting biogeography over time. Stable isotope analysis is a powerful tool to examine ancient patterns of wildebeest distribution and mobility in the context of pastoral expansion. Through sequential sampling of wildebeest molaris from Rift Valley archaeological sites spanning the mid to late Holocene for carbon, oxygen, and strontium isotope analysis, a history of their annual migration cycles as herders and their livestock spread throughout their native range may be documented.

Jarrell, Katherine (Cornell University) [132] Modeling Maritime Travel in the Bronze Age Cyclades (Greece)

In this paper, I model maritime connections in the central Cyclades (Greece) to better understand small world network interactions during the Early Bronze Age (ca. 3100–2000 BCE). Using Geographic Information Systems (GIS), I create a cost raster of local and seasonal wind and wave patterns in the Aegean. Based on this, I generate an anisotropic model of the time it takes to sail outward from various settlements. When compared with ethnographic and archaeological evidence about travel times for habitual interaction, I predict which Early Cycladic communities would have interacted with one another on a regular basis. This allows for a more complete understanding of the intensity and frequency of Early Cycladic intercommunity relations. By relying on travel times rather than absolute distance, this model offers an understanding of community interactions based on meaningful scales of human movement and social time.

Jazwa, Christopher (Pennsylvania State University), Douglas J. Kennett (Pennsylvania State University) and Bruce Winterhalder (University of California, Davis) [383] Territoriality among Coastal Villages on California’s Northern Channel Islands

The location of archaeological settlement sites is influenced not only by the distribution of ecological resources, but also cultural factors including conflict between neighboring populations. The ideal free distribution is a human behavioral ecology model that has been used to understand the establishment and persistence of settlement sites in the archaeological record. On California’s northern Channel Islands, the number and location of settlement sites expands over time until the Medieval Climatic Anomaly (1150–600 cal BP), consistent with the predictions of the ideal free distribution. Afterward, total population on the islands continued to increase, but the number of major settlement sites decreased. We argue that this pattern, which is consistent with the ideal free distribution model, is in part due to territorial conflict. Rather than focusing settlement on all the best ecological locations, there are buffer zones between villages that were unoccupied. This includes the depopulation of sites that were occupied early and persistently throughout the Holocene. Many of the occupied sites are in defendable locations with large viewsheds. This study provides a useful case study for understanding the relationship between ecological and social factors in settlement distributions, illustrating the explanatory value of balancing general models and specific cases.

[351] Beyond “Document and Destroy” Mitigation: Fill In the Blank

The National Historic Preservation Act requires federal agencies to consider the effects of their actions on historic properties. In contrast to many other federal agencies, the Army Corps of Engineers, Regulatory Branch does not initiate undertakings on its own behalf. Rather, it is tasked with verifying permit applications from other agencies and the public. The Regulatory Branch is neither a proponent nor opponent of the permitted action. As a neutral party, one of the more challenging aspects of the Section 106 process is developing meaningful mitigation to resolve adverse. However before the consultation process reaches this point, the efforts to avoid and minimize the effects on historic properties plays an important role, contributing to and limiting the options to resolve the adverse effects. Examining permitting actions by the Seattle District Regulatory Branch, this paper presents efforts taken to avoid and minimize adverse effects and how these influenced the efforts to find and craft mitigation to resolve the adverse effects. A major challenge is balancing the conflicting agendas and requests of the consulting parties. The process to consider the consulting party’s opinions and the efforts to identify and develop the mitigation measures and their efficacy is presented.

[226] Western Stemmed Occupations of the Northern Great Basin

Recent research into the chronology and character of Western Stemmed Tradition occupations at the Paisley and Conney Caves provides new insight into the settlement-subsistence patterns and social organization of the period >13,000 to 9000 cal. BP. Human populations may have been larger, more social, and territorially constrained than previously envisioned. Long distance movement of obsidian artifacts across the landscape probably reflect brief population agglomerations (festivals) scheduled to coincide seasonally with peak periods of biologic productivity (late summer–early fall). Pronghorn and rabbit drives, in particular, in and around grasslands surrounding lowland lakes and marshes offered the perfect opportunity to meet potential mates, trade, gamble, exchange gossip, and keep abreast of social developments.

[274] Using Geochemistry, Phytoliths, and Ethnographic Analogy to Interpret Neolithic Settlements in Southwest Asia

Our understanding of Neolithic sites in southwest Asia is often impeded by the lack of preservation of biological evidence. As a result, they often consist of a series of structures, the construction and function of which, remains elusive. In order to address this problem we conducted a study which used phytoliths and geochemistry from an ethnographic site in Jordan, Al Ma’tan, to determine if certain building construction techniques and anthropogenic activities leave specific phytolith and elemental signatures. We sampled a range of context categories and our results found that certain building techniques and anthropogenic activities leave specific phytolith and elemental signatures. [375] Prehistoric Rock Art and Historic “Graffiti”: Petroglyphs at a Multicomponent Site in Eastern New Mexico

Recent field investigations at Los Ojitos, a multicomponent site in the Middle Pecos River Valley, have focused on refining the site chronology and documenting the land-use practices of Hispanic homesteaders who settled this area in the late nineteenth century. Like earlier visitors to this site, the Hispanic settlers were attracted to the clean water provided by several little springs (“ojitos”) that empty into the river. Survey of one of these spring-fed drainages identified at least 45 petroglyphs—many concentrated in a shady alcove—that range from prehistoric horned serpent figures and undated abstract designs to historical-period carvings of names, anthropomorphs, and possible gaming boards. This paper presents the results of this survey and reflects on the different ways archaeologists have approached and investigated prehistoric and historical-period rock art in this area.

[2] Walakpa as Case Study: Rescuing Heritage and Data from a Vanishing Site

Walakpa is an iconic Arctic site with spectacular preservation, due to frozen conditions. Although many believe it to have been fully excavated, Stanford was only able to reach a third of the way to sterile soil due to permafrost, so earlier occupations of the site remain unstudied. Long considered stable, Walakpa began eroding rapidly in 2013. A single recent storm removed over 30 m of cultural stratigraphy along a 100+ m front. Need for rapid response prompted a large volunteer effort in 2016, with support from the landowner (an Alaska Native village corporation) and the municipality, as well as many individuals. I will briefly describe the data recovered. Walakpa is only one of many such significant sites in the north, all under threat from climate change. Using Walakpa as an example, I will discuss the implications for our ability to contribute to the expansion of scientific knowledge of the past, and discuss how choices we make in the next few years will impact our science for the foreseeable future.

Ceramics Provenience: Chemical Analysis of Ceramics and Clays in Eastern Hungary via LA-ICP-MS

This project explores the provenience of ceramics found at the Bronze Age Békés 103 cemetery. By answering the question of where these ceramics came from, it is possible to hypothesize which Bronze Age communities used the cemetery. To do this, clays were collected throughout Eastern Hungary for chemical analysis. Clay is often found along river banks, but many modern rivers may have been polluted. Instead, paleo-meanders of modern rivers were chosen as collection sites; these were identified using QGIS. This revealed the chemical variability found throughout the region. Then, by comparing the chemical composition of the clays to that of the Békés 103 ceramics, the farthest possible extent of cemetery usage was determined. Preliminary analysis of the clays was performed using XRF. Both the ceramics and the clays were analyzed by LA-ICP-MS.

Petroglyphs As Time Markers for Pleistocene Occupation of the Great Basin

The association of cupules and pit and groove petroglyphs is possibly the oldest form of “rock art” in the Americas as evidenced in the northern Great Basin. Recant methods of dating petroglyphs, made possible by unusual paleoclimatic circumstances, have resulted in what may be the identification of the ‘North America’s oldest petroglyphs.” Three sites located on the shores of ancient Pleistocene Lakes, two at Lake Lahontan in northern Nevada and one at Long Lake in southern Oregon, have given evidence of this style of petroglyph’s great antiquity. At Winnemucca Lake in the far northwestern sub-basin of the Lake Lahontan system, absolute dating was possible on a tufa dome of calcium carbonate deposited by variable lake levels of the Younger Dryas. In all three cases the pit and groove/cupule petroglyph style is present on the shores of Pleistocene pluvial lakes that are now dry lakebeds.

Strangers in a Strange Land: The Lake Koshkonong Oneota Locality in Context

The distribution of Oneota sites in Wisconsin has long been recognized as clustered within distinct areas referred to as Localities. At least seven localities are now generally accepted by Oneota researchers in Wisconsin; several others appear to exist in northern Illinois. However, recent research at the Lake Koshkonong locality shows that it stands as a distinctive outlier among all of the other localities. It is unique in terms of landscape patterns, subsistence strategies, distance from other localities, and interregional and/or interlocality economic and political relationships. A demonstration of this distinctiveness, and an explanation for it, are offered.

Jew, Nicholas P. (University of Oregon), Taylor Dodrill (University of Oregon) and Scott M. Fitzpatrick (University of Oregon) [223] Stable Oxygen Isotope 518O Analysis of Crocus Clam (Tridacna crocea) from Palau, Micronesia: Evaluating a Proxy for Sea-Surface Temperature Reconstruction

For thousands of years and on a global scale, shellfish have been a key resource for peoples living in island and coastal environments. Not only were they critical food resources, but can act as records of paleoenvironmental conditions. In this study, we evaluated whether the crocus clam (Tridacna crocea) could satisfactorily record ambient water temperature via the incorporation of oxygen isotope ratios into the calcium carbonate matrix during shell growth. Modern Tridacna crocea were collected from intertidal zones near the prehistoric (ca. 3000–0 BP) site of Chelechol ra Orrak in the northern Rock Islands of Palau and compared with samples from the archaeological assemblage. The shells were sampled for stable oxygen isotope analysis, fractionation equations applied, and temperatures compared to modern reported nearshore temperatures to determine the efficacy of T. crocea’s temperature recording. X-ray diffraction was also used to determine the shell’s biomineralogical composition, necessary for selecting the appropriate water temperature conversion equation. Results demonstrate that this species is an accurate proxy for estimating ambient sea-surface temperatures (SST), particularly long-term changes due to its slower growth rate.

[26] Agriculture Development in the Bronze Age Hexi Corridor-Archaeobotanic Evidence from Xichengyi Site

The combination of crops and weeds found in the site reflects a typical rainfed agriculture dominated by foxtail millet and broomcorn millet. Under the external cultural influences, wheat and barley started to be cultivated. Since late Machang culture and, through the agricultural development during the “Transitional type" period, were widely cultivated during the period of Siba culture, when marijuana appeared in the crop assemblages. The integrated study of archaeobotanical and zooarchaeological remains, and isotope analysis indicate a subsistence strategy dominated by dry farming during Siba culture in Xichengyi site. Meanwhile, husbandry accounted for certain percentage, with occasional hunting and gathering.

[24] Research on Neolithic Settlements in the Guanglu Island and the Liaodong Peninsula, China

The Liaodong Peninsula was a hub that documented interactions across distinctive Neolithic cultures in northeastern China and the northern Korean Peninsula. The Neolithic sites in the Liaodong were neighbors with the Liao River (Liaohe) culture to its north; located across the Yellow Sea from the Huanghe culture; and were adjacent to the Chulmun Neolithic culture in Korea across the Yalu River. Thus Liaodong is a key region to understanding cultural interactions throughout the Neolithic period in Northeast Asia. The Institute of Archaeology of the Chinese Academy of Social Sciences has conducted fieldworks in several Neolithic shell midden sites in the Guanglu Island in Liaodong for the last decade. This study focuses on changes in settlement patterns in the Guanglu Island and coastal sites in Liaodong.

[153] Assessing Edge Damage in MSA Lithic Assemblages: Experimental Proxies for the Analysis of Use and Postdepositional Damage

Given the low frequency of retouched stone tools in many Middle Stone Age (MSA) assemblages, the analysis of edge damage on unretouched artifacts offers a promising depth of insight into tool-use behavior. Taphonomic process such as trampling, however, can also cause edge damage on lithic artifacts. As part of the investigation of GaJj17, an MSA site in the Koobi Fora region (Kenya), we conducted an experiment designed to investigate differences between edge damage resulting from use and resulting from postdepositional damage. Damage was inflicted on the edges of a series of ignimbrite flakes in a variety of experimental contexts (e.g., butchery, trampling). These experiments mimicked processes that may inflect damage on tool edges. We assessed the relationship between edge angle and the intensity and continuity of edge damage in these experimentally damaged artifacts. A qualitative assessment of the intensity and continuity of edge damage was used to distinguish use from postdepositonal damage. These criteria were applied to in situ and surface collections from GaJj17. These analyses sought to test whether the archaeological assemblages exhibit patterns of damage more similar to experimental use or trampling. This research was sponsored by the National Science Foundation IRES Program (OISE-1358178 and 1358200).

[332] Functional and Organizational Variation among Late Mesolithic Sites in Southwestern Germany

Because sites of the Late Mesolithic are relatively rare in southern Germany, and are mostly represented by caves, three open-air sites of this period provide unique insights into this period. Two of the sites are located on a lakeshore and the third is in a river valley. All three possess excellent preservation of organic materials that facilitate analysis. The contents and spatial organization of these sites will be examined in the context of their functional role and their implications for understanding the lifeways of the last hunter-gathers in the region.

[167] “The South” as Object of Knowledge between Archaeology and History

With a focus on writing about the medieval period in southern India, this paper will interrogate how south India came to be defined as an object of knowledge, and thus, a space for representation. Narratives on the south Indian past, from the writing of the Dravidian proof in early nineteenth-century Maddras to Nilakanta Sastri’s iconic History of South India in the year of India’s independence, have engendered polyvalent inheritances for current historiographical projects. In unpacking these inheritances, this paper is interested in the mechanisms of the constitution of historical facts. While the history of medieval south India has typically drawn from textual sources, both literary and epigraphical, archaeology makes different promises of retrieval and representation. Yet, archaeologists too must contend with inheritances of method and narrative, often rooted in the particularities of the object of knowledge. Taking a cue from the attentiveness of deconstruction toward the processes of historiography, archivisation and the representation of knowledge, this paper interrogates the relationship between evidence and narrative. It is especially interested in the impetus for new evidence, and the role of newly generated facts in plugging perceived gaps in our knowledge of “the south.”

[167] Settlement, Socio-environmental Practice and the Long Durée of Landscape Production in South India: A Regional View from Maski, Raichur District, Karnataka
For five seasons, the Maski Archaeological Research Project has been collecting new multi-period archaeological and environmental data on changing patterns in settlement, agricultural, pastoral and metallurgical land-use practices from a 64km² study area surrounding the large multi-period site at Maski. Our research documents significant temporal changes in the size, configuration, density and location of settlements, as well as those among a myriad of other sites (e.g., pastoral camps, field stations, iron working facilities, rock art complexes, water retention features, and mortuary sites), and ‘off-site’ artifact distributions dating to between the South Indian Neolithic and Medieval Periods (3000 BCE–1600 CE). Occupational histories of geo-environmental contexts (e.g., inselberg slopes and terraces, pediment slopes, peneplain and river terraces) point to shifts in social and environmental practices that transformed a range of soils, water and mineral sources into social and economic resources. We discuss how, through the deployment of strategies and technologies of control (social and environmental), opportunities and inequalities of access to these resources were constructed and contested across an ever-changing political landscape. In doing so we argue for a regionally unique social and environmental history in which ecological vectors of social difference contributed to the production of a temporarily dynamic political landscape.

Johansson, Lindsay (University of Colorado, Boulder)  
[339] People and Animals on the Move: Insights from the Promontory Caves on Proto-Apachean Faunal Use and Hunting Practices  
The faunal assemblages recovered from the Promontory Caves by Julian Steward, and more recently by John Ives and Joel Janetski, suggest that the subsistence practices, hunting patterns, and mobility strategies of those using the caves ca. AD 1100 to 1300 differed greatly from those of later peoples who used similar ceramics in the same region. While there are many potential explanations for these differences, this paper uses faunal data to argue that large game hunting, together with the mobility patterns of the animals hunted and transport decisions made by hunters living in the Promontory caves, may have adversely affected large game populations in the area and, as a result, prompted some proto-Apachean individuals to leave the Great Salt Lake region when large game populations became less reliable. Because of the heavy dietary focus individuals living in the Promontory Caves placed on large game, it is possible that when these individuals left the area, they followed migrating game, eventually ending up in new places such as the Dismal River region.

Johnston, Christine (Western Washington University)  
[240] Reinventing by the Wheel: Ceramic Networks and New Approaches to the Study of Political Economies  
This paper explores the value of network analysis as a method for the quantitative assessment of trade systems with the aim of profiling the structural nature of their associated political institutions. This study will focus on trade in the Eastern Mediterranean during the Late Bronze Age (ca. 1700 to 1200 BCE), and includes a network analysis of Cypriot and Mycenaean pottery circulated throughout Egypt, Cyprus, and the Levant. The analysis of ceramic distribution networks demonstrates a high degree of variability in consumption and import-distribution systems across the regions of study. Network centralization and density measures indicate diverging mechanisms for import circulation, which coincide with the contrasting political institutions extant in this period. The networks of ceramic trade in Egypt and the Levant will be contrasted to examine the correlation between network measures and the summarised political structures in these two regions during this period. Results of this analysis will demonstrate the efficacy of network methods for the examination of political economy and traded materials.

Johnson, Eric (Harvard University)  
[261] Measuring Household Wealth Using Mound Accumulation Rates in Skagafjörður, North Iceland  
Characterizing inter-household inequalities has long been a fundamental task of archaeology, but a fine-tuned measure of household wealth is often troubled by the inability to account for time or demographics in the archaeological record. This project tests the ways that Iceland, settled by Norse populations between AD 870 and 930, provides a temporally-sensitive mode of measuring household wealth through average rates of midden and architectural accumulations while also providing a context for studying the emergence of inequality in a previously uninhabited landscape. In 2014, a deep-coring survey of 11 occupational sites was conducted in the region of Langholt in Skagafjörður, Northern Iceland to supplement shallow-coring practices that transformed a range of soils, water and mineral sources into social and economic resources. We discuss how, through the deployment of strategies and technologies of control (social and environmental), opportunities and inequalities of access to these resources were constructed and contested across an ever-changing political landscape. In doing so we argue for a regionally unique social and environmental history in which ecological vectors of social difference contributed to the production of a temporarily dynamic political landscape.

Johnson, Erlend (Tulane), Ellen Bell (UC Stanislaus) and Marcello A. Canuto (Tulane)  
[71] Tracing the Emergence of Maya Lordship at Secondary Centers of the Copan Polity: An Examination of Residential Differentiation and Access at Centers in the Cucuyagua and El Paraíso Valleys  
In this paper we contend that Copan fundamentally transformed the political structures and social institutions of centers in outlying areas as it expanded and integrated these regions. Evidence from our areas of study, the Cucuyagua and El Paraíso valleys, suggest that these regions had long lived autochthonous populations prior to Copan’s expansion into these regions in the Late Classic period. Using evidence from other non-Maya sites in Western and Central Honduras we contend that while varied political systems in these valleys lacked the same degree of social and political hierarchy typical of Maya culture. By examining how Late Classic period site layouts and residential patterns changed over time, we will evaluate to what degree Maya style political hierarchy was adopted in each valley. The data suggest that integration within the Copan polity an adoption of Lowland Maya style political relations led to significant structural changes that allowed local rulers to accrue greater wealth and prestige than had previously been possible. At the same time the degree to which these changes occurred varied from center to center, which may point to differing mechanisms and processes by which these institutions were introduced.

Johnson, Jack (Burke Museum, Univ. of Washington)  
[51] Chronometry at Bear Creek, a ~12,000-Year-Old Site in Western Washington  
Extant deposits at the Bear Creek site are highly compositionally variable, including fibrous peat, fluvial sands, volcanic tephra, and diatomaceous earth, reflecting a series of significant Holocene changes to the local environment. Multiple methods were used to directly date each of these sediments, including radiocarbon dating, single-grain IRSL dating of feldspar, OSL dating of fine-grained quartz, and tephra dating. Results from independent chronometric methods were then integrated with Bayesian analysis performed in OxCal 4.2 to allow statistical assessment of the stratigraphic compatibility of individual dates, to identify significant outliers, and to generate a comprehensive site chronology. Results show a high degree of success; individual dates were generally stratigraphically compatible, with excellent statistical agreement between independent chronometric methods. Results therefore firmly establish the antiquity of the early Bear Creek cultural component at ~12,000 years old and provide a detailed depositional history spanning roughly 9,000 years of local environmental change.

The Emergence of the Bel’sk Settlement Complex: Landscape, Population Histories, and Social Structure

Assessing Defensibility: Geospatial Analyses of Preclassic to Colonial Highland Maya Settlement Patterns

Postclassic Maya settlement patterns have long been explained in terms of the increasing defensibility in the transition from Classic period settlement patterns. Drawing on arguments for the increased militancy and conflict that characterized the Maya region in the wake of the Classic “collapse,” this narrative has endured despite minimal cross-context, large scale assessment. This paper presents the results of a large-scale, in-congress diachronic analysis of Maya settlement patterns, defensibility and agrosuitability from Preclassic to Colonial periods. Working from Edwin Shook’s site survey data, we employ geospatial and statistical approaches to determine defensibility and its intersection with historic land use practices in order to provide cross-comparable and quantifiable data on changing site defensibility across multiple time periods and in different regions. While our results address and nuance defensibility and violence narratives, we also provide insight into the variable historical trajectories, experiences and motivations of diverse Maya communities reflected in heterogeneous settlement patterns.

Pochteca from Cahokia, an Evaluation of the Implications of Mississippian Period Contact between the American Bottoms and the Northern Yazoo Basin in Mississippi

Drawing primarily on data from the Carson Mound Group located in the Mississippi River floodplain of northwestern Mississippi, this paper considers the timing, duration, and nature of the substantial evidence for what appears to have been direct contact between the polity that centered on Cahokia and the people who built the mounds at Carson. Distinctive northern traits include raw material, lithic technology, projectile point styles, ceramics, and architecture. These traits appear for a very short span of time during the founding of Carson which is one of the earliest Mississippian Period sites in the northern Yazoo Basin. There is the suggestion that Cahokia played a role in the transformation of Woodland into Mississippian in this part of the Southeast.

The Emergence of the Bel’sk Settlement Complex: Landscape, Population Histories, and Social Structure

During the Pontic Iron Age, ca. 700–300 BCE, large fortified settlement complexes that encompass areas between 100 ha and 5,000 ha emerged along the forest-steppe and steppe boundary in Ukraine. At Bel’sk, the largest settlement complex of its kind with three separate settlements were linked by a fortified wall spanning 33 km, delineating a massive urban internal space from its hinterlands. Despite one hundred years of periodic archaeological investigation, much about the Bel’sk settlement complex remains an enigma, including its role in Pontic interregional or more localized socioeconomic dynamics. A collaborative Ukrainian-American-Austrian team, funded by the National Geographic Society, began new work at Bel’sk focusing on the analysis of remotely sensed imagery that allow us to explore population levels for each settlement, the construction of the fortifications, and the agropastoral land needed to support the settlement complex. Isotopic analyses of human and animal remains recovered from the cemeteries located at Bel’sk and beyond were also conducted to investigate the degree of mobility in human and animal populations present. In this paper, we discuss the important socioeconomic role of settlement complexes like Bel’sk in the movement of people and livestock in and out of the Pontic forest-steppe/steppe regions.

Multiethnic Colonial Communities and Endogamy: Evaluating the Dual Diaspora Model of Moquegua Tiwanaku Social Organization

The Moquegua Valley Tiwanaku colonial enclave was comprised of two Tiwanaku-affiliated populations: camelid agropastoralists who used Omo-style ceramics and maize agricultural specialists associated with Chen Chen-style ceramics. Despite living in close proximity, Chen Chen- and Omo-style communities maintained distinct social and cultural boundaries for several centuries. Goldstein’s dual diaspora model suggests that Omo- and Chen Chen-style Tiwanaku colonists represent two separate but interconnected ethnic diasporas, comparable to maximal ayllus, whose members maintained affiliations with their ancestral homelands. Goldstein suggests that members of Chen Chen- and Omo-style maximal ayllu communities also maintained separate ethnic identities in part through endogamous marriage practices. This study evaluates the biological implications of the dual diaspora model. Biodistance and exploratory data analyses of basicranial and temporal bone landmarks are used to evaluate patterns of gene flow among samples of human skeletal remains from five archaeological sites in the middle Moquegua Valley, Peru. Overall, results suggest that maximal ayllu affiliation influenced gene flow within the Moquegua Tiwanaku colonies, but Omo- and Chen Chen-style communities were not strictly endogamous. While normative marriage practices favored maximal ayllu endogamy, there were exceptions to this general pattern. These exceptions were likely structured by myriad factors, including family-based social organization.

Multiethnic Colonial Communities and Endogamy: Evaluating the Dual Diaspora Model of Moquegua Tiwanaku Social Organization

If It Were Your Grandma: A Tribal Perspective on NAGPRA in Utah

In 1990, the Native American Graves Protection and Repatriation Act (NAGPRA) was passed. The passing of NAGPRA was a huge step forward for indigenous rights; the law allowed tribes to decide the ultimate outcome of Native American burials found in any context on federal or tribal land. In Utah, there are also state laws that require similar standards of protection on private land. That being said, the repatriation process can be long and painful for many tribe members who are concerned with the welfare of their ancestors. Oftentimes, tribe members must fight the interests of archaeologists to demand the respect that they feel their ancestors deserve. Through evidence gained from interviews with tribe members in Utah, I will show the perspective of the tribes on grave repatriation and NAGPRA associated practices. I will then present possible solutions for the problems raised by tribe members. Hopefully, this paper can help to create a culture of mutual respect and understanding between archaeologists and tribe members.

INDIVIDUAL ABSTRACTS OF THE SAA 82ND ANNUAL MEETING 281
Faunal Analysis of Two Columbia River House Feature Sites: Hole-in-the-Wall-Canyon (45KT12) and French Rapids (45KT13)

As part of ongoing thesis work, a taxonomic and taphonomic faunal analysis was conducted for the zooarchaeological collections (n = 5,000) of two house feature sites, Hole-in-the-Wall Canyon (45KT12) and French Rapids (45KT13). Both sites are located near Vantage, Washington, within the inundated area of the Wanapum Reservoir, and date ca. 2400–200 BP. Originally excavated as part of large scale archaeological salvage work prior to dam construction in the summers of 1961–1962, the fauna was never analyzed. The study area represents a significant spatial gap in analysis and reporting of faunal data along the Columbia River. While fauna from house feature sites has been reported for areas to the north and south along the Columbia River, as well as for sites along the Snake River, almost no significant quantifiable faunal data has been reported for the Columbia between its confluence with the Wenatchee River (river mile 468) and Snake River (river mile 325). Preliminary identifications include deer, sheep, rabbit, dog, muskrat, sucker, salmon, minnow, and mussel, and further analysis is underway. The thesis will report on differences and similarities between the analyzed faunal collections and other reported house feature faunal assemblages along the Snake and Columbia Rivers.

Johnson, Meghan (Archaeological Investigations Northwest, Inc.) and Marci Monaco (Archaeological Investigations Northwest, Inc.)

Dittman Cache Replication

Experimental replication of the fourteen bifacial blanks recovered from the Dittman cache, site (35MA375) located near Salem, Oregon, provided information that will help answer numerous technological questions as research on the site continues. This study attempts to determine if the bifaces were prepared at the Dittman site or transported there in their current state of reduction. Our primary goal is to demonstrate what debitage would be present if the bifaces were manufactured at the site. Two sets of fourteen bifaces were produced in a controlled setting. One set by an experienced flintknapper and one set by two novice flintknappers. The individual reductions were timed, collected, and analyzed. Debitage was separated by size, type of termination and whether the platform was present, absent, or crushed. The replicated bifaces were compared to the cache bifaces and the debitage was analyzed by reduction stage. The experimental data can be used to determine if the bifaces were produced at the Dittman site. The data can also be used to answer questions regarding the reduction strategy, technological approach, implications of obsidian quality selected, possible skill level of the flintknapper, and to determine if the cache was intended for local use or trade.

Johnson, Nadia (Penn State) and Kenneth G. Hirth (Penn State)

Altica and the Role of Middlemen in Formative Obsidian Exchange

Altica’s location, in the Patatachie Range 10 km away from the Otumba obsidian source, suggests a potentially significant role in the distribution of Otumba obsidian. Altica may have served as an important middleman and processing site in Formative obsidian exchange, but a greater understanding of the nature of these exchange relationships is required to define this role. This paper combines geochemical sourcing and technological data from obsidian from nine Early and Middle Formative sites, including Altica, in order to reconstruct the movement of obsidian in this period. The intent of this study is to identify the sources and consumption sites, as well as the physical form in which obsidian was transported—in rough cores, macroblades, or finished products. In doing so, the paper will assess role that intermediary sites like Altica could have played in the processing and distribution of obsidian into downstream sites.

Subsistence and Seasonality during the Thule Phase (ca. 1000 BP to Contact Era) at Point Spencer, Alaska

Intensification of marine resource use is well documented over the last 1,000 years in northern Alaska, but the role of other resources in the subsistence economy is poorly understood. In order to better understand the full range of subsistence activities, and to reconstruct season of site occupation, we undertook analysis of faunal materials from several Thule Phase sites located on Point Spencer, Alaska. The subsistence remains from a large site near the tip of the peninsula (TEL-8) were found to be dominated by sea mammals, primarily ringed seals (Pusa hispida), with bird remains dominated by eiders (Somateria spp.) and some sea ducks and mergansers. By contrast, least auklets (Aethia pusilla) dominated the bird fauna of the other sites along the peninsula, and fewer sea mammal remains were identified. These sites also contain large quantities of fish bone, in contrast to TEL-8 site where fish bones were extremely rare. The variety in faunal remains suggest that this region was an important subsistence gathering location across multiple seasons and that local diet was relatively diverse. These results contribute new data to a limited but growing body of research on diet and subsistence activities in Arctic hunter-gatherer groups over the last 1,000 years.

Testing for Environmental Rebound: Untangling a Multicausal Event

“Environmental rebound” has been proposed by a large number of researchers to explain the disjuncture between the reports of American environments by early Spanish explorers and the long-term human impacts evidenced in the archaeological record of North, Central, and South America. However, by definition environmental rebound may be caused by multiple factors: changes in human population numbers, settlement patterns, resource acquisition and/or land use may all have contributed to a rebound of environmental conditions to historically observed levels. The presence of these multiple potential causes as well as their intertwined nature makes it difficult to definitively demonstrate rebound in the archaeological record. In this paper, I review the literature (archaeological and other) on environmental rebound associated with the Columbian Exchange; explore the different ways scholars have tested for rebound; and assess the potential of different avenues for moving forward in understanding rebound events.

Lithic Use in the Upper Yadkin River Valley and Its Implications for Southeastern Late Woodland Exchange Networks

Mississippian and Piedmont Village Tradition (PVT) communities contemporaneously occupied the North Carolina and Virginia Piedmont and adjacent areas from AD 1100–1600. Discussions of trade and exchange, however, tend to focus on Mississippian political economies. Previous work at PVT sites has identified nonlocal lithic materials, some moving between Mississippian and PVT areas, suggesting a regional network that included both cultures. Our work focuses on the fourteenth-century Redtail site (31Yd173), a small, dispersed PVT settlement in the upper Yadkin River Valley. We compare
total proportions of local to nonlocal materials between Redtail and other sites in the valley to examine variations in material use over time and space. We also examine the context, spatial arrangement, and material type of different tools to understand how access to particular materials influenced their use at this site. This work provides new information on PVT exchange behavior, which is critical to understanding the complete scope and structure of Southeastern regional trade networks. The influence of Tom and Charlotte’s approach to research, teaching, and mentoring is apparent throughout every aspect of this project, from the analytical methods to the collaborative approach that values undergraduate students as legitimate scholars.

The late twelfth and early thirteenth centuries AD in the southern Levant are a period of increasing political centralization, ending the political instability caused by the fragmentation of the ‘Abbasid Empire in the tenth century AD. While the eleventh and early twelfth centuries are marked by near-constant shifts in political sovereignty, by the thirteenth century control was contested only between the Ayyubid rulers of Cairo and Damascus. A third center—Karak, in central Jordan—was, however, able to achieve political autonomy, if only briefly, during the thirteenth century, largely through maintaining economic autonomy. The elites of Cairo and Damascus recognized and attempted to disrupt this economic autonomy, but with only limited success. This paper presents evidence from recent archaeological research at one of the “nodes” of this economic strategy, the copper ore resource district of Faynan, in southern Jordan, where copper production saw a brief revival during the twelfth and thirteenth centuries AD. This strategy of maintaining political autonomy is also compared to other strategies that have been archaeologically and historically observed in the Levant both earlier and later in the Islamic periods.

[151] Population Aggregation at the Early Bronze Age Settlement of al-Lajjun, Kerak Plateau, Jordan

The University of Minnesota Duluth Project is working at al-Lajjun to understand the initial period of population aggregation in the southern Levant. At this time, settlements of 5,000–10,000 people, some with fortification walls, developed. The economic and political organization of these larger groups of people, whether hierarchical or haphazard, competitive or cooperative, embedded in or separate from kin groups is under debate. Our research seeks to add to this discussion by detailing the intrasite location of craft production and the distribution of architectural features at one such third millennium site. Al-Lajjun is unburied by later settlement so the visibility of artifacts and architectural features offer a valuable space within which to experiment with intensive site survey and GIS mapping techniques. During our initial season, we identified two interior areas inside the fortification wall with concentrations of lithic debitage and established the feasibility of extensive artifact mapping. In our second season, we mapped and recorded at least 100 domestic and nondomestic architectural features visible on the surface of the site. Next steps include excavation to understand the function and sequence of occupation of the various structures and additional intensive survey to map the distribution of craft production across the site.

[165] Bioarchaeological Approaches to Reconstructing Upper Paleolithic Environments in the Cantabrian Region, Northern Spain

The Cantabrian Region of Northern Spain was an important refugium during the harsh conditions of the Last Glacial Maximum, when ice sheets covered much of Northern Europe and populations were pushed further south. Late Upper populations in the Cantabrian region thrived at this time, and there is an increase in the density of archaeological sites is seen, in addition to cultural changes such as the creation of rich cave art assemblages. Understanding the climatic and environmental conditions experienced by humans and animals in the region is key to understanding the region’s importance during the Upper Paleolithic. Specifically, what the environment like was on both an individual site level and regional level is crucial in understanding the conditions experienced by the humans living during the Upper Paleolithic. The use of δ13C and δ15N stable isotope analysis of animal bone collagen from hunted ungulates, in combination with more traditional environmental proxies can produce detailed paleoclimatic reconstructions directly linked to the moments when these sites were being occupied. Results show that environmental and paleoclimatic changes were occurring in the region at this time, impacting on the behavior of Upper Paleolithic humans and animals, observable on an individual site level and regional level.

[337] Archaeobotanical Realities at Yaxnohkah: A Pollen Grain of Truth on Preclassic Land Use

Examination of sediments from several reservoirs at the Preclassic site of Yaxnohkah Campeche, Mexico reveals less than stellar pollen preservation, but still useful botanical data. Thus, pollen grains show varying degrees of degradation, requiring the use of exacting extraction methods. Cultigens and economic taxa are abundant in the samples demonstrating that we are sampling in the right place, but cyclic wetting and drying has resulted in the loss of fragile taxa, skewing the botanical record. Pollen data can still be obtained, but requires careful analysis and interpretation to identify past activities at this large, important site. Upcoming excavations will focus on the collection of sediments from additional reservoirs and wetlands rich in clay, where oxidation has been less damaging.

[286] Cooperation and Violence in Prehistoric California: A Brief Interregional Evaluation

Intergroup cooperation in prehistoric California has traditionally been evaluated via the relative intensity of exchange—tracked archaeologically with shell beads and obsidian. Transported great distances (most commonly via down-the-line exchange) trade items in abundance imply amiable intergroup relations, if not actual cooperation. Violence, on the other hand, as represented in the ethnographic and bioarchaeological records, is generally assumed to represent hostile interactions between individuals and groups. Models that consider these alternative interactive options generally assume that times of non-violence most likely coincided with increased intergroup economic cooperation (e.g., trade). In some instances intensity of violence indeed correlates with paleoenvironmental variability, specifically with upturns in violence during intervals of climatically-induced resource scarcity. Here we evaluate dichromatic patterns in both trade and violence from several regions of California and find surprisingly that trade and some forms of violence did not necessarily alternate, but rather, at some times, co-varied, peaking simultaneously, and then declining.

[309] Storage, Cooking, and Transport: A Preliminary Residue Analysis of Ceramics from Mai Adrasha

This paper outlines the preliminary investigation of a collection of diagnostic and undiagnostic ceramics recovered from the site of Mai Adrasha, located in the Shire region of Ethiopia. Mai Adrasha is one of the largest and arguably most significant early town sites west of Aksum dating to the Pre-Aksumite to Early Aksumite periods (twelfth century BCE–second century CE) located in the Western Tigray. The site consists of a cemetery and a domestic area characterized by a collection of stone walls and ceramic and lithic assemblages. Study of this site will yield important information on the early prehistoric period and uncover insights into the social, economic, and political organization of the Aksumite polity and what preceded it. Our goal here is to present the initial results of a series of ceramic residue analyses conducted on a small sample of ceramics excavated by the UCLA Shire Project’s 2015 field season. Each ceramic sherd was analyzed using gas-chromatography/mass spectrometry (GC/MS) at UCLA. These results will help address questions concerning the production, consumption, and use life of ceramic vessels at Mai Adrasha, and will hopefully shed some light on Mai Adrasha’s standing in the broader cultural landscape of Northern Ethiopia.

Jordan, Amy (University of Washington)

[36] "Make little use of pots": A Review of Earthenware Assemblages from Three Nutmeg Plantations on the Banda Islands, Maluku Province, Indonesia

In his 1544 voyage to Maluku, Galvao noted that residents “make little use of pots.” Despite their purported “little use,” earthenware is ubiquitous in Metal Age Malukan sites, but few detailed studies of these assemblages have been presented in the literature. In this paper, I reviewed the ceramic assemblages from multicomponent sites in the Banda Islands, Maluku Province, Indonesia. The Banda Islands were the world’s sole source of nutmeg prior to the seventeenth century and was a center of early experimentations in European colonialism while concurrently being a node in a regional Asian trade network. The time periods of assemblages range from Neolithic to early twentieth century. The characteristics of tempers and designs of ceramics suggest differential access to the long distance trade network based around the Banda Sea and may be associated with changing social patterns associated with the global spice trading.

Jordan, Jillian M. (University of New Mexico)

[162] Late Classic Ceramic Production and Communities of Practice at Uxbenka, Belize

Archaeological approaches to ancient Maya communities often assume that spatially distinct architectural groups are tantamount to social groups, but proximity is likely not the only salient organizing principle. Members of prehistoric communities, like modern ones, defined the community in which they belong based on who they choose to interact with, which often lies at the intersection of kin, status, gender, ethnic, economic, and spatial affiliations. Employing a communities of practice theoretical framework, this paper examines the ceramic manufacturing process from resource acquisition to final production. This paper examines the ceramic production processes from resource acquisition to final production. The assemblages range from Neolithic to early twentieth century. The characteristics of tempers and designs of ceramics provide abundant evidence for profound variability and endless transformation in the ways in which humans related to northern animals; at the same time new scientific methods are transforming the depth, quality and diversity of information about these shifting relations, as well as their social and ecological contexts. Suggestions for future research priorities are presented in the conclusion.

Jorgenson, Ian (Southern Methodist University)

[287] Quantifying the Relationship between Geography and Social Networks

Social Network Analysis (SNA) has become an important tool for archaeologists. However, unlike other social scientists who work with living populations, archaeologists do not have direct access to the social networks of ancient peoples. Indeed, they rely on material culture to infer the presence, strength, and properties of social networks in the past. A standard approach is to compare assemblages of an artifact class among a group of sites, and quantify the similarity of those assemblages pairwise as a proxy for social networks. Pairs of sites with high similarity scores are inferred to be more strongly networked. For many artifact classes, the assumed link between assemblage similarity and strength of social network is well supported. However, this assumption is potentially problematic when assemblage similarity is based on geochemical sourcing of artifacts. In these cases, the distances between sites and the sources of the raw materials may do a better job of explaining patterns in assemblages among sites. This research develops a method for quantifying geographical similarity of sites to raw material sources using least-cost path analysis within a GIS framework, establishing a baseline of expected assemblage similarity given local geography, which can then be compared to the results of SNA.

Jordan, Peter (Arcetic Centre, University of Groningen, Netherlands)

[35] Life beyond Circumpolar Cosmologies: New Themes in the Archaeology of Arctic Human-Animal Relations

In Arctic Archaeology, human-animal relations have traditionally been studied in terms of ecology, optimality and adaptation; more recently, there has been growing interest in understanding how spiritual obligations affected treatment of circumpolar animals and their physical remains. Although these symbolic perspectives were initially useful, many tended to draw on ethnography, especially when using the concept of a single overarching Circumpolar Cosmology; unfortunately, this can reduce prehistoric human-animal interactions into the same endless cycle of respectful hunting, reciprocal release of animating essences, and their eventual regeneration into new forms of life. This paper undertakes a critical reflection on the current state of Arctic human-animal studies, and concludes that we need to move beyond thinking in terms of fixed cosmologies, and engage more fully with the variety of possibilities of the long-term Arctic archaeological record. In fact, rather than a single timeless cosmology, these sequences provide abundant evidence for profound diversity and endless transformation in the ways in which humans related to northern animals; at the same time, new scientific methods are transforming the depth, quality and diversity of information about these shifting relations, as well as their social and ecological contexts. Suggestions for future research priorities are presented in the conclusion.

Landscape and Dietary Change in Formative Period Coastal Oaxaca

This paper presents the results of an isotopic study of human dietary change during the Formative period (2000 BCE–300 CE) in the lower Río Verde Valley of Oaxaca. Approximately 60 individuals were sampled for δ13C and δ15N using teeth and long bones. The study examines trends in the consumption of maize and marine/estuarine resources relative to regional environmental change. Interdisciplinary research along the drainage system indicates that environmental change in the lower Verde was triggered by anthropogenic landscape change in the highlands. Geomorphological research in the Nochixtlán Valley in the Verde’s upper drainage basin provides evidence for anthropogenic erosion due to land clearance for agriculture beginning in the Early Formative period. Paleoenvironmental research in the lower valley shows that the erosion in the highlands altered the drainage system, which led to an expansion of the agriculturally productive floodplain. Sediment discharged into the Pacific Ocean also contributed to the formation of bay barriers and back barrier estuaries. The expansion of the floodplain and the formation of the estuaries created highly productive habitats that may have contributed to population growth and dietary change. The isotopic study evaluates how human diet was affected by the changes in lowland environments.

Death and the Origin of Enduring Social Relations

Knowledge of Formative Period Mesoamerican archaeological sites often comes from narrow windows into buried sites. One feature has been a partial exception to this rule: burials. Groups of Formative Period burials, often accompanied by objects, have been recovered in many parts of Mesoamerica. Using models of mortuary treatment that saw burials as reflecting individual identity, burials provided one of the first ways researchers could examine the emergence of stratification within these settlements. Yet such analyses were open to critiques of the assumption that burial treatment was a simple reflection of social status and identity. In previous research on published burials from Tlatilco, I showed that clusters of burials there were products of social action by people associated with specific residential groups or neighborhoods within the settlement. I was able to demonstrate within-village variation not rising to the level of emergence of firmly delimited social strata but illuminating how stratification emerged, with intergroup distinction, age-related uniformity, and gendered trends evident in women’s burials. This paper considers in detail the burial assemblages of males not previously analyzed, refining models that might be applicable more broadly in other Formative villages in the process of creating distinctions in wealth, status, and authority.

Stress and Daily Life in an Andean Reducción Town: Preliminary Osteological Analyses of Juvenile Burials in a Church Sacristy

Juvenile mortality and morbidity is a sensitive marker of overall group health, as juvenile individuals are more susceptible to circulating endemic diseases and nutritional stress. Thus, reconstructing relative frailty of the juvenile population at Mawchu Llacta provides important data about daily life at this colonial site, in a relatively understudied transitional period of Peruvian history. In this paper, we present the results of preliminary skeletal analyses of burials excavated from the sacristy at Mawchu Llacta. These burials included 21 individuals whose ages ranged between birth/infancy and eight years old. While preservation of the remains varied depending on depth of the burial, dentition and some cranial and long bone remains were well-preserved enough to allow for macroscopic, paleopathological analyses. We particularly focused on recording indicators of nutritional and/or immune stress (such as periosteal reactions, porotic hyperostosis, cribra orbitalia, and linear enamel hypoplasia) as a way to investigate overall frailty of the burial sample. Here, we present initial results and interpretations of this skeletal analysis, and suggest future projects that will help us more fully understand routine risk and stress experienced by people living at Mawchu Llacta.

Traditional Wooden Structures on an Ancient Quartzite Quarry Site, Manitoulin Island, Canada

Ancient quarry extraction locations on elevated bedrock outcrops continue to be used in the modern era for traditional activities such as constructing bent wooden sweat lodges and wooden shelters for fasting and meditation, which are built and maintained in modern times, over at least several decades. Other special “powerful” locations such as a cave in a Bar River Formation quartzite adjacent bluff are visited and used for spiritual activities by local First Nations members. As part of the sacred cultural landscape these topographically elevated quarry locations also appear to be “maintained,” as broken glass from hilltop parties has been removed to clean the area. The continued traditional use for fasting and meditation may restrict other interpretive activities at such quarry workshop sites, as walking paths and visits by tourists are not too compatible with traditional activities such as fasting.

[41] *Battlefield Archaeology in Ancient Europe and Southeast Asia: The Challenge of Remote Histories and Personification of War Events*  
Archaeological studies of ‘warfare’ in their cultural settings have multiplied over time and include analyses of fortifications, military equipment, warrior paraphernalia, and human skeletal trauma, usually spanning broad time scales and including diverse archaeological contexts (e.g., town walls, weapons production workshops, cemeteries) that are often remote from the actual locales where warfare is carried out. In contrast, ‘battlefield’ archaeology focuses on relatively temporally compact events occurring within actual fighting spaces and on the personal ‘minuia’ of battle experiences and outcomes for individual participants and factions. In the case of recent wars, a sizeable and diverse historical record and oral histories, more visible and better preserved sites, and a wider array of forensic science options have produced good results in not only identifying combatants, but also inferring the various factors (mechanical, environmental, and human decision-making) involved in war casualties. However, differing temporal scales, degrees of historical reference, and preservation of archaeological remains challenge battlefield archaeologists dealing with premodern war events. To illustrate the difficulties of reconstructing battlefield events in the distant past and investigating their impact on regional political and social landscapes, several case studies from Bronze Age and Iron Age Europe and pre-sixteenth century Southeast Asia are analyzed.

[35] *Exploring Human-Animal Relations among the Okhotsk Culture in Northern Japan*  
This paper investigates long-term human-animal interactions among Okhotsk cultures in Hokkaido, northern Japan. The Okhotsk Culture were maritime foragers, with a common set of procedures or in terms of more specific beliefs for each species. In Okhotsk traditions, our study examines cultures that predate the Okhotsk, for instance the Late Jomon period. We are applying organic residue analysis of pottery to identify the home animals’ and subjecting particular terrestrial and aquatic species to specific processing and consumption practices. To trace the origins of some of these traditions, our study examines cultures that predate the Okhotsk, for instance the Late Jomon period. We are applying organic residue analysis of food processing technologies such as tools and pottery containers to elucidate how different marine and terrestrial animals were treated, for example, according to a common set of procedures or in terms of more specific beliefs for each species.

[280] *Colonial Negotiation in the Frontier Province of Beneficios Altos*  
The frontier location of the Spanish colonial province of Beneficios Altos, Yucatán provides a unique case study for investigation into the lives and strategies of colonial Maya individuals and communities. Given their proximity to a notoriously porous southern border and the documented record of significant numbers of people who escaped colonial authority by crossing that border, those communities and individuals living within the boundaries of Beneficios Altos can largely be considered to have remained by choice. A process of colonial negotiation carried out primarily through daily, mundane interactions between agents representing and/or opposing the interests of the Spanish Empire established the foundation by which residents of Beneficios Altos communities (both Maya and non-Maya) maintained and created distinct cultural and ethnic identities. This paper details the process of colonial negotiation and draws upon archaeological and documentary data to demonstrate examples of its effect on the Beneficios Altos population and landscape during the colonial and early national periods.

Kahn, Jennifer (College of William and Mary)  
[278] *Houses of Power: Community Houses and Specialized Houses as Markers of Social Complexity in the Precontact Society Island Chiefdoms*  
World-wide, communal houses and specialized houses represent hallmarks of social complexity. In precontact Society Island chiefdoms, social complexity was materially marked by architectural differences between elite and commoner residences. Yet perhaps more pronounced are architectural differences and varied spatial patterning between residential houses, communal houses, and specialized houses. This paper provides a spatio-temporal analysis of communal and specialized houses on the Ma'ohi landscape. Communal houses, notably fare manahini (elite meeting houses), fare 'arioi (houses for the fertility sect), and fare ia manaha (houses for storing ritual items) differ from everyday residences in their large size, elaboration, and spatial proximity to ritual sites. Specialized house sites, including those for craft activities and those to house ritual practitioners, sometimes mimic residential houses in their size and architecture, yet have different suites of activities associated with site occupation. Tacking back and forth from the microscale to a landscape approach highlights how communal and specialized houses not only materially marked socioeconomic rank, but created landscapes of power, or landscapes of inclusion and exclusion based on one's rank and bounded status. In this way, communal houses and specialized houses serve as important hallmarks of increasing social complexity in the late prehistoric Society Island chiefdoms.

[57] *A Satellite Remote Sensing Model for the Ancient Traffic in Upper Mesopotamia*  
Roads reflect motivations and needs behind many relations of past societies; they imposed spatial order on agricultural production, enabled transportation of bulk-goods, and mediated hegemonic power. Considered not only as the container of action, but also the action itself, the road has much more to say on the ancient movement praxis. This study focuses on Bronze Age roads (hollow ways) in Upper Mesopotamia. At this space-time, the movement embedded within production economies contributed to the formation of hollow ways. In pursuit of this phenomenon, the study constructs a typology of roads based on the volume of ancient traffic. Therefore, the aim is not only to document locations of hollow ways—the container, but to build a model for the movement—the action. It is hypothesized that variations in the ancient traffic differentially changed soil physical characteristics (soil compaction/moisture) so that past variation in traffic is still detectable on satellite data. In particular, CORONA is deployed for a remote sensing based archaeological survey of hollow ways. Next, Near-Infrared and Short-wavelength Infrared portions of the spectrum are exploited to generate proxy variables (vegetation/moisture indices). Finally, these proxy variables are used to model variations in ancient traffic on hollow ways.
biogenic calcite and aragonite precipitated from these mixed waters reflects a unique regional age variance, known as its ΔR value. Therefore, in areas topography, currents, trade winds, and local climate, control the upwelling and mixing of deep and surface water. Radiocarbon dates obtained from materials of the same age. This study examines the local MRE and the associated ΔR correction factors for Cuba and discusses the implications of upwelling, marine carbonates are 14C deficient and return radiocarbon dates that may be significantly older or younger than terrestrially dated materials. However, many forms of archaeological data are small but complicated, collected under very different conditions and sampling protocols. Moreover, archaeology has many different institutional stakeholders that create and manage data, making centralized aggregation more difficult. Because of these complications, this paper advocates a “Slow Data,” incrementalist, approach to building Big Data. As illustrated by Open Context and other Linked Open Data providers, larger datasets can be assembled from data contributions scattered across the Web. While Linked Open Data (especially when combined with text-mining) offers paths for data aggregation, bringing together diverse data still involves potentially contestable judgement calls that require specialized knowledge, thought, and labor investments. Therefore, archaeological Big Data needs community-wide commitments to practice more open and more reproducible research.

Obsidian in the Wari Empire: Sourcing Material from the Capital Using pXRF

This paper examines the procurement and consumption of obsidian within the Wari capital (AD 600–1000) in the Ayacucho highlands of Peru. During the Middle Horizon, the Wari Empire expanded and controlled much of the Peruvian Andes, largely through the import, export and regulation of critical resources extracted from subject territories and populations. This project hypothesizes that obsidian may have operated as one such critical resource for imperial control and seeks to examine this hypothesis at the imperial capital of Huari. As part of ongoing dissertation research, analysis was conducted on obsidian collections of varying contexts deriving from the site of Huari, using X-ray fluorescence to determine the source location for each of the samples to explore varying temporal and spatial patterns of consumption of obsidian by imperial populations as well as the relationships between the capital and the hinterland regions from which the obsidian was extracted.

A Student’s Perspective on the Unidentified Persons Project, San Bernardino, California

Beginning in 2006 as a response to California Senate Bill 297, the Unidentified Persons Project is the first statewide attempt to apply modern DNA analysis to cold cases in San Bernardino County. In 2014 the project became an accredited field school through the Institute of Field Research and proceeded to have two consecutive field seasons in the summers of 2014 and 2015. This paper will present a student’s perspective on the most-recent 2015 field season and will discuss both the rewards and challenges of the project. While providing a breakdown of the classroom, field, and laboratory components of the field school, this paper will also discuss the broader themes that emerged throughout the season, including the dynamics between students, professors, and law enforcement, and the realities of pursuing careers in forensic archaeology and anthropology. Overall, the Unidentified Persons Project is a profound initiative that gives back to the community and provides an incredible learning opportunity for its students. The field-school structure of the project should continue to be studied and treated as a model for other counties in California and other states looking to inspire similar initiatives nationwide.

What to Do about Avayalik Island 1: A Remote Central Place in the Paleoeskimo World

In 1978 archaeologists partially excavated a frozen Middle Dorset Paleoeskimo midden on Avayalik Island, a far outer island at the tip of Labrador, Canada’s uninhabited northern coast. They recovered hundreds of organic artifacts unlike any found in Labrador’s other Middle Dorset sites, which contain only lithic tools. Faunal remains suggested a North Atlantic quite different from that of the present day. In 2016 Kaplan returned to Avayalik and documented the ongoing destruction of the site. Frozen deposits are thawing, compromising organics remains and destabilizing the terrace on which the site is located. Additional structures were identified, some slumping down the terrace’s eroding faces. The 2016 visit also revealed that this remote place was a vibrant central place in the Dorset world. How should we respond to the deterioration of a site whose significance is not yet understood, given the major logistical and financial challenges of accessing the island and given that archaeometric techniques now are available to analyze it in ways not possible in 1978? How should northern archaeologists, funding agencies, and permitting bodies respond to site endangerment that stands to compromise our ability to ever understand the cultural and environmental history of the region?

Fluid Ethnoarchaeology: A Study of British-Era Water Fountains in Athienou, Cyprus

The Athienou Archaeological Project (AAP) has conducted excavation and survey work in Cyprus since 1990. Ethnoarchaeological and ethnographic research have accompanied the other field investigations to create a holistic examination of the community situated at the southern end of the Mesaoria, a fertile agricultural plain in the central part of the island. The semi-arid summer climate makes access to water a major concern of the residents of Athienou. A number of public fountains scattered throughout the town are a remnant of the British colonial presence in the twentieth century. In the summer of 2016, an AAP team recorded all of the extant fountains. Most of the water stations occur on a heritage corridor along which the municipality, with assistance from the national government, has restored a number of traditional structures. The fountains and the buildings together reflect an effort to preserve elements of past village life that are rapidly disappearing. In addition, the fountains are a modern example of the age-old effort to provide sufficient water in the region; in the Malloura Valley south of Athienou, this aspect is reflected in a qanat system of underground channels cut through bedrock to provide water for people, livestock, and irrigation of crops.

Unusual Elements, Special Contexts: Bear Ceremonialism in Context at Feltus, Jefferson County, Mississippi

During the Coho Creek period (AD 700–1200), people constructed three earthen mounds at the Feltus site in Jefferson County, Mississippi. Before, during, and after the construction of these earthworks, Feltus was a location for ritual gatherings characterized by communal feasts and ritual post activities. Archaeological investigations at Feltus produced not only a large amount of bear bone, but a range of skeletal elements that are unusual at prehistoric sites. The nature of these remains and their association with ritual gatherings makes clear that bears were particularly important to the people who gathered at Feltus. Throughout Eurasia and North America, preagriculturalists saw bears as people, albeit different-from-human people, who possessed the spiritual power to link the human and spirit worlds. Importantly for our interpretations of the Feltus data, bears are commonly seen as kin, as healers, and especially as food providers. The material remains of large feasting events including bear remains, pipe smoking, and the setting of large standing posts align remarkably well with traditional bear ceremonies. These findings not only help us to understand the origins and meaning of the activities taking place at Feltus, but also expand our understanding of the geographic and temporal extent of bear ceremonialism.

A Preliminary Study of Epiclassic Diet at Cerro Magoni in Tula, Mexico, Using Stable Isotope Analysis and AMS Radiocarbon Dating

In this paper, we present preliminary paleodiетary data and radiocarbon dates for 12 burials recovered from Cerro Magoni, an Epiclassic (ca. AD 600–900) hilltop settlement in Tula, Mexico. Stable carbon (δ13C) and nitrogen (δ15N) analyses of bone collagen were used to assess the diet of individuals buried near the summit of the settlement. The production of bone collagen requires essential amino acids derived from protein, therefore stable carbon analyses reflect the origins of dietary protein, particularly C3, C4, and CAM (crassulacean acid metabolism) plants. Additionally, stable nitrogen values reflect trophic position in biological systems and can be used to differentiate between marine and terrestrial food sources. Finally, AMS radiocarbon dates of the burials will also be presented. These dietary data and radiocarbon dates will be further contextualized through a comparative discussion of our current understanding of food production and consumption in the Tula region during the Epiclassic and Early Postclassic (ca. AD 900–1200) periods. To our knowledge, this analysis is the first isotopic reconstruction of diet in the immediate Tula area and will provide the basis for future research regarding diet, migration, and identity in the Tula Valley during the Epiclassic period.

The Paleolithic Site Mal’ta in Eastern Siberia: New Discoveries and New Situation

Mal’ta is located in southern part of Eastern Siberia, near Baikal. This site has been known as unique Paleolithic settlement, including a double human burial of two children, 30 human figurines carved from ivory, and 15 dwelling clusters. While the original interpretation of Mal’ta was that of a single Russian-Japanese joint research for confirming the site formation process and high-precision AMS dating on Mal’ta site. In this paper, we would like to make a report on current results of new AMS dating and new situation from new excavation in Mal’ta site.

Creating and Curating a 3D Dataset: Establishing Categories for Ancient Maya Musical Instruments Using 3D Scans

The Maya Music Project is dedicated to documenting ancient Maya musical instruments throughout the Maya area. Over the past year and a half the project has been documenting instruments housed in both archaeological laboratories and museums in Guatemala, Belize, and the United States in order to better understand the types of musical instruments that were played by the ancient Maya. At the time of writing this abstract, the project has worked with over 250 musical instruments, and has made 3D models of 98 of those instruments. In the fall of 2016, the project will be making 3D models of the instruments housed in the Museum of Fine Arts, Boston and the instruments housed in the Peabody Museum’s collection at Harvard University. By performing typological analyses on these artifacts, interesting trends of stylistic attributes begin to emerge that were present throughout the Maya area. The project also played, recorded, and 3D printed playable replicas of many instruments, and has proven that the Maya had a sophisticated understanding of pitch. This talk will discuss trends of stylistic attributes, the sounds that the instruments can produce, and the role that 3D technology can play in this type of analysis.

New AMS Dates for Paquimé, Northern Chihuahua, Mexico

In an effort to resolve some long standing questions about the chronology of the site of Paquimé, accelerator radiocarbon dates were obtained from bone collagen of 77 burials. Bone samples were obtained as part of a larger project to explore life history and diet at the site. We address three questions: the temporal relationship between the Viejo period (Convento site) and Medio period (Paquimé), whether or not the “non-interred” individuals from the Medio phase at Paquimé date to the later occupation (the proposed Diablo phase suggested by Charles DiPeso), and the likely closing date of Paquimé. Making use of Baysian modeling, our results indicate likely overlap between Convento and Paquimé, deposition of non-interred specimens from the Medio phase at Paquimé date to the later occupation (the proposed Diablo phase suggested by Charles DiPeso), and the likely closing date of Paquimé date to the later occupation (the proposed Diablo phase suggested by Charles DiPeso), and the likely closing date of Paquimé. We gratefully acknowledge funding through an Insight Grant from SSHRC and permission to study and obtain samples from The National Institute of Anthropology and History (INAH), Mexico and from the Centro Cultural Paquimé in Casas Grandes, Mauricio Salgado, Director.

Kay, Andrea (University of Lausanne) and Jed Kaplan (University of Lausanne) [38] Modeling Human-Environment Interaction in Sub-Saharan Africa: Archaeological Data, Ecological Questions

The African Iron Age transition is characterized by a shift from nomadic hunting and gathering societies to food-production, ferrous metallurgy, and centralized states and empires across most of the continent. Because of the magnitude and persistence of the change, understanding the African Iron Age is critical for assessing the present state and potential future of Africa’s ecosystems. Because the transition occurred episodically and at different times in different regions, and because large parts of Africa are poorly studied archaeologically, unambiguous evidence for human influence on the environment is lacking in large parts of the continent. Thus, in order to better understand the process, pattern and impact of anthropogenic activities on the environment over the African Iron Age, we are developing a continental-scale quantitative model of human-environment interactions. This model is informed by archaeological data synthesis and information on the physical environment. Here I present a new series of maps of the distribution of livelihood systems in Iron Age Africa that are used to drive our quantitative model. The maps represent a synthesis of archaeological, archaeobotanical, linguistic, and ethno-historical data. While large data gaps still exist, my maps demonstrate the potential of using archaeological information for large-scale modeling.

Keach, Levi (Desert Research Institute) [107] Howdy Podner! The Strange Story of Soda Bottles on a Cold War Battlefield in Southern Nevada

In 2016, Desert Research Institute archaeologists identified 26NY15768, an artifact scatter consisting primarily of Vegas Vic brand root beer bottles dating to 1953. 26NY15768 is located in Frenchman Flat on the Nevada National Security Site, known as the Nevada Proving Grounds at the time of deposition. The Nevada National Security Site, under various names, has served as the United States’ continental nuclear test site since it was withdrawn from the Las Vegas Bombing and Gunnery Range at the close of 1950. The location of this site is intriguing given the date. During 1953, two nuclear tests occurred on Frenchman Flat associated with Operation UPSHOT-KNOTHOLE. I describe the site and consider possible explanations for its existence. Evidence for and against each explanation is drawn from historical documents and topographic analysis.

Kealhofer, Lisa, Peter Grave (University of New England, Armidale, NSW Australia) and Ben Marsh (Bucknell University) [27] Changes on the Land: Gordion in the First Millennium BCE

Throughout the first mill BCE, the inhabitants of Gordion engaged with multiple changes in political power and agricultural strategies, within a diverse landscape with shifting climate regimes. Over most of this period, the city, its industries, and its hinterland population thrived. Using multiple lines of evidence, both material and environmental, this paper explores what we know about changes in the organization of different production spheres at Gordion in order to understand how changing political and economic strategies intertwined with this diverse, dynamic, and unpredictable environment.

Kearns, Catherine (University of Chicago) [242] On Some Classical Roots of the Anthropocene: Where Does Mediterranean Archaeology Belong?

In the long run-up to deciding the Anthropocene’s scientific status there have been few archaeological voices, as many have noted, revealing the proposed epoch’s narrow periodization of human-environment relationships. None seem to be more absent than classical archaeologists, an omission which reflects not only disciplinary cleavages but also tacit concents about the classical world as paradoxically generative of and divorced from modern geopolitics and human-nature interfaces. From the early arguments of George Perkins Marsh about humanity’s ancient, unintended environmental degradation, to the trending fascination with climatic disasters in old world societies, however, past Mediterranean contexts have been foundational yet ambivalent sources in modernity’s attempts to understand global anthropogenic change. At stake in efforts both to codify or to critically “provincialize” this anticipated era are thus important biases toward specific historical and material records. It is worth considering the Anthropocene’s (and its challengers’) oblique engagements with classical antiquity, given that so much of the rhetoric derives from the nature/culture discourse rooted in western
Europe (and America). This paper ponders the Anthropocene’s imaginaries of nature and the human past that look askance at Mediterranean (pre)histories and archaeological evidence, and thus chiefly asks what an ancient Mediterranean critique of the epoch might offer.

Keegan, William (Florida Museum of Natural History) [32] On the Edge of the New World: Colonizing the Bahamas

The Bahama archipelago is the last place colonized in the New World, and the first encountered by Europeans. Previous efforts to explain the arrival of human colonizers used the stepping-stone model of expansion that began in the Orinoco River drainage of lowland Venezuela. Communities island-hopped through the Lesser Antilles, expanded into the Greater Antilles, and continued their northward migration through the southern Bahamas after crossing the last open water gap between Hispaniola and the Turks and Caicos Islands. We now know that none of this is true. The Bahamas are not visible from any of the surrounding land areas, most of which were first occupied from 10,000 (Florida) to 4,000 (Greater Antilles) years before the Bahamas (circa AD 700). In 1995, Berman and Gnivecki made the case that the central Bahamas were the first colonized by colonists that came from Cuba. This was not further explored because there was equal or better evidence that the southern Bahamas were colonized earlier from Hispaniola. Part of the issue is how archaeologists envision island colonization. This paper takes a fresh look at the processes of island colonization with specific reference to the Bahama archipelago.

Keehnen, Floris (Faculty of Archaeology, Leiden University) [395] Treating “Trifles”: The Indigenous Adoption of European Material Goods in Early Colonial Hispaniola (1492–1550)

This paper discusses the cultural implications of European materials recovered from early colonial indigenous spaces on the island of Hispaniola. The exchange of exotic valuables was vital for the emergent relationships between European colonists and indigenous peoples during the late fifteenth- and early sixteenth-century Caribbean. As the colonial presence became more pressing and intercultural dynamics more complex, formerly distinct material worlds increasingly entangled. Archaeologists have long given minimal attention to these material correlates of indigenous colonial transition. Nevertheless, more than fifty years of archaeological work in Hispaniola has revealed a select number of indigenous sites yielding such foreign artifacts, or objects with European influence, occasionally appearing in reworked, repurposed, or copied forms. Among these are glass beads, metal items, and glazed ceramics, found in a variety of contexts and ranging from singular finds to direct associations to indigenous valuables. This paper presents an overview of these findings in order to explore indigenous agencies in the ways of handling these objects related to the differential impacts of colonial power on the island. As such, this paper aims to advance our understanding of the materiality of things in these encounters and the transformations they brought about in indigenous material culture repertoires.

Keenan Early, Erin [181] Applying ZooMS to Gault Site Faunal Material: Identifying the Unidentifiable and the Case for Database Expansion

The Gault site is a well-known Clovis-age occupation site in Texas, with further evidence of pre-Clovis activity. In addition to an abundance of lithic artifacts, the site has yielded thousands of faunal remains. Unfortunately, the taphonomic processes to which these bones have been subjected have resulted in the vast majority of them being morphologically unidentifiable beyond small, medium, and large mammal. This greatly restricts researchers’ abilities to understand the human-environmental relationships at this site. However, the application of the peptide mass fingerprinting technique ZooMS promises to allow for the reconsideration of these otherwise limited materials by opening the door to biomolecular identification to the genus or species level. Recent initial analysis of Gault faunal material from two areas of excavation has yielded results indicating that collagen preservation in some samples is sufficient to allow for ZooMS identification. These results demonstrate the need for the expansion of the reference database to include more North, Central, and South American species. Such an expansion would enable the reconsideration of otherwise severely restrictive faunal assemblages, and allow us to increase understanding of the earliest American’s lifeways.

Keeney, Joseph (National Park Service; University of Alaska Fairbanks) and Robert C. Bowman (Northern Land Use Research Alaska; University of A) [257] Testing Potential Archaeological Applications for Surficial Magnetic Susceptibility Probes in Shallow Depositional Environments: A Study from Agiak Lake in Alaska’s Brooks Range

Magnetic susceptibility (MS) is the measure of a material’s potential to hold a magnetic field, the variation of which can indicate anthropogenic forces acting upon a substrate. In Alaska, diachronic MS analyses have been useful when investigating environmental change and anthropogenic variation through time in deeply-stratified subarctic interior sites. Synchronous MS approaches, on the other hand, use surficial MS probe mapping to analyze contemporaneous variation across space and can reveal shallow-buried cultural areas and features. Despite successful reports from European studies, synchronous MS approaches are virtually absent in the North American literature, especially from Alaska. This pilot study investigated surficial MS probing’s potential as an efficient and less-destructive means for identifying past human activity areas and features within shallow depositional contexts such as those typical of Arctic Alaska. We selected Agiak Lake in Alaska’s central Brooks Range for its expansive and well-documented mid-Holocene tent ring complexes and shallow depositional environment. Through the process of MS mapping and multiple means of verification, we were able to confirm anthropogenic signals related to the known features, identify multiple undocumented features within and away from visually-identifiable ones, and examine a potential method for assessing culturally-significant relationships between intrasite features.

Keen-Zeber, Amanda [191] see Pober, Rachel

Kehoe, Alice (Independent) [393] Following the Data for Long-Distance Travels
Part of the postcolonial movement is recognition of long-distance trade and other interactions in the Americas. As late as mid-twentieth century, anthropologists were discouraged from conducting research in the Americas. Unilineal cultural evolution constructed by Enlightenment didactics and continued in Western “rise of civilization” histories and textbooks such as Johnson and Earle's Evolution of Human Societies (2nd edition 2000) is closely connected to the Doctrine of Discovery (1493) legitimizing European conquests and domination in the Americas. Ethnographic, ethnohistorical, and archaeological data, and indigenous histories, abundantly evidence cross-continental and sea travel routes in the Americas from paleoamerican times continuing to and after European contacts. Many railroad and highway routes today follow precolumbian routes. Plotting routes such as the Santa Fe Trail, and the distribution of linguistic or cultural elements such as Mobilian Jargon can lead archaeologists to recognize precontact connections. Connections should also be premised for water routes—ethnohistorian Helen Tanner advised, “Look to the rivers” and to their junctions with seas. This paper represents the “historical turn” taken by a growing number of American archaeologists thinking out of the box of customary American history reflecting Manifest Destiny ideology.

Kehua, Zhou

New Archaeological Discoveries in Sichuan

Recent years have seen a large number of archaeological discoveries in Sichuan; especially during the construction of the Xiangjiaba Hydropower Station in Yibin, Southern Sichuan, which led to four years of excavation covering an area of over 6,000 m². These excavations brought to light a large number of remains from the late Neolithic, Shang, Zhou, Qin, and Han periods, greatly advancing our understanding of local cultural developments. The present paper will introduce some of these recent discoveries, focusing on four main questions: 1) how these discoveries help fill the gaps in our understanding of the local cultural sequence; 2) how they elucidate the connection between the Three Gorges region and the Chengdu Plain during prehistoric times; 3) how the evidence pertains to the Shu expansion toward the south; and 4) how they enrich the amount of archaeological material available for the Han period.

Kelker, Nancy

Forgery and the Precolumbian Art Market

Why forgery? “Because,” as Willie Sutton once said, referring to why he robbed banks, “that’s where the money is.” Forgery is a common problem in the art market with works by contemporary living artists as well as “old masters” having been and, continuing to be, faked. Some segments of the market, specifically precolumbian antiquities, are worse than others in the sheer number of forged and faked works being offered for sale in upscale galleries, online, and by independent, direct-to-the-collector dealers. The history of precolumbian art forgery is a long one beginning with the Spanish Conquest and steadily gaining in momentum after 1821. This paper will look at how the art market, historically and in modern times, drives the manufacture of forgeries, and at some of the modern producers and purveyors of these false works.

Kelley, Alice

Geometric Morphometry versus Traditional Stone Artifact Typology in the Hoabinhian of Northern Vietnam

Hoabinhian typologies dominate stone artifact analysis in discussions of late Pleistocene archaeology in mainland Southeast Asia. Although, the objective reality of the types in this system has been questioned, there has been little empirical work to test the usefulness of the commonly used types as discrete entities. We collect 3D scan models of 110 artifacts from Mau A, a recently excavated site in northern Vietnam, where the Hoabinhian was first described. We derive semi-landmarks along outlines in three planes for each artifact, and use Principal Component Analysis and k-means analysis on elliptical Fourier analysis coefficients to explore patterns in morphological clusters. We identify which outline is most informative for traditional types, and demonstrate that substantial morphological overlap is present between the traditional types. Our results reveal where continuities and discontinuities exist between the traditional types, and highlight the importance of recording measurements of continuous variables when collecting data from stone artifact assemblages.

Our results reveal where continuities and discontinuities exist between the traditional types, and highlight the importance of recording measurements of continuous variables when collecting data from stone artifact assemblages.

Linguistic Archaeology of the Sierra Sur, Oaxaca

In this paper the potential for productive relationships between linguistics and archaeology is discussed in the context of the Sierra Sur region of Oaxaca, Mexico. The material remains of most traded goods decompose too swiftly to be studied hundreds of years after their circulation in trade networks. However, the vocabulary that describes these goods has the potential to survive in contemporary languages. Thus, comprehensive study of linguistic data can support historical and archaeological theories on the migrations of people, goods, and values. As a test case, research was conducted using the traditional comparative linguistic method and phylogenetic relations mapping software to trace phonetic changes in the Southern Zapotec spoken across five towns in the Sierra Sur. By comparing words for the trade items cited in previous archaeological studies of the region to Swadesh words (words which are considered to be borrowed less frequently), the towns could be tied to trade routes outside the Sierra Sur, connecting the Valley of Oaxaca to the Southern Coast. This paper will discuss how these findings relate to and pave the way for archaeological studies on the trade and migration of this understudied region.

Keller, Hannah [152] see Sender, Rachel
In the summer of 2015, the Public Archaeology Laboratory, Inc. (PAL) conducted data recovery excavations at Susquetonscut Brook Pre-Contact Site 11 (SB 11), a multicomponent site in Franklin, Connecticut. Prior archaeological investigations had produced a high density of precontact artifacts, but very few artifacts that would have suggested a sizeable postcontact occupation. However, the data recovery yielded 1,798 postcontact artifacts, revealing a substantial postcontact component to the site. Diagnostic artifacts indicate that the postcontact component at SB 11 is early to mid-eighteenth-century, although the postcontact occupation may have begun in the late seventeenth century. This paper presents an assessment of the postcontact assemblage from SB 11 and explores how the site fits in the context of early eighteenth-century settlement in the New London and Norwich area of southeastern Connecticut. This research also seeks to investigate how the material culture at SB 11 might offer insight into the recognition of postcontact sites that do not have extant foundations or other surface features.

[283] Redefining Cahokia: City of the Cosmos

By the early nineteenth century the group of earthworks we now recognize as Cahokia mounds was called the Cantine mound, with Monks Mound referred to as the “Great Cahokia” mound. Actual boundaries for the site were not established until the 1950s. For the inhabitants, the site was probably without bounds and our definition of Cahokia is to a large extent fulfills our society needs that relate to legal aspects of ownership and historical significance. The natural landscape is a palimpsest of features related to its creation by the Mississippi river and its tributaries. At this point Cahokia is composed of at least 110 earthen mounds and other visible architecture and modification of the natural landscape within an area of about 13 km² that has been altered to varying degrees over a period of over centuries. As Eastern North America’s initial urban center, this presentation focuses on the nature of its definition from a landscape perspective and as an American Indian cosmogram and in the end the manner in which it has changed as it defies our attempts to define this unique place we now call Cahokia.

Kelly, Kenneth (University of South Carolina)
[370] Seeking Out Slavery in Colonial Saint Domingué (Haiti)

Saint Domingue was the most important European colony of the Caribbean region, producing vast amounts of wealth through the labor of enslaved Africans and their descendants. It was also the setting of the only large scale slave revolt that succeeded in overturning the slavery system. In spite of this importance to Atlantic studies, African Diaspora studies, and historical archaeology, very little substantive research has been conducted on sites associated with the dwelling places of the enslaved laborers. In summer of 2016, I traveled to Haiti and surveyed nearly 30 plantation sites to determine if the slave villages could be identified, and their potential for contributing toward developing comparisons with other slave-based colonies of the French colonial world. This paper presents the results of that research.

Kelly, Robert L. (University of Wyoming)

The use of large radiocarbon datasets has the potential to transform archaeology and its place in the social and natural sciences in the coming decades. Radiocarbon “big data” enhances the unique contribution of archaeology to reconstruct human demography over vast spans of time. This move toward big data is confronted by some central challenges in archaeological method and theory, such as the use of legacy data of disparate quality and working over broad spatial and temporal scales. For some, these challenges pose insurmountable barriers to the use of radiocarbon big data. We disagree: radiocarbon big data can be used with appropriate kinds of questions, ones that concern processes working at broad temporal and spatial scales. This presentation discusses our ongoing work to develop a radiocarbon database for the United States, focusing on the problems of data collection and potential for using these data to ask questions regarding long-term human demographic change, human-environment interactions, and cultural dynamics.

[159] The Fish of Fort Morris: A GIS-Based Study of Human-Environment Interaction during the American Revolutionary War

Situated at the mouth of the Medway River in coastal Georgia, Fort Morris provided protection for the bustling port city of Sunbury. During the Revolutionary War the fort was first controlled by American forces and later by the British, and while the fort’s history is well-known in local lore, archaeological analyses are shedding new light on everyday life at the site. This paper draws on the identification of fish bones to provide an inventory of the fish taxa consumed by soldiers at the fort on both sides of the conflict. Because soldiers often collected fish while on patrol or in their spare time, the taxa present can provide substantial clues to reconstructing movement and food collection in the past. We present GIS-based analyses that link the identified fish taxa and their respective biological and environmental needs to bodies of fresh, brackish, and marine water in the vicinity of the fort. We combine these data with least cost path and viewed analyses to understand soldier movement near Fort Morris during a time of war. Ultimately, we demonstrate how something as simple as fish bones from the garbage of Revolutionary War soldiers can directly reconstruct their physical movements through past landscape.
Remotely Sensed Seasonal and Interannual Variability of Vegetation and Temperature Indices from Ancestral Pueblo Fields in the Lower Rio Chama Basin, New Mexico, USA

Kessler, Nicholas (University of Arizona)

An analysis of multispectral satellite imagery in the lower Rio Chama basin, in northern New Mexico, reveals that seasonal patterns of vegetation cover (NDVI) are significantly altered by Prehispanic agricultural features surrounding ancestral Tewa pueblos. Interannual variability of NDVI on previously cultivated upland surfaces is similar to a model derived from terrain attributes of minimally-modified watersheds. However, in relic agricultural fields late-summer and autumn NDVI tends to be higher, and temperatures somewhat warmer, than expected. Though there is some uncertainty, this effect...
Capital with three secondary sites. Extensive test pitting from monumental and household contexts at Uc'í and other sites, both on and off the causeway, this polity, headed by Uc'í, was integrated by an 18 km long intersite causeway system by the Terminal Preclassic and connected the emerging regional.

Over the past decade, the Ucí-Cansahcab Regional Integration Project (UCRIP) has utilized multiple scales of analysis, from broad household excavations to large swathes of lidar collection, to examine the social processes of community (dis)integration of a polity in the northern Maya Lowlands. (Midnight Terror Cave, Belize, and Chichén Itzá, Mexico) do not differ significantly from a small-scale horticultural reference model of mortality. New ways that archaeologists, descendant communities and people of the general public are now interacting with archaeological materials as well as some of the challenges, benefits and problems associated with these platforms. This poster will explore the effects of 3D scanning and printing, social media platforms such as Sketchfab and legal implications of this wide availability of cultural history on the field. It will also explore the ways in which this technology is being used and could be used in the future to make archaeology more accessible.

The recent incorporation of 3D imaging into the field of archaeology has opened many doors with regard to accessibility of archaeological materials. Promotes research by inviting a much broader research discussion, and also poses questions of ownership of materials. This poster will explore the effects of 3D scanning and printing, social media platforms such as Sketchfab and legal implications of this wide availability of cultural history on the field. It will also explore the ways in which this technology is being used and could be used in the future to make archaeology more accessible.

Keyser, James (Oregon Archaeological Society)

Cheval Bonnet: A Crow Calling Card in Blackfeet Country

Cheval Bonnet is a small petroglyph site on Cut Bank Creek, just east of the Blackfeet Indian Reservation that shows a Crow Indian coup counting scene and three other horses, two of which can be identified as the products of Crow artists by their form and the stylized war bonnet worn by each animal. Located in a hidden canyon adjacent to a major stream crossing, the site represents a “calling card” similar to other biographic images drawn both as petroglyphs and aboriglyphs during the late Historic period.

From Household to Polity: (Dis)integration along the Uc’í-Cansahcab Causeway in the Northern Maya Lowlands

Over the past decade, the Uc’í-Cansahcab Regional Integration Project (UCRIP) has utilized multiple scales of analysis, from broad household excavations to large swathes of lidar collection, to examine the social processes of community (dis)integration of a polity in the northern Maya Lowlands. This polity, headed by Uc’í, was integrated by an 18 km long intersite causeway system by the Terminal Preclassic and connected the emerging regional capital with three secondary sites. Extensive test pitting from monumental and household contexts at Uc’í and other sites, both on and off the causeway, allow for comparing economic practices and household identities during this political shift. Recent excavations from Uc’í clarify the chronology of the regional capital and indicate an apex during the Terminal Preclassic as well as a relatively robust “Protoclassic” ceramic presence, such as experimental forms and decorative embellishments. The presence of a structure with iconography indicating rulership and a high quality of life of the households at the secondary site of Ucanha underscores the successful integration of this region during this period. However, by the first few centuries into the Early Classic Ucanha experiences a decline, although Uc’í does not, thereby showing integration and disintegration are variable even at the regional scale.

Modeling Channel Morphology at the Clovis-Type Site, Blackwater Draw, New Mexico

Blackwater Locality No. 1 (the Clovis-type site) served as a catchment for spring-fed streams during the late Last Glacial Maximum (~19,150–12,900 cal yr BP), providing a water source for the Paleoindian occupants of the Southern High Plains. During episodes of high effective moisture, water flowed out of the basin via an outlet channel into Blackwater Draw proper. Coinciding with the changing climate of the early Younger Dryas (~12,900–11,500 cal yr BP), the flowing waters of the outlet channel were obstructed, impounding the waters of a shallow lake. This study uses the distribution of well-defined stratigraphic boundaries to create a series of surface models corresponding to the Clovis, Folsom, and Late Paleoindian occupations at the site. Stratigraphic data and sediment samples were collected from systematic hand augering of the outlet channel. Where the surface models indicate pronounced changes in the channel, sediment samples were more intensively analyzed to identify their origin and depositional environment. The models, coupled with sedimentary data, shed light on the processes responsible for ponding of the lake and provide snapshots of the changing morphology of the outlet channel, ultimately contributing to a richer understanding of the changing landscape during this critical time in prehistory.

Kieffer, C. L. (Museum of Indian Arts and Culture, University of New Mexico) and Jack Baker (University of New Mexico, Anthropology)

Statistically Comparing Demographic Distributions of Mortuary Assemblages

This analysis includes data from 50 archaeological mortuary assemblages variously attributed to sacrifice, warfare, and standard mortality processes. The research compares two sites, both attributed to sacrifice, to those produced by the two alternative processes of warfare and standard mortality and explores the question of whether these assemblages may be differentiated from them based on the age distribution of deaths. The analysis incorporates a novel feature in that preservation bias is directly modeled using Monte Carlo experiments. The results suggest that the two sacrifice assemblages (Midnight Terror Cave, Belize, and Chichén Itzá, Mexico) do not differ significantly from a small-scale horticultural reference model of mortality.
proposed by Gurven and Kaplan (2007), but do differ significantly from other sites in the sample in the proportion of the assemblage comprised of 6 to 10 year olds at the site of Midnight Terror Cave. This finding is in line with ethnohistoric and ethnographic accounts that indicate children were often selected for sacrifice to the Maya rain gods in caves and cenotes. [66] Discussant

Kielhofer, Jennifer (University of Arizona) [279] A Soil-Stratigraphic Record of Landscape Evolution and Human-Environment Interaction at the Yangguanzhai Archaeological Site, North-Central China
This paper presents the results of soil-stratigraphic investigations and stable isotope analysis at Yangguanzhai, a Middle Neolithic site (~5500 cal. years BP) in the Wei River Valley of north-central China. At Yangguanzhai, there is a well-preserved sequence of alternating sediment and buried soils, indicative of multiple fluctuations in landscape stability. Human occupations are associated with three buried soils: the two lower soil horizons contain Middle Neolithic (~6000–5000 cal. yrs. BP) artifacts and features, while the upper horizon contains Han Dynasty artifacts (~2500 cal. yrs. BP). Unweathered between the burial of the soils may signify that flooding and floodplain deposition during the Late Holocene. Stable isotope analysis on bulk soil and sediment carbonates offers insight on Middle Neolithic paleovegetation and paleoclimatic conditions. δ13Ccc values range from −4.76 to −7.83‰, reflecting a higher proportion of C3 biomass within a mixed C3/C4 ecosystem. Agricultural cultivation of millet during the Neolithic may be responsible for the C4 signal. S18Occ values range from −8.13 and −9.48‰, suggesting strong summer monsoonal conditions. Based on these analyses, Middle Neolithic groups at Yangguanzhai experienced warm summer temperatures, strong monsoonal rainfall, and seasonal climatic variation. However, human activities (agriculture) may have influenced pedogenesis and the isotopic signature of carbonates. [6] Discussant

Kiesow, Danielle (Indiana University of Pennsylvania) [17] Reservation Archaeology in an NPS Setting: Native-White Relations and Land Use on the Grand Portage Reservation, 1854–1930
Grand Portage National Monument (GRPO) is located within the Grand Portage Reservation in Northern Minnesota and is primarily concerned with interpreting the events and impacts of the fur trade in the eighteenth century. In an effort to increase the Grand Portage Ojibwe representation and in compliance of Section 110, GRPO conducted archaeological excavations in the summer of 2016 of the historic yard of a Bureau of Indian Affairs (BIA) building to explore land use and plant use throughout time and to better identify the occupation of the building. The Grand Portage BIA Complex excavation is one of the first efforts in Grand Portage to learn more about the history of the Reservation and history of BIA occupation on a local and regional scale. Preliminary results of the study discuss the artifact assemblage from the yard and house waste found in the four excavated units, the soils in and around the site, phytolith analysis taken from soil samples in the units and outside the site, and historic documentation from BIA employees. Additional consideration is given to the differences in soils and artifact assemblages from the Grand Portage BIA Complex site and 21CK12, located within the vicinity, that highlight differences in socioeconomic lifestyles.

Kilgore, Gertrude (Texas Tech University), Brooke Bonorden (Texas Historical Commission) and Brett A. Houk (Texas Tech University) [280] Machetes, Metates, and Majipca: San Pedro Maya Involvement in the Colonial Economy at Kaxil Uinic Village, Belize
Following the outbreak of the Caste War in the Yucatán (1847–1901), a group of San Pedro Maya established the village of Kaxil Uinic in northwestern Belize (formerly British Honduras). In the wake of the Battle of San Pedro between British and Maya forces in 1867, the Lieutenant Governor of British Honduras issued a decree to delegitimize San Pedro Maya claims to land, undermining their subsistence economy and forcing them into wage labor for the logging and chicler industry. O. Nigel Bolland (2003:111) characterizes the period during which Kaxil Uinic was inhabited (ca. 1880–1931) as the consolidation of British jurisdiction over the Maya and their incorporation into the colonial social structure. A critical analysis of archaeological and archival data gathered over two field seasons reveals that the inhabitants of Kaxil Uinic selectively participated in the colonial economy according to their needs. Strategic interaction with logging firms, the chicler industry, and the colonial administration allowed the residents to maintain some social, political, and economic autonomy through the supplemental use of imported goods and cash alongside locally made tools and vessels. Data from Kaxil Uinic demonstrates this amalgamation of Indigenous and European technologies, where residents navigated the ever-changing cultural landscape of British Honduras.

Killick, David (University of Arizona) and Frances Hayashida (University of New Mexico) [164] Lung-Powered Copper Smelting on the Pampa De Chaparri, Lambayeque Department, Peru
We report here the archaeometallurgical analysis of residues associated with two banks of four lung-powered copper smelting furnaces at site 256AO1, discovered during Hayashida’s full-curation survey of the Pampa de Chaparri in 2008. Calibrated radiocarbon dates place the operation of the furnaces in the Middle Sican period, ca. 1000–1200 cal AD. The furnaces are similar in size and shape to those excavated by Shimada and Epstein at Cerro Huaringa, which is only 15 km away; the smelting process that we reconstruct differs in some significant respects. At Cerro Huaringa, copper prills were trapped in a pasty slag, which was crushed on giant grindstones (batanes) to recover the metal. At 256AO1, fluid slags separated cleanly from copper, and there are no batanes. The ore smelted was weathered chalcopyrite (CuFeS2) and furnace atmospheres were evidently very reducing, as at least some of the metal was contaminated with metallic iron. This was removed by refining the metal on shallow ceramic plates, about 20 cm in diameter, under a more oxidizing atmosphere. The copper metal contains 1–5% arsenic, but we are unable to determine whether arsenic minerals were part of the ore, or whether they were deliberately added.

Kilpatrick, James (University of Toronto) [191] Weber Fractions, Standardization, and Variation in Artifact Form
Scholars have debated the relevance of variation and standardization in artifact assemblages since the nineteenth century. Variation in artifact assemblages is used for developing typologies and examining temporal changes in artifact form. Standardization in artifact shape is an important indicator of the cognition of early humans, socioeconomic organization, and the emergence of craft specialization. Research into the causal factors of variation includes testing humans’ sensory perceptions, biomechanical studies of our motor skills, and experimental replication. These studies suggest there is a physiological threshold beyond which humans are unable to perceive size differences below 3%. The current proposal is based on an
experiment that quantified humans’ ability to perceive minute size differences in three-dimensional (3D) objects without the aid of an external scale. A hand ax and a Levallois core were laser scanned and 3D printed as a size-scaled series decreasing by 1%. Size ratio tests were administered to 30 participants using the printed models. The experiment demonstrated that humans’ ability to perceive size variation decreases rapidly below 3% volumetric difference between objects. The results suggest that humans’ inability to accurately detect minute size differences may explain some of the variation in artifact form introduced into the archaeological record.

[92] The Ones Who Stayed Behind? Genome-Wide Affinities of Okunev Remains from Bronze Age South Siberia and the Enduring Dialogue of Ancient DNA and Physical Anthropology

Genome-wide ancient DNA data from Upper Paleolithic Siberians and deep time series in Europe challenge many traditional models of relationships between Native Americans, West Eurasians, and East Asians in physical anthropology—by recasting them as fusions of prehistoric ancestry streams that may unexpectedly cross-cut or fracture these categories. We evaluate new and published genome-wide data from remains attributed to Okunev—an archaeological culture of the Middle Yenisei and eastern steppe in southern Siberia (latter third–first half second millennium BC), famous for slab graves, massive stelae, and fantastic zoomorphic and anthropomorphic petroglyphs—to test an unusual physical anthropological hypothesis. Russian anthropologists have argued Okunev remains to exhibit pronounced affinity to Native Americans, surpassing that of other ancient groups from the region as well as recent Siberians and Central Asians. Kozintsev et al. (1999), in the most systematic investigation, suggested Okunev people to derive much of their ancestry from late-persisting “collateral relatives” of Native Americans who remained in Eurasia. We evaluate this proposal in special light of the “Ancient North Eurasian” concept (sensu Lazaridis 2014) and offer considerations on the future of skeletal morphology in framing and motivating investigations of human population history.

Kim, Ha Beom (University of Oregon) and Gyoung-Ah Lee (University of Oregon)

[325] Preliminary Spatial Analysis of the Middle Mumun Culture’s Land-Use Pattern in Southcentral Region of Korea

This study investigates the land-use pattern of the Middle Mumun culture (c. 29/2800–2400 cal. BP) in south-central region of Korea from a spatial analytic perspective. By employing inter-settlement visibility analysis and geographical variable comparisons, this study explores social and environmental contexts affecting cultural decisions of the Middle Mumun people for their settlement locations. Through our analysis, we find that relationships across the Middle Mumun settlements may have emerged gradually over time through interactions among neighboring groups, and that the locations of these settlements reflect landscape preferences of the Middle Mumun people. We suggest a long-term bottom-up processes of emerging social unity as an important concept to better understand the complex context of Middle Mumun settlement choices.

Kim, Nam (University of Wisconsin-Madison)

[20] The Co Loa Settlement: Biography of an Anomalous Place

In the archaeological study of ancient large-scale settlements, there is considerable debate regarding definitional criteria for categories of “city” and “urban.” New field studies from different world areas have enriched our understanding of the variability of past settlement configurations along dimensions of utility, meaning, space, scale, and demography. In northern Vietnam, the remains of monumental constructions of the prehistoric settlement of Co Loa still stand today. Dating to the first millennium BCE and encompassing some 600 hectares in size, this settlement was unprecedented in Southeast Asia. Recent field investigations have provided new insights for this large-scale and relatively anomalous settlement, one exhibiting signs of highly centralized political power and a dispersed, low-density form of ancient large-scale settlement. This paper offers an overview of the settlement, illustrating several local-historical and regional trends in order to provide a context for the early story of Co Loa and its occurrence. The case offers a glimpse into alternative pathways for trajectories of settlement development, both in Southeast Asia and worldwide.

Kim, Nanny (Heidelberg University)

[333] Mapping Mining Remains in the Borderlands of Southwest China

About 43 very important silver mines and some six copper mines are known to have been worked between the early fifteenth and the mid-nineteenth century across the Far Southwest of China and in the borderlands beyond. Written sources on mining in the Ming and Qing periods are so scarce that in some cases we identified sites before eventually finding their historical names. Under ideal research conditions, this paper would present archaeological surveys on these sites. In the real world of greatly improved transportation and quickly changing landscapes, we attempt to cover as many of the sites as possible in very preliminary fieldwork surveys. In these, we try to collect spatial information on slag dumps, settlements, and temple sites, presenting finds and an approach that uses geographic information systems for analyzing spatial data. The mapping of settlements, mining areas, slag dumps, and transport networks provides a tool for integrating various data for a comparative grading of mining sites, and for gaining insights into past societies.

Kimball, Larry (Appalachian State University)

[264] The Recognition of Hafting Traces on Native American Stone Tools

As Keeley (1982) pointed out some time ago, the recognition of microwear traces due to hafting is an important source of information not only about how stone tools were prepared for use, but how their differential discard affects the recognition of site structure and site function. This is because the economy of different hafting arrangements and the act of “retooling” is different for hafted versus unhafted tools. In an effort to consider the variable range of hafting traces among Native American lithic technologies, a sample of over 2300 tools from Paleoamerican through Historic Cherokee industries from 40 sites in eastern North America is discussed to provide a better understand of the patterning of hafting traces. In rank order, general tool groups exhibit a variable but expected pattern of percentage of hafting traces: arrowpoints (86%), bladelets (76%), end scrapers (74%), Paleoamerican points (70%), blades (66%), Archaic and Woodland points (57%), utilized flakes (57%), retouched flakes (52%), flake tools (30–50%), drills (46%), bipolar flakes (22%), and bipolar cores or pieces equifoliates (9%). It is argued that such microwear data from archaeological specimens is a useful first step to address the question of hafting, but also to guide future experimentation.

Kime, Alexander [394] see Guilfoyle, David
Disease. This highlights the importance of taking a multifaceted approach to weaning studies, and the contribution that this type of approach can make to understanding early life histories within past natural and social environments.

Twenty years of research at the large prehispanic Maya site of Maax Na in northwestern Belize have yielded insights not only into site organization and function, but also into its role in the Three Rivers Region. Ongoing investigations of a marketplace and of local caves indicate that Maax Na, while probably not the political capital that its neighbor La Milpa was, nonetheless had a distinct and important regional function as a religious and marketing center. Investigation of water management and agricultural areas further illuminate its role and add to the range of practices documented for the region. To complement this site-centric research, we have also pursued broader inquiries that link Maax Na with other communities. These include investigations into the small, agriculturally specialized site of Bolsa Verde, midway between Maax Na and Dos Hombres, and chemical sourcing of limestone monuments at Maax Na and other sites, to understand patterns of procurement and distribution. The picture emerging from this research is of a complex region, where sites of all sizes played distinctive and interconnected roles. It challenges common models of Maya polities, where one large site dominates in every aspect, and invites us to consider alternative views of regional dynamics.

Sacred Worlds and Pragmatic Science in the Aftermath of Conquest. The Hidden Caves of Cerro del Convento

In the sixteenth century, Dominican priests attempted to eradicate various non-Catholic ritual practices in Nejapa. Native peoples apparently regularly visited Cerro del Convento, a Sierra Sur landmark, to perform rituals and leave offerings. In the late 1500s, priests from the Dominican doctrina in Nejapa visited Cerro del Convento to destroy and burn all evidence of “idolatry.” Between 2009 and 2013, members of the Proyecto Arqueológico Nejapa Tavela surveyed and excavated at Cerro del Convento to document the occupation and use of the site. Our work shows that the rockshelters associated with Cerro del Convento were visited as early as the Late Formative (500 BC). The mesa top served as a residential and ceremonial center during the Classic and Postclassic period, a time of increased conflict and military incursion. During the Late Postclassic and Early Colonial periods, the caves and rockshelters became pilgrimage destinations and were used for storing of agricultural products. We argue that the Dominican efforts to eradicate idolatry may have had a more pernicious function of exposing hidden reserves of foodstuffs. Cerro del Convento remained an important regional landmark precisely because it met both the sacred and pragmatic needs of indigenous peoples during the turbulent years of conquest.

Absorbed Residue Evidence of Datura Use in Mississippian Contexts

We recently identified residues indicative of the preparation of Datura in ceramic and shell vessels dating to the Mississippian period (900–1600 CE) of the southeastern United States in the collections of the Gilcrease Museum. Datura is a genus of flowering plants whose seeds and flowers contain tropane alkaloids that produce hallucinogenic effects when consumed by people. The use of Datura for a variety of medicinal ritual practices is well established among Native Americans today and in the recent past. The only other evidence for its use in North American prehistory comes from the recovery of charred seeds, a rare occurrence in the archaeological record. Absorbed residues present an opportunity to learn more about Datura use in the past and connect recent medicine traditions. In this paper we will use archaeological and iconographic information to explore ancient contexts of use and possible transmission as part of cultic institutions.

Sculpting, Renewal, and Perdurance of Illinois Hopewell Mounds

Investigations of Illinois Valley Middle Woodland (Hopewell, ca 50 cal BC–cal AD 400) mound structure have traditionally emphasized the organization and composition of initial, or primary, features that anchor these monuments. Particular attention has been placed upon the distinctive ramp and tomb complex that centers initial ritual activity at mound sites and its connection to mortuary activity, cosmology, and creation. In contrast, archaeologists have typically underappreciated subsequent building episodes that transform tumuli into massive monuments. Often referred to simply as “capping layers” because they obstruct access to central features, these earthen additions transform and sculpt the external structure of mounds in meaningful ways that reconfigure Middle Woodland people’s landscape through repetitive performances that reinforced received and transmitted wisdom. In this paper, we focus on the communal and regenerative nature of mound sculpting, particularly the reconfiguration of structures that shift activity and attention away from mortuary contexts and creation narratives to practices that emphasize renewal and perdurance throughout the Middle Woodland period and beyond.

Data Integration in the Service of Synthetic Research

Children of the Atacama Desert: The Complex Interactions between Breastfeeding, Weaning and Environmental Stress in One of the World’s Harshest Environments.

Infant feeding practices and the weaning process have important implications for early life health and mortality patterns. In particular, the concept of weaning stress is often invoked as an explanation for increased infant or child mortality and morbidity. In this paper we evaluate the concept of weaning stress and the bioarchaeological methods used to interpret its presence. We highlight the intimate connection between stress and the weaning process in our own research in the northern Atacama Desert, northern Chile, by combining paleopathological and incremental isotopic methods. We use a case study from the Formative Period (1400 BC–500 AD) to illustrate the interaction between breastfeeding, weaning, physiological stress and metabolic disease. This highlights the importance of taking a multifaceted approach to weaning studies, and the contribution that this type of approach can make to understanding early life histories within past natural and social environments.
Addressing archaeology's most compelling substantive challenges requires synthetic research that exploits the large and rapidly expanding corpus of systematically collected archaeological data. That, in turn, demands an integration procedure that preserves the semantics of the data when combining datasets collected by multiple investigators who employ different systematics in their recording. To that end, we have developed a general procedure that we call query-directed, on-the-fly data integration that is deployed within the iDAR (the Digital Archaeological Record) digital repository. The integration procedure employs ontologies that are mapped to the original datasets. Integration of the ontology-based dataset representations is done at the time the query is executed, based on the specific content of the query. In this way, the original data recording is preserved and data are aggregated only to the extent necessary to obtain semantic comparability. Our presentation draws examples from the largest application to date: an effort by a research community of southwest United States faunal analysts. Using 24 ontologies developed to cover a broad range of observed faunal variables, we can now integrate faunal data from 37 projects investigating the late prehistoric northern Southwest, including more than 378,000 individually recorded specimens.

Kirakosian, Katie V. (Kaplan University)

By definition, hunter-gatherer societies rely upon few, if any, domesticated animals. Domestication is counter to many hunter-gatherer worldviews, where human and nonhuman animals are seen as sharing a literal biological connection. From here, in essence, domestication is akin to slavery. Examples from the ethnohistoric and archaeological records will be used to illustrate how local Native groups in southern New England treated wild and domestic animals and animal remains in culturally prescribed ways, which pushes against the notion that animals should be placed in such a dichotomy in this context. Counter to the idea that humans are “rulers” over the animal kingdom, the Woodland Indian concept of Manitou shows how animals, in fact, also controlled humans in very real ways.

[380] Fishponds and Aquaculture in the Ancient Hawaiian Political Economy

The political economy of ancient Hawai‘i, prior to European contact in 1778–1779, has often been characterized as based primarily on a “staple economy” with highly intensified forms of both irrigated and dryland agriculture. Less appreciated is the role of intensive aquaculture of two species (milkfish and mullet) using several kinds of often extensive fishponds. This paper explores the role and significance of such aquaculture in the late precontact Hawaiian political economy, drawing especially upon extensive archaeological and ethnohistoric data from the island of Moloka‘i. It is argued that on Moloka‘i, fishponds rivaled pondfield irrigation in their ability to provide the elite ruling class with a dependable source of surplus.

[346] The Study of Castles throughout Europe: Limitations of Multiregional Studies

For much of Europe, castles represent a point of cultural heritage and national pride. Yet, even though the study of castles has long been of interest to scholars, few researchers have moved beyond intraregional analyses to examine interregional trends in the manifestation of these monuments. Traditional archaeological investigations examining cross-cultural differences have been hampered primarily by language barriers and differences in how researchers approach questions pertaining to the encastellation of medieval Europe. The rising use of satellite data and GIS software in archaeological research might represent one such way to get around these barriers. This paper will focus on the potential benefits of large-scale, geospatial investigations of castles, provide an example of an analytical framework from which appropriate research questions can be asked, and examine three disparate regions—Sicily, Bohemia, and Scotland—to look at the geospatial similarities and differences between castles in each of them. It will then conclude with a look at some of the difficulties in taking such a multiregional approach in terms of computational space needed, differences between datasets between regions, and the problem of using present landscapes as a proxy for medieval ones.

[142] Butchering Practices at the Vore Buffalo Jump (48CK302): Investigating Organization with the Nearest Neighbor Test

Spatial recognition of organization at mass kill sites is often commented on in the literature but is rarely systematically investigated. The goal of this paper is to investigate social organization of butchery with the nearest neighbor test. The lack of these sorts of methods in the literature is primarily due to the ever-changing methods of archaeological excavation and limited ability to easily analyze provenience data. In the literature, observations of organization and spatial patterning have relied on site maps of excavation blocks and in-field observations. In this paper, statistical methods are applied to a mass kill site of Bison bison from the Vore Buffalo Jump (48CK302) to investigate the organization of butchery. Using a nearest neighbor test, pairwise bootstrapping tests, and a chi-square analysis, this study finds that these methods can give insight into dense stratified bone beds and locate patterns more confidently.

[191] Semiosis in the Pleistocene Scene

One of the distinctive aspects of human behavior is the ability to think symbolically. However, the ability to track this capacity archaeologically is complicated by debates on what makes an object symbolic. Rather than initially asking if materials are symbols/symbolic, we offer that it may be better to ask if and how they are signs. A more nuanced view of “symbol” in the archaeological record, combined with aspects of Peircean semiotics, can help to bridge the gap between the material record of the past and current interpretive assessments. We argue that using the Peircean distinction between qualisigns, sinsigns, and legisigns provides support for this endeavor. The glimmers of early symbolic behavior (the sporadic occurrences of objects with embedded social meanings in the early/middle Pleistocene) can best be seen as sinsigns, “one-off” occurrences, whereas sites that show long-term presence of such materials are demonstrating the presence of legisigns, the codification of ideas. To illustrate this approach we apply these ideas to...
of sites and landscapes, (2) still photos to create 3D models of artifacts, rock carvings, and landscape features, and (3) the merits of having 3D prints of artifacts. A recent visionary study by Klassen, Sarah (Arizona State University), Jonathan Weed (Massachusetts Institute of Technology) and Damian Evans (École française d’Extrême-Orient) reveals that scholars working in this region and beyond.

One of the largest puzzles for archaeologists at Angkor is untangling the extremely complex chronological development of the site. The region was host to hundreds of years of urban occupation arising out of a long tradition of habitation through the Bronze and Iron Age. Decades of archaeological investigations have established relational frameworks through which it is now possible to do more precise dating. Recent lidar investigations and the associated mapping and ground truthing have documented over 1,400 temples and 8,000 reservoirs. In this paper, we group temples with associated reservoirs based on alignments, proximity, and known historical relationships. We then combine several disparate datasets into a relational database that is provided online. Recent lidar investigations and the associated mapping and ground truthing have documented over 1,400 temples and 8,000 reservoirs. In this paper, we group temples with associated reservoirs based on alignments, proximity, and known historical relationships. We then combine several disparate datasets into a relational database that is provided online. We argue that having a more sophisticated understanding of the development of Angkor can assist in asking more robust questions of the archaeological site.

Megalithic architecture appeared suddenly in northwest Kenya 5,000 years ago in tandem with the earliest pastoralists in the region. As Lake Turkana’s levels dropped, these people built “pillar sites”—massive feats of labor and coordination that represent one of the earliest instances of monumentality in Africa—in a brief explosion of material and architectural elaboration. The burials associated with these pillar sites are highly ornamented, with thousands of beads made from stone, bone, and ostrich eggshell that would have been brilliantly colored when worn. This paper takes a first look at sourcing, mineralogy, and the context of these bead assemblages, excavated by the Later Prehistory of West Turkana Project, as an entry into understanding the radical conceptualization of self and society that took place. During this era of climate instability and economic innovation, people felt compelled to procure a wide variety of minerals, gather them together, and place them with their dead, suggesting novel approaches to the ways they understood the worlds of the living and the afterlife. These beads in turn provide insight at the level of individual perception into how people grappled with social changes and, potentially, differentiation in early complex societies.

Klein, Cecelia [80] Blindfolds and the Eternal Return in Late Postclassic Central Mexico

Scholars have invariably interpreted the blindfolds worn by certain figures in Aztec painted manuscripts as a sign of—in their words—“transgression,” “sin,” and “punishment.” This talk challenges the simplicity and inherent Eurocentrism of that reading. It is true that the Aztecs perceived a person’s mistakes to plunge him into darkness and chaos, and that blindfolds, at one level, symbolized that disorder. The cause of a moral error, however, was embodied by certain objects and substances that also contained the power to cure the damage caused—and thus to restore order and wholeness to the social fabric. For the Aztecs the blindfold enabled this reversal. It did so, I argue, because, by blocking vision and light, it symbolically returned the wearer to the primordial darkness of the earliest years of the Creation when, sources tell us, “It had always been night.” Blindfolds allowed their wearer to tap into the creative energy of this darkness, thereby undoing the damage caused. This new understanding of blindfolds as having ambivalent meaning for the Aztecs therefore resonates with Mircea Eliade’s concept of the “Eternal Return,” in which people the world over symbolically return to the distant past in order to restart the present.

Klemmer, Amy (University of Wisconsin—Milwaukee) [232] Preliminary Faunal Analysis at the Coastal Site of Rio Chico, Ecuador (OMJPLP-170)

The Rio Chico site is situated on the central coast of Ecuador, a region that is heavily influenced by climatic events such as El Niño Southern Oscillation (ENSO). Rio Chico was occupied almost continuously for 5,000 years (ca. 3500 BCE to 1532 CE), and therefore provides an opportunity to study...
coastal resource usage over a long temporal span. This poster presents a preliminary zooarchaeological analysis of the relative abundance of fish and other classes of fauna at the site. A sample of faunal remains from the Florida Atlantic University field school excavations conducted in 1997, 1998, 1999 and 2003 is identified to the class level and serves as the basis of this analysis. This analysis provides a foundation for further research to ascertain if there was relative stability or change in resource usage at Rio Chico over time. Prehistoric data analyses from coastal regions impacted by catastrophic weather patterns related to ENSO are relevant to the modern-day management and sustainability of coastal fisheries. A better understanding of resource usage at sites such as Rio Chico can provide important knowledge of the ways in which humans living in coastal regions may have responded to environmental instability over time.

[84] From Southern Brazil and Northwest Mexico: Swimming across Landscapes with the Fishes

Prehistoric societies included multidimensional natural, economic, social, political, and ritual landscapes. In this paper we briefly describe landscapes from the southwestern coast of Brazil during the Archaic period and from the Casas Grandes Medio period (AD 1200–1450) in northwest Chihuahua, Mexico. More specifically, we address ritual landscapes from shell mounds to hilltops. These components of landscapes are highlighted in honor of research conducted by Paul Fish and Suzanne Fish that inspired our work.

[184] Terminal Pleistocene–Early Holocene Occupation Span and Technological Provisioning Strategies at Pluvial Lake Mojave, California

This paper represents a first attempt to reconstruct the occupation span of Terminal Pleistocene–Early Holocene foragers around pluvial Lake Mojave, Mojave Desert, California. Models suggest and research indicates that foragers were more sedentary and made shorter moves around large, productive resource patches (large lakes, marshes), but made more frequent and longer distance moves when resource patches were small and/or widely scattered. Lake Mojave at its Pleistocene maximum was 300 km² and reasonably considered a large resource patch; whether foragers used it this way is unknown, though. To address this, I consider (following the lead of other researchers) whether the lithic technology at Lake Mojave fits a provisioning place or provisioning individual strategy. The provisioning place strategy is expected when occupation span is long and the provisioning individual strategy when the occupation span is short. Given Lake Mojave’s large size and expected patch productivity, the provisioning place strategy is anticipated. Several variables will be used to differentiate between these strategies: toolstone selection and proximity, tool kit structure (degree of curation) and diversity, and artifact replacement patterns. Data to address these issues come from analyses of the extant Campbell and Brainerd collections, and my ongoing research along the shorelines of Lake Mojave.

Knight, Charles (University of Vermont)

[42] Quantifying Obsidian Extraction at the Zaragoza-Oyameles Source Area of Puebla, Mexico and What This Means for Understanding Ancient Mesoamerican Economies

Typically overlooked in economic models of commodity production, distribution and consumption in Mesoamerica, is some discussion on the initial procurement of the materials that form the basis of the ancient economies we study. Significant cultural issues, such as labor coordination, territoriality, group identity, knowledge transmission and wealth, which are all wrapped up in a dynamic political and ideological milieu, are at play in the discrete geographical loci where material procurement occurs. Focusing on the procurement of obsidian at the Zaragoza-Oyameles source area in eastern Puebla, Mexico, I present quantitative data on the extent of raw material extraction and, where possible, the type and degree of early stage tool production at the source. Results of detailed topographic mapping of these extraction loci, and the analysis of intensive collections made from their surface, provide a fundamental baseline of data for all subsequent discussions on the role of obsidian in ancient Mesoamerican economies.

[242] Deep Time versus Archaeological Time: Disentangling Stratigraphy, Periodization, and Historical Narrative

The earth sciences have periodically contributed to shifts in archaeologists’ theoretical and methodological approaches to space and time (“deep” time and sociocultural evolution, stratigraphic laws and contextual interpretation). The Anthropocene seems to herald another such shift, but the category/concept remains controversial given its bridging, by design, of science and politics. This paper argues that archaeologists can clarify our discipline’s engagement with these debates by comparing archaeological and geological periodization. An assessment of differing approaches to sedimentary layers reveals conflicting disciplinary logics concerning evidence and historical narrative. These differences extend beyond scaling individual disciplines “up” or “down” through space and time, or how to incorporate nontraditional lines of evidence into the existing interpretive frameworks of particular disciplines. This paper points to a number of conceptual matters that must be addressed as part of a possible disciplinary reordering in response to the challenges of global warming and other environmental crises.
Knodell, Alex

A Paradigm Shift in Regional Archaeology?
The pace and scale of technological change in field- and lab-based applications in remote sensing, spatial sciences, and digital media (to name only a few) have fundamentally transformed archaeological research design and practice, especially on a regional level. But have these technological advances changed the discipline in ways that might constitute a paradigm shift? Have they resulted in new disciplinary priorities? Or do they simply represent newer, faster ways to pursue agendas not so different than before? This paper examines positive and negative examples of what may constitute a paradigm shift in regional archaeology and what implications that may have. The first case concerns remote sensing and spatial technologies. The second has to do with digital media. A critical examination from the perspective of scientific revolutions suggests that new priorities have emerged in direct response to certain technological opportunities, especially since the 1990s. It is more difficult to assess our current state in the twenty-first century—although seemingly characterized by exponential growth in everything “digital,” few would argue that in every case this represents some unqualified good. A further challenge is that disciplinary change tends to be apparent mostly in hindsight. Nevertheless, such field-shaping developments call for careful scrutiny.

“Where Individuals Are Nameless and Unknown”: Osteobiography Reveals the “Big Man,” the Ritualist, the Heiress, and the Priest

In 1957, Christopher Hawkes (of the ladder of inference renown) wrote: “the most scientific and therefore the best, because the purest, kind of archaeology is the prehistoric kind, where individuals are nameless and unknown, and so cannot disturb our studies by throwing any of their proud and angry dust in our eyes” (quoted in Christopher Evans, Historicism, Chronology and Straw Men: Situating Hawkes’ “Ladder of Inference,” Antiquity 72[276]:398–404). Because the social identity of the deceased cannot be identified from human remains without analysis, osteobiography, the bioarchaeological reconstruction of the lives and deaths of individuals from the past, is essential. This is as true for historic as for prehistoric people, not only for those “without history,” but even those named individuals who are said to be “historical.” This contribution introduces a Bronze Age “Big Man,” an Iron Age ritualist, a medieval aristocratic heiress, and an Archbishop of Canterbury (and martyr), a mix of the historic and prehistoric, all nameless without analysis and none throwing much dust in our eyes.

Ko, Jae Won (Jeju Cultural Heritage Institute)

Peopling of Jeju in the Late Pleistocene and Early Holocene

Paleolithic sites in Jeju Island have been found in the Quaternary sediment layers that are related to volcanic activities. Accordingly, research has been closely related to the geological investigation on sediment formation and volcanic activities. This presentation focuses on two Paleolithic sites, Oeodongdong along the north coast and Sangsugasae cave along the south coast. The Oeodongdong site contains choppers and is dated to 32,000 BP; the Sangsugasae cave site represents the Terminal Pleistocene, which dates to 25,000 BP. This study investigates the relationship between the Terminal Pleistocene Paleolithic culture and the Early Holocene Neolithic culture, known as the Gosaunri culture.

Archaeology of Salmon Ceremony in the Japan Sea Coastal Regions: A Comparative Study with the Northwest Coast of North America

As in the Northwest Coast of North America, salmon may have played a critical role for the development of subsistence and political economies as well as ritual systems during prehistoric and historic northern Japan. This paper explores the Jomon salmon ceremony in the Japan Sea coastal regions based on the analyses of the (1) ecology of salmon, (2) rock arts (petroglyphs), (3) salmon remains and their archaeological contexts, (4) zoomorphic stone figurines (clubs), and (5) ethnohistory (folklore) of salmon rituals and their spatial distribution. All of the evidence from the analyses suggests that ecological conditions of salmon have a significant effect on Jomon salmon ceremony in the Japan Sea coastal regions.

Kocer, Jacqueline

i examine the behavior of emulation wherein an artisan reproduces a craft on a less valuable or precious material to mimic a desired symbolic prestige good. I present cross-cultural examples of artisans making copies of a craft using different materials. Under what circumstances do people create counterfeit objects? Examples from the Gallina area (AD 1100–1300) of the American Southwest are discussed. The Gallina occupied an area on the periphery of a more socially complex polity (Chaco), and they appear to have lacked access to the prestige goods that they were counterfeiting. I further discuss symbols of prestige and how they might be used by the emulating group.

Low Impact, High Resolution: Unraveling and Learning from 10,000 Years of Hunter-Gatherer Use of Eagle Cave

On the northeast fringe of the Chihuahuan Desert, one of the largest rockshelters in the Lower Pecos Canyonlands, Eagle Cave, preserves an extraordinary record of hunter-gatherer life spanning more than 10,000 years. Ongoing investigations by the Ancient Southwest Texas Project of Texas State University beginning winter of 2015 have re-excavated a 4 m deep trench through the center of this massive rockshelter in order to document and sample complex stratigraphy and to stabilize and backfill archaeological units left open in 1963. Spanning 13 field months, we have used continuous Structure from Motion 3D mapping as our primary documentation method while employing microstratigraphic excavation techniques and rigorous
multidisciplinary sampling led by geoarchaeology to explore Archaic and Late Prehistoric features such as shallow pits, earth oven beds, and latrines. We have also sampled Paleoindian deposits containing surface hearths, butchered bison bone, decomposing fiber beds, and mammoth remains. This presentation summarizes our methodological approach and field interpretations and highlights the site restoration effort as well as ongoing analyses from the 2015–2017 Eagle Cave investigations.

Landscape Preference and Precontact Site Location Modeling in the Central Plains, USA

The Cultural Resource program at Fort Riley provides an ideal setting for developing and testing models for precontact settlement within the Flint Hills region of the Central Plains. Precontact populations utilized the patchy environmental resources available within the Flint Hills by means of specialized activity locations in varying topographic zones. Many of these small sites have been identified through extensive pedestrian surveys of the Fort Riley Installation. These survey data have been used to test existing site location models in addition to providing more information about the different resource exploitation strategies of precontact peoples in the region. This broad view of the survey data has both refined and developed new research questions about landscape use within Fort Riley, particularly in regard to the National Register of Historic Places (NRHP) evaluation process.

Koetje, Todd (Western Washington University)

Neadertals, Denisovians, and Modern Humans: What Material Culture Differences Can We See During Their Overlap?

The time frame from 50–30 kya contains evidence for at least three distinct human populations spread across northern and western Eurasia. These groups faced serious environmental challenges, and seem to have existed in widely spread, small populations with perhaps very similar basic cultural adaptations. As indicated by shared genes, these groups were evidently in contact. How are these populations represented in material culture? To what extent can we begin to see typological and technological patterns in material culture that might distinguish them? Preliminary comparisons suggest only very subtle distinctions. Is this the Bordes-Binford debate’s revenge?

Kohler, Tim (WSU/SFI/CCAC)

Thinking Outside the Map: Alternative Approaches to Data Visualization

One of the more promising applications of Geographic Information Systems (GIS) in archaeology is the potential to incorporate aspects of human perception and experience of the landscape. Visibility analysis has been applied extensively to archaeological contexts, and models of movement, acoustics and other sensory experiences have recently received greater consideration. But despite the promise of moving beyond measurements of geographic space, most applications of experiential modeling continue to rely on standard cartographic tools for representing and analyzing relationships between archaeological phenomena. In this paper, I explore how digital technologies offer alternative (i.e., non-map-based) visualization techniques can be used to better represent and support analysis of human-scale spatial relationships. As a case study, I use regional survey of Late Intermediate Period (1000–1450 CE) hilltop fortifications from south-central highland Andes. Specifically, I examine alternative visualization techniques for modeling intersite relationships in terms of visual perception and travel time—rather than geographic distance. This case study contributes to broader discussions of the potential for digital technology to transform both how we represent and analyze archaeological data.

The First Cultural Landscapes of Europe—and Before . . .

Cultural landscapes appear relatively late in the human history. In Europe, between c. 40–20,000 BP, people for the first time seem to have transformed (parts of) their environment intentionally on a significant spatial scale in order to make places and areas “fit” for future activities. Already between 40,000 and 30,000 BP, prominent natural formations and hidden places were marked with signs and symbols to enable distant communication. From c. 25,000 BP onward, on-site constructions, such as dwelling structures, were deliberately “built” to facilitate livelihood. By 20,000 BP, hunter-gatherers probably used fire as a landscaping tool as well. The timing of these developments makes clear that the emergence of cultural landscapes does not simply coincide with the appearance of anatomically modern humans in Europe. This paper briefly discusses the evidence for the thesis that the cultural landscape is a late development. However, it also criticizes the idea that the earliest cultural landscapes can be understood properly from conventional geographical perspectives. Thirdly, the paper explores what could have characterized human niche construction in the millennia before c. 40,000 BP. How did Late Pleistocene hunter-gatherers organize their living space if not by means of cultural landscapes in a more or less classical sense?

Investigating the Maya Polity at Lower Barton Creek, Cayo, Belize

Discussant

Chair
Over fifty years of settlement research in the Belize River Valley has made the region one of the most intensively investigated areas of the Maya Lowlands. Recent lidar research by the Belize Valley Archaeological Reconnaissance Project identified the previously unknown center of Lower Barton Creek in the southern extent of the Belize Valley, filling in a major gap in our understanding of settlement histories. In this paper, we present the results of settlement survey based on spatial analysis of lidar data and the results of excavations in the Lower Barton Creek site core. The goal of this research was to contextualize the site’s occupation within the ancient sociopolitical dynamics of the Belize River Valley. High-resolution AMS 14C dating and ceramic analysis indicate that Lower Barton Creek was settled by the Middle Preclassic Period (~700–300 AD cal), and quickly grew into a large regional center. A hiatus in activity at the site occurs after AD 300, coinciding with an extended drought documented in regional paleoclimate records. Ceramic evidences indicates that the site core recovers after AD 700 and continues to develop until its abandonment in the Terminal Classic Period around AD 900.

If the Dead Could Return: The Politics of World War II–Era Human Remains in Eastern Europe
Although World War II hostilities ended in 1945, still today the graves and remains of both combatants and civilians continue to be unearthed, especially in Eastern Europe. These discoveries of graves become entwined with the dynamic physical and geopolitical landscapes, whereby the post-human remains take on new, contested identities. Their unique identifications to name or nationality are sublimated, as their collective national or ethnic identities become prioritized. Combatants tentatively identified as German are typically interred near where they fell, in foreign lands, as a gesture of reconciliation. However, the Second World War exacerbated ethnic hostilities in the former Yugoslavia. There the uncertain identification of World War II combatants allows bioarchaeological materials to take on new meaning as they become representations of continuing feelings of loss and animosity that have been manipulated for contemporary ideological purposes. The indexically of these enduring remains keeps the memories of the war salient in current political agendas, such that the past is not really past.

Kooiman, Susan (Michigan State University)

Cooking and Cuisine: Culinary Clues and Contexts in the Archaeological Record
Identifying specific foods exploited and consumed by people from past societies is important, but decisions concerning nutrition and social identity can only be fully understood through the study of food preparation techniques and recipe development and traditions. Cooking and cuisine embody the intersection of the biological and the cultural. Their centrality in both everyday and ritual life makes them ideal throughfares into the exploration of adaptive, social, political, and ideological tenets and behaviors of past societies. For this reason, ancient cooking techniques and the social and cultural aspects of food choice have become topics of increasing interest. There are multiple evidences through which to access past diet and cooking, including macrobotanical and faunal remains, food processing technologies, chemical and microscopic food residues found on cooking technologies, experimental replication and ethnographic analogy. Each method yields unique and complementary data about past diet and food processing. This diversity holds the potential for collaborative efforts across multiple independent methods resulting in more complete social and cultural interpretations of past cooking habits and food selection.

Koons, Michele (Denver Museum of Nature & Science)

Climate Change and Moche Politics: A View from the Northern Chicama Valley, Peru
In this paper I will discuss the different lines of evidence pertaining to detecting El Niño and La Niña events at the site of Licapa II and surrounding Northern Chicama Valley. Flood deposits, dune encroachments episodes, malacological data, canal destruction and rebuilding events, and radiocarbon evidence are used as proxies to help understand the intensity and timing of ENSO events. I compare evidence from Licapa II to other sites inside and outside the Chicama Valley to highlight the localized impact of ENSO events. The local nature of destruction from such events has repercussions for the way that political relationships functioned at the sub-valley, valley, and intervallay level.

Koonz, Rex (University of Houston)

H. B. Nicholson and the Gulf Coast
While known primarily as an Aztec specialist, H. B. Nicholson was instrumental in beginning a dialogue on regional iconographies. A key example of this dialogue was his work on deity complexes. Building on his mastery of the ethnohistorical data, Nicholson’s work on deity complexes attempted to locate particular deity groups with certain regions. This essay looks at Nicholson’s hypotheses on Gulf Coast iconography and how those hypotheses have helped shape the regional iconographies now being constructed.

**[51] Bear Creek (45KI839) Data Recovery Investigation and the Paleoarchaic Settlement of the South Salish Sea during the Late Pleistocene-Holocene Transition**

The Bear Creek site (45KI839) in Washington State’s central Puget lowland is among the earliest lithic artifact-bearing, professionally excavated archaeological sites on the Pacific coast between Haida Gwaii and the Santa Barbara Channel. Data recovery excavations in 2013 provided an unprecedented view of Native American settlement in a rapidly changing coastal lowland setting during the Late Pleistocene-Holocene (LPH) transition. We summarize the results of these excavations and attendant analyses and address some broader implications of the research to date, including the settlement of the earliest peoples in western North America, patterns of land use in the Pacific Northwest’s dynamic post-glacial environment, and rethinking regional culture-historical sequences. The Bear Creek LPH component contains a lithic assemblage akin to the Western Stemmed Tradition in the interior although it also shows elements of continuity with later regional technological traditions. The lithic assemblage and other contextual data meet expectations derived from models of WST settlement of the interior Pacific Northwest which originated from a Pacific coastal migration.

**[29] Does Technology Hinder or Assist Storytelling? A Critical Theory Approach to Archaeological Representation and Relational Data**

Advances in archaeological science are throwing new light on old concerns about representations of the past. Methods such as GIS allow archaeologists systematically to analyze multiple variables at once and rapidly to view data from various vantage points. Critics argue that such methods lose sight of the experiential aspects of history—the cultural differences that influenced how different people participated in social life and told stories about their past. This paper argues that this critique creates a false dichotomy between categories for archaeological explanation and practices that structure social experiences. In particular, the paper draws on critical theory and the philosophy of action to demonstrate how objective renderings of archaeological data can be consistent with subjective, experiential practices of storytelling. Stories are told by emphasizing situated relationships among people, materials, and spaces. New technology, with its capacity to create truly relational ontologies, can enhance archaeologists’ abilities to tell stories in ways that mirror cultural understandings, reveal essential cultural differences, and represent complex ecologies. As an example, the paper presents photogrammetry and GIS research from the heartland of the Incas, to tell a story of how forcibly resettled workers created a political community and challenged an empire by building their houses.

**[235] Will Your Childhood Years Kill You Earlier? A Study Exploring the Relationship Between Height, Stress, and Age at Death**

Could shorter legs mean premature death? Stature is a highly complex trait which seems to be influenced by many different factors. To name a few, genetics, social status, through to environment, diet, or health issues. However, it has been observed for some time that taller people live longer. For the purpose of current research, data from 10 multi-period sites were collected. The main focus of project is to explore the correlations between height and age-at-death. Additional to this, as it is broadly suggested that environmental factors have significant impact on body height, this research seeks to explore whether individuals that experienced stress during childhood or adolescence are more likely to be shorter and die younger? As an indicator of childhood stress, linear enamel hypoplasia was analyzed. The next question considered, are shorter people more likely to show stress markers developed in adult life? Therefore, cibra orbitalia was analyzed. All possible associations were explored, taking into account sex and origin of the individuals. Does childhood stress result in shorter body height, and is stature indeed connected to the age at death?

**[347] Communities of Practice and Sound-Related Archaeological Collections**

This paper explores an alternative method for examining ephemeral aspects of material culture, such as sound, in the production processes of ceramic precolumbian aerophone construction. In a case study of a museum collection from the G-752Rj site in Greater Nicoya, I demonstrate that it is possible to identify groups of producers and evidence of knowledge transfer between persons that may reflect communities of practice. This research has the potential for examining regional trade and migration of sound related concepts as well as building upon our conceptions of everyday practices of past peoples.

**[190] Preliminary Results of New Excavations on Jens Munk Island, Foxe Basin, Arctic Canada**

Paleo-Inuit groups settled and inhabited the Canadian Arctic from 2800 BC until the arrival of Thule Inuit groups approximately 1200 AD. Previous archaeological research indicated that Paleo-Inuit populations were particularly large and stable in a “core area” comprising Foxe Basin, Nunavut, and adjacent regions. The diverse and supposedly stable resources of this area allowed people to continuously inhabit the region for almost 3,000 years, including a supposedly smooth transition from the early (Pre-Dorset) to late (Dorset) phases of the Paleo-Inuit Period. The core area model persists in archaeological research indicated that Paleo-Inuit populations were particularly large and stable in a “core area” comprising Foxe Basin, Nunavut, and rethinking regional culture-historical sequences. The Bear Creek LPH component contains a lithic assemblage akin to the Western Stemmed Tradition in the interior although it also shows elements of continuity with later regional technological traditions. The lithic assemblage and other contextual data meet expectations derived from models of WST settlement of the interior Pacific Northwest which originated from a Pacific coastal migration.

Applied Digital Technologies and GIS Spatial Statistics at Tzak Naab, Northwestern Belize

The ceremonial center of Tzak Naab, located in the northern hinterlands of the major Maya city of La Milpa, displays many idiosyncratic and unique elements in its built environment that speak to the relationship of the site with the natural landscapes it inhabits. The site core is constructed on three large tiers which overlook the Dumbbell Bajo, a large seasonally inundated wetland. Within this area, aspects of (in)visibility are employed to control movement through—and perception of—space. We investigate these issues using various digital and GIS technologies in order to show how different platforms may be understood at scalar levels ranging from the local to the regional. We also consider the feasibility of Real Time Kinematic mapping in Central America and the ways in which underutilized mapping techniques may be combined with spatio-statistical testing that combines recent and legacy data.

Children’s Health in Archaic Texas: A Paleopathological Analysis of Juvenile Remains

While many dissertations, theses, and publications have repeatedly touted the relatively low number of juvenile burials at Texas mortuary sites, this research project serves to reconsider their importance in the archaeological record. The Archaic Period mortuary sites of Ernest Witte and Morhiss on the Western Gulf Coastal Plains of Texas have an abundance of juvenile skeletons on which to conduct an analysis. Juvenile bones are especially susceptible to erosomatic stress where adult bones may not be affected. By studying the remains of these children from a paleopathological perspective, a connection can be made to diet, lifestyle, and overall community health. This study aims to prove that a consideration of juvenile presence and contributions in past societies is important to reconstructing and understanding the past.

The Complement of Geochemical Soil Data to Artifact Patterns in the Study of Craft Production: A Case Study from Cancuen, Guatemala

This paper will discuss the various activities that took place on the exterior stone patio floor of the M6-12 domestic structure at Cancuen, Guatemala, and compare it to previously published findings of the M10-4 and M10-7 structures. These structures typically have a low investment in construction and appear to be nonelite in status, characterized by earthen mounds surrounded by limestone flagstone floors and perishable superstructures. These surfaces often appear to be communal activity areas where multicrafting took place. These activities included large-scale lithic production, including jade and pyrite, subsistence activities, and other types of craft production, some of which are highly visible. Geochemical ICP-MS analysis of soils can help to present a clearer and more holistic picture of the spatial patterning of these activities and the nature of economic structures that may not be readily visible to the naked eye.

Community, Territory, and Polity in Postclassic Highland Oaxaca

In late prehispanic Oaxaca, Mexico, the community was a territorial polity cross-culturally comparable to the city-state. Sixteenth-century native and Spanish sources describe aspects of these communities. Full-coverage archaeological surveys have mapped dozens of cases, providing information on size and internal structure not available in the documents. This study compiled evidence regarding population, territory size, boundary marking, internal complexity, political status, languages, hydrology, and agricultural practices for some 60 communities that have both full-coverage archaeological survey and documentary data. Communities (city-states) usually had less than 10,000 inhabitants; the largest had 100,000. Larger city-states were also the capitals of greater states made up of subordinate communities. Territories were small—usually less than 100 km². All had shrines or temples, many of which were located at the edges of the territory. Polities were simultaneously urban (over half the population living in large towns or cities) and had strong rural development. Communities had this same form regardless of language or predominant agricultural practice. Larger cities and the capitals of greater states were located in larger valleys. They had key positions in the Mesoamerican world-system. The similarity in form despite environmental differences echoes conclusions about Hohokam communities made by Paul and Suzanne Fish.

Did Bears Make the Fur Trade Possible? Seasonal Resource Scheduling during Wisconsin’s Early and Middle Historic Periods

Data have been found to suggest increased consumption of bear meat at Eastern Wisconsin sites during the seventeenth and eighteenth centuries. While bear remains are rare at these sites, they occur at generally higher densities than at Late Prehistoric Late Woodland and Oneota sites in the same region. Ethnohistoric evidence, supported by zooarchaeological data from the eighteenth century Meskwaki Grand Village (Bell Site) indicate that ritualized disposal behaviors may have impacted the archaeological visibility of bears, even after they became a more common dietary component. The increased consumption of bears appears to be related to changes in settlement and subsistence patterns associated with the influx of resettled peoples, their fur-trading related scheduling needs, climate change, and possible shifts in belief systems related to the great cultural stresses of the period.

Lidar has exponentially increased our knowledge of ancient agricultural systems and land use, especially within the Maya world. This paper explores a new lidar dataset for the Maya Lowlands in Northwestern Belize where archaeological and geoarchaeological teams have studied ditched and raised field systems for over 25 years. Through surveys and excavations, researchers in Northwestern Belize have shed light upon the importance of Maya wetland agriculture, but questions of spatial scale still remain. We are currently using increasingly advanced remote sensing techniques to better understand how intensive and expansive modification of lowland wet environments was within this region. This new dataset demonstrates the complexity of ancient Maya wetland agriculture in regard to spatial distribution as well as regional hydrology and topography. This imagery, considered alongside previous remote sensing data and both aerial and pedestrian survey, provides a robust dataset by which we can quantitatively consider the extent of wetland agriculture throughout in Northwestern Belize and throughout the Maya world. Further, this dataset provides insight into natural and anthropogenic wetlands in Belize, and provides a baseline for ongoing and future research for archaeology within tropical wetland systems.

Krasinski, Kathryn (Adelphi University), Brian Wygal (Adelphi University), Charles Holmes (University of Alaska Fairbanks) and Barbara Crass (University of Wisconsin-Oshkosh)

This paper examines what might be called the “palimpsest panel” rock art tradition of the northern Rio Grande region of New Mexico. Palimpsest panels are rock faces with petroglyphs that have accrued in a layered fashion through time. Prior research into such panels has typically focused on questions of chronology, each layer representing a distinct culture-historical era of iconographic production or a chapter in a linear chronology. Here, however, I move away from the traditional chronological approach, in order to examine the iconographic data present in the form of representation itself, the so-called palimpsest. The way that meaning develops through the act of layering is a process by which the icons interact and modify one another. Such an approach reveals not only the rich, information-laden periods between discrete chronological chapters but also demonstrates that palimpsests are far more than the sum of their parts.

The earliest archaeological sites in eastern Beringia occur at the gateway of the ice free corridor in interior Alaska. The Holzman site was discovered in 2015 along Shaw Creek in the Tanana Valley and dates to the late Pleistocene. Bison and caribou remains as well as mammoth ivory in the lowest components of the site demonstrate the importance of big game hunting during the colonization of Beringia and the interaction of humans with mammoths during the last phase of their extinction in interior Alaska. Abundant gastroliths suggest birds were also processed at the site. Zooarchaeological analysis, bone hearths, and associated lithics indicate definitive use of the materials by the earliest Alaskans.

[47] Looking for Fish of the Right Age: Using GIS in Conjunction with Salmon Genetics to Identify Key Submerged Drainages

Geospatial analysis of Beringian bathymetric data provides powerful tools for formulating predictive modeling of submerged sites of Pleistocene age. With the acceptance of Pre-Clovis archaeological sites in the Americas (Jenkins et al. 2012), attention has shifted to alternative models of the peopling of the Americas. A Coastal Migration hypothesis has been proposed by Erlandson et al. (2013, 2015), however any evidence of such a route is now submerged. Ice free areas along the Pacific margin of North America would have provided refugia for early peoples. Inspired in part by Haida traditional histories, this analysis is attempting to identify streams that could have supported anadromous fish species, like salmon. In addition to being an attractive resource in their own right, anadromous species provide marine derived nutrients to a variety of terrestrial taxa. More broadly, incorporation of genetic data and contemporary population studies provides insight into the effects of climate change on economically important species. This study provides preliminary results of hydrologic analysis as well as recommendations for future inquiry.

[156] Agouti Commensalism? An Open Question in the Prehistoric Lesser Antilles, West Indies

Light isotope data for bone collagen, bone apatite, and tooth enamel apatite have been collected for prehistoric agouti (Dasyprocta sp.) recovered from secure archaeological contexts on Carriacou (Sabazan and Grand Bay) and Nevis (Coconut Walk) in the Lesser Antilles, West Indies. Stable carbon isotope ratios of individual specimens exhibit a wide range of values for both bone collagen (–20.0‰ to –11.5‰; avg = –17.8‰) and bone apatite (–13.6 to –6.5‰), with apatite-collagen spacing also quite varied (3.6‰ to 9.9‰; avg = 7.0‰). Corresponding nitrogen isotope ratios from these samples also exhibit heterogeneous values (6.2‰ to 11.7‰; avg = 8.0‰). The frugivorous feeding habits of agouti suggest they should exhibit a more consistent dietary pattern; however, results underscore marked dietary variation and suggest a degree of commensalism for some, but not all, individuals sampled from Carriacou and Nevis. Results are consistent with two models for human–agouti interaction: 1) mixed hunting of wild animals with captive management of others; and 2) garden hunting of agouti drawn to human agricultural fields. We explore the archaeological and ecological implications of both models.

The presentation takes up a northern way of expression opposed to a southern one—namely the stylistic depiction and focus on animals and mixed animal/human designs prevailing in the Nordic Barbaric area opposed to a focus on the naturalistic ideal of the human body throughout the classical world. The complexity and continuity of this Nordic art form indicates that it was structurally incorporated in an overarching principle that reflects social and cosmic order. The mixed animal-human designs create species that cross-cut traditional categories and enforce reflections on such relationships. On such a basis certain motifs within the Animal Art open up to a pre-Christian understanding of the potential for interchangeability between not only animals and humans—but also objects, where a basic transformative logic is evident. It is, however, a question whether the hybridity in the representations, in their bringing together of different elements and the overcoming of boundaries, might be taken as an expression of a relationship in real life without opposition or distinction. And whether investment of creativity in their representation might be taken as an indication of the essentiality of these designs in respect of ideas of a transcending relationship between animals and humans.

[151] The Impacts of Urbanization on Archaeological Site Preservation in Afghanistan

Urbanization is a significant force affecting the preservation of archaeological sites across the globe. Even in war-torn countries such as Afghanistan, urbanization dramatically outpaces looting and other forms of site destruction that have been highly visible in the media. We present data on how urbanization has affected archaeological site preservation across Afghanistan. Using the city of Herat as an example, we present a method for predicting how urban growth will affect archaeological sites in the coming decades. This method draws on historical aerial and satellite imagery, historical maps and gazetteers, modern urban planning data, and predictive modeling within a GIS.

Kroot, Matthew (Santa Clara University) [54] Back to Basics: Analyzing Knapped Stone Recovered During Survey in Southeastern Senegal
Archaeological ethics require all sites identified on survey to be reported and described in a manner as to allow for the archaeological community to understand their research potential. This can present a challenge in regions without a significant body of previous research to aid in the interpretation of finds. The Bandafassi Regional Archaeological Project in southeastern Senegal faces just such a situation. A research question driven survey strategy, directed at the archaeological record of the Atlantic Era and using current methods for regional analysis, has produced a wealth of knapped stone finds from preceramic periods, which cannot be easily interpreted and reported in any useful manner. This is due to a lack of established detailed local culture-history chronologies for preceramic periods, utilizing technological and morphological typologies for knapped stone artifacts. This paper explores how methods of analysis borrowed from other well-researched regions have and have not been successful in generating interpretations. In many ways, this process has required a return to some of the earliest and most basic methods in archaeology, as well as an alteration of research strategies in order to meet the basic recording and, therefore, interpretive requirements of regional survey.

Krug, Andrew (University of Missouri), Andrew Fernandez (University of Missouri), Brenton Willhite (University of Missouri), Christine VanPool (University of Missouri) and Clayton Blodgett (University of Missouri) [237] From Plain Wares to Polychromes: A Geospatial Evaluation of Ceramics in the Casas Grandes Region
The past 25 years have seen a significant increase in archaeological fieldwork in the Casas Grandes Region of Chihuahua, Mexico. Among significant issues in Casas Grandes archaeology is the relationship between sites close to Paquimé and those in its borderlands. Investigations into ceramic distributions across the landscape have the potential to provide a greater understanding of the relationship between sites and their relationship to Paquimé. In this study, we reexamine Carpenter’s (2002) influential map of ceramic types distribution by examining ceramic assemblages (e.g., Casas Grandes Polychromes, Salado Polychromes, and El Paso Polychrome) at various sites (e.g., Brand’s surface collections, Janos joint project surface collection, and excavated wares from Galleana, Villa Ahumada, and 76 Draw) within the region. These data are analyzed via ArcGIS, which contains analytical applications that can be used to address the mechanisms behind geospatial variation. Ultimately, we find that a few ceramic type “zones” need to be reconsidered and likely remapped.

Krus, Anthony (Scottish Universities Environmental Research Centre) [81] Gathering Shells and Time: A Bayesian Approach to Shell Mound Formation in Southwest Florida
Archaeologists have longed grappled with how to effectively date shell mound deposits in Florida. Interpreting radiocarbon dates from shell samples has been a dominant method; however, these interpretations have not fully assessed the possibility that radiocarbon samples might not truly date their corresponding archaeological context. For example, recent research on Mound Key demonstrates that shell from middens was likely used to construct shell mounds, therefore the redeposition of old shells further complicates interpretation of the radiocarbon data. In this paper we critically evaluate the existing radiocarbon samples for shell deposits at two sites (Mound House and Big Mound Key) located on Florida’s southwest coast and use a Bayesian approach to create site chronologies informed by stratigraphic contexts and feature formation processes. The selection of radiocarbon samples at these sites was not taken with a Bayesian approach in mind; however, the available data lends itself nicely to Bayesian modeling. The results address previous conclusions about the timing and span of activity and the suitability of certain shellfish species for radiocarbon dating. Together, the models for these sites and Mound Key provide regional insight into the timing and tempo of shell mound activity in southwest Florida.

Kruspe-Peeples, Melissa (Arizona State University) [129] Landscapes Legacies in Central Arizona: Archaeologists and Ecologists Working Together
Archaeologists have long used environmental data to reconstruct the past. Recently, environmental scientists have come to realize the value of incorporating archaeological viewpoints in understanding modern ecological systems. It has been shown that human activities, even those that are relatively non-intensive, have the potential to result in long-lasting ecological transformations. Cross-disciplinary alliances between archaeologists and environmental scientists are necessary if we are to truly understand the modern and future trajectory of ecological systems. One outstanding example of such an alliance is the Legacies on the Landscape Project spearheaded by Katherine Spielmann. Working together, not just borrowing from other disciplines, a collaborative team of archaeologists, soil scientists, and plant ecologists developed innovative research designs to study the Perry Mesa landscape in Central Arizona and document the long-term ecological transformations. In this paper I will provide an overview of the collaborative process of this project and review the document the ecosystem changes brought about by the thirteenth- and fourteenth-century occupation by sedentary agriculturalists. Conclusions will focus on the ways in which the collaborative alliance has helped to advance the fields of archaeology and ecology.

Kubicek, Richard (University of Wisconsin-Milwaukee) and Patricia Richards (University of Wisconsin-Milwaukee) [341] $1.87 Each, Four Feet Long and Over; $0.87 Each, Less than Four Feet: A Spatial Analysis of Coffin Type and Coffin Hardware from the Milwaukee County Poor Farm Cemetery.
Excavations at the Milwaukee County Poor Farm Cemetery (MCPF) in Wauwatosa, Wisconsin, in 1991 and 1992 recovered 1,649 individuals associated with Milwaukee County’s practice from the mid-1800s through 1974 of providing burial for institutional residents, unidentified or unclaimed individuals sent from the Coroner’s Office, and community poor. In 2013, Historic Resource Management Services of the University of Wisconsin-Milwaukee recovered an additional 632 individual coffin burials representing over 800 individuals. Richards (1997) proposed a land use timeline for the portion of the cemetery excavated in 1991 and 1992. This poster presents the consolidated data from all excavated graves to date. In particular, we focus on associating the distribution of coffin hardware and coffin type with other classes of material culture in order to interpret spatial patterning and refine the land use history of the Milwaukee County Poor Farm Cemetery.
Urban Micromorphology at Bronze Age Palaikastro, Crete: Evidence of Transitions
Sequences at Bronze Age Cretan settlement sites are defined by destructive events, natural or anthropogenic, that capture cultural material in a particular time and space. The traditional approach of studying urban archaeological contexts based on these snapshots of material culture is not completely suitable for analyzing transitional phases that occur between these events. However, detailed micromorphological examination of the sediments present in these transitional stratigraphic sequences can fill the gaps in understanding how and when sites transition from one phase to another. Being able to identify the temporal and spatial relationship and exact nature of these transitional periods of destruction, abandonment, or other processes is essential in forming these interpretations, and approaches focusing on these transitions have not been systematically practiced at Bronze Age Cretan sites to date. This paper will discuss the results from the soil thin section analyses conducted during the 2013–2015 Palace and Landscape
at Palaikastro (PALAP) excavations and will elucidate the anthropogenic activities, processes of site formation, and broader landscape transformation in these transitional periods.

[301] An Agricultural Landscape on the Northern Mimbres Frontier, South-Central New Mexico, USA

The Cañada Alamosa is the northernmost frontier of the ancestral Pueblo Mimbres people of the U.S. Southwest. Intensive survey of a side canyon has defined a distinct agricultural landscape composed of small pueblos, farmsteads, field houses, shrines, and other features. Occupation was centered around alluvial fans located on the first terrace above the drainage, fed by runoff from upper terraces, rather than the floodwaters of the drainage bottom itself. While the Cañada Alamosa has significant later Tularosa and Mesa Verde occupations, use of this agricultural landscape is confined to the Classic Mimbres phase, AD 1000–1130. This agricultural landscape reveals both spatial and temporal diversity in farming practices in the eastern Mimbres area, with implications for the understanding of social and economic changes in this part of the region during the later years of ancestral Pueblo occupation.

[204] Navigating Social Memories and Reshaping Built Environments: An Analysis of Postclassic Reoccupation in the Yucatán Peninsula

Societal regenerations are common events in world history. Be they in ancient times, the recent past, or the present, such regenerations are instructive and encourage reflection on several critical issues. How, for example, do those exercising political authority negotiate traumatic social memories? And how, if at all, are preexisting built environments modified? To address these and other questions, I examine the regeneration of communities and the reestablishment of political authority in the northern Maya lowlands during the Postclassic period. In this presentation, I analyze the built environments at a series of coastal and inland sites in the eastern Yucatán Peninsula, and suggest patterns in Postclassic reoccupation and Postclassic treatment of the Classic period past. In doing so, I emphasize the importance of place, the past, and the built environment to the operation of political authority, as well as the usefulness of archaeology in understanding ancient, historical, and contemporary events.

Kusimba, Chapurukha

[136] Contextualizing Ritual and Collapse in Eastern and Southern African Chiefdoms and States

The role of ritual in the rise of complex societies is well understood in many regions of the world. In contrast, the roles ritual may have played in state collapse, regeneration, and resilience remains inadequately theorized in archaeological studies of the political dynamics of complex societies. This paper will evaluate the role of ritual in the emergence, resilience, and collapse of chiefly and state societies in Eastern and SouthEastern Africa. Social and symbolic factors especially the role of ritual and ritual experts, who included master smiths, rain makers, healers, soothsayers, and shamans has been evaluated in the study of state formation in Africa. This paper will examine evidence of the role of ritual and the context of an emerging theoretical perspective in archaeology of the collapse of the state in Africa. I argue that understanding how ritual knowledge and expertise was nurtured, used, abused, and discarded in the service of the state is critical to unveiling how power was negotiated between communities, among various disparate stakeholders, both during the precolonial, colonial, and postcolonial Africa to address overlapping forms of social, political, economic, and technological interactions.

Kuwanwiswima, Leigh (Hopi Cultural Preservation Office)

[34] Hopi Migration Traditions: A Fulfillment of the Spiritual Covenant

For thousands of years, the Hopi clans have traversed both the South and North American continents. Today, this presence is evidenced by the thousands of Hopi/Puebloan archaeological ruins. As well, esoteric ceremonies of today are ancient ceremonies and reinforce a living connection to our cultural history and religion. This great migration period of Hopi people was in fulfillment of a spiritual covenant between clans and our spiritual deity and guardian called Ma’sawu. Ma’sawu is the guardian and caretaker of this fourth world. So to earn the honor of living with him, clans submitted to this covenant to place our cultural footprints on both continents. If clans completed journeys to the four cardinal directions, then they were instructed to wait and eventually be led to their final spiritual home, the Hopi mesas in northern Arizona. This fulfillment of the covenant would grant the Hopi people a title of universal stewards. Today these footprints are represented by ancient Hopi ruins, landscapes, burials, pottery sherds, petroglyphs, and trails.

[143] Assessing the Population History of the Atacama Desert using 3D Geometric Morphometric Methods

Many scholarly debates in South American archaeology have centered on the discovery and cranial morphology of the earliest inhabitants known as Paleoamericans that predate 8000 years BP. Although it was initially hypothesized that cranial differences between Paleoamericans and later populations may reflect distinct biological populations or migration patterns that occurred after the initial colonization of South America, recent genetic data show biological continuity throughout the Holocene in western South America. Given that the current archaeological evidence suggests an early and rapid Pacific coastal migration occurred during the colonization of the Americas, and that several early archaeological sites are located along the coast and in the highlands of Chile, our study focused on a skeletal series from the Atacama Desert where several Paleoamerican skeletons have been excavated. Using 3D scanning and geometric morphometric methods, we examined morphological variation among the Paleoamericans and other prehistoric populations of the Atacama Desert covering a 9,000-year temporal sequence. Our results show biological continuity among several groups within our skeletal series from this region, suggesting that gene flow and complex trade networks contributed to the evolutionary adaptations and population history of the Atacama Desert throughout the Holocene.
Kvetina, Petr (Institute of Archaeology Prague, Czech Republic) and Jiri Unger (Institute of Archaeology Prague, Czech Republic)  
**Digital On-Site Presentation of the Invisible Past**  
The aim of the paper is to demonstrate the possibility of broad spectrum of digital methods for presentation of archaeological sites. This approach is extremely valuable in locations where there is neither any preserved construction, nor any relic of the original appearance of the past structures and landscape. Such sites usually meet with indifference both from the public and from institutions involved in preservation of historical monuments. The possibility of creating virtual and augmented reality proved to be a potential tool to grasp the invisible and to describe the disappeared. On the examples of several Central European sites spanning from the Early Neolithic to Medieval times we show a potentially powerful tool for digital heritage management. Several technological platforms can be interconnected to provide a classical static approach of exhibiting artifacts (in the form of open library of 3D scans), which however may be expanded with dynamic level including augmented and virtual reality, videos and other interacting features. The acquired digital records can also serve as open access sources for research and educational purposes at all academic levels.

**Ancient Residues Indicate Prehistoric Subsistence and Culinary Practices in the Korean Peninsula during the Middle Holocene**  
This study attempts to understand ancient human subsistence using stable isotope analysis on the organic residues extracted from the archaeological potsherds collected from prehistoric coastal shell midden sites in the southern part of the Korean peninsula. In Korean archaeology, shell middens are useful for isotope analysis because they provide suitable condition in terms of organic preservation. To date, the subsistence of these prehistoric coastal and island dwellers remains poorly known. However, this may be addressed through the study of ceramic containers, which were often used for culinary practices, by extracting organic residues of the foodstuffs that remain on the interior wall or inside of the clay matrix. Carbon isotope analysis on those residues provides an opportunity to understand ancient human subsistence strategies in the region.

Kwan, Daniel (University of Toronto)  
**A Thin Section Petrographic Study of Early to Late Shangshan Ceramics from Zhejiang, China**  
Ceramics from the early Holocene Shangshan Culture, in Zhejiang Province, China, have been subjected to thin section petrographic analysis in order to characterize clay groups, view production patterns, and aid in the development of a complete understanding of the Shangshan technological tradition. Analysis has revealed a pattern in the local production of ceramic vessels likely related to the transformations in cooking methods and dietary patterns that coincided with new evidence for the beginnings of rice domestication in central China.

Kwok, Cynthia, Sandra Garvie-Lok (Department of Anthropology, University of Alberta) and Mary A. Katzenberg (Department of Anthropology & Archaeology, University)  
**Exploring Sex-Based Variation in Infant Feeding Practices in Byzantine Greece Using Stable Isotope Analysis of Dentin Serial Sections**  
This paper explores whether sex-based differences in infant feeding practices existed at the early Byzantine Greek site of Nemea (fifth-sixth c.). Dentin serial sections were obtained from the permanent first molar and first premolar from 31 adults (11 males, 8 females, 12 unidentified) and analyzed for stable carbon and nitrogen isotopes. The isotopic data demonstrated that most individuals were breastfed and fully weaned at a mean age of 2.6 with a range of 1.8 to 3.6 years. Sex-based differences were not observed as boys and girls on average were fully weaned at 2.5 (1.9 to 3.3 years) and 2.4 (1.9 to 3.6) years respectively, contrary to the patriarchal structure of Byzantine society. These results are discussed in the context of Byzantine society through the use of written sources. Compared to traditional analyses using subadult bone collagen, dentin serial sections can capture nuances within infant feeding practices and the value of this latter method is highlighted.

Ladefoged, Thgn (University of Auckland) and Benjamin Davies (University of Auckland)  
**Emergent Landscapes: Simulating the Distribution of Residential Features in a Hawaiian Dryland Agricultural System**  
Cultivation in the Leeward Kohala Field System (Hawai’i Island) required sufficient rainfall for crops to flourish. Periodic droughts restricted production to upper elevations where orographic rainfall was higher and more dependable, likely influencing the labor needs and settlement patterns of resident populations. We employ a series of spatially-explicit agent based models incorporating cultural conceptions of kapu (sacred) and noa (profane) in conjunction with environmental parameters and individual decision-making. The models explore how the ecodynamics of land use and postdepositional processes within this highly productive rain-fed agricultural system combined to pattern the distribution of archaeological features we observe in the present. We propose that the construction and expansion of cultivation in response to variation in seasonal and annual rainfall produced a palimpsest landscape of periodically abandoned and reused residential features and temporary structures.

Laffey, Ann (University of Florida)  
**Big Plans for Small Pots: Development of an Organic Residue Analysis Protocol for Ancient Wari Miniature Wares**  
Excavations from the Mongachayaq sector of the site of Huari uncovered an impressive burial that contained over 300 miniature vessels. The vessels were offered by a people known as the Wari (c. AD 600–1100), an ancient culture thought to be responsible for one of the Andes first great empires. Even more remarkable, the vessels retained the desiccated remains of their contents. The anthropological insight that can be gained has direct implications for a better understanding of Wari practices and continuity of ritual behavior in the Andes in general. If it can be verified that the vessels contain a fermented beverage known as chicha it will speak to a long-held tradition in the Andes of offering the drink to dead ancestors. Furthermore, if compounds associated with hallucinogenic plants can be identified, it will add new elements of understanding to Wari ritual practice. This paper follows the development of an organic residue analysis protocol that will be used to delineate the content of the miniature vessels. It begins with macro and
micro archaeobotanical analyses and leads into chemical analyses, which include bulk stable isotope analysis, gas chromatography-mass spectrometry, compound specific stable isotope analysis, and high performance liquid chromatography.

Integrating Faunal and Lithic Evidence from Quina Mousterian Contexts in Southwestern France to Investigate Neanderthal Subsistence Strategies and Mobility

The interpretation of Middle Paleolithic archaeological assemblages has been the subject of spirited debates among researchers of Neanderthal behavior for over half a century. While these debates have classically centered on analyses of lithic assemblages (e.g., the “Bordes-Binford debate”), it is important to recognize the value of incorporating the associated faunal records in our approach to these questions. Differences in lithic assemblages may be affected by factors like mobility, which may in turn be influenced by subsistence strategies. Changes in prey resource type and availability during differing climate periods could impact how Neanderthals navigated their landscape, affecting both hunting and prey processing practices as well as tool-making decisions. Future research into Neanderthal behavior could benefit from a more holistic approach in which foraging theory is applied to the faunal record and then aligned with studies of lithic attributes relating to mobility. An application of this approach will be discussed in terms of Quina Mousterian archaeological (faunal and lithic) assemblages in southwestern France.

Lakevold, Courtney (University of Alberta; Government of Alberta) and Jennifer Hallson (University of Alberta) [339]

Population Size and Structure in the AD Thirteenth-Century Occupation of Promontory Cave 1

The extraordinary preservation and narrow time frame (AD 1240–1290) for the occupation of Promontory Cave 1 on Great Salt Lake allow for unusual insights into the population and demography of its Promontory Culture inhabitants. We use two methods to determine population size. First, with accurate data on the habitable space in Cave 1, we calculate space needs per person from ethnographic accounts of Western North American hunter-gatherer groups in order to estimate likely group size. Second, artifact densities are calculated and projected into the entire cave volume using mathematical and GIS methods. The number of moccasins will be the focus because of the sound ethnographic knowledge of their use and discard rates. We apply accumulation equations to these projection results to determine population size, taking into account the duration and time of the occupation of the cave. These two methods will be compared and discussed to provide a likely size for the population inhabiting Promontory Cave 1.

Archaeology of Iron in the Lingnan Region and the Imperial Strategy of the Han Dynasty in its Southern Peripheries

Although the imperial strategy of the Han Empire in its southern peripheries attracts significant scholarly interests, how to synthesize the issue of ethnic integration and imperial expansion within the study of material culture is still widely under-addressed. Especially, how the Han’s control over the movement and distribution of iron—a strategical resource for agricultural and military conquest—is almost overlooked in the literature. This presentation presents the latest statistical studies on the assemblage of iron objects from burial contexts in the Lingnan region to identify relations between the procurement and burying of iron and the ethnicity as well as rank of tomb owners. Through a comparison with the distributional pattern of iron objects found in Han tombs in the Yungui plateau after the Han conquest, this study also attempted to depict the distribution of iron materials on a macro-regional scale in order to articulate the underlying political strategies reflected by the strategic material.

Lamb, Céline (University of Kentucky) [101]

Constructing Rural Complexity: Intra-household Relations of Community and Inequality at Chunhuayum, Yucatán, Mexico

The concept of rural complexity acknowledges that social, political, and economic complexity is not limited to large urban centers (Iannone and Connell 2003; Schwartz and Falconer 1994). Like urbanites, hinterland residents are involved in diverse and shifting interactions through which they form, maintain, and reinvent relations of communality and social differentiation. Chunhuayum, a small settlement located in the Northern Lowlands and occupied from the Late Preclassic through the Late Classic, presents an excellent case study to address ancient Maya complexity from a hinterland perspective and at the microscales (household and communities) of human interaction, due to its separation from larger centers, its lack of monumental architecture, and its internal heterogeneity. Using recently collected data concerning settlement patterns, domestic architecture and household assemblages, I infer: 1) the degree to which households were integrated into a cohesive community, 2) local inequalities, and 3) the material and social practices that may have expressed, (re)produced, and structured understandings of communality and distinction over time. Reframing discussions of complexity to focus on the micro-levels of human interaction within a lower-order rural settlement, this research contributes to a more inclusive and nuanced understanding of ancient Maya social complexity.

[181] Feathered Fauna: A Look at Bird Usage among the Fremont

Bird use among the Fremont is a topic that has been under studied in recent times by archaeologists. We seek to address this lack of current information regarding how birds were used by the Fremont. Although birds likely only played a secondary role in the subsistence economy when compared to large mammals, birds were clearly a supplemental food source. In addition to being a food source, wing and leg elements of large birds were sometimes modified and used as a bone resource for constructing cultural artifacts such as beads and whistles. Indeed, birds likely played an important role in both subsistence and social activities in Fremont society. There has also been research arguing for the existence of a Fremont bird cult. Newly obtained bird bone data from sites in Utah Valley have bird bones found in a variety of contexts. We will compare new bird bone data to other Fremont sites excavated in the past several decades, to present a more recent analysis about bird use among the Fremont.

Lambert, Stephanie (Brigham Young University), Elizabeth Whisenhunt (Brigham Young University) and Spencer Lambert (Brigham Young University)

Ventilation tunnels were commonly used by the Fremont to circulate air within their subsurface buildings. However, there is evidence that ventilation tunnels at Wolf Village, a Fremont site south of Utah Lake, were used for more than just circulating air. Our research will explore possible ritual abandonment practices of the Fremont by analyzing the six ventilation tunnels and their associated artifacts uncovered at Wolf Village. Evidence of ritual abandonment practices can include finding articulated animal bones and high value artifacts, such as figurines and trade items, purposefully placed in the ventilation tunnel just prior to disuse. We will compare our findings from Wolf Village to ventilation tunnels at other Fremont sites. By studying ventilation tunnels and the items found in them, we can gain greater insight into possible abandonment practices and expand our knowledge of the Fremont culture.

[274] Detecting the Functions of Patios in a Classic Maya Regal Palace at La Corona, Guatemala

Classic Maya regal palaces were political institutions with many functions, ranging from domestic and ceremonial to administrative. This paper presents the results of the multifaceted study of three adjoining patios of the palace at the Classic Maya Center of La Corona, Guatemala. Research suggests that these patios, dating to final phases of occupation in the Late Classic (eighth and ninth centuries AD), were open spaces dedicated to activities relating to the preparation of food, the manufacture of artifacts, as well as the storage and discard of both perishable and durable goods. This study exhaustively sampled these spaces to study the composition of their stucco floors, associated micro- and macro-artifacts assemblages, and macrobotanical remains. The results of the artifactual, flotation, and ICP-MS analyses of the sampled patios indicate the ancient functions of those spaces to a scale much finer than traditional archaeological methods could. This study will use these data to consider the economic and logistical roles of the members of Classic Maya palaces in order to better understand the pragmatics associated with the exercise of power in ancient Maya society.

Lancelotti, Carla (Universitat Pompeu Fabra)

The concept of Anthropic Activity Markers as ethnography-derived models to interpret archaeological activities has seen a remarkable development in recent years. In this talk we present the results of MoMAR (Modelización de Marcadores de Actividades Antropológicas: de lo etnográfico a lo arqueológico), a multidisciplinary project that combined cross-cultural studies with analyses of phytoliths, starch, multi-element geochemistry and spot-tests to analyze domestic plant-related activities in the past. The main focus of the project is on arid and semiarid areas. Starting from the Standard Cross-Cultural Sample (SCCS), we build and coded a small database that includes, alongside environmental data, ethnoarchaeological information (e.g., features that can be identified in archaeological record). We then used these data to create models of distribution of the above-mentioned proxies. Ethnography-inspired models were validated through ethnoarchaeological studies and applied to a domestic space in classical Greek Olynthos. This approach allows for a better identification of how people used domestic spaces in the past for plant-related activities, specifically food processing and consumption.

Landau, Kristin (Northwestern University)

[71] The Consequences of State Collapse: Evidence from the San Lucas Neighborhood during the Terminal Classic

Understanding the growth and dissolution of state entities has long been a topic of anthropological inquiry. More recently, archaeologists are promulgating dynamic and careful conceptions of how leaders acquire power, and whether and why surrounding residents may support them. By turning our attention to the political economic relationship between Maya rulers and the local population, we can identify successful and failed attempts to maintain states. In this paper, I combine political anthropology with urban studies and practice theory to illustrate how the intermediate scale of neighborhoods can be useful for assessing state dynamics. I focus on the neighborhood of San Lucas during the Terminal Coner ceramic subphase (ca. AD 820–900) to examine the transition between the death of the last major ruler and the full onset of the Postclassic. Multiple lines of evidence from four architectural groups indicate that San Lucas residents enacted different living strategies in response to the dissolution of central government. For example, households established in the Preceramic continued to support small families, while higher status living arrangements were quickly abandoned. Such data offer a more nuanced picture of who emigrated from Copán and when, allowing us to infer the aftereffects of state collapse on residing populations.

Landry, Shannon (Alpine Archaeological Consultants, Inc.)

[368] Red or Green? Examining the Reliability of Macaw Postcranial Identification

Archaeologists consider macaws highly valuable trade items which served an important economic and ritual role in the prehistoric Southwest. Costly to acquire, brightly colored, and difficult to keep, macaws are often an exciting indicator of social complexity. There is a consensus that the bright red Scarlet Macaw was used and traded with greater frequency than the emerald green Military Macaw in the American Southwest. Yet variation in size and morphological similarity of Ara sp. postcrania make species level identification of macaws exceedingly unreliable, making past identifications based on postcranial elements problematic. Aside from small-scale, though valuable, lines of inquiry on the topic (e.g., Bullock 2007), this problem remains understated. This poster explores the potential impacts of past, present, and future macaw postcranial identification and interpretation; offers suggestions for modern faunal analysts; and considers the methodological barriers that have led to this point.
Lane, Brian (University of Oregon)

Defining Territories: Exploratory Analysis in Polynesia

Territory boundaries can often be difficult to identify archaeologically despite their importance in understanding the larger population process of competition between groups in the past. This analysis tests our ability to define archaeological territories on islands based on geospatial relationships between resources and fortifications. Territories are the result of historical processes of competition between groups. Testing of this method is conducted for the island of Rapa, Austral Islands, French Polynesia. The island is an ideal location due to the importance of competition and territoriality in our understanding of the island’s prehistory and the circumscribed nature of islands.

Pastoralisms of the Andes: A Southern and Central Andean Perspective

In this paper we contrast and compare the development of pastoralism at two opposite yet complimentary geographical locations with a focus on pastoralist impact on the environment. In Argentina we present the evolution and development of pastoralism (c. 3300–400 BP) in the arid highlands of Antofagasta de la Sierra, as societies negotiated the shift from hunter-gathering to a more mixed, but increasingly, pastoralist economy culminating in complex agropastoralist adaptations. Similarly in the central Andes, we consider the enduring landscape modifications and transhumance patterns of complex agropastoralists located in Ica highlands (2100–400 BP) and their relationship with agricultural communities. In so doing, this presentation argues for the concept of the many, different and varied types of pastoralism present in the Andes; ranging from an early transhumant hunter-gatherer-horticultural pastoralism to a tethered, fully integrated agropastoralist model for the latter period. Adopting a political ecology approach we consider how human agency and an expanding pastoralist frontier have impacted on and developed landscapes. We thus consider changes and shifts in the landscape of resource areas, settlement location and concomitant herding patterns as well as human-induced alterations in pasturage. Finally we focus on the wider implications of pastoralism in the development of Andean society.

Lane, Rachael (University of Sydney)

Apples and Oranges? Positioning Regional Archaeology in a Global Perspective

This paper focuses on issues and methodological approaches to the comparison of archaeological sites, scaling from a regional to a global perspective, with a specific focus on settlement archaeology. The key issue appears to be the logical difficulty of contextualizing regional culture historical data within theories of global settlement patterns. A secondary problematic issue related to the one aforementioned is in the comparison of datasets with highly variable integrity at both these scales, which adds to the difficulty of building viable comparative methodologies. Furthermore, the constraints on archaeologists conducting comparative research, arising from the non-standardization of data and practice within a globalized world are far from trivial. That said, the fact that archaeology is practiced differently all over the world resonates with Bruce Trigger’s argument that archaeological theory and method generated in different social and national contexts is a more viable pathway toward understanding the past than is the formulation of a single coherent empirical archaeological theory, or the kind of general theory that David Clarke advocated in the 1970s. This paper also attempts to utilize the tension between Trigger and Clarke to investigate issues impacting global comparative research in archaeology now and in the future.

Langdon, Steve

Tlingit “Streamscaping” as Landesque Capital Formation

The Tlingit heen sati (“stream master”) was responsible for establishing and maintaining respectful relations with salmon as a trustee for his clan. The portfolio of obligations included both pragmatic duties controlling access and harvests and ritual responsibilities, such as greeting the arrival of salmon each year with welcoming ceremonies, practices anchored to the Salmon Boy mythic charter that identified the fundamental similarity of humans to salmon as persons. Another dimension of Tlingit interaction with salmon was the modification of in-stream features that was intended to accomplish different purposes through a variety of forms. The term “landesque capital” is a conceptual frame formulated to characterize landscape modifications among agriculturalists but is here utilized to examine the range of in-stream modifications developed by Tlingit through which to interact with salmon. It will be suggested that a particular form of landesque capital formation was motivated by Tlingit understanding of the “ish,” a deep pool of slowly moving water in a stream, as a location of special importance to salmon as persons and beings. The long term consequences of in-stream modifications to create other features similar to the “ish” will be highlighted, particularly as related to increasing and regularizing salmon productivity.

Organic Artifacts and Organic Residues in Island Southeast Asia and Australia: Seeking Intangible Behaviors in the Deep Past

Exploring intangible behaviors—such as the decoration of oneself, or the manufacture of clothing or baskets—in the deep past is often beyond the reach of archaeologists. The microscopic examination of use wear and residues, however, allows researchers to gain significant insights into such ‘invisible’ behaviors. Organic artifacts recently excavated from sites located in both northern Australia and Timor-Leste (Island Southeast Asia) were microscopically examined for use wear and residues, and resulted in the identification of early decorative traditions in each region. Shells artifacts from the sites of Jerimalai, Lene Mara, and Matjui Kuru 1 and 2 in Timor-Leste represented the earliest shell beads in Southeast Asia and the earliest shell appliqués in Island Southeast Asia, while bone artifacts from Carpenter’s Gap 1 and Riwi, Kimberleys, Australia, resulted in the identification of the earliest example of a personal ornament on the Australian continent. Such research demonstrates the power of use wear and residue research for examining some of the most remarkable aspects of early human communities.

Langlie, BrieAnna (Loyola University Chicago)

Engineering an Ecosystem of Resistance: Late Intermediate Period Farming in the South-Central Andes (AD 1100–1450)

In the fifteenth century, the Inca built the largest precolumbian empire in the western hemisphere. In southern Peru near Lake Titicaca, an ethnic group known as the Colla violently resisted conquest by the Inca for several years. Because of their military prowess, the Inca named one quarter of their empire, Collasuyo, after this group. The Colla’s ability to resist Inca subjugation was facilitated by their decentralized economy evident in their
construction and management of a new agricultural ecosystem. At the hillfort Ayawiri, archaeological data indicate that the construction of terraces and the production of agricultural products were managed by kin groups. The terraces surrounding Ayawiri are irregular in form indicating no centralized authority oversaw construction. Furthermore, there is no irrigation system that would have required cooperation among farmers to manage the flow of water. This farming system provided households with economic autonomy that was resistant to incorporation into stable political forms, including the Inca Empire. The Colla were only integrated into the empire after they relocated from their hilltop communities atop terraced fields to valley-bottom towns. My case study provides key insights into the ways autonomous farming communities engineer ecosystems that can defy statecraft and resist integration into empires.

Lanoë, François (University of Arizona), Joshua Reuther (University of Alaska Fairbanks Museum of the North) and Charles Holmes (University of Alaska Fairbanks) [47] Mobility and Resource Exploitation during the Late Glacial in the Shaw Creek Flats (Eastern Beringia)

The colonization of Beringia during the Late Glacial period (about 14,500–11,700 cal. BP) represents the first permanent settlement of the subarctic and provided a pathway to the colonization of North America. The Shaw Creek Flats and nearby middle Tanana river, in central Alaska, constitute the densest area of identified Late Glacial sites; these are generally characterized by low-density occupations and diverse technological complexes. Recent research suggests some of these sites were specialized, short-lived locations dedicated to a single or few activities. Based on the spatial association of artifacts and faunal remains, the site of Swan Point C24b is interpreted as a workshop related to the production of composite tools, and the site of Keystone Dune is interpreted as a camp related to hunting activities. Specialized sites can be seen as logistical forays oriented toward the exploitation of specific resources within a larger economic landscape. Logistical sites, along with other, more residential sites, provide insight as to the strategies of landscape use employed by Beringian people in the Shaw Creek Flats.

Lapeña, Queeny (University of California, Los Angeles) and Stephen Acabado (University of California, Los Angeles) [198] Resistance through Ritual Feasts: The Role of Domesticated Pigs (Philippine Sus scrofa) in Ifugao’s Fight against Spanish Colonialism

Successful resistance against a colonizing power involves effective martial organization and a complex polity. Due to violence and diseases, established polities in the Americas and the Philippines were devastated following Spanish conquest. Nevertheless, several groups have been documented as actively resisting conquest by establishing settlements in remote mountainous settlements. In the Philippines, scholars have suggested that Spanish conquest of the Magat Valley urged the Ifugao to strategically resettle in the Cordillera Mountains between AD 1600 and 1700. Shortly after, they adopted wet-rice agriculture and built extensive rice terraces. The subsistence shift was accompanied by an increase in the consumption of domesticated pigs, a pattern that we argue is associated with increased ritual feasting. The agricultural movement, hence, established a ranked society and elsewhere in the globe, local interpolity conflict is linked with the expansion of ritual feasting. This investigation presents a case where feasts were entangled in the maintenance of the ranked social order that emerged from Ifugao’s resistance against Spanish conquest. In the Philippines and elsewhere in the globe, local interpolity conflict is linked with the expansion of ritual feasting. This investigation presents a case where feasts politically and economically consolidated previously dispersed Ifugao communities.

Lapham, Heather (University of North Carolina—Chapel Hill) [385] Black Bear Use through Time in the Southern Appalachians

Historic accounts of Fort San Juan, a Spanish garrison built near the native village of Joara in the late 1560s in western North Carolina, inform us that chiefs from neighboring towns brought “meat and maize” to the soldiers on various occasions. Based on the high proportion of bear in the fort faunal assemblage, it seems likely that the foods gifted to the Spaniards included bear meat. A recent zooarchaeological study suggests that native peoples provisioned the soldiers with some prime bear meat and meat dishes in a prepared or partially prepared state. Thinking about possible sources of these provisioned meats, we review the archaeological record of black bears (Ursus americanus) in the southern Appalachian Mountains and adjacent Piedmont region of Virginia and North Carolina from the fifth through the seventeenth century to better understand Native American bear procurement and use. Differences among the sites in geographic location, occupation period, disposal methods, and other variables suggest changing patterns of bear use through time. We explore reasons for these patterns, and present a brief contextual study of bear remains from several sites to more clearly define the role of bear in ritual, mortuary practices, and subsistence within these communities.

Lapp, Jennifer E. [370] Why Pacific Nicaragua Should Not Be Considered Mesoamerican during Prehistory

During precolombian times, it is well-known that the societies of Mesoamerica developed monumental architecture with a high level of complexity. During this same period, much if not all of lower Central America never achieved higher complexity other than that of chiefdom level. Honduras is the one major exception. While the societies of Nicaragua had similar gods and ceramics much of this can be explained through other means. The gods that were similar were “lesser” gods and not the main gods that the Mesoamerican groups held central to their beliefs. The ceramics utilized had some similar motifs, but were unique in their own right. This can be seen by the many studies that are coming out in the more recent years. The burials and settlement sizes were significantly different. It is believed that the settlers of Nicaragua during prehistory were a mixture of Mesoamerican and South American heritage. The various sites of Nicaragua illustrate the fact that precolombian Nicaragua should be considered a group of its own.

Lara Barajas, Israel (INAH) and Fiorella Fenoglio (INAH) [183] Aspectos bioarqueológicos de los grupos prehispánicos del semidesierto quetetano durante el Epipónico

El hallazgo y recuperación de los restos de un bulto mortuorio que contenía el esqueleto de un individuo masculino permitió, dadas sus características, plantear la hipótesis de que se trataba de un cazador recolector que habió en esta zona antes de la llegada de los grupos sedentarios a la región; para confirmar dicha hipótesis se realizaron diferentes fechamientos a los materiales arqueológicos de éste y otros contextos hallados en la zona. En esta ponencia se dará a conocer los resultados del estudio bioarqueológico, de la datación y trataremos esbozar las implicaciones socioculturales que estos resultados tienen para la comprensión de las sociedades que habitaron la región.

Health Mecca of the West: The Archaeology of a Tuberculosis Sanatorium

Eighty years ago, Cragmor Sanatorium in Colorado Springs was a celebrated asylum for wealthy tuberculars and one of the premier facilities in the West. The history of the sanatorium is colorful and perhaps legendary. It includes housing movie stars, Mafioso and millionaires in the 1920s to 1930s and later Navajo patients in the 1950s. Once it became part of the University of Colorado system in 1965, much of the original history was subsumed under the growing campus. This project seeks to recover some of the ephemeral features of the sanatorium that could help us put the history in context and better understand the fanciful stories that surround the sanatorium through the material culture. As part of a survey and inventory of the cultural resources of UCCS funded by the Colorado State Historic Fund, we identified, recorded and tested several features and sites associated with the original functioning of the sanatorium. Although this project is in the beginning phases, we illuminate institutional practices and failures as well as suggest alternative healing strategies employed by physicians and patients.

Larmore, Sean P. (ERO Resources Corp.) and Kevin P. Gilmore (HDR)

On the Road to Becoming Apache: The Western Dismal River Culture at the Plains/Foothills Margin

Discovery of new sites as well as the reanalysis of museum collections over the last 15 years has renewed focus on the Western Dismal River (WDR) culture, which we hypothesize represents the ancestral Apachean occupation of the western margin of the Great Plains and into the foothills and high country of the Rocky Mountains, AD 1300–1650. Once thought to represent the initial entry of ancestral Apache in the region during the initial Na-Dene diaspora from the north, this culture is now recognized as transitional between the Promontory Culture at Franktown Cave (AD 1180–1280), which represents the initial ancestral Apache entry into the area, and the later Eastern Dismal River culture (AD 1650–1725) of the Central Plains. A decrease in regional population possibly related to climate change could have provided an advantage to WDR people who were adapted to marginal upland environments. The technology and material sources represented in WDR material culture reflects both familiarity with their environment born of long tenure and reciprocal trade relationships resulting in the exchange of raw material and ideas with groups in the Southwest and Great Plains. This intermediary role between the Plains and the Southwest represents the early stages in historical Apache ethnogenesis.

Pilgrims and Pebbles: The Taskscape of Veneration on Inishark, County Galway

This paper explores how a relational approach centered on the concept of taskscape could reinvigorate analyses of how pilgrimages create, sustain, or transform human-environment relations. Medieval and modern traditions of pilgrimage in Ireland are renowned for their engagement with “natural” places and objects, such as mountains, springs, and stones. Some take this focus as evidence of an animistic pre-Christian heritage, but few have questioned how such practices structured peoples’ ideas and interactions with the environment in Christian centuries. Eight years of research on the island of Inishark, County Galway has brought to light an early medieval pilgrimage landscape in which many shrine monuments acted as the foci of veneration and the deposition of water-rolled pebbles, including both decorated and undecorated pieces. Interweaving archaeological, textual, and folkloric evidence, I investigate the gathering, curation, and embodied interaction with pebbles in the context of contemporary processional rituals and cosmology. Considering the taskscape of human and nonhuman actions that brought pebbles to shrines suggests how the experience of pilgrimage afforded ideas of divine creation, reinforced notions of sacred hierarchy, and sustained monastic agricultural regimes.

Lassen, Robert (Gault Project at Texas State University) and Erin Keenan Early (Gault Project at Texas State University)

Radiocarbon Dating at the Gault Site: A Case Study in Collaboration between AMS and ZooMS to Analyze Promising Faunal Samples

The Gault site is a lithic procurement site and campsite in Central Texas with components ranging from earlier than Clovis to the Late Prehistoric. For the most part, absolute dating at Gault has relied on optically stimulated luminescence (OSL), which has a high standard error. AMS dating on sparse charcoal samples has been conducted as well, but with mixed results. In particular, the charcoal from the Clovis and lower strata failed to yield viable radiocarbon dates. While faunal preservation tends to be poor, the degree of preservation varies from sample to sample. Recent research by Harvey et al. (2016) indicates that ZooMS (zooarchaeology by mass spectrometry) can be used to screen bones for suitability for radiocarbon dating. By considering a combination of m/z range and minimum number of peaks, the peptide mass fingerprinting technique is purported to determine whether collagen preservation is sufficient for AMS dating. This project therefore seeks to assess the viability of this new screening methodology in different taphonomic conditions than those of Harvey et al., with the ultimate hope of gaining valuable collagen-based dates for the earliest components of the Gault site.

Latham, Katherine (University of Alberta)

Working Like Dogs: A Systematic Evaluation of Spinal Pathologies As Indicators of Dog Transport in the Archaeological Record

The use of dogs to pull or carry loads is well documented in the recent and historic past, but the origins of these working relationships are not well understood. Although it is likely that humans utilized dogs for transport activities in the prehistoric period, there is no clear archaeological evidence of dog transport until the historic era. Some archaeologists have suggested that pulling or carrying loads leaves unique signatures of stress on the skeletons of dogs. The use of skeletal indicators for identifying archaeological dogs is problematic because none of the indicators proposed have been systematically evaluated in known transport dogs or in dogs and other canids not engaged in transport activities. Without such data it is unclear if it is appropriate to attribute these skeletal abnormalities to specific occupational etiologies. This paper presents results from a large scale study of modern dogs and wolves that evaluates the occurrence of two spinal pathologies previously used as indicators of dog transport. These pathological lesions are spondylosis deformans and bent or twisted spinous processes. The goal of this study is to test the reliability of these pathologies as indicators of dog’s involvement in transportation, including burden carrying and sled pulling.

[244] Experiments in Social Complexity: The Halaf Period and Evidence from Domuztepe

The Late Neolithic Halaf period (c. 6100–5200 cal. BCE) is one of critical importance for understanding the emergence of social complexity in the Ancient Near East. During this period, people in Northern Mesopotamia were beginning to experiment with altering the scale at which their social, economic, and political networks were structured. By examining gradual shifts in the scale of cooperation within groups, we can identify changes in social interaction and organization. I demonstrate this using evidence of Halaf peoples’ agropastoral production systems and of large-scale feasts at the Halaf site from the site of Domuztepe (ca. 6000–5450 cal. BCE) in southern Turkey. Evidence of cooperation and emergent inequality at Domuztepe correlates with evidence from the broader Halaf region of cooperation and coordination in raw material procurement, craft production, and accounting practices. Together these data indicate that at Domuztepe, and perhaps at other population centers during the Halaf period, people began to experiment with new forms of social integration and organization.

[38] Environmental Variation and Technological Change: Results of an Agent-Based Simulation

Computer modeling is an increasingly important aspect of evolutionary anthropology and archaeology. Computer models of change in cultural and technological forms are often highly revelatory of the ways in which large-scale evolutionary patterns arise from the local interactions between individuals. As such, the results of these models may have broad implications, both within the anthropological sciences and without. This paper details simulation results from an agent-based model of cultural evolution that focuses on the processes of technological innovation and diffusion. In particular, the model discussed here examines the emergence of different technological strategies in the context of spatial structuring and environmental variation. Drawing from both population genetics and cultural evolutionary theory, this model is oriented around previous work on evolutionary dynamics and parameters such as cultural selection and drift, and population size and density. Model results are discussed in the context of current archaeological understandings of the relationship between technological complexity, specialization, and environmental change.

[198] Health and Nutritional Stress in Periconflict Ifugao, Philippines

The Ifugao of the highland Philippines responded to Spanish colonial incursions in adjacent lowland towns in the early 1600s by consolidating their political, social, and economic resources. This period saw the introduction of wet-rice agriculture and subsequent expansion of irrigated terraced agriculture in the region. These social and economic changes suggest an increased reliance on rice and a decreased dependence on a broad-spectrum diet. It is hypothesized that changes in diet and larger population density would be reflected in deteriorating health of the population. For this study 23 fetal to early juvenile (24 months) skeletons and teeth as well as the fragmentary teeth and skeletons of six adults recovered from the Old Kiyangan Village site were analyzed for health and diet data, including a subset analyzed for light stable isotopes. Adult are generally healthy. Fetal and subadult health indicate maternal nutritional stress during gestation as well as nutritional stress and the possibility of trauma in the first years of life. These patterns are stable through time, from before the Spanish colonial incursion through the abandonment of the village. Light stable isotope analyses also find that the diet remained relatively steady throughout the time period of intensifying wet rice production.

[341] Analysis of a Late Archaic Hearth Feature at the Debra L. Friedkin Site in Central Texas

The Debra L. Friedkin Site (41BL1239) near Salado, Texas, is the oldest known, continually occupied site in North America. While the previous focus of excavations and analyses at the Friedkin Site has been on Paleoindian strata, this site also has extensive early and late Archaic components, and recent excavations in 2015 and 2016 uncovered a 3 m × 5 m series of five overlapping hearth features in the late Archaic strata (14C 4000–1250 BP). Projectile points, tools and organic materials such as bone and charcoal were recovered in and around these features, creating an assemblage from which multiple dates can be derived. Through a spatial analysis of projectile points and radiocarbon dating, this complex hearth feature provides the opportunity to better understand not only the site formation processes of the Friedkin site, but also the occupational chronology of the late Archaic Period of central Texas.

**A Multi-Method Approach to Prospecting Stranded Paleo-Coastal Sites on Quadra Island, British Columbia**

Despite increasing support for the first peopling of North America via a coastal route, only a limited number of postglacial (Late Pleistocene–Early Holocene) archaeological sites have been identified on the Northwest Coast. This research aims to identify high potential locations for evidence of the Early Period archaeological record (pre-10,000 cal BP) on Quadra Island, BC. Quadra Island has experienced dramatic sea level regression over the past 14,000 years following the Last Glacial Maximum. These (now inland) paleo-shorelines represent key areas for archaeological prospecting. Through a multi-method approach using sea level history, LiDAR and GIS modeling techniques, prospection for stranded paleo-coastal sites can be greatly improved. LiDAR and GIS modeling are up-and-coming technologies in Northwest Coast archaeology. Using the local sea level history with LiDaR allows detailed “bare-earth” visualizations to be created and reveals hidden archaeological and paleo-coastal features. These features, such as inland paleo-shorelines, can be remotely targeted beneath the rainforest canopy for archaeological foot survey. Through integration of these technologies into a multi-method prospection approach, time and effort during fieldwork can be maximized, and archaeological site identification can be increased.

Lavi, Ron (Manot Cave Project) and Lauren Davis (Ben Gurion University)

**The Stratigraphy of Area E, Manot Cave**

Area E is located close to the upper end of the main talus, at the NW side of the cave. It is built of sediments which originated outside the cave, mainly the local Terra-Rossa soil that was washed into the cave with rainwater, mixed with limestone rocks, some of them originating in the cave itself from decaying and falling roof and wall parts. Two main sedimentary units were observed so far: Unit 1—Colluvium made of soil with limestone rocks in varying sizes. This colluvium contains very little to no archaeological finds at all, and only a small amount of bones of bio-origin, namely hyenas’ activity. Unit 2—Colluvium made of soil with limestone rock, usually of small to medium size. This colluvium contains abundant archaeological material. Within Unit 2, at least nine separate archaeological layers were detected, consisting of horizontal accumulations of flint items, splintered bones, bone and antler tools, shells, art objects, and combustion features, namely hearths and ash accumulations. These archaeological accumulations are separated by soil containing very little archaeological material. Some of the accumulations are up to 15 cm thick. Possible human-made stone features were also detected in Area E.

**Oregon Tribal Historic Preservation Offices: Problems and Challenges of Starting and Maintaining a THPO**

In 1992, amendments were made to the National Historic Preservation Act (NHPA) to include provisions for Indian tribes to assume the responsibilities of the State Historic Preservation Officer (SHPO) on tribal lands, and establish the position of a Tribal Historic Preservation Officer (THPO). THPOs are responsible for conducting a comprehensive survey of tribal historic properties and maintaining an inventory of such properties, preparing and implementing a tribal-wide historic preservation plan, and assisting federal agencies in the NHPA Section 106 review of undertakings on tribal land. There are a total of nine federally recognized tribes in Oregon, of which six having a federally recognized THPO, and two agreeing to participate: the Confederated Tribes of Grand Ronde and the Cow Creek Band of Umpqua Tribe of Indians. The goal of this research is threefold: to understand the challenges that these tribes faced when they first began the process of creating their THPO, to find ways to make starting and operating a THPO less of a challenge, and to understand how they measure success (i.e., budget size, staff size, educational outreach, etc.).

**Visualizing Nineteenth-Century Nipmuc Landscapes**

The Nipmuc people once lived seasonally mobile lifestyles among the lakes, rivers and hills of what is now Central Massachusetts. Colonial encroachment affected this lifestyle greatly, at first in the form of policing and restricted mobility and pressure from the colonial government to own and farmland in severalty, and then later, in the late eighteenth and early nineteenth centuries, the Nipmuc community was largely dispossessed of their land by surrounding Euro-American farmers. As a result, the nineteenth-century Nipmuc community was widely dispersed across Central Massachusetts, living on land they did not own, renting in the city and on larger farms in the countryside. They tended to move often, rarely leaving much documentary evidence of their dwelling history. These events have contributed to an inadvertent narrative of disappearance and erasure that poorly reflects the continued occupancy of the Nipmuc community on the New England landscape. In this paper, I use GIS as a tool to visualize the New England landscape as an Indigenous community space in the nineteenth century, regardless of its ownership, divisions and transformations at the hands of Euro-American settlers and the difficulties, past and present, inherent in representing Native spaces with Western style maps.

Lawler, Brooks (University of Alaska Fairbanks)

**Preliminary Insights into Prehistoric Toolstone Preference of Two Igneous Materials in the Tanana River Drainage, Interior Alaska**

This project examines prehistoric human mobility and raw material preference for tool manufacture in the Tanana River Drainage, Interior Alaska. A geographic approach is used to investigate the distribution of prehistoric obsidian and rhyolitic artifacts in relation to the sources of these materials. The objective of the investigation is to reveal spatial patterning in the distributions of artifacts made of these two materials, relative to each other and relative to the cost of obtaining these raw materials from their sources on the landscape. My initial hypothesis based in human behavioral ecology and optimal foraging theory, stated if prehistoric hunter-gatherers acted to optimize their energy expenditure they could be expected to favor raw materials with the lowest cost of acquisition. The frequencies of different raw material types are examined for thirty-five sites with artifact assemblages that have identified source groups. Those frequencies are compared with geographic information systems models of travel cost. The results of the analysis suggest that the hypothesis does not represent a complete picture of prehistoric human behavior. A more realistic model of human behavior was hypothesized from additional analyses, such that prehistoric hunter-gatherers may have exploited certain material opportunistically and seasonally.

One of the fundamental research questions of the Ancient Southwest Texas project was to determine if there was Paleoindian occupation of Eagle Cave. Excavations during the 2016 field season explored the Paleoindian age deposits and revealed tantalizing evidence of human presence at that time. One clear occupation was revealed (discussed in another presentation in detail by Castañeda et al.) but beneath this were several deposits that appear to be decomposed fiber beds which are associated with a low density of artifacts. This presentation discusses the Paleoindian-age sediments and their archaeological implications.

[377] Relationality, Circularity, and Monumentality: Ontological Materializations in the Belle Glade Monumental Landscape

The Belle Glade monumental landscape exhibits a high level of monumentality, with architectural features ranging from large circular ditches to massive geometric arrays of earthen architecture. However, this unique architectural evidence few archaeological interpretations. Those that have been put forth have largely emphasized etic explanations, many of which have been refuted with the acquisition of new archaeological data. Additionally, recent ecological studies show that the physical landscape itself was much different than previously envisioned. These studies make it apparent that this was an aqueous landscape subject to water flowing across its entirety for nine months of the year. Much like the physical landscape they are a part of, the Belle Glade monuments are also unlike anything else in North America. I argue that in order to comprehend the architecture of this landscape we need to shift our line of thought away from thinking of these features as strictly functional architectural elements and envision them as monuments that embody the alterity of the landscape itself. By engaging the ontological turn of anthropomology I will show how the Belle Glade people materialized their ontology in monumental form by embodying the relational elements of their landscape in architectural form.

[355] Beads Associated with Infant Jar Burials/Supine Child Burials: Evidence of Social Inequality in Early Ifugao Culture

Beads have been used as social markers in many Southeast Asian cultures. The Ifugao Archaeological Project excavations conducted between 2011 and 2012 recovered beads associated with infant jar burials at Old Kiyangan Village, an early Ifugao site in the Philippines. Preliminary analysis shows that prestige beads were concentrated in burials located near the center of the village. Case studies from Southeast Asian sites in Thailand and Cambodia show similar distributions of material types and locations, allowing inferences about social ranking. The concentration of nonlocal goods suggests social ranking was in effect during the occupation of Old Kiyangan Village and, therefore, the precolonial social structure of Ifugao was stratified before European contact.

During the Epiclassic Period (650–950 CE) was the peak of Xochitecatl-Cacaxtla. It became the most important center in the Puebla-Tlaxcala Valley. There were numerous small groups who vied for a place in the landscape after the fall of Teotihuacán in the central highlands. There was a clear hierarchical division, as the society was formed by the elite, priests, and groups of peasants. The artisans were different specialists whose work allowed for the biological and social reproduction of “asentamieto” and whose activities involved the exploitation of various natural resources.

[336] Landholdings and Social Standing: Land Use in the Territory of Bova, Calabria, in the early 1800s

Spatial analysis of land-use data from Napoleonic era Cadastral records provides a window into the social and economic status of individuals in the town of Bova (Calabria, Italy) during the post-Medieval period. Using GIS to explore the cadastral records and archaeological evidence from field survey conducted by the Bova Marina Archaeological Project, this study explores how economic strategies and social relations in this community located in the foothills of the Aspromonte is reflected in the types of crops grown, their position within the landscape and the number and size of holdings. Access to better drainage, roads and rural housing is addressed as a way of understanding the economic and social dynamics of a community that had been a feud of the Archbishop of Reggio and where the church still had much influence even 20 or more years after the official end of feudalism.

[238] Gastrointestinal Parasites of the Camelids of the Archaeological Site of Huanchaquito (Peru): First Results

The health status of domestic’s cameld is an original research topic in the past Central Andes. The discovery of more than 200 well-preserved camelids in Huanchaquito in the northern coast of Peru was the opportunity to perform palaeoparasitological analyses on 20 samples taken from preserved intestines and faeces recovered during the excavations. Extractions of the parasites using RHM standard protocol raised to the observation in 55% of the samples of several helmint taxa belonging to the Orders of Trichocephalida and Echinostomida. In addition, 45% of the studied individuals tested positive to coccidian (protozoa) belonging to the Eimeriidae family. Size of the oocysts showed important variation probably due to the presence of several species. Four Eimeria sp. species are known today by camelids, among which E. macusaniensis, potentially lethal for llamas. This new data shows the high level of infection of camelids and brings new perspectives on the herd health status, the living conditions of these animals, and the Chimú herding practices.

[233] Rural Life during and after the Fall of the Wari Empire: A Stable Isotope Analysis of Childhood Diet and Geographical Origins at the Village of Qasa Pampa, Ayacucho, Peru

Life in a rural village can be vastly different from life in the metropolis, and when an empire collapses the effects can reach even the smallest village. For Qasa Pampa, an agricultural village that was occupied in Wari (ca. 650–850 CE) and post-Wari (ca. 1000–1200 CE) times and located several...
kilometers away from the capital of Huari, life for its population may have been quite distinct from their capital counterparts. Stable carbon and oxygen isotope analysis can shed light on the dietary habits and geographic origins of Qasa Pampa inhabitants, respectively, both during and after the collapse of the Wari Empire. From the reconstruction of these dietary habits pre- and post-collapse, we aim to understand the impacts of imperial policies and practices on daily life of a lesser village, and also how that lifestyle was altered after the collapse. Results show that carbon enriched foods, likely maize, were consumed in high quantities during childhood throughout the whole occupation (mean δ13C from tooth enamel = −5.8‰; N = 31 enamel samples). The mean δ18OVPDB = −9.2‰ (s.d. = .9) and the stable oxygen values range from −11.7 to −7.7‰, suggesting that there might be nonlocal individuals interred at Qasa Pampa.

Leach, Peter (Department of Anthropology, University of Connecticut) and Brian Robinson (Department of Anthropology, University of Maine) [186] Consumer-Grade Drone Mapping and Centimeter-Level Intertidal Geomorphic Changes at the Seabrook Marsh Site, Hampton, New Hampshire

The Seabrook Marsh site [SBM] in Hampton, New Hampshire is a ca. 3500–4500 BP multicomponent site beneath 1–2 m of salt marsh peat and exposed at a rapidly eroding shoreline. Like most intertidal archaeological sites SBM occupies a dynamic environment. Daily tidal fluctuations slightly modify surficial sediments, but on a monthly, seasonal, or annual scale the magnitude of changes is quite significant. The resulting landscape modifications range from minor erosion and deposition to catastrophic failure of shoreline elements through undercutting and rotational slumping. To quantify ongoing erosion at SBM we used a consumer-grade drone and with three surveys recorded 12 months of intertidal geomorphic changes at 6-month intervals. Photographs were collected at 10 m altitude within 1 hour of low tide. We then used digital photogrammetry software to create orthophotograph mosaics and digital elevation models [DEMs]. Our data exhibited roughly 8 mm resolution and were sufficient to resolve bootprints and minuscule features in DEMs. Data processing in ArcGIS ensured exceptional spatial congruity between surveys. GIS-based spatial comparisons resolved centimeter-level intertidal sediment dynamics and landscape alterations. These data provided a high-resolution assessment of critical areas at SBM that will be the target of upcoming excavations.

Leader, George (University of Pennsylvania), Aylar Abdollahzadeh (University of Pennsylvania), Sam Lin (University of Wollongong) and Harold Dibble (University of Pennsylvania) [40] The Effects of Exterior and Lateral Platform Morphology and Raw Material on Flake Size and Shape: Results from New Controlled Experiments

Previous controlled experiments have illustrated that exterior platform angle and platform depth have a strong influence on the size and shape of a flake. Using specially made cores and a hydraulic knapping machine we present results from two new controlled experiments. The first of these involves altering the exterior and lateral margins of the platform and seeing the effects these changes have on flake mass in relation to platform depth. In the second controlled experiment, glass cores (which were used in all of our previous experiments) are replaced with cores made from basalt, obsidian and flint. In this experiment, the emphasis is on the amount of force required for the removal of flakes from each raw material in relation to platform depth. The results from both experiments have important implications for the prediction of flake size based on these important independent variables.

Bone assemblages from modern landscapes can help address a variety of issues, from the degree to which bone scatters accurately reflect local habitats to what variables condition the deposition, preservation, and spatial distribution of faunal material. In 2015, systematic pedestrian survey recovered ~350 bone specimens within a 200 m x 200 m area of open grassland about 2 km north of Olduvai Gorge in the Ngorongoro Conservation Area (NCA). Weathering profiles suggest an exposure, and thus accumulation, time of many years. Find density is well under one bone specimen per square meter, although spatial analysis reveals significant clumping. The findings from the NCA “background scatter” are used better understand the paleoecology and taphonomy of Olduvai Gorge’s well-known early Pleistocene faunal assemblages.

LeBrell, Emilie (Oakland University) and Geoffrey McCafferty (University of Calgary) [326] About Face: A Head-On Examination of Precolumbian Social Identity

A desire for art to reflect social identity is made apparent through prolific representations of human faces in precolombian ceramics. The ceramic art of Greater Nicoya and the surrounding regions demonstrates an intrinsic drive to communicate distinct group characteristics and illustrates the importance of individuals’ bodies as instruments of both personal expression and social relationships. Physical expressions of collective identity foster a sense of belonging and satisfy the human desire for order and social organization in everyday life. External decoration and modification, hairstyle, tattooing, jewelry, and garment design are all important elements of both self and group identities. These varieties of ornamentation ultimately convey the importance of physical appearance as a device to communicate distinctive group traits. This paper seeks to decode the complex social messages conveyed by human faces on ceramic vessels and figures from Greater Nicoya and neighboring areas. By gaining a better understanding of social identity through depictions of human faces in ceramic art, we can begin to understand more of the complex social messages and shared ideals of the enigmatic indigenous groups of Greater Nicoya and its neighboring regions.

Leclerc, Natasha (Memorial University of Newfoundland) [223] Shellfish, Seasonality, and Subsistence in Sechelt Inlet: Understanding Intertidal Resources with High-Resolution Bivalve Sclerochronology

This paper presents the results of annual growth pattern analysis and geochemical analysis of live-collected and archaeological shells from the Sechelt Inlet, southern British Columbia. Annual growth line analysis of butter clams (Saxidomus gigantea) from three sites in this region revealed an intensive
pattern of shellfish collection relative to other large village sites on the Pacific Northwest Coast. This variability suggests there may also be differences in seasonal collection patterns. To understand seasonal harvesting practices we analyzed live-collected and archaeological shells to ensure precise seasonality estimates through high-resolution stable oxygen isotope sclerochronology (combined analysis of growth patterns and stable oxygen isotopes). Salinity values in this region were measured at ~15 PSU during the summer months, lower than other previous calibration studies. This lower salinity regime must be considered when inferring seasonality from geochemical data because of the opposing effects of temperature and salinity on stable oxygen isotope values. We also analyzed live-collected little neck clams (Protothaca staminea) to evaluate if this species can also be used as a reliable indicator of shellfish harvest intensity and seasonality. Combined with faunal data, we develop a nuanced understanding of seasonal subsistence practices in the Sechelt Inlet over 5,900 years.

Ledford, Kelly (Florida State University) and Tanya Peres (Florida State University) [340] Constructed Spaces and Managed Species: Niche Construction Theory and “Wild” Turkey Management during the Mississippian Period in the Southeastern United States

Pre-Columbian peoples of the Southeastern United States systematically altered their environment through forest clearing, gardening, terraforming, and urban planning. The end result of these activities encouraged certain native animals like the wild turkey (Meleagris gallopavo silvestris) to occupy these constructed and managed environments, especially forest-edges and agricultural fields. The sustained daily interactions between species resulted in a special and complex human-turkey relationship. In some areas of the Americas the end result is evidenced as domestication, while in the Southeastern United States, a unique style of free-range turkey management was in place by at least AD 1250. Working from the theoretical basis of niche construction theory, we bring together the ethnographic and ethnohistoric record of Southeastern Native Americans, biological literature on wild turkeys, and morphometric data from a Mississippian Period (ca. AD 1250–1450) archaeological turkey assemblage to present a more nuanced understanding of the cultural engagement of a not-so wild species.

Ledin, Lauren (University of Chicago) and Hongbin Yue (Institute of Archaeology, Chinese Academy of Socia) [72] Foundations of Childhood: Bioarchaeology of Subadults at the Late Shang Capital of Yinxu

Oracle-bone inscriptions and pre-Han texts say little about children, making bioarchaeology the best available method to study childhood during earlier periods. In 2004, extensive excavations were carried out on building foundations in Dasikong Village, a Late Shang (c.1200–1046 BC) lineage neighborhood found on the outskirts of modern-day Anyang, Henan Province, China. This led to a uniquely high recovery of subadult remains as younger subadults are often found in and around foundations. For this paper, the age, biological sex, and mortuary contexts of 49 of the subadult individuals were reassessed to explore whether a child/adult binary and later conceptions of childhood are suitable descriptions of the role of Late Shang subadults. Surprisingly, artifacts traditionally considered adult proxies of power were interred with individuals as young as 10–12, suggesting the age group assumed for adult roles should be expanded to include individuals under 15. Patterns in grave good type and number, mortuary treatment, and skeletal age additionally suggest that the current understanding of a child/adult binary is not an effective way to grasp the social identity of Late Shang subadults. In this paper we propose instead that Late Shang subadults passed through a number of socially recognized stages reified in mortuary treatment.

Ledogar, Sarah (University at Albany–SUNY) and Jessica Watson (University at Albany–SUNY) [248] Testing the Effectiveness of 2D Morphometric Data for Identifying Species in Galliformes

Galliforms, or game birds, are one group of birds commonly utilized by prehistoric people that are particularly difficult to classify beyond family. In addition, bird bone assemblages are often fragmentary and poorly preserved, making avifauna notoriously difficult to identify to species, even by trained specialists. Nonidentified bones lead to a decrease in information available about taxa present at the site, hunting preferences of the site inhabitants, environmental conditions, and other issues commonly studied by archaeologists. In this paper, we examine a series of skeletal morphometric traits in 12 gallinaceous species from North America and Europe to determine the range of shape and size variation among these species using principal component analyses. We also test whether the use of morphometrics can enhance the classification of Galliformes using discriminant function analyses. We ask: How can we differentiate between species with bones alone? Can bone measurements discriminate beyond family to species or genus in Galliformes? How effective are morphometrics for zooarchaeologists?

Lee, Boyoung (University of Oxford), Mark Pollard (University of Oxford, Research Laboratory for Arch) and Holger Kramer (University of Oxford, Department of Physiology, An) [96] Proteomics for Silks: Identify and Distinguish B. mori and Other Species

Silk fiber generally known is made from a species called Bombyx mori, which was domesticated about 2,000 years ago in China. This is reared by human and the process is called sericulture. However there are other wild silk species that are not domesticated but still used in textile making. In an archaeological context, the proof of sericulture could be an index of the cultural and technological development of a location: it implies that there was a developed economy to import or produce silk—and in latter case also had the knowledge and technology to do so. To know what it is and where it came from is an integral part of the process. However, so far in textile analysis, identification of different species of silks has not been attempted due to the limitation of knowledge and method. Thus in study, it aims to adopt proteomics technique to identify and distinguish B. mori and other wild silks, even from historical and archaeological samples. The results from peptide identification using LC-MS/MS and MALDI-TOF from 7 different species of silks were promising. This would suggest a solution to the current disputes over early silk findings and the settlement of silk-making industry and technology.
Lee, Christine [276] Conservation Recommendations for Human Skeletal Remains Excavated from Desert Oases, Cave Shelters, and Permafrost in China and Mongolia

Tomb excavations have been documented in East Asia for over 100 years, however the focus has been on artifact collection. The systematic excavation and collection of human skeletal remains is new to this region. This study will outline three cases where there was a demonstrated need for the implementation of conservation techniques. The first case included several naturally mummified skulls from Xinjiang, Province, China. A graduate student had decided to wash the skulls to remove skin and hair. A month later white crystals were seen growing out of the skulls. The second case involved four naturally mummified cave burials from southwestern Mongolia. Once removed from the dry environment, they began to decompose again. The last case was excavated from permafrost in northern Mongolia. After the tombs were opened, it began to rain inside from the melting ice. The skeletons were bagged in plastic and stored in cardboard boxes for a year before the author examined them. When examined all of the bones were coated in white mold. This study will give recommendations for the treatment and storage in these particular cases.

Lee, Gyoung-Ah (University of Oregon) [24] Chair

Lee, Gyoung-Ah [24] see Lee, Hyunsoo

Lee, Hyunsoo (University of Oregon) and Gyoung-Ah Lee (University of Oregon) [24] Neolithic Resource Use and Niche Construction on Jeju Island, Korea

One of the key subjects in island archaeology is how islanders adapted to isolated environments and sustained with local resource. Jeju Island sites reveal Early Holocene Neolithic settlements, dating 2,000 years prior to any of Neolithic sites in the Korean mainland. Accordingly, Jeju Island offers an opportunity to understand any shift in subsistence strategies amid the changing Early Holocene environments. A sudden appearance of arrowheads and grinding slabs in the Early Holocene Jeju has been often interpreted as evidence for an increasing importance of edible flora and terrestrial games. This trend may link to worldwide transition to the broad-spectrum subsistence transition. Such a hypothesis has not been tested due to a lack of archaeobotanical studies in Jeju. Our project will investigate both macroscopic and microscopic plant remains in Neolithic sites on Jeju along the coast and uplands. We aim to compare resource utilization among the Korean mainlanders and Jeju islanders and to develop a model on diverse niche construction in Korean Neolithic period.

Lee, Jinok (University of Texas, Austin) [33] Neolithic Human-Landscape Interactions in Eastern China: Preliminary Results from Liangchengzhen

Cultural trajectory of the Yellow River catchment is characterized as complex and integrated feedback process of environment-landscape-human interactions. Landscape history of the Neolithic site, Liangchengzhen, provides a good example of prehistoric agricultural land use and its impact on local landscape, as well as how the human-landscape process possibly affected rapidly increasing social complexity during the Longshan period and subsequent hiatus in eastern China. Through a combination of geomorphological and microbotanical studies of on- and off-site landscapes of Liangchengzhen, evidence has been identified for local landscape history, including erosion of hill slope soils and redeposited soil layers containing rice phytoliths dating to the middle–late Longshan period. This finding provides evidence for late Neolithic rice farming strategies utilizing natural wetlands and redeposited soils. Sediments from subsequent periods, however, revealed evidence for a massive alluvial build-up, probably indicating a sudden change of regional environmental and alluvial regime. The landscape history of Liangchengzhen can shed light on 1) agricultural production of late Neolithic, and 2) the impact of landscape dynamics on prehistoric societies.

Lee, Lori (Flagler College) [74] Intersectionality and Health Consumerism in Antebellum Virginia

This presentation explores intersectionality in the context of health consumerism in antebellum central Virginia. Health consumerism incorporates the modern sense of patients’ involvement in their own health care decisions and the degree of access enslaved African Americans had to resources that shaped their health and well-being experiences. To emphasize the multilayered nature of health and illness, this analysis engages Margaret Lock and Nancy Schepers-Hughes “three bodies model.” The three elements comprising this model consist of 1) the individual body—the physical body and personal experience of the body, including the mind; 2) the social body—the body as it is socially represented in various symbolic and metaphorical forms; and 3) the body politic—regulation, surveillance, and control of bodies (both individual and collective) in reproduction and sexuality, work and leisure, and sickness. This model allows for the assessment of intersectionality across domains of power. Public health is a growing research focus that uses an intersectional approach. I argue that understanding intersectionality in past health approaches is critical for understanding modern public health challenges.

Lee, Rachel (University of Washington) [278] Household Change and Social Complexity in Prehistoric Korea

Household archaeology has made important contributions to the study of large-scale social transformations through the remains of the everyday. This paper examines the role of households, themselves, in the social changes that occurred during the Early and Middle Mumun Pottery Periods (ca. 1500–500 BC) in Korea. During this time, incipient social inequality developed alongside another significant change—households that were previously composed of multiple families became single-family units. Excavations of pithouses are presented from Daepyeong and Pyeonggeo-dong, two Mumun settlements from the Nam River region of southern Korea. I examine household changes at these settlements and their relationship with increasing complexity. In particular, I argue that the breakdown of multfamily households raised the potential for competition in Mumun society, ultimately helping to create a sociopolitical context for inequality to develop at densely populated settlements such as Daepyeong.

Lefebvre, Karine (CIGA—UNAM) [322] Ruptura y Continuidad: El impacto de la conquista tarasca en la región de Acámbaro–Maravatio
A mitad del siglo XV, el joven reino tarasco llevó a cabo una importante fase de expansión de su territorio. Es en este marco que la región de Acámbaro-Maravatio, ubicado a unos 130 km de la laguna de Pátzcuaro (corazón del reino), cayó en mano de los tarascos. Pero la conquista no se persiguió más allá y el sector de Acámbaro se convirtió en una zona de frontera. La dominación tarasca de la región fue breve, apenas unos 80 años.

Sin embargo, estas ocho décadas fueron suficientes para que el poder tarasco ejerciera su dominación sobre las poblaciones, el territorio y sus recursos. A partir de la confrontación sistemática de datos arqueológicos e históricos, volveremos en varios cambios y permanencias registrados en la región en distintas esferas (política, económica y cultural) de la sociedad tras la conquista tarasca, tal como la continuidad del patrón de asentamiento, la conservación parcial de la élite local, la importación de artefactos desde el centro del reino, la integración diferenciada de los distintos grupos étnicos que residían ahí. Lo anterior permitirá reflexionar sobre la política de expansión y el nivel de control que los tarascos ejercieron sobre los territorios y las poblaciones sometidas.

Bahamian hutia (Geocapromys ingrahami) are small sized rodents endemic to the Bahamas. Fossil and subfossil records indicate broad geographic distribution of the rodent across the Bahamas in the past, while today Bahamian hutia naturally occur on one island. Bahamian hutia have received little attention archaeologically resulting in critical gaps in our understanding of both natural and anthropogenic patterns in Bahamian hutia distribution and life history. In conjunction with “traditional” zoarchaeological data (e.g., morphometric ranges, geographic distribution, and archaeological context), multiple isotope proxies from bone collagen, bone apatite, and tooth enamel apatite are presented to address geographical origins, management and dietary ecology of sampled archaeological hutia. For example, with respect to bone collagen, mean d13C (–19.5‰) and d15N (5.9‰) values support a predominantly C3-based dietary regime. Interestingly, one individual exhibits a large D13C apatite-collagen spacing of 11.8‰, which suggests some C4 carbohydrate food source in addition to C3-based protein in its diet. Strontium isotope ratios of second molar tooth enamel for all specimens assayed reflect 87Sr/86Sr of modern seawater, between 0.7091 and 0.7092. The data suggest significant indigenous human influence on Bahamian hutia in the past, providing a historical background for Bahamian hutia ecology and distribution today.

El Camino Real de Tierra Adentro: Public Perceptions and Management

Management of the Jornada del Muerto segment of El Camino Real de Tierra Adentro National Historic Trail over the last nine years has provided insights into a wide range of behaviors and perceptions about a physical manifestation of history and its meaning and role in our lives. As with many historic/archeological sites, there is a mythic El Camino as well as an archaeological/historic El Camino. Trail management is sometimes a question of balancing and enhancing and sometimes a question of dispelling and deterrence. The story of the trail goes deeper in time and lasts longer than the three centuries that are cited as its period of significance. Those perceptions of the trail and the meanings that derive from them color the ways that the Bureau of Land Management and the National Park Service manage and interpret El Camino for various members of the public. This presentation focuses on those perceptions, the public’s interpretation of the trail, and the management issues that arise from the interactions among the agencies charged with management and the members of the public for whom it is managed.

Leght, Megan (CUNY Graduate Center) and Christina Halperin (Université de Montréal)

Classic Maya Textiles and the Crafting of Communities

One of the striking features of contemporary Maya textiles is that their production techniques and aesthetics can be highly regionalized. These textiles manifest strong village, town, and community identities while simultaneously reproducing other identity formations (e.g., gender, ethnicity). Likewise, Classic period Maya (ca. 300–900 CE) political formations were highly regionalized with multiple, shifting centers of gravity. Nonetheless, relatively little is known about the variability of Classic period textiles across the Maya Lowlands and whether textiles were caught up in the political fissions and regionalisms identified in hieroglyphic texts. This paper explores several Classic period Maya textile and garment traditions that have been previously overlooked in the literature. We suggest that unlike other crafting communities, those surrounding textiles often defied the boundaries of petty politics.

Leitermann, Garrett (New Mexico State University)

The Applicability of Laser-Induced Breakdown Spectroscopy (LIBS): A Case Study of Sourcing Ceramics in the Northern Mimbres Area

The use of Neutron Activation Analysis (NAA) has been the primary technique for ceramic sourcing studies within archaeology for the last several decades. Laser-Induced Breakdown Spectroscopy (LIBS) is an atomic emission spectroscopy technique that provides archaeologists with a time and cost effective alternative to NAA. LIBS has been used by the author on a large sample of corrugated sherds originating from two Classic Mimbres sites within the Gila National Forest of New Mexico in an attempt to explain the presence of a high volume of distinctively non-Mimbres corrugated wares within the region. More precisely, the author will attempt to use LIBS to test if the significant presence of nonlocal corrugated wares is indicative of high levels of cultural interaction or trade with other cultural groups or if their presence is the result of the adoption or copying of technological and stylistic techniques by local producers. The applicability of LIBS for ceramic sourcing studies will be demonstrated by the results of the author’s research.
Lekson, Stephen (University of Colorado) [393] Big (Pre)History in North America: A View from the Southwest

While there are hopeful signs of change, for most of the last half century American anthropological archaeology has been highly skeptical or openly hostile to continental-scale dynamics, particularly north of Mexico. Why was that? This paper briefly explores the history of our discipline, contrasts it to Europe and Latin America, and remarks on emerging, more realistic frames-of-reference for the prehistory of Native agricultural societies in North America. Examples begin with old chestnuts in the Southwest and Mississippi Valley, and move out: from sea to shining sea, and from north and south as far as corn was grown. Summarily, of course.

Lemke, Ashley (University of Texas at Arlington) and John O’Shea (University of Michigan) [286] Cooperation or Competition? The Underwater Archaeology of Communal Hunting Structures

Forager cooperation can be difficult to detect in archaeological contexts. One approach is to focus on built structures, such as drive lanes or fishing weirs, which required the participation of multiple persons. Yet such features are ephemeral and variable due to disturbance and destruction. One way to circumvent these challenges is to target areas with excellent preservation, such as underwater contexts. For example, the cold, fresh water of the Great Lakes preserved 9,000-year-old stone built hunting structures. Due to their submerged setting, these features are virtually intact, and their social and environmental contexts can be investigated on a regional scale. Structures range from simple hunting blinds to complex drive lanes; and their formal attributes including placement on the landscape can be used to infer group size, composition, and seasonality. Yet while communal hunting is often held up as a classic example of forager cooperation, permanent built structures raise issues of ownership, property, and territoriality which are at odds with ideals of egalitarian hunter-gatherers. Therefore, the use of such structures by early Holocene foragers may reflect both cooperative and competitive behaviors. We present results from research under Lake Huron on communal hunting structures to comment on the nature of forager cooperation.

LeMoine, Genevieve (Bowdoin College) [35] Weasels, Seals, Bears: Late Dorset Miniature Carvings as Indicators of Individual Hunter/Prey Relationships

Miniature carvings recovered from Paleo-Inuit Dorset culture sites (2800–700 BP) across the Canadian Arctic and northwestern Greenland offer tantalizing glimpses of human-animal relations of this prehistoric group. Recently scholars such as Matt Betts and Mari Hardenberg have begun a productive line of inquiry drawing on representational ecology to contextualize and enrich understanding of the social nature of these relationships and the symbolic role of the carvings of polar bears in particular among the Dorset. Their studies, and most others, consider a broad range of carvings from sites across the north. This paper builds on such work but focuses on subset of carvings: those found tightly grouped in situ, which can be interpreted as having belonged to a single individual at a particular point in time. These “caches” of amulets lend themselves to a consideration of the specific, individual, relationships between hunters and the animals they preyed on, needed protection from, or relied on as helpers, and from there, a better understanding of specific practices of Dorset hunters. Carving caches from Iita, Greenland, and the Arvik and Tasiarulik sites on Little Cornwallis Island, Canada will be the focus.

Lenssen-Erz, Tilman (African Archaeology, University of Cologne), Brigitte Mathiak (Data Center for the Humanities, University of Colo), Eymard Faeder (African Archaeology, University of Cologne), Maya von Czerniewicz (African Archaeology, University of Cologne) and Joana Wilmeroth (Dept. for Computing in Arts and Humanities, Univer) [210] Scenic Narratives of Humans and Animals in Namibian Rock Art

In prehistoric rock art the notion of “scene” always played an important role but a clear and widely accepted definition of scene does not exist and little was written about what constitutes a scene. If informing context lacks, Gestalt features are often taken to identify what can be considered a meaningful scene. If we consider a scene as displaying a social animated configuration, then the Gestalt laws alone are an insufficient tool. Particularly in scenes including humans and animals interaction should be considered as well. Here we present a formal approach that provides a rigid framework for the definition of scenic coherence encompassing Gestalt and interaction. This approach allows quantification across the large corpus of Brandberg rock art and it shows that just 2.4% of all scenes show “encounters” of humans and animals. Only once in 117 encounters the animal is clearly in a dominant role. Our data suggest that combining humans and animals in scenes (not in juxtaposition) may be a narrative of hierarchical agency. For the future we aim to grasp the structures of scenic narratives through cooperation with computer science, exploring whether algorithm based data mining enables us to identify underlying rules of scene formation.

Lentz, David L. (University of Cincinnati), Nicholas Dunning (University of Cincinnati) and Vernon Scarborough (University of Cincinnati) [285] Resilience and Regime Shift at the Ancient Maya City of Tikal

Over the time span of nearly a millennium, the ancient Maya polity of Tikal went through periods of growth, reorganization and adaptive cycles of various connected scales. Recent data show that following the reorganization of the Late Preclassic period, Tikal experienced an extended period of technological innovation and population growth that stretched the carrying capacity of the available landscape. A hydraulic system was constructed that provided water for the community during the dry seasons: a powerful development in an area without a permanent water source. Agriculture was intensified using a combination of root crop agriculture, irrigated fields, arboriculture, household gardens, short fallow cropping systems and bajo margin cultivation. The net product of these diverse production activities undoubtedly helped to underwrite an enormous amassing of economic and political capital during the Late Classic period. Ultimately, in the mid-ninth century AD, expansive growth combined with multiple system disturbances led to a collapse of the city’s social structure followed by abandonment of the site. The application of resilience theory as a conceptual framework has been useful in helping to interpret the complex web of the underlying social and ecological domains that contributed to Tikal’s demise.

**Irish Independence in the Crapper? Irish Republican Army Buttons in San Francisco**

This paper examines two Irish Republican Army buttons discovered in a privy associated with a late nineteenth-century household in San Francisco in order to elucidate how Irish immigrants became Irish Americans on the West Coast. Archaeologists and historians have studied the Irish Diaspora, this they have largely focused on the Northeast. While the Irish Republican Army is familiar to contemporary audiences, many people are unaware of the organization’s nineteenth-century roots in the United States. The brass miniature pasted onto one of the buttons was a 25pRA soldier who participated in Canadian Raids waged by the Fenian Brotherhood in the 1860 and 70s. The physical journey of the garment from the Northeast to California engendered the object with import. This paper will attempt to answer the questions of who owned this item and why was it discarded by analyzing the remainder of the collection with insight from historical documents. In addition, this paper will examine assemblages from other Irish households in the neighborhood to better understand how Irish ethnicity identity is expressed through material culture.

**Ancient Cacao Groves in Yucatán: A Palynological Approach**

Cacao had a transcendental role in the life of prehistoric people of Mesoamerica, becoming part of their economic, ideological and social system. Due to the morphological and environmental characteristics necessary for the growth of cacao tree, the main producers were concentrated in places like southern Mexico and Central America. However, written sources of the first colonizers in Yucatán disclose that the indigenous nobility of that time had at their disposal cacao orchards in different hollows called rejolladas or ts’ats. Pollen and radiocarbon analyses were made from sediment cores at ts’ats Xkakhuil from the eastern Yucatán. The presence of Theobroma cacao pollen confirms the use of these species, at least from the Post Classic period, when Mayapán was the controller of trade in the north of the peninsula. But the vast iconography of cacao at Chichén Itzá reflected the ideal environment of cultivation of this plant, and the occupation of some rejolladas and ts’ats during the heyday of this city could trace the beginning of this practice centuries before.

**The North Sea and the “Long” Viking Age: Connections and Communication**

This talk presents the results of a northern European collaborative pilot study on the compilation and analysis of internationally-derived datasets of metal-detected material culture. Drawing on nascent heritage initiatives across northern Europe designed to protect and record our at-risk portable material culture, the project seeks to develop and trial a methodology for the synthesis and analysis of metal-detected datasets from England, Denmark, Belgium, and the Netherlands, resulting in the first international synthesis of this material. The project focuses on the North Sea littoral in the Iron Age/Early Medieval period leading up to and throughout the “Viking Age” (c. AD 700–1100)—a period characterized by extensive long-distance networks of trade, migration, and communication. In addition to piloting cross-border data synthesis, the project will analyse the distributions and long-distance routes of movement of artifacts and people, thus shedding light on the interconnectedness of the “Long Viking Age” in the North Sea. The results will be of interest to those making use of metal-detected data regardless of period specialization, particularly with reference to strategies for the effective integration of these diverse and problematic datasets.

**Patterns and Outliers in Prehistoric Island Mobility: Comparing the Strontium Data**

During the colonization of islands in the Pacific and Caribbean by agropastoral communities, a variety of proxies (e.g., material, genetic, zoogeographic) indicate substantial interisland and intercommunity contact. It has been suggested that this contact represents an adaptive response to intrinsic demographic fragility during the initial phases of island colonization, and that this connectivity imperative faded in the aftermath of initial dispersal as overall population density increased. Here we evaluate this model by synthesizing and comparing increasingly available 87Sr/86Sr data from funerary populations in the Pacific and Caribbean. Highlighting possible limitations in a comparatively small body of data (not least statistical limitations relating to small sample sizes and problems pertaining to geochemical characterization), we nonetheless tentatively suggest broad patterns, as well as outliers, as regards post-juvenile mobility in both areas. We relate these patterns to recurring types of sociodemographic organization in early agropastoral island communities (especially in terms of general trends in interisland mobility over time), and discuss the broader implications for understanding how island environments imposed—or did not impose—constraints on the organization of communities cross-culturally.

Warm or Cold Season of Capture? Oyster Middens from Block Island, Rhode Island

Previous research on Block Island, Rhode Island, indicates that during the Woodland Period, the island was likely occupied year-round and maritime resources accounted for a significant portion of peoples' diets. Native American sites on the island include semipermanent villages near the Great Salt Pond and fishing, temporary seasonal, and task specific camps away from villages. Season of occupation for these sites is important to frame our understanding of a developing maritime economy. Several oyster middens (Crassostrea virginica), associated with Woodland Period sites were identified on Block Island during a Phase I and II survey of the coastline, conducted to document and salvage archaeological sites exposed and disturbed by Hurricane Sandy. Archaeological oyster shells were powdered at the terminal growth band and analyzed for stable isotope values ($\delta^{18}O$). To determine season of capture, archaeological $\delta^{18}O$ values were contrasted with modern oyster shell $\delta^{18}O$ values, collected from three separate locations on Block Island; these were sampled incrementally from the terminal growth band along the hinge to estimate modern seasonal shell growth. A number of the archaeological sites also contained faunal remains indicative of season of capture (Atlantic Sturgeon and Grey and Harbor Seals) providing a check for shell-derived season of capture estimates.

A Tale of Two Villages: Exploring the Role of Villages with Massive Shell Accumulations as Anthropogenic Coastline Modifications in Prince Rupert Harbour

3D mapping, percussion coring, and radiocarbon dating are used to explore the geoarchaeology and chronology of two villages composed of massive shell deposits in the Prince Rupert Harbour. We map out accumulation and development of these sites through time and demonstrate that they are major anthropogenic coastline modifications, which, with dozens of other large villages in the area, form a substantial built environment. As well as providing well-drained terraformed terraces on which to build houses and conduct village life, these locations buffered against foreshore erosion and relative sea level change, thereby increasing resilience of communities and establishing enduring places that were occupied for millennia. However, radiocarbon analyses of the two villages show that each formed differently. One was occupied nearly continuously for the last 6,000 years with expansions and contractions and periods of punctuated shell accumulation, while the other was occupied 2500–1500 BP, was constructed rapidly, and maintained its original occupied area through time. We argue that though we can generate hypotheses about how these constructions functioned to shape the Harbour's cultures, the two cases' different chronologies and developmental histories indicate that there are also specific histories behind these mounds' accumulations, which require other lines of evidence to unpack.

The Maya: Historic Archaeology and Archaeology of Historic Periods

The study of the ancient Maya has become complicated over the past 30 years. As the ancient Maya writing has been deciphered, these texts provide an historical record of parts of the ancient social and political systems. This development has moved the study of the Maya past into the realm of historic archaeology. In addition, the study of the colonial period in the Maya area has focused upon Spanish and indigenous texts to understand this historic period but additionally to create analogical models of Maya systems that could be used to understand the nature of the ancient Maya world. Even ethnological studies of modern Maya people and communities have become a focal point for the study of the prehistoric Maya. Such an approach within the academic world has positioned the Maya of today as a model for understanding the past. The secondary nature of the living Maya is echoed in the modern representation of the Yucatan as a place of sand and ruins—not part of the living twenty-first century. This paper will examine the nature of historic archaeology and the archaeology of the historic past and heritage of the Maya in the Yucatán and throughout the lowlands.

Wayfinding: Paths, Pathway Markers, and Navigational Monuments at Wari Camp and Beyond

Social life never proceeds in the absence of a spatial dimension that defines, brackets, segregates, alters or otherwise organizes interaction. The power to organize space emerges historically from the sweep of institutional arrangements across society and operates along many different dimensions and scales, at once establishing boundaries all the while insidiously permeating them. This historical process—this “social production of space”—is what we refer to as landscape. Landscape has been a foundational concept for research at the Programme for Belize site of Wari Camp for almost 15 years. We have explored how the spaces of social life there facilitated control by political leaders over a diverse array of people and landforms, and how people through their various institutional affiliations devised a multiplicity of provisioning strategies. Yet only relatively recently have we begun to detect the manner in which people and things moved within and among these spaces. Our paper celebrating the 25th anniversary of research at Programme for Belize tackles this particular dimension of place-making. We focus on the identification of paths, pathway markers and navigational monuments because their distributional patterning provides unexpected insights into both community and regional landscapes.

Fire Up the Uhmw: Deciphering Botanical Residues from Earth Ovens in Pohnpei, Federated States of Micronesia

In Pohnpei, Micronesia, the uhmw, or earth oven, is one important way of preparing food. These ovens are typically located in cookhouses next to residential sites. Pohnpeians use heated stones on the ground to cook food and cover items with large leaves while cooking. It is clear that uhmw are a
long-standing Pohnpeian tradition, as multiple examples have been found in the archaeological record. In this paper, we ask what botanical residues from umhw can tell us about the prehistory and history of Pohnpeian culinary practices. We analyze microbotanical remains (phytoliths, raphides) and macrobotanical remains from umhw features on Temwen Island, Pohnpei. We also integrate analysis of the cookhouse structures. Finally, we discuss Pohnpeian umhw in larger Pacific context, including the social importance of earth ovens throughout the region, highlighting the importance of the study of botanical residues in understanding past culinary practices.

Levine, Abigail (University of California, Los Angeles)
[391] Not Quite One and the Same: Repetition and Rule in the Inka Provinces
The use of molds for pottery manufacture is an integral part of the ceramic tradition of the North Coast of Peru, dating to at least as early as AD 100. Analysis of mold-made Chimu-Inka monkey effigy vessels excavated from mortuary contexts at the sites of Farfan and Tucume suggest that Late Horizon fineware production occurred in local workshops rather than in a centralized facility—a pattern consistent with other studies of Inka pottery production from around the Central Andes. The use and repetition of the monkey icon in these contexts—facilitated through the use of molds—is especially significant. The use of monkey icons has a long history in the region, dating to the Formative Period, and is common in the Late Intermediate Period mortuary assemblages. Although Inka presence on the coast resulted in the abandonment of certain motifs, the monkey effigy vessel persists throughout the Late Horizon. Importantly, while the use of distinct sets of monkey molds indicates production in disparate facilities, general similarities in form and style nonetheless speak to larger scale artistic canons and principles. Adherence to these selected local traditions was likely a critical facet of state-sanctioned or ritually significant contexts in areas colonized by the Inka.

Levine, Marc (University of Oklahoma)
[135] Mixtec Goldworking: New Evidence for Lost-Wax Casting from Late Postclassic Tututepec, Oaxaca
Gold jewelry and ornaments produced in Late Postclassic Oaxaca were among the finest ever made in Mesoamerica. Yet the paucity of archaeological evidence for metallurgical production in Oaxaca has frustrated efforts to better understand these spectacular objects and their role in Postclassic society. This paper presents the results of an analysis of 42 ceramic molds from the Late Postclassic (1100–1522 CE) Mixtec Capital of Tututepec. I argue that the molds were utilized to cast internal cores, which played a pivotal role in the overall process of lost-wax casting. No other molds of this type have ever been reported from Mesoamerica. The presence of casting core molds, in conjunction with ancillary household evidence for metallurgical production, suggests that Tututepec was an important metalworking center. Finally, I discuss how metallurgical production and gold jewelry may have figured in Tututepec’s political, social, and economic spheres.

Levine, Mary Ann (Franklin and Marshall College)
[188] Moravian Travels through the “Spirit’s Nest”: Archaeology of Colonialism at Madame Montour’s Otstonwakin
In 1741, Moravians, a sect of German pietists established a settlement in Pennsylvania which became the principal religious and administrative center for the Moravian Church in North America. Moravian missionaries soon traveled to nearby Native American communities including Otstonwakin, an eighteenth-century multinational village along the West Branch of the Susquehanna River. Madame Montour served as a frontier diplomat and go-between at Otstonwakin and hosted a succession of visitors into her home including several Moravian missionaries. Moravians sought to have Otstonwakin become an important part of the mission structure in the region and describe it as the “spirit’s nest,” a place where evil spirits were thought to be present. This paper examines eighteenth century colonial encounters through the maps, diaries, and travel accounts left by Moravians who sought to proselytize to Native Americans at Otstonwakin.

[29] Cyber-Archaeology, Scientific Storytelling, and the GIS Nexus
Since 1999, UC San Diego Levantine Archaeology Laboratory excavations have been “paperless” with the aim of developing digital data acquisition, curation, and 2D and 3D dissemination tools for archaeological and cultural heritage data. GIS provides the nexus for our data flow because all archaeological data collected in the field has a geospatial footprint. The X, Y and Z coordinates of the archaeological data provides the organizational and visualization principle of the archaeological endeavor. Our real-time GIS data recording software, ArchField, provides the main data-recording tool during the excavation process. Tablet based Open-Bug, records the metadata concerning the contextual aspects of the excavated material culture; and ArchaeoSTOR serves as a web-based geospatial database that pulls together a wide range of digital data in different formats from lidar, airborne photography, terrestrial and marine geophysics, Structure from Motion (SFM) and more. This data-flow provides the perfect tool kit for objective scientific storytelling, in our case, for the contentious field of Biblical Archaeology. To more effectively tell these stories, ‘Big’ cultural heritage data is moved over high-speed fiber optic networks and ultimately displayed in personal VR displays and total immersive 3D CAVE environments so that more people can experience the stories.

[7] Calibrating Variation in Domestic Midden Assemblages among Aztec Period Households in Western Morelos
Archaeologists and geographers calibrate the flow of commodities among households and settlements to infer patterns of production, consumption, economic function, and social class. Michael Smith and his colleagues developed sophisticated measurements of wealth and social class using residential architecture attributes and domestic artifact assemblage diversity from excavations at three Aztec Period sites in Morelos. Here, data from over 4,000 surface collection units in eight Aztec Period sites in the Coatlán del Rio Valley, Western Morelos, are partitioned into over 300 domestic middens. Collections are from plowed fields without direct surface evidence of house foundations, and were generated by occupants from a variety of household sizes, ranging from single, isolated houses to patio complexes with as many as five or six structures. I use 38 ceramic vessel classes, 15 stone tool classes, spindle whorls, and figurines to measure the flow of ceramics and lithics among households, identify artifact suites that likely correlate with economic functions, and infer stone tool and textile production localities. I compare patterns in the Coatlán data to those discussed by Smith and others at the excavated sites of Capilco, Cuxexomate, and Yautepex to expand their interpretations regarding Aztec Period social and economic organization in Morelos.

[83] Revealing La Milpa: Integrating Residential Data from the Core and Periphery
The programme for Belize Archaeological Project represents a regional research program aimed at elucidating the nature of Maya political, social, and economic integration within the northeastern Petén. Toward this end, extensive research is being undertaken at the primary center of La Milpa. Research conducted by the authors has been motivated by numerous objectives. Of specific interest is understanding the role of La Milpa within the changing political landscape of the region. In addition, our research examines the degree to which social status affects both economic and ideological activities at the courtyard level. To address these questions, we draw upon a large corpus of residential data collected over the past 25 years. We integrate an intensive analysis of elite lineages within the La Milpa core with an extensive examination of residential space throughout the periphery. Contrary to original interpretations, our results suggest that La Milpa was home to an entrenched elite class as early as the Late Preclassic. Consequently, we propose a revised model of political growth and power. Furthermore, we revisit population estimates for La Milpa and examine the extent to which status affected differential economic and ideological activities across the social hierarchy.

[290] Regional Variability in Stable Isotope Food-Web Baselines and Sex-Based Differences in Diet: An Example from Early Agriculturists in Southeastern Utah
This paper provides an isotope-ecology context for Cedar Mesa, Utah, by presenting isotope data on over 400 modern botanical and archaeo-faunal specimens from the area. While carbon data fit with regional expectations, nitrogen isotope ratios throughout the Cedar Mesa food-web show depletion in 15N relative to other ecosystems in the intermountain west—consistent with nitrogen inputs from cbtypodic soil crusts. In light of this localized isotope baseline, we reassess previously published isotope studies of Basketmaker II (BMII) burials by comparing modeled whole-diet isotope ratios with the feasible diet polygon (e.g., convex hull) defined by local resources. Implications for translating sex-based differences in BMII bone chemistry into engendered subsistence strategies are also discussed.

[193] How Do Hunter-Gatherer Children Learn to Make Material Culture? a Meta-Ethnographic Review
This poster aims to extrapolate forager-wide trends in how, when, and from whom hunter-gatherer children learn to produce material culture. We use a meta-ethnographic approach, which allows for the systematic extraction, synthesis, and comparison of quantitative and qualitative publications. We extracted a total of eleven publications from psychology, cultural anthropology, and ethnarchaeology, including studies on the Bakas, Aka, San, Kaitetye, Gidra, Pentan, Batek, Khany, Cree and Sioux. Our findings suggest that, cross-culturally, forager children learn to make simple tools effectively by middle childhood, but continue to learn and perfect the skills of complex, multicomponent tool manufacture well into adulthood. From infancy, adults make models of tools like bows, arrows, and digging sticks to give children, from which they are expected during early and middle childhood to reverse engineer their own small tools. During middle childhood, the playgroup is especially important, creating miniature camps complete with hearths and dwellings. As they enter later childhood and adolescence, children begin to receive their first direct instruction on the production of complex material culture like basketry, sledges, or skis. These findings suggest that children create and contribute to material culture in vital ways that archaeologists often fail to consider.

Li, Jiawei (School of Life Science, Jilin University), Ye Zhang (School of Life Science, Jilin University), Xiyuan Wu (School of Life Science, Jilin University), Yongbin Zhao (College of Life Science, Jilin Normal University) and Hui Zhou (School of Life Science, Jilin University)

The genetic diversity of the ancient Mongols, especially the Gold family of Genghis Khan remains unclear. Gangga site was a nomadic site dated to the eighth to tenth centuries AD in the HulunBuir grassland, northeast China. This site belonged to the Shiwei population, believed to be the direct ancestors of the ancient Mongols. Nine graves at the Gangga site were excavated with log coffins, which were considered the characteristic burial custom of the royal ancient Mongols, included the Gold family of Genghis Khan. This suggested the Gangga people had a close relationship with the royal ancient Mongols. In this study, mitochondrial and Y-chromosome aDNA were extracted to analyze the genetic structure of the Shiwei population at the Gangga site. Haplogroups D, F, C, B, G, N9a were typed in the mtDNA. Haplogroup C-M130 was detected in Y-chromosome aDNA. Gangga people exhibited a high frequency of Haplogroup C-F3918 (belonging to C3*), indicating it may be the main Y-haplogroup in the Shiwei population. In addition, all Gangga
males buried in log coffins exhibited C-F3918 suggesting that C-F3918 might be the characteristic Y-chromosome haplogroup of the royal ancient Mongols.

**Taming the Flood: Religious Response to Climatic Crisis and the Cult of the Great Yu in Early China**

This paper deals with changes in religious practices during a period when ‘Nature’ is least stable in early China. It focuses on the rapid spread of new ritual practices and emergence of new ritual networks during the Longshan period (ca. 2300–1800 BCE) as evidence for religious responses to the extraordinary climatic crisis of the late third millennium BCE. It explores the diverse manifestations of the ecological crisis in geomorphological evidence and their implications for a changing perception of ‘Nature’ in the Longshan society. The choices of sacred places and ritual forms used for prehistoric ritual engagements with the violent forces of nature reveal that the legacy of the Longshan religious tradition had significant contribution to the emergence of the cult of the Great Yu in early China.

**At the Margin of a World System: Cultural Histories between the Eurasian Steppe and Northwest China**

After 4000 BC, prehistoric populations in southern Kazakhstan and the western side of the Ural regions in Central Asia began to migrate toward southwestern Siberia. At the same time, Yangshao culture began to spread, and the scale of their expansion toward the northwest was the greatest. The causes are likely multifold. Firstly, the emergence of agriculture in Holocene led to the increases in population pressure. Secondly, the arrival of the Copper Age increased the demand for metals such as copper and gold. The latter may also have been a significant cause for the appearance of new metallurgy exchange spheres to the west of the Ural regions. These large-scale population migrations had a long lasting impact on the prehistoric cultures of southwestern Siberia and Xinjiang. The exchanges between the painted pottery-agriculture of the east and the pressure stamped pottery, animal husbandry of the north stimulated the formation of early East-West interaction pathway. This was an important pathway for cultural and trade exchanges between the East and the West. Here, I will name it the proto-Silk Road. This wide road greatly initiated the complexity of prehistoric societies in China, and laid down the earliest foundations for what is known as the Silk Road today.

**Reconstructions of 8N-11 and Reforms of Late Classic Copan**

8N-11 is a sub-royal elite residential compound located at the end of the eastern causeway (sac be) in the densely settled Las Sepulturas zone about 850 m from the Copan Main Group. Monumental architecture, carving style and representations of figures with royal attributes demonstrate the high status that residents of the 8N-11 enjoyed in Copan society. In collaboration with the Honduran Institute of Anthropology and History and the Anthropology Department of Harvard University, Project IACASS (Institute of Archaeology, of Chinese Academy of Social Sciences), started field work at the group in 2015, aiming a comprehensive culture history of the people who lived here. Construction sequence (four phases) documented to date shows the social, economic and ideological evolution of the group in consonance with the development of the royal family in the city core, especially during the reigns of 11–16 dynasties. Themes restricted to the royal court were conveyed early in architectural sculpture at 8N-11.

**Casting Metals for the Qin First Emperor and His Underground Empire**

Among the most spectacular finds at the Mausoleum of China’s First Emperor (259–10 BC) are the Terracotta Army built to protect him in the afterlife, and the two sets bronze chariots designed and buried to facilitate his travel in his underground empire. Thousands of terracotta warriors are equipped with casting bronze weapons, including swords, lances, halberds, spears, crossbows, and arrows, and the quality and quality of bronze weaponry provide an extremely rare opportunity to investigate patterns of standardization and labor organization of bronze production within such a context. In addition, the bronze chariots comprise 4,000 parts assembled together, including numerous cast gold and silver ornaments that offer information about knowledge of transfer, technological changes, and cultural identity, particularly when compared to the forging, filigree, and granulation used to produce early Qin gold objects (techniques assumed to derive from Western influences). The casting technique employed here seems more consistent with an indigenous tradition manifest in cast weapons and ritual bronze produced for centuries in the central plains of China. This presentation will show the research results from combining compositional, microscopic, statistical, and spatial analysis, to investigate the human behavior, imperial logistics, and cultural interaction behind the metal production for the Qin First Emperor and his afterlife.

**A New Variability of Cobble-Tool Industry Associated with a Bone Tool Technology from the Luobi Cave, South China (Ca.11–10 Ka): A Comparative Perspective from Southeast Asia**

The characterization of Paleolithic culture in South China and their relationship with mainland Southeast Asia remains ill-defined and unclearly known. The lithic industry of South China has been characterized as simple “cobble-tool” industry persisting from early Pleistocene to Holocene and the most representative industry of Southeast Asia was also marked by pebble-tool techno-complex termed Hoabinhian during late Pleistocene-early Holocene. The possible cultural link of the two regions was proposed by some scholars but the technological characteristics and variability within the two industries was elusive. In this research we conducted technological analysis on a “cobble-tool” industry associated with a bone tool technology from the Luobi Cave, Hainan Island, dated to ca. 11–10 ka and compared it with a well-studied typical Hoabinhian of Laang Spean in Cambodia. The major difference of two has rejected the Luobi Cave as a potential Hoabinhian site, indicating a high originality and a new variability in the tool kit of modern human groups during late Pleistocene-early Holocene transition in South China and Southeast Asia. This study represents the first step toward deciphering the cultural variability in this region from a technological view and suggests that behavioral modernity and cultural variability should be evaluated in regional and subregional scale.

Li, Yiping (Research Center for Chinese Frontier Archaeology, Jilin University)

**Social Difference between Songze Culture and Liangzhu Culture as Reflected on Jade Artifacts**

The Liangzhu Culture (3300–2000 BC) and the Songze Culture (4000–3300 BC) are two Neo-olithic cultures in the lower Yangtze River Delta in China. The two cultures are quite similar in many aspects especially those reflected on ceramics. This research intends to study the difference of social hierarchy between two cultures through an analysis of jades collected from over 20 archaeological sites in the Lake Tai region. By doing so, it is argued that jades in the Songze Culture are precious materials and are seen as symbols of wealth; and in the Liangzhu Culture, jades become sacred and are more exclusively accessible to the ruling class.
Li, Yue (School of Cultural Heritage, Northwest University), Yue You (School of History, Capital Normal University), Yiting Liu (Department of Archaeology, Graduate School of Chi), Nuo Xu (Xi’an Museum) and Jianxin Wang (School of Cultural Heritage, Northwest University) [116] Abnormalities of Horse Vertebrae from Xigou Site and Shirenzigou Site in Xinjiang
This research examines seven horse skeletons unearthed from the burials and sacrificial pits of the late Warring States Period to the early Western Han Dynasty at the Shirenzigou and Xigou sites in Xinjiang. Vertebrae were observed for lesions such as hyperostosis, asymmetry, spinal fusion, horizontal fractures on epiphyses, and dorsal inter-pressing or joining of the vertebrae. Because the abnormalities are similar to those identified as the result of horseback riding in archaeological research outside China, as well as in veterinary medicine and osteology, their presence here is highly suggestive of human use for riding. This is consistent with saddles found in other sites and petroglyphs near the Shirenzigou and Xigou sites that show riding scenes, providing additional clues for the appearance of horseback riding during the late Warring States and early Western Han in Xinjiang.

Lian, Huiru, Dorian Q. Fuller and Yijie Zhuang [78] A Glimpse of Rice Exploitation at Mojaoshan Site, Liangzhu Culture: Archaeobotany and Rice Charring Experiment
Located at the Lower Yangtze River, China, Mojaoshan Site is a “palace” and center of Liangzhu Culture. On the edge of the Mojaoshan platform, a waste accumulation of rice (H11) was found in recent years. Based on the archaeobotanical remains from this accumulation, this paper tries to preliminarily discuss the rice exploitation at Mojaoshan Site. By conducting a charring experiment aiming to distinguish the rice broken before charring from rice broken after charring, the research tried to identify rice-processing stages in the charred materials. The result shows that most rice recovered from Mojaoshan site was rice charred with husk (Oryza sativa Subsp. Japonica Temperate japonica group [syn. Sinica]) and Liangzhgu people were likely to adopt an early harvesting strategy to optimize the yield of rice. Also, rice in Mojaoshan site was threshed, winnowed, sieved and stored under a clean state. The exploitation of rice provides a solid foundation for the development of Liangzhu culture and also reflects the highly complexity of Liangzhu Culture.

Liebmann, Matt (Harvard University) [34] Movement Encased in Stone: Revealing Ancestral Jemez Migration through Obsidian Source Provenience
Based on the results of collaborative research performed in conjunction with the Pueblo of Jemez, this paper uses a pXRF study of 2222 obsidian artifacts from 29 Ancestral Puebloan villages in northern New Mexico to provide insights into Jemez movement between AD 1175–1700. The results reveal clear evidence of migration between these villages and the Valles Caldera. These movements steadily increased in intensity throughout the precolonial period. This pattern was disrupted by Spanish colonialism in the seventeenth century, only to be reestablished following the famous Pueblo Revolt of 1680. This paper explores the complex factors underlying these shifting patterns of obsidian procurement, and concludes that they were apparently linked to larger intertribal hostilities and alliances during the tumultuous first century of colonization in the Pueblo world.

Lieskovsky, Tibor (Faculty of Civil Engineering, Slovak University of Technology in Bratislava), Milan Kovac (Department of Religious Studies, Faculty of Philo) and Tomas Drapela [131] Usability of Lidar Data for Archaeological Survey in the Uaxactun Area, North Petén, Guatemala
The paper deals with validation and quality estimation of spatial data acquired in the focus area of the project “Proyecto arqueologico regional—Uaxactun” as a part of a LIDAR project supported by the PACUNAM. The project has two high-quality 3D models of the Preclassic city of Uaxactun and the site of Dos Torres acquired by detailed topographical survey of the focus area at its disposal. The DEMs serve as basis for the evaluation of spatial accuracy of the lidar DSM and an etalon for calibration of filtration methods. To evaluate the ability of lidar data to identify archaeological structures, we will use data acquired by pedestrian survey realized in the course of the project in seasons 2009–2016 and also data from previous surveys (Acevedo 2012; Puleston 1983). The result will be a definition of the abilities and limitations of current LIDAR data in the focus area.

Lieverse, Angela (University of Saskatchewan), Samantha Purchase-Manchester (University of Saskatchewan), Andrzej Weber (University of Alberta) and Vladimir Ivanovich Bazaliiskii (Irkutsk State University) [330] A Novel Examination of Infection among Middle Holocene Hunter-Fisher-Gatherers of the Cis-Baikal, Siberia
This research uses novel methods to investigate infection—specifically sinustis, otitis, and mastoiditis—and better understand physiological stress and lifeways among middle Holocene hunter-fisher-gatherers from Siberia’s Cis-Baikal region. Two hundred and fifty individuals from three cemeteries are examined, together representing two distinct biocultural periods (Early Neolithic [EN], 8000–7000/6800 BP, and Late Neolithic–Early Bronze Age [LN–EBA], 6000/5800–3400 BP) and two micro-regions (South Baikal and the Angara River Valley). An endoscope was used to document sinustis and otitis, and a handheld digital X-ray system was used for mastoiditis. Sinustis was present in over two-thirds of observed individuals (70.6%), while otitis and mastoiditis (considered together) were found to be nearly ubiquitous (99.4%). The frequency of sinustis decreased significantly from the EN to the LN–EBA, being consistent with the results of previous research on physiological stress. On the other hand, it did not appear to reflect differences in occupational phases (for the cemetery of Shamanka II, only), sex, or age at death. These new approaches to examining infection have expanded our understanding of past hunter-fisher-gatherer lifeways in the middle Holocene Cis-Baikal and have opened the door for their use at other sites.

Lim, Sangtaek (Pusan National University) [24] Beyond Activity Areas, Beyond Burial Spaces: Islands as a Monumental Place for Coastal Foragers
Coastal foragers of southern Korean Chulmun period had actively exploited marine resources from the initial phase (6000–4500 BCE), and they also have a complex network with groups of Japanese Kyushu Island from that time. Researchers usually have thought that islands served as economic patches for coastal foragers with large numbers of shell mounds. However, based on several burial sites recently excavated at some islands like gadeok, Yeondae, Yokji, we now need to reconsider islands as being just resource patches. We have to shift our view of islands fundamentally—not just as a materialistic “space” for resource exploitation or burials but as an empirical “places” for rituals, memories, living activities and so on for foragers. In
doing so, islands acquired meaning of “spaceness” of their own, which can be connected with monumental characteristics of islands. Islands are monumental places for coastal foragers of Korean Chulmun period and economic, ritual practices, including resource exploitation and burial making, all of which enhanced the “spaceness” of islands.

Lin, Kuei-chen (Institute of History and Philology, Academia Sinica) [213] 
Standardization in Pottery Production of the Jinsha Site, Chengdu Plain, China
In earlier studies, scholars have focused on the measurement of vessels’ dimensions to assess the degree of standardization. It should be noted however that not all dimensions are culturally salient or equally important. Moreover, when manufacturing processes can be decomposed into multiple stages, cultural idioms are characterized by being either institutionalized or unconscious ways might affect and be sought in any of these stages. This has called for analyses on ceramics by using different scientific strategies. Through testing the dimensional measurements and mineral compositions of several vessel types that were popular in the Jinsha site (ca. 1200–650 BC), it appears that their degrees of standardization, though vary with both loci and phases, are generally greater than vessels found in other sites at the outskirts. The spatial pattern of the pottery kilns unearthed in this early urban center, Jinsha, might be a key to the formation of consensus. I suggest that the production scale should lie between households and workshops, in which kilns were close but meanwhile were spaced by buildings or other features such that they can be loosely bonded. Such manner of production organization might also reveal the pattern plural social groups co-resided in Jinsha.

Modeling the Effects of Knapper Decision-Making and Social Learning on Flake Assemblage Variability
Paleolithic archaeologists are keen to infer the means by which flintknapping knowledge was acquired and transmitted among past toolmakers from lithic assemblages. The inferences generated from recent studies, which tackle this issue with a variety of analytical approaches, are often fraught with equifinality because the same range of lithic variability can be explained by multiple learning scenarios. To help address this issue, we examine the extent to which different knapper decision-making processes result in recognizably different lithic assemblages. Our agent-based model simulates the formation of a flake assemblage over a range of knapping options, with each option marked by variable parameters of flake size, utility, and failure risk. The decision-making process for choosing the desired knapping option at each time step is set to resemble that expected under either emulation (copying the final form) or imitation (copying the production steps). Results indicate that an imitative decision-making process can achieve higher rates of successful flake production than an emulative process when the assessment error of the available knapping options is large. The findings help connect emergent properties of a lithic assemblage to different forms of knapper decision-making, with implications for inferring past social learning mechanisms from the stone artifact record.

Trace Metals in Soils as Indicators of Past Human Activities at Hanwangdu East, Anyang, China
Through chemical analyses of soils, bones, and organic residues, archaeologists can identify anthropogenic impacts on environment at archaeological sites. In this research, we are interested in understanding if and how bronze production had impact on the environment during Bronze Age China. Soil samples from Hanwangdu East, a Middle Shang period site at Anyang, were analyzed by using inductively coupled plasma mass spectrometry (ICP-MS). The purpose of this project is to 1) evaluate if ICP-MS is a proper method to analyse soil samples regarding of soil-metal concentration; 2) compare soil samples from different contexts, such as ash pits, water wells, canals, and house structures, of the same time period, and samples from features of different time period to identify anthropogenic influence on soil-metal concentration related to bronze production. We expect to see different geochemical signals in the soil depending on the various contexts of this site. We hope to gain a better understanding of the anthropogenic and natural soil properties at Anyang, especially during the Middle Shang period.

Lindeman, Michael (Desert Archaeology) and Henry Wallace [335] 
Ancestral Ties during a Period of Social Upheaval: An Example from the Early Classic Period in the Tucson Basin
The transition to the early Classic Period (ca. AD 1100–1300) in the Tucson Basin has its roots in the disintegration of long-lived Preclassic Period (ca. AD 500–1100) villages in the eleventh century. The breakup of these villages engendered a variety of responses among the constituent social groups including the use of ancestral ties to place, real or constructed, to stake claims to land. Early Classic period settlement at the site of AA:12:46 begins during the fluid period immediately following the breakup of the Preclassic villages. During the twelfth century a corporate group made up of three households settled at the site. The choice of location was not random with the households building within the confines of a plaza of a short-lived village abandoned 400 years before. The new inhabitants made an overt display of their connection to ancestors and place. We suggest that this was important amid the social tensions of the twelfth century to establish rights to the adjacent floodplain farmlands and the water needed to irrigate their crops. While AA:12:46 is a good example of this process in the Hohokam region, other instances of Classic Period construction in Preclassic plazas are considered here.

Lindquist, Shayna (University of Kentucky) [320] 
Intraregional Variation in the Obsidian Industry of the Eastern Lower Papaloapan Basin of Mexico
The Tres Zapotes regional systematic survey, conducted from 2014–2016, yielded an obsidian assemblage spanning across the Formative and into a Postclassic occupation. Furthermore, similarities and differences in technology and sources utilized were observed within the RRATZ assemblage, facilitating an examination into the intraregional variation in obsidian artifact production and use. In addition, one unusual artifact type was recovered that may reflect specialized scraping activities and that were perhaps lowland-centric. The scraper artifact possibly models a highland type that is generally
attributed to maguey processing; however, the maguey plant is rare in the lowlands and the typology differs considerably in other respects as well, suggesting the scraper may have been used for processing another material, such as ixtle. This paper thus will provide a preliminary analysis of variation in the RRATZ obsidian assemblage and further investigate the potential of a lowland-centric scraper artifact within the regional polity.

Lindstroem, Gunvor (German Archaeological Institute) [221] Torbulok: A Sanctuary in the Hellenistic Far East

A sanctuary of the Hellenistic period was recently discovered at the village of Torbulok in southwest Tajikistan. Its discovery was based on a random find of a large limestone vessel, identified as a perirrhanterion—a vessel for Greek purification rituals. The excavations, started in 2013 by a German-Tajik team, gave insights into the structure of the sanctuary and confirmed the dating to the third and second century BC, as Bactria was part of the Hellenistic world. The unearthed installations and objects show the performed rituals were inspired not only by Greek customs—as the purification ritual—but also by local traditions, with a high importance of water and ashes. The site seems to have functioned as a pilgrim sanctuary, associated to an ancient settlement at distance of ca. 30 km.

Linford, Samantha (University of Colorado Boulder) [390] Ceramic Sociology Revisited: Ceramic Design Analysis in the Sand Canyon Locality

Tracing complicated social links such as kinship through the material record has fallen in and out of favor in anthropological discourse. The ceramic sociologists of the 1960s and 1970s (Hill 1966; Longacre 1970) focused on tracking kinship through spatial patterning of ceramic designs among Pueblo sites in the American Southwest. The concept of ceramic sociology sparked many critiques within archaeology (Allen and Richardson 1971). These critiques were tied to a need for better understanding of formation processes, proper and accurate classifications of ceramic designs and the degree to which social organization such as, kinship can be identified. The issues raised by the ceramic sociologists are important and deserve a solution, or at the very least a conversation. Kinship studies in anthropology have reemerged allowing this research to address the critiques previously leveled at ceramic sociologists. Analyzing style data from ceramics at the Sand Canyon locality in southwest Colorado, the issue of proper and accurate classifications of ceramic design are revisited in the application of the conceptual metaphor theory. Formation processes and kinship construction are addressed through ethnographic and linguistics studies providing a reworked commentary on material culture patterns correlated to kinship relations.

Ling, Johan and Per Cornell (Department of Historical Studies: University of Go) [28] Rock Art, Warfare, and Long-Distance Trade

For most of the twentieth century the Bronze Age rock art in Southern Scandinavia has been seen as a manifestation of an agrarian “cultic” ideology in the landscape. In this context the dominant ship image and the armed humans have been perceived as abstract religious icons, not as active symbols relating to real praxis in the landscape. While violence and war related social and ritual traits indeed are common features in the Scandinavian rock art from the Bronze Age and the violence on the rocks is uncanny. It is, beyond any doubt, a dimension of rock art that we cannot deny or be blind to. The rock art appears at the same time as Scandinavian societies became engaged in long distance trade of metal and local warriors would have increasingly from the Bronze Age and the violence on the rocks is uncanny. It is, beyond any doubt, a dimension of rock art that we cannot deny or be blind to. The rock art appears at the same time as Scandinavian societies became engaged in long distance trade of metal and local warriors would have increasingly played an important role. Elite households investment in the maritime forces of production, ships and warriors, was therefore a crucial feature for engagement in this kind of action. This would have favored the rise of maritime polities in Scandinavia. In this paper, I argue for the notion that the praxis of carving ships onto the stone could have served to manifest the agency of the maritime warriors.

Lingle, Ashley (Cardiff University) [73] Reflexive Conservation Research at Çatalhöyük

Çatalhöyük, like many earthen sites, is a complex exercise in preservation. Since it was first excavated in the 1960s there have been efforts to preserve the archaeological substrate. A significant part of this program was the application of aqueous polymer systems applied as a consolidant to the plaster and mud brick surfaces. This practice of attempting to strength walls by polymerization was reviewed by means of laboratory testing in the 1990s, and continued to some extent unchallenged for the following 20 years. In recent years, however, it became necessary to revise the suitability of this polymer system. As the aims for stabilization shifted from temporary to long-term display, and site monitoring improved, specific deterioration patterns emerged which correlated with failure of the polymer rather than deterioration of the archaeological substrate. This dilemma provided an interesting opportunity to review the practice, and challenge the adequacy of a methodology that is not unique to Çatalhöyük. To achieve this Fourier Transform Infrared microspectroscopy was coupled with a holistic study of the environment at the site. As a result, a new interpretation of the performance of polymer systems within the archaeological substrate allows for a more informed conservation practice in the future.

Linn, Meredith (Barnard College) [74] “Irish Fever”: How the Intersection of Ethnicity, Class, and Typhus Fever Created an Epidemic of Prejudice in Nineteenth-Century NYC

During the height of the Great Hunger in Ireland in the late 1840s, epidemic typhus fever infected thousands aboard emigrant ships destined for New York City. Suddenly, a disease that had long been known as “jail-fever” or “ship-fever” became the “Irish fever.” It was no longer associated with a place, but with a people. This paper will explain why (for many Americans) the intersection between typhus fever and the bodies of rural Irish laborers created a new disease, one they used to naturalize and expand previous ideas of Irish racial difference. It will use the archaeological record to interpret how immigrants attempted to heal themselves and to destabilize stereotypical caricatures of “Pat” and “Bridget.” In doing so, this study will employ intersectionality theory beyond its original emphasis on the intersection between gender and other identities (although gender has important roles in this study too). It aims to draw greater attention to the importance of both the social construction of medical knowledge and particular illness status in the lives of immigrants and in the development of racial and ethnic categories.
Costly Gobbling: Raising Turkeys in the Central Mesa Verde Area

In the Central Mesa Verde (CMV) area of the Southwest, turkey bones increased markedly relative to those of artiodactyls in sites of the late AD 1100s and 1200s. We present an exploratory model of the proportional contribution of turkeys, artiodactyls, and small mammals to the animal protein component of the diet. Assuming a demand of 5 to 10 g of animal protein/person/day, we estimate that more than half that demand was met by turkeys in the mid-1200s. Both turkeys and humans relied heavily on maize; raising a “food turkey” would have annually required a third as much maize as would an adult human. Depending on turkeys for animal protein may have created a “rigidity trap.” High population and aggregation led to wild game depletion. Continued population growth promoted more dependence on turkeys, requiring even more reliance on maize (and fresh water sources) in a CMV subsistence economy based on dry farming. The Northern Rio Grande (NRG) received substantial migrations from the CMV in the late 1200s. Although turkeys became more important in the NRG after AD 1250, our model indicates artiodactyls continued to supply the majority of animal protein there.

Lipe, William [142] see Matson, R.G.

Spatial Association between Rapa Nui (Easter Island) Ahu and Freshwater Sources

The famous ahu and moai monuments of Rapa Nui (Easter Island, Chile) are features associated with multiple relatively small-scale communities distributed around the island. These communities are marked archaeologically by repeated sets of domestic architectural classes surrounding ceremonial features (i.e., ahu and moai) that potentially served to functionally integrate local populations. Described in this fashion, this settlement pattern offers the potential to explain the substantial investments in monuments using a multilevel and signaling based evolutionary framework. Such an explanation, however, requires the identification of the set of resources over which individuals compete as well as share. Here, we suggest that freshwater may have played a critical role in the formation and functioning on prehistoric Rapa Nui communities. We demonstrate this potential by examining the varying spatial association of a number of archaeological features with the location of freshwater. We argue that freshwater resources were a key factor leading to the structure of prehistoric communities and the unprecedented level of cultural elaboration on this tiny and remote island.

Cerámica mayólica en un sitio posclásico del Valle intermontano de Maltrata, Veracruz

El valle de Maltrata, enclavado en la Sierra Madre Oriental, al centro-oeste del estado de Veracruz, ha tenido una remota y continua ocupación humana, que data desde la época prehispánica hasta nuestros días. Este valle es importante por formar parte de una de las principales rutas de comunicación y comercio entre la Costa del Golfo y el Altiplano Central, con evidencias olmecas, zapotecas, Teotihuacáncas, cholultecas, aztecas. El asentamiento del periodo Posclásico, ocupó principalmente la parte central del valle, donde se encontró gran cantidad de fragmentos de cerámica mayólica, colonial y prehispánica. Se identificaron diversos tipos de cerámica mayólica de los siglos XVI–XIX en el recorrido sistemático de superficie. Aquí veremos cómo se distribuyó la población hispana con base en la cerámica mayólica, profundizando en la relación hispana-indígena en los años después de la conquista y, durante la época Colonial, desde la arqueología histórica. El trabajo es relevante pues no hay estudios sobre cerámica mayólica en la región de las grandes montañas del centro de Veracruz. Los materiales recuperados por el proyecto “Arqueología del valle de Maltrata, Veracruz” (Instituto de Antropología, Universidad Veracruzana e Instituto de Investigaciones Antropológicas-UNAM) continúan aportando valiosa información para la reconstrucción de la historia prehispánica y poshispánica.

Remote-Sensing Prospection of Recuay Architecture in the Jancu Region, Calllejón de Huaylas, Peru

The Recuay tomb of Jancu has contributed significantly to our understanding of Recuay mortuary practices and ancestral veneration. This subterranean tomb, which housed the remains of several elite individuals and finely crafted offerings, is typically discussed in isolation from its broader context. To date, no formal archaeological research has been conducted in the surrounding region, but recent preliminary surveys by the authors revealed numerous Recuay and Post-Recuay residential and funerary structures. Due to the relative inaccessibility of the region, remote-sensing technology offers a feasible alternative to pedestrian surveys as a method to characterize the distribution of prehispanic architecture in the area. As a preliminary
step in elucidating the sociopolitical context of the Jancu elite tomb, this study aims 1) to identify extant architecture near Jancu, and 2) to test the utility of widely accessible remote sensing options (low-resolution aerial photographs, Google Earth imagery, and Landsat IV satellite imagery) in an alpine environment. The results of this study will be tested during planned fieldwork in summer 2017, contributing both to refining the interpretations of mortuary practices and its ties to territoriality and ancestral veneration during the Recuay occupation of Jancu and to improving methodologies for archaeological survey in remote alpine environments.

Litteral, Matthew (University of South Florida)

More Than a Pair of Hands: The Education and Rights of Local Field-Workers

The archaeologist abroad must be held responsible for the fair treatment of his/her locally sourced workers. Fair treatment should go beyond providing a pay check comparable to standards in the United States. Archaeologists should feel ethically obligated to provide a wealth of knowledge to local field-workers. There remains much inconsistency in adherence to SAA principles of ethics. Particularly principles 2 and 4, as they relate to the accountability to local peoples and comment to public education. In recent years, archaeology has made great strides in the realm of community outreach. Nevertheless, the rights and education of local field-workers are still frequently overlooked. Educating locally sourced workers is often far from being the top priority of the archaeologist abroad. What is uncovered through fieldwork is, first and foremost, the heritage of the community. Ensuring that the community is informed should be a primary goal of archaeologists, not only due to ethical concerns, but because the local population is an invaluable resource. In this paper, I present data on the prevalence of proposed local education components in U.S.-funded archaeology projects abroad. I then propose methods which may be employed for effectively informing locally sourced workers.

Liu, Chin-hsin (California State University Northridge), Adam Lauer (International Archaeological Research Institute, I), Stephen Acabado (Department of Anthropology, University of California), Katherine E. Quitmyer (Department of Anthropology, University of Florida) and John Krigbaum (Department of Anthropology, University of Florida)

Faunal Management and Human-Landscape Interactions at Ifugao, Luzon, Philippines

One major contribution of the Ifugao Archaeological Project in the northern Philippines (Luzon) is associating the origins of the Ifugao wet-rice terrace complex with local resistance against Spanish colonial expansion. With the establishment of wet-rice agriculture in the highlands by the early seventeenth century, it is anticipated that the acquisition and management of fauna would have been modified to adapt to new strategies of crop production. In this context, it is hypothesized that changes in faunal diet over time would serve as a proxy to landscape change and animal management. For this study, identified faunal remains representing four taxa (43 teeth and 29 bones) recovered from Old Kucapungane Village are analyzed for light stable isotopes. Bone samples processed to data demonstrate good collagen yields and interesting patterns that reflect anthropogenic input. For example, carbon isotope ratios for Sus are very heterogeneous (in contrast to sampled bovines and deer), a pattern that supports the expectation that some individuals were opportunistic and/or refuse feeders most likely associated with human habitation. Isotopic data for sampled fauna are presented and discussed in light of the occupation of Old Kuyangan Village, and animal management in the context of Spanish colonial impact and local resistance.

Liu, Chung Yu (Department of Anthropology, National Taiwan University)

Settlement Configuration and Social Structure: Applying Spatial Comparative Analysis in Old-Kucapungane

This article aims to examine the differences of social structure revealed 1) by the interpretations of the archaeological record through spatial analysis and, and 2) by the data obtained through ethnographic research, both for same ethnic group. Applications of spatial technologies in archaeology began in the early 1980s. Although these GIS-based technologies brought about new research perspectives, their ‘effectiveness’ and ‘correctness’ needs more in-depth investigations. Using Old-Kucapungane as a case study, this research compares the social structure reconstructed through space syntax, and the social structure observed from ethnography. Old-Kucapungane is an abandoned slate house settlement in Taiwan. The Kucapungane people lived in the settlement for the past 600–700 years. However, they were forced to move out 50 years ago due to government policies. Nonetheless, since they abandoned Old-Kucapungane relatively recently, a small amount of the current population still has memories of how living in the settlement was. This inevitably makes Old-Kucapungane a perfect example for a comparative study between archaeology and ethnography. The results of this research will be tested during planned fieldwork in summer 2017, contributing both to refining the interpretations of mortuary input. For example, carbon isotope ratios for Sus are very heterogeneous (in contrast to sampled bovines and deer), a pattern that supports the expectation that some individuals were opportunistic and/or refuse feeders most likely associated with human habitation. Isotopic data for sampled fauna are presented and discussed in light of the occupation of Old Kuyangan Village, and animal management in the context of Spanish colonial impact and local resistance.

The Use of Chenopodium Plants in China

This article reviews the use of Chenopodium plants in Chinese archaeobotanical record. We will draw attention to two regions particularly, Northeast and Southwest China. We will consider the use of Chenopodium food in the context of origins of agriculture in China.

Liu, Yu, Jigen Tang (Professor) and Jianyu Liu (Dr.)

Pursuing the Mineral Sources of Yinxu Bronze Objects (13th–11th BC): Study on the Lead Ingots from Anyang, China

The bronze objects played a more significant role in the formation of Chinese ancient civilization than any other early civilizations, especially in late Shang and Western Zhou dynasty (13th–11th BC). So far more than 2,000 bronze vessels and thousands of other type bronze objects were excavated from Yinxu, the capital of late Shang dynasty (13th–11th BC), located in Anyang, Henan province. The discussion of the mineral sources of Yinxu bronze objects last a long time because of rare ingot found in Anyang. Recently 300 pieces of lead ingots excavated from Anyang provide some new clues to solve the problem. Through Metalloscope observation, SEM-EDS and ICP-MS analysis of 12 ingot samples, the composition, microstructure, trace elements, and lead isotope data were analyzed. The results show that the ingots are not pure lead but lead-copper alloy. The lead isotopes data belongs to “ordinary common lead,” and is very close to those data from bronze objects or slags of the 4th phase of Yinxu period, which implies that the bronzes mineral source were probably from the same lead ore at that time, and the “highly radioactive lead” data probably indicates not the lead ore but the copper ore, such as Tongkuangyu in Zhongliaoshan zone.

Livesay, Alison (University of Oklahoma)

Exploring Mimbres Social Memory through Burials and Architecture

Social memory has become a topic of increasing investigation in the field of archaeology. While social memory in archaeology can often be very theoretical and abstract, it can also be very tangible and concrete in its archaeological manifestations. In this poster, I illustrate various social memory practices with specific emphasis on the reference process, strengths of associations, and intimacy past peoples had with their history as observed in
The late 1980s and 1990s saw an explosion of landscape studies in archaeology. The notion of landscape was herald as a “usefully ambiguous concept” that allowed archaeologists to connect material evidences with sought out narratives. The following paper is meant as a work in progress where I try to uncover the essential components that make up an archaeological approach to the study of landscape. The orientation I proffer calls for an approach that is analytical in spirit, and that most likely resembles an act of bricolage. It does not seek out the pursuit of the next theoretical concept but instead concerns itself with what characterizes a landscape archaeology study.

Ljungkvist, John (Uppsala University) [15]

Centuries of Warrior Boat Graves: The Valsgärde Burial Ground

The Valsgärde burial ground is one of key sites for the Viking phenomenon project. This burial site was used for more than 1,000 years. It is the best preserved and the only “entirely” excavated boat grave site in Sweden. Here we can follow the changing burial rites and interactions with the world during the first millennia AD. Valsgärde has been seen as a place where an unbroken series of male elite individuals were buried for nearly eight centuries. However, detailed studies of all burials, both inhumation and cremations, reveal that use and role of the site has undergone major changes. The composition of burials stretch from a wide variety of status, gender and age variation in the seventh century, to only rich female and male burials of the ninth/tenth century, to exclusively rich male burials during the major Christianization phase in the eleventh century. This place evidently became important to maintain an elite community’s presence and history in the landscape, in this case primarily warriors buried in chambers and boats. In some phases are burials disappearing, but they eventually reappear and thus are the history the site and the warriors ancestry maintained.

Llobera, Marcos [158]

Not Landscape: Landscape Archaeology as Bricolage

The late 1980s and 1990s saw an explosion of landscape studies in archaeology. The notion of landscape was herald as a “usefully ambiguous concept” (Gosden and Head 1994) that was to be applied everywhere only to be later scrutinized and criticized. The emergent interest in landscapes helped archaeologists expand their understanding of the widely diverse range of relationships people maintain with their surroundings, and precipitated a (Gosden and Head 1994) that was to be applied everywhere only to be later scrutinized and criticized. The goal of the paper is to highlight what is and is not especially unique about the Hasinai Caddo.

Livingood, Patrick (University of Oklahoma) [197]

Leadership Specialization among the Caddo and Their Neighbors of the Southeast

One of the remarkable aspects about the Hasinai Caddo is the nature of their specialized leadership roles. This paper is going to take a comparative approach using ethnohistoric documents to examine the differences between the Caddo and their neighbors with regard to the types of specialized roles that exist, the types of divisions and circumscriptions on authority that exist for leaders, and the level of formality or informality in leadership function. The goal of the paper is to highlight what is and is not especially unique about the Hasinai Caddo.

Lobo, Jose [277]

Settlement Scaling: Simple Equation, Familiar Variables, Rich Story

The basic mathematical statement of settlement scaling involves a very simple equation (a “power law function”) and variables long used in anthropology and archaeology to study the effects of demography on social processes. One could interpret the settlement scaling framework as another instance of the allometric relationship found very widely in the biological realm. But what may be more important is the fact that the framework actually incorporates a lot of accumulated insights from mathematics with sought out narratives. The following paper is meant as a work in progress where I try to uncover the essential components that make up an archaeological approach to the study of landscape. The orientation I proffer calls for an approach that is analytical in spirit, and that most likely resembles an act of bricolage. It does not seek out the pursuit of the next theoretical concept but instead concerns itself with what characterizes a landscape archaeology study.

Locascio, William (Florida Gulf Coast University) and Matthew Colvin (University of Georgia) [377]

Prehistoric Tree Island Use in the Northern Everglades: New Evidence from the Late Archaic

A season of test excavations at a late archaic tree island site in south Florida has produced several interesting, if broad, patterns in the practices of prehistoric peoples living within this landscape. Stratigraphic evidence further supported by AMS dating reveal use of the tree island spanning nearly 1,000 years of periodic long-term human occupation. Evidence attests to a certain “social fabric” at the settlement, suggesting its identity as a memorable place on the landscape, a quality contrary to what might be expected of existing models of tree island use in the prehistoric Everglades.

LEADR at MSU: A Lab Approach to Digital Cultural Heritage in the Classroom

Founded in August 2014, LEADR is both a physical space and a curriculum development initiative established as a collaboration between the Departments of History and Anthropology, and Matrix at Michigan State University. Fully equipped with large screens for group work, computers, cameras, 3D printers and scanners, microcomputing equipment, and other technology, LEADR is well equipped to facilitate innovative digital cultural heritage instruction and project development. The decentralized learning space facilitates collaboration and openness, and encourages experimentation and play. Sessions in LEADR create opportunities for students to take the content and methods that they have read and discussed in the classroom and apply them in hands-on experiences where they can build, experiment, and play, and then reflect on their experiences. Sessions focus on the critical use
of digital sources, tools, technology, and digital storytelling, often with at least one visit aimed solely at “flipped classroom” style guided work time. These courses are intended to prepare students with the digital skills relevant to careers in the contexts of archaeology, graduate school, and as citizens in the digital age. This session will address LEADR’s approach to curriculum development and course objectives, including successes and failures over the last two years.

[83] Exploring Migration and Kinship of the Ancient Maya through Isotopes and aDNA in NW Belize
As a uniquely sustained archaeological research program that has annually excavated in the Rio Bravo Conservation and Management Area for 25 years, the Programme for Belize Archaeological Project (PfBAP) offers a wealth of knowledge for bioarchaeological research. This paper examines ancient Maya burials from northwestern Belize, spanning the Late Preclassic (250 BCE–250 CE) to the Terminal Classic (850–950 CE). Detailed here are stable isotope, ancient DNA, and osteological analyses from a small subset of individuals from the sites of Dos Hombres, Medicinal Trail, and Sak Chen. These data provide information regarding the migration, kinship, and health of the ancient Maya from northwestern Belize. The interplay between sustainability and population and demographic changes over time are postulated given the presented data and analysis.

Lodge, Spencer (Desert National Wildlife Refuge)

[142] Fire on the Mountain: Roasting Pits in the Sheep Range on the Desert National Wildlife Refuge
Within the Sheep Range in southern Nevada, I identified more than 200 roasting pit features with Google Earth, and subsequently recorded 193 of them. A color change that turns local dolomite and limestone white following exposure to high temperatures during use in an earthen oven allowed these features to standout in aerial imagery. Following documentation of these features, roasting pit distribution was analyzed according to midden size and vegetative community throughout the Range to identify patterns of use. Additional statistical analysis was performed to test the usefulness of aerial identification in zones with dense tree cover (Pinyon/Juniper). Finally, experimental work with limestone and dolomite from the Sheep Range was conducted to determine the temperature at which these materials change color. X-ray diffraction was used as well on tested rocks to identify material type and elemental makeup.

Loebel, Thomas (Illinois State Archaeological Survey)

[264] Use Wear and Assemblage Composition: The Role of Endscrapers in Paleoindian Technological Organization
Historically, microwear studies have focused around resolving issues centered on tool form and function. However, microwear also offers the opportunity to investigate site level activities surrounding “soft” technology, particularly in situations where organic preservation is poor or absent. In addition, when combined with a holistic approach to assemblage composition, microwear can provide larger insights into the organization of technology and larger patterns of adaptation. In this paper I discuss the results of microwear analysis of over 300 endscrapers from six early Paleoindian sites spanning the Eastern Woodlands, the results of which illuminates our understanding of early Paleoindian adaptations across time, space, and gender.

Loendorf, Chris (Gila River Indian Community)

[335] Classic Period Settlement Patterns along the Middle Gila River
This paper summarizes archaeological data that show a substantial decrease in population occurred between the Sedentary (ca. 950–1150 AD) and Classic Periods (ca. 1150–1500) along the middle Gila River in the Phoenix Basin. This decrease coincides with well documented increases along the lower Salt River. Extensive data suggest this pattern subsequently reversed in the Historic period, when people were again concentrated along the middle Gila, and the lower Salt River was extensively depopulated. The Salt and Gila Rivers have substantial differences in the topography and elevation of their drainage basins, which create divergent discharge regimes. Holocene climatic data suggest that conditions for irrigation along the Salt and Gila Rivers varied through time, and this variation may in part account for the differences in settlement patterns. These shifts in settlement patterns also affected ideological, economic, and political relationships within the region.

[178] A Social Perspective on Wood Remains: Rural Colonization and Urban Growth in the Saint Lawrence Valley, 1600–1900 AD
Dendrochronology is widely used as a dating tool in archaeology. In North America, the wood record is especially associated with colonial dynamics when farmlands were cleared, rural buildings were erected and young cities drew upon timber resources from expanding hinterlands. In the Saint Lawrence Valley, colonization began in the early seventeenth century and developed in waves, as prime agricultural lands were saturated and became launching pads for secondary colonization into marginal regions and industrializing cities. Some wood species were valued commodities whose sale injected cash into rural economies, while other species were conserved for local construction and still others became firewood. Colonists with greater socioeconomic power had access to more valued species, as compared to ordinary farmers and entrepreneurs. Such social dynamics are shown by a
broad-based dendrochronology program at the Université de Montréal, led by the Groupe de Recherche en Dendrochronologie Historique (GRDH). Since 2002, more than 80 sites have been studied from the Saint Lawrence estuary to eastern Ontario, providing more than 800 samples. This paper describes a dendro-archaeological approach that considers wood species, dating dates, and tree provenance within their archaeological context, and focuses on socio-environmental relations as revealed by the study of archaeological wood.

Lofaro, Ellen (University of Tennessee), George Kamenov (Department of Geological Sciences, University of F), Jorge Luis Soto Maguino (Dirección Desconcentrada de Cultura de Ayacucho, A) and John Krigbaum (Department of Anthropology, University of Florida) [331] Identity, Residential Mobility, and Anthropogenic Lead in Early Colonial Huamanga (Ayacucho), Peru

La Iglesia de la Compañía de Jesús de Huamanga, the earliest Jesuit church in modern-day Ayacucho, Peru, was built in AD 1605 near the main plaza. Famous for its baroque art, this standing church is in need of extensive renovations. In a partial restoration in 2008, an archaeological excavation uncovered human and faunal remains underneath the church floor proper, and underneath the floors of associated chapels. Upon examination, only indigenous individuals appear to be buried underneath the church floors; significantly, few individuals show signs of stress or disease. Likewise, ethnohistorical documents show indigenous Peruvians using the Spanish legal system, church service and labor agreements to evade forced labor at the mines of Huancavelica and Potosí, among others. Analyses of strontium isotopes reveal that one-third of the individuals were not born locally, correlating with census records documenting rural migration into the city. Lead isotope results are narrow and lead concentrations are high, indicating the presence of anthropogenic lead, potentially resulting from pollution caused by extensive mining during the period. These data argue that indigenous people actively shaped their lives through migration and used Spanish religious and legal systems to avoid the harshest occupations, thus moving beyond the stereotypical Black Legend trope.

Loftin, Samuel [366] see Copeland, Sandi

Loftis, Kat and Robert J. Speakman (CAIS, University of Georgia) [86] Analysis of XAD as a Pretreatment Method for Radiocarbon Dating Bone

The presence of exogenous organic carbon is a major concern when radiocarbon dating bone. A particular source of error and frustration in the field of radiocarbon dating has been the analysis of bone that has undergone humification. Humification occurs during burial and results from a combination of two distinct processes: Maillard reactions involving indigenous organic carbon, and the complexation of collagen with soil humic substances. Soil humic substances—composed of fulvic acids, humic acids and humins—are hydrophilic, predominately aromatic, heterogeneous complexes that originate from the polymerization of plant and animal biomolecules. As such, the ages of humic substances reflect the numerous and composite geochemical reactions that lead to their formation. The radiocarbon date of humified bone, then, reflects the age of the bone as well as the exogenous humic carbon. Pretreatment methods, such as XAD solid-phase extraction and single-amino acid radiocarbon dating, have been developed to eliminate contaminant carbon and provide a purified collagen sample for dating. Here we present results from our study in which collagen was reacted with a soil humic standard and the effectiveness of chemical purification of the collagen using XAD resin was assessed.

Lohse, Jon (Coastal Environments, Inc.), Derek Hamilton (SUERC), Takeshi Inomata (University of Arizona) and Hector Neff (California State University, Long Beach) [81] Fire and Ash: Formative Period Environmental Chronologies in Eastern Mesoamerica

Recent dating work has led to revision of regional political chronologies in the Guatemala Highlands. In particular, key Middle and Late Formative phases now date as much as 300 years later than previously believed. This reanalysis brings these phases in line with significant environmental conditions stemming from volcanism and drought. In this paper, we present new high-precision chronologies for these environmental records, and compare these records against regional political chronologies in order to suggest how cultural developments may have been influenced by these factors.

Lokhov, Dmitrii [332] see Kato, Hirofumi

Lombardo, Umberto (Universitat Pompeu Fabra) [325] Estimating the Precolumbian Population of Southwestern Amazonia.

Estimates of population density in pre columbian Amazonia have been based on calculations of the carrying capacity of the environment, generally classified as varzea, terra firme, and savannah. These estimates, however, have been criticized because they overlook the fact that 1) the Amazon environment is far more diverse in terms of soils, vegetation, and climate than this simplistic classification, and 2) precolumbians increased, both intentionally and unintentionally, the productivity of the land through raised field agriculture and terra preta. Moreover, at the time when these estimates of precolumbian population size were formulated, most of the current archaeological data about Amazonia was unavailable. Here, we estimate the population density of the Monumental Mounds Region (MMR), in the Bolivian Amazon, based on archaeological evidence and ethnochronological analogies. We calculate a minimum population size based on the amount of work needed to build all the earthworks present in the MMR and a maximum population size based on the use of modern indigenous groups make of natural resources. In particular, we focus on the use of wood: comparing archaeological data, ethnochronological evidence, and forest primary production.

Lonaker, Sydney (Arizona State University), Julie Hoggarth (Baylor University) and Jaime Awe (Northern Arizona University) [236] Methods for Intensive Data Collection on Terminal Deposits in the Belize River Valley, Belize

Terminal deposits, defined here as dense midden-like assemblages that contain nonelite and elite paraphernalia (i.e., utilitarian and decorated ceramic vessels, faunal remains, obsidian blades, ground stone tools, and human remains) have been discovered at sites across central and northern Belize. Despite the research on these features, there is little consensus on what type of activities these deposits represent. In the past, archaeologists have labelled these deposits as de facto refuse, primary or transposed middens, problematic deposits, termination rituals, garbage associated with feasting events, evidence for rapid abandonment, and post-abandonment rituals. Systemically testing these hypotheses is difficult, as research projects excavate these deposits using a range of methods. This makes direct comparisons across regions challenging. In an effort to better understand the composition, deposition, function, and spatial patterns of these terminal deposits, the Belize Valley Archaeological Reconnaissance Project (BVAR) developed standardized documentation and excavation protocols for excavating terminal deposits. This presentation describes the methods used in these excavations, including photographing, mapping, and intensive recording of dateable organic material and polychrome ceramics. We propose these new approaches for creating comparable datasets across regions.

Long, Elizabeth (Texas State University, Anthropology Department, Graduate Student) [390] Saenger Pottery Works: Preliminary Report: Unlocking a Town’s History through their Pottery

Saenger Pottery Works: Preliminary Report: Unlocking a Town’s History through their Pottery
This investigation of historical ceramics is conducted on a collection that dates from 1886 to 1915. Saenger Pottery Works was in operation from ca. 1885 through ca. 1915. The size, form, and function variability of the ceramics inform about production techniques used and what forms are preferred over others. The sherds previously collected are currently dated based on makers’ marks, stylistic attributes, and the period of kiln operation. However, issues with the dating method need resolution due to occupation by multiple groups and the inability to use proper dating techniques. The issues in provenience and provenance are discussed because the pottery, while attributable to the site, do not have records of excavation. Background research is a joint effort with the president of the town Historical Society. One result was the discovery of an African American cemetery, which appears on maps from 1836 until 1893. Additionally, a darker history is revealing itself with the discovery of a long-forgotten disturbing criminal with familial ties to current residents. The investigation seeks to find the historical significance Elmendorf has in the development of San Antonio and the State of Texas. Research is currently on going, and an excavation of the Saenger site is under development.

The Earliest Occupation of Colombia: Balance and Perspectives at the Beginning of the Twenty-First Century

In First Americans research in Colombia, the last three decades of the twentieth century were significant in terms of enthusiasm and motivation. Studies carried out by scholars such as Ruth Grunh and Alan Bryan in Venezuela and other places were fundamental references for Colombian teams and encouraged advances in Pleistocene archaeology. Gonzalo Correal, Thomas Van der Hammen and Gerardo Reichel-Dolmatoff, among others, followed widely their contributions. Following Colombian generations of archaeologists discovered in the 1990s, new sites were discovered and new interpretations of site contexts were considered according to theoretical and methodological issues of the era. However, the balance in production and publications lacks continuity in the beginning of the twenty-first century; there are few accomplishments despite a growing number of opportunities for developing studies. Overall, there has been a general increase in research on the first occupants of the Sub-Andean mountains, with interesting findings related to processes of initial horticulture in central and southwest Colombia. But this trend has declined over the last decade. This presentation memorializes and acknowledges pioneers such as Ruth Grunh, and promotes new opportunities for the future research of the amazing search of the first South Americans.

Lopez, Cira Martinez, Cira Martinez López (Instituto Nacional de Antropología e Historia) and Robert Markens (Universidad Nacional Autónoma de México) [9]

La greca escalonada como símbolo del poder político en Oaxaca prehispánico

Debido a que la greca escalonada es uno de los motivos más perdurables y ampliamente difundidos en el tiempo y espacio mesoamericano, su significado ha despertado desde hace tiempo el interés de varias generaciones de estudiosos. Por su forma geométrica y abstracta, el signo se presta a una gran diversidad de interpretaciones. Esta presentación tiene la finalidad de acercarse al significado de la greca escalonada en objetos del arte e inmuebles en Oaxaca prehispánico mediante un análisis de documentos coloniales y creencias de los pueblos tradicionales que quedan vigentes.

Lopez, John (Skidmore College) [179]

Tenochtitlán: A Cultural History of Water

Located today in Chicago’s Newberry Library, the 1524 Nuremberg Map, representing the prehispanic city of Tenochtitlan on the eve of its conquest to Hernán Cortes, is an ink-and-watercolor image on paper, measuring 47.30 × 30.16 cm. Produced by an anonymous author in an unknown workshop in the German city of Nuremberg, it first appeared in the Latin edition of Cortés’ Second Letter to the Spanish monarch Charles V. It is the earliest printed map of a New World city and although it is a highly Europeanized image of the Aztec capital, the map is believed to have been based on a now-lost drawing made by the hand of an indigenous author. An eye-see perspective, valued for depicting large geographic areas such as cities, it provides the viewer with a 360-degree view of the precolombian city and its surrounding aquatic environs. Much has been written about the Tenochtitlán’s religious and political history, but water as a methodological lens to scrutinize the city’s social and cultural history has received considerable less attention. Through study of historical images, this paper explicates the undergirding currents of water to Tenochtitlán’s attitudes toward its public sphere.

López, Laura María (CONICET-FCNyM, Universidad Nacional de La Plata) and María Teresa Planella (Sociedad Chilena de Arqueología) [388]

Chenopod Data in Two Countries of South America: Advances in Knowledge about the Use of Chenopodium in Argentina and Chile from Early Holocene (9000–11,000 BP) to Historical Times (250 BP)

Argentina and Chile are the most austrian American countries where Chenopodium species are recovered in several archaeological contexts. In both countries from the north to central and south, various issues are addressed from these findings such as hunter-gatherers subsistence strategies and chenopod grain morphological changes. Multi-proxy methods are used based on pollen, macro and micro botanical remains analyses, and isotopic data. However scarce botanical evidence has carried an uneven depth studies about the ancient presence of chenopod species, in particular quinoa, in the different regions. The objective of this contribution is to present the complete evidence about the presence and consumption of Chenopodium in Argentina and Chile marking on new data. Advances in research have allowed knowing the manipulation of wild chenopod since early times and probably the development of different practices related to protection, transplantation, selection, and processing techniques. In this way the adoption of domesticated chenopod could have been easier among the first farmer and horticultural societies that lived far from the domestication centers. New issues are raised to be solved with future research, following the aim to get better insights into this pseudo cereal and preserve its cultivation in both countries.

Lopez Bravo, Roberto (Universidad de Ciencias y Artes de Chiapas) and Elizabeth H. Paris (University of Calgary) [218]

The Jovel Valley of Highland Chiapas from the Classic Period to the Postclassic Period

In contrast to the sociopolitical instability and depopulation observed at many sites in the Southern Maya Lowlands during the Classic to Postclassic transition, Highland Chiapas was characterized by stability and demographic expansion, as suggested by our excavations in the Jovel Valley, where small cities and towns maintained their roles as political and economic centers throughout this period. In this paper, we examine patterns of continuity

INDIVIDUAL ABSTRACTS OF THE SAA 82ND ANNUAL MEETING 339
and change evidenced by recent excavations at the cross-valley monumental centers of Moxviquil and CV-38 (San Pedro y San Pablo). Founded near the beginning of the Late Classic period, these centers experienced a period of prosperity during the Early Postclassic, marked by the expansion of residential settlement into new areas. The occupation of domestic spaces for multiple generations is reflected in numerous building phases and renovations to residential terraces and houses. Both sites are characterized by distinctive architectural building styles that combine adobe and masonry techniques, including an adobe ball court at CV-38, and the use of adobe brick foundation walls and puddled adobe floors in outlying residential areas. We also observe a significant transformation in burial practices during this period, from rectangular masonry tombs to communal graves in mortuary caves.

López Corral, Aurelio [322] see Meanwell, Jennifer

The Geopolitical Implications of Sub-flow Variation within the Zaragoza-Oyameles Obsidian Source

Chemical analysis of obsidian is a useful proxy for studying the control of obsidian goods exchange and the presence of prehispanic geopolitical boundaries. Recent studies on obsidian sourcing show that during the Late Postclassic period (AD 1250–1519), regional altepemeh imported obsidian from several sources within highland Mesoamerica. Analysis of data suggests that no single political entity fully controlled the distribution of obsidian goods from a particular source, suggesting that perhaps a single obsidian source was geopolitically exploited by several rival altepemeh. In order to examine this issue, we used pXRF analysis to analyze variation in sub-flow chemical signatures of 20 locations within the Zaragoza-Oyameles source area (located in Puebla, Mexico). Results were then compared to chemical signatures of archaeological obsidian artifacts from Late Postclassic sites of the Puebla-Tlaxcala region. Here, we present our preliminary results with special reference to the economic relationship between competing rival political entities.

Starfish in the Offerings of the Great Temple of Tenochtitlan

Recent excavations carried out by the Templo Mayor Project in Tenochtitlan’s sacred precinct uncovered a significant number of calcium carbonate plates, which, in spite of their advanced degree of deterioration, can be identified as consisting of the endoskeletons of sea stars. These organisms belong to the Asteroidea (from the Greek aster: “star” and eidos: “in the shape of”) class, most of which exhibit radial symmetry and have thin, discernibly pentagonal bodies. Sea stars inhabit marine environments in nearly all longitudes and latitudes. Among the excavated plates, five species have been identified thus far: Astropecten duplicatus from the Atlantic, and Pentaceraster cumingi, Nidorelia armata, Luidia cf. superba, and Astropecten regalis from the Pacific. These remains were found in seven caches (Offerings 124, 126, 136, 137, 141, 163, and 166) deposited in the Templo Mayor, all of them corresponding to Phase VI (1486–1502 CE).

Las piedras verdes en el Centro de Jalisco

Los objetos trabajados en una extensa variedad de piedras verdes fueron altamente apreciados por las culturas mesoamericanas desde tiempos tempranos. Lo anterior aplica para el Occidente de México, en donde su uso se encuentra ligado a las actividades económicas, rituales y políticas realizadas por las elites, desde el Formativo medio, documentado en sitios de los complejos Capacha, El Opeño y Pantano, y generalizado a partir del Formativo tardío entre los grupos pertenecientes a la tradición de tumbas de tiro, momento en el que parece generalizarse un estilo propio de la región. Este trabajo versará sobre los usos sociales de las piedras verdes y sus cambios desde el Formativo temprano al Epiclásico.

Technologies and the State: Analyzing the Impact of Economic Growth through Archaeological Science

Mexico’s government attempts to eradicate poverty through infrastructure building and welfare policies have changed the social dimension of griddle and basket making at Cuentepec, in the State of Morelos Mexico. For generations, the house embodied the knowledge of making griddles and baskets, evoking people to remember fragments of the social practices of distant pasts and collectively lived histories. The act of remembrance is compromised with the building of welfare landscapes. Memory is intimately linked with the landscape, as it creates a sense of place that legitimizes the many identities and social worlds that have existed through time. In this hybrid landscape of welfare and memory, we characterized the technology of griddle making and approached the spatial and chemical analysis of residues left by the cycle of activities that interweave domestic tasks with production for more than a decade. In addition, we introduced a social impact assessment to our study to corroborate our findings. Results from these investigations provide a framework for evaluating the potential of applying archaeological science to analyze the impact of economic growth to the preservation of ancient technologies.

[80]  Night and the Underworld in the Classic Period Ulúa Valley, Honduras  
As the sun set and the light dimmed in the Classic Period Ulúa Valley, Honduras, the nighttime sky and a soundscape of nocturnal animals emerged. The transition between day and night was marked not only by the shifting sensory experience of the nightscape but also by the passage of the sun through the underworld, as the realm of death and the ancestors came alive. The night was inhabited and animated by liminal animals and ancestors that moved between the world of the living and the dead. The prevalence of representations of animals that are nocturnal, crepuscular, and/or associated with the underworld in the corpus of figurart artifacts, and especially those associated with life-cycle rituals, suggests that the nighttime was crucial to everyday life, death, and renewal. Their animal (and sometimes zoo-anthropomorph hybrid) bodies were frequently whistles, which would have animated a soundscape that accompanied transition-marking events. Solar and life-cycle rituals on the monumental scale featured large figural censers that heralded the passage between life and death, which—at night—became a two-way journey between the earthly world and the underworld.

[374]  Toward a Unified “Heritage Ecology”: Developing a Systems-Based Approach to Research in Archaeology and Heritage  
Archaeologists and researchers in heritage-based disciplines frequently study the complex interactions between human societies and natural environments. All too often, however, research proceeds from the premise that natural patterns, stressors and events promote direct cultural changes or adaptations on the part of human societies. Instead of perpetuating this linear and causal understanding of the relationships between nature and culture, this paper develops a new, holistic framework that encourages researchers to understand cultural and natural elements as part of a broader network of multidirectional associations and connections. In order to break down this false opposition between nature and culture, the paper expands upon previous definitions of “heritage ecology” and provides a new conceptual model that facilitates the analysis of agentive and multidirectional interactions between natural and cultural forces and actors. Dividing this model into three types of components—fabrics, elements and actors—the paper then applies a “heritage ecosystem” approach to a case study in the Pacific island nation of Vanuatu. The paper concludes by offering suggestions as to how researchers may employ the framework within other research settings.

Losey, Robert (University of Alberta)  
[340]  Living with Reindeer in Arctic Siberia: The View from Arctic Yamal, Russia  
Reindeer are an essential part of daily life and special events across a broad stretch of northern Eurasia, but their long-term history with people has remained elusive. Ethnographers have characterized reindeer as living in “intermittent co-existence” with humans, or as “semi-domesticates,” “pastoral herd animals,” and even “slaves.” Archaeology has struggled to characterize human-reindeer relationships, with even the geographical origins of modern domesticated deer remaining unclear. The Yamal Peninsula of Arctic Siberia has a remarkable record of human interaction with reindeer, including habitation sites with abundant deer remains, harness equipment dating back 2,000 years, and a rich iconography in which these animals are commonly depicted. This paper presents our ongoing efforts to integrate these sources of information to produce an enriched understanding of human-reindeer engagement in the Siberian north. Described in the presentation will be preliminary results of zooarchaeological analyses of the region’s faunal assemblages, and experimental work with replicas of the reindeer harness equipment from several sites in Yamal. These technical studies are discussed using a theoretical perspective that envisions domestication as an ongoing, multidirectional, and multispecies process that involves changes in genotypes and phenotypes, but that also involves sociality, shared labor, and numerous crafts.

[175]  Recording and Interpreting Mississippian Rock Imagery at Painted Bluff, Alabama  
As part an overall effort by the Tennessee Valley Authority to conserve, manage, and present Middle Mississippian era pictographs and petroglyphs to a visiting public, Stratum Unlimited recorded 101 motifs from 47 panels at Painted Bluff, a steep south-facing limestone cliff overlooking the Tennessee River in northeastern Alabama. Results from the recording include an assessment of pictograph and petroglyph techniques, types and numbers of motifs, stratigraphic overlap and sequencing of techniques, and identification and interpretation of certain motifs.

Loughlin, Michael L. (University of Kentucky)  
[320]  Classic Period Architectural Variation and Interregional Interaction: A View from the Tres Zapotes Hinterland  
During the Protoclassic (AD 1–300) and Early Classic (AD 300–600) periods, the Eastern Lower Papaloapan Basin (ELPB) experienced an important reorganization. The political influence of the large center at Tres Zapotes began to wane and a series of new centers were established across an increasingly independent, but fragmented political landscape. Eschewing the architectural cannons of the Tres Zapotes polity, these new centers are characterized by diverse configurations revealed by pedestrian survey and lidar mapping, many of which feature monumental platforms and/or “Standard Plan” layouts, architectural forms more common in Central and South-Central Veracruz. I argue that the use of these nonlocal styles reflects a
reorientation of interregional interaction in the ELPB toward the large polities in Central Veracruz, such as Cerro de las Mesas. These interactions are further evidenced by the appearance of Mixtequilla style ceramics in the ELPB during the Early Classic period.

Loughmiller-Cardinal, Jennifer [287] see Cardinal, J. Scott

Loughmiller-Cardinal, Jennifer (University at Albany, New York) [392] They Are What They Eat: A Need to Know More about Diet through Residues, Hieroglyphic Texts, and Images of the Classic Mayas Among the various sources of information about what foodstuffs comprised the Classic Mayan diet, we lack resolution on daily, domestic, and the various ritual and event foodstuffs. Beyond the archaeologically recovered macrofossil and faunal data, the identifications of drugs and ritual foodstuffs are less well established. Speculative and presumed behaviors that surround these goods tend to bias methods of analysis toward known substances and preconceived interpretations, thereby potentially obscuring empirical data on actual behavior. In the case of the “chocolate vases,” the residues did not match our assumptions. Are there other assumptions we have made that maybe leading us astray? There are a number of other residues and contexts to which we should be paying special attention, and we need more appropriate methods of acquiring residues from limited-preservation soils and contexts.

Lovata, Troy (University of New Mexico) [192] Manito Trail Arborglyphs: Expressions of Place and Conceptions of Wilderness in Historic Graffiti from New Mexico, Colorado, and Wyoming

Chicana/o scholars Levi Romero and Vanessa Fonseca define the Manito Trail as a late nineteenth- through mid-twentieth-century diaspora of New Mexicans traveling to work across the state of Wyoming. Manitos labored in herding, ranching, farming, mining, and lumber extraction, as well as in-town jobs. Some returned to New Mexico annually while others made Wyoming their permanent residence; yet most never fully lost contact with their homeland. Although Wyoming has a small Hispanic population whose presence hasn’t always been recognized by the public at large, there is a rich archive of literature, poetry, and music related to the Manito Trail. This presentation outlines an ongoing project recording the material culture of the Manito Trail—in the form of arborglyphs or historic graffiti left on aspen trees by sheep herders and other laborers in Rocky Mountain forests. Arborglyphs are found at both ends of the Manito Trail—in northern New Mexico and adjacent areas of Colorado as well as Wyoming. They are material evidence of the culture history of the region as well as a conduit to understanding people’s conceptions of the wilderness, mountains, and forests in which they labored.

Low, Marika (University of Wollongong) and Alex Mackay (University of Wollongong) [54] The Organization of Hornfels Blade Production during the Early Later Stone Age (ELSA) in the Eastern Cederberg, Western Cape, South Africa

The Early Later Stone Age (ELSA) represents the onset of sustained microlithic technology in southern Africa. The ELSA is, however, poorly defined with respect to its technological characteristics and organization. In this paper we identify key features of the ELSA at Putslaagte 8 (PL8) rockshelter in the south-west of southern Africa, dating ~25–22 ka. The assemblage features relatively expedient production of hornfels blades using natural ridges of cobbles from the nearby Doring River. A second, distinct component is the reduction of quartz-bipolar cores to very small sizes. We then examine evidence from the open-air site Uitspankraal 7 (UPK7) on the Doring River, which contains a similar hornfels blade production system to PL8. Differences between the PL8 and UPK7 assemblages suggest an organizational system involving the staged production, use and discard of artifacts in different landscape settings. Hornfels blades appear to have been produced at the river and transported into the surrounding landscape, with limited transportation of cores. Quartz-bipolar systems, in contrast, appear to have involved local acquisition, reduction and discard of non-riverine rocks. Intriguingly little evidence of quartz-bipolar was found in the open-air sample, raising the possibility that different ELSA technological components were organized in distinct patterns at the landscape-scale.

Lowe, Llyneth (Centro de Estudios Mayas, UNAM) [292] Génesis del Museo Yucateco durante el Segundo Imperio (1863–1867)

El presbítero Crescencio Carrillo y Ancona fue un destacado intelectual yucateco y precursor del estudio científico de la arqueología maya, que culminó sus esfuerzos con la inauguración del Museo Yucateco en 1871 en base a sus propias colecciones. El análisis de diversos documentos de archivo ha hecho posible conocer los antecedentes de tal institución durante el Segundo Imperio mexicano. El emperador Maximiliano mostró un notable interés por la historia y las culturas indígenas, al igual que la emperatriz Carlota, quien realizó una visita a Yucatán en 1865, acompañada por el padre Carrillo, apreciando la importancia de conservar los sitios arqueológicos, así como de fundar un museo local. Como resultado de ello, en 1866 el Comisario Imperial de Yucatán decreta la creación del museo e instala una Junta de Arqueología y Artes que establecería los lineamientos para su formación a partir de la donación de piezas “tales como vasos o trastos, figurillas, idólos, estatuas, piedras esculpidas o grabadas, cascabeles, planchuecas de metal, armas, instrumentos, adornos, ornamentos, libros, pieles pintadas o mapas,” además de proteger y registrar el patrimonio material. La caída del Imperio al año siguiente frena la realización del proyecto, que tiempo después se concretaría con apoyo del gobierno federal.

Lowman, Shannon, Nicola Sharratt (Georgia State University) and Bethany L. Turner (Georgia State University) [233] Social Transition at Tumilaca la Chimba: A Bioarchaeological Analysis of Terminal Middle Horizon and Late Intermediate Period Mortuary Contexts

The centuries following Tiwanaku state decline circa AD 1000 were characterized by political fragmentation and social flux. In the Moquegua Valley, Peru, the first 250 years following the state’s demise are referred to as the terminal Middle Horizon (AD 1000–1250), a period during which considerable
cultural continuity with Tiwanaku is evident despite political collapse. The following Late Intermediate Period (LIP) (AD 1250–1450) is marked by major changes in material culture, domestic architecture, and ceremonial practices as the valley likely underwent a process of population replacement. Drawing on skeletal data from one site (Tumilaca la Chimba) with both terminal Middle Horizon and LIP occupations, this poster examines stress and health across this turbulent transition. An osteological analysis of 20 individuals from the terminal Middle Horizon cemeteries and 23 individuals from the LIP period cemetery reveals significant differences in age and sex distributions and in differences in dental and skeletal pathologies between the two periods. These results provide insights into nutritional stress and disease exposure between these two occupations and underscore the importance of a bioarchaeological perspective in understanding the impacts of major social and political transition in the Andes.

Lowry, McKenzie [124] Seismic Mitigation for Collections at the J. Paul Getty Museum through Mountmaking
As recent earthquakes in Oklahoma and Virginia have shown, even regions generally thought to be far from seismic zones are never truly immune to their effects. The development over the last 30 years of seismic mount systems that safely capture objects in 360 degrees can offer solutions relevant to collections in a diversity of environments. Focus on this goal for the past few decades has led to a realization that more can be done to protect collections in advance of threats, leading to the evolution of mountmaking as a form of preventative conservation. This paper will examine how modern mountmaking can mitigate destructive forces for collections on display. Examples of earthquake damage to collections will be examined and discussed in conjunction with modern preventive techniques, both simple and complex.

Loyola, Rodrigo, Isabel Cartagena (Facultad de Ciencias Sociales, Departamento de Ant) and Lautaro Núñez (Instituto de Arqueología y Antropología, San Pedro)
[134] Tecnología lítica y movilidad durante el poblamiento temprano del Desierto de Atacama Meridional (Chile)
Actualmente se reconoce que los grupos humanos que colonizaron el Desierto Meridional de Atacama (22–25°S) desde la transición Pleistoceno tardo-Holoceno temprano (12.6–10.2 ka AP) accedían a la amplia diversidad de ambientes disponibles en este árido paisaje. Desde los oasis de borde de salar, los paleohumedales y quebradas de la precordillera, hasta los paleolagos de la alta puna, estos espacios fueron articulados a través de circuitos de movilidad estacional. Por otro lado, la colonización de esta parte del desierto también fue un proceso biogeográfico estructurado en el tiempo. A medida que se dispersaban por el territorio, los grupos de cazadores-recolectores seleccionaron, incorporaron y se adaptaron paulatinamente a los nuevos ambientes. El registro lítico -estrechamente vinculado a la dimensión espacial de los grupos humanos- nos brinda una entrada excepcional para evaluar los cambios ocurridos durante este proceso. A través de la comparación de conjuntos líticos de contextos tempranos, planteamos que la variabilidad de los sistemas técnicos y los cambios en las estrategias de movilidad responden a un proceso continuo de aprendizaje, en el cuál los grupos acumularon información del entorno y desarrollaron un conocimiento acabado del paisaje.

Lozada Mendiesta, Natalia (MPhil Student/PhD candidate UCL-Institute of Archaeology)
[327] Ceramic Variability and Social Interaction in the Middle Orinoco: On Multiethnic Communities and Ceramic Traditions in the Late Occupation Period (500–1500 AD)
The Atrues Rapids in the Middle Orinoco region are mentioned in the historical sources as a key trading center linking the Western Llanos of the Orinoco and the Guyana, where people, goods and ideas were exchanged. A recent study in Picure Island, located in the rapids, presents a variety of ceramic temper wares, beads and quartz crystals associated in stratigraphically excavated contexts. The ceramic sherds recovered in Picure are closely related to other archaeological sites in the Middle Orinoco. Besides the presence of common ceramic traditions and complexes, it confirms a dual temper ware assemblage for the late occupation composed by the Arauquínoid and Valloid ceramic traditions. Both traditions exhibit distinctive temper wares and stylistic traits that under the normative approach have been related with different cultural groups. Nonetheless, both have been associated with Carib speaking parties and in certain contexts appear to share decorative motifs, usually explained as a product of contact and diffusion. From a communities of practice perspective, the characterization of technical traditions through macroscopic and microscopical analysis of ceramic sherds from Picure intends to contribute novel insights to the discussion of how to understand ceramic variability in a multiethnic interaction context in prehispanic times.

[298] Teotihuacan Influence in the Maya Area as Documented by Archaeological Fieldwork and Museum Collections
There is extensive evidence of the exchange that occurred between Teotihuacán and the Maya area and new evidence has continued to surface in recent archaeological literature and in museum collections. This paper has several main objectives, first to revisit the history of research and analysis of iconographic symbols and epigraphy within the Maya area that notes a Teotihuacán influence. Secondly, to point out that the Maya obtained Central Mexican symbols and writing not merely for their exoticness but rather for what they represented as powerful instruments used within sacred ritual activity at Teotihuacán. Finally, this investigation offers new perspectives found within museum collections on cultural and ideological exchange between Teotihuacán and the Maya.

Lozano Bravo, Hilda (UNAM, Estudios Mesoamericanos.)
[353] Life on Floors: The Archaeometry of Teotihuacán’s Living Surfaces
Archaeometric studies promote interdisciplinarity. Therefore, through this framework we can analyze other materials which facilitate the understanding of the society which created, modified, and used them. To sum up, with this methodology we seek to comprehend the characteristics of the materials used to build the city of Teotihuacán. Currently, there are archaeological studies underway which intend to discover the Sun Pyramid Square’s chronology of occupation. Furthermore, we are also conducting physical analyses that aim to understand the floor structure; some of these include optical microscopy, SEM, XRF, FTIR, Raman, and Pixe. Moreover, these analyses are being complemented by the identification of the floor’s mineralogical composition through soil micromorphology. In fact, we were able to identify similarities and differences between the materials used in the manufacture of floors. That is to say, that this discovery may indicate that preferences toward certain raw materials could be related to the technological advances that were achieved over time in Teotihuacán. Finally, we propose that these studies suggest that the same surfaces which were used in prehispanic times are themselves an archaeological material that must be taken into account to reconstruct the history of this place.

Lucet, Genevieve (IIE-UNAM) [217] Spatial Roles in Cacaxtla: A Delineation from the Study of Its Architecture

The archaeological site of Cacaxtla, in the central highlands of Mexico, had its heyday during the Mesoamerican Epiclassic period. Its architectural characteristics define it as a place for residential and government activities, in contrast with the neighboring hill Xochitecatl, where constructions typify ritual purposes. Excavations were not accompanied by scientific studies of materials for the understanding of functions of rooms, porches, and courtyards that make up the site. Therefore, it is necessary to resort to other sources of information derived from the analysis of structural, spatial, and formal features of these buildings in order to obtain hypotheses about their spatial roles. The observable diversification of built spaces corresponds to different design solutions applied in order to meet different needs. By defining and describing these features, we will distinguish some aspects of these needs and try to derive possible spatial roles. To perform this analysis, we will review the spatial composition of the site, the formal characteristics of rooms and courtyards, connections, and visual communication between the constructions and with the environment, the different formal solutions of the facades, the presence of hearths and altars and, of course, the spectacular murals as essential elements of meaningful characterization of the architecture.

Lucas, Virginia (University of Nevada, Las Vegas), Claire Ralston (University of Nevada, Las Vegas), Anna Osterholtz (Mississippi State University), Andre Gonciar (Archaeotek Canada) and Angelica Balos (Ministry of Culture, Hunedoara County, Romania) [294] Sacrifice or Feasting: Fauna Interpretations of the First Iron Age Romanian Commingled Assemblages at Magura Uroiului

The Magura Uroiului rock formation, located at the confluence of the Mures and Strei Valleys, is a natural, dominating fortress on the landscape. This rock formation has been utilized by groups including, the Hallstatt, Celtic, and Late Iron Age Dacian. The focus of this presentation is the First Iron Age mortuary monument located at the base of the rock face. This monument yielded both human and animal remains, with primary and secondary burial practices of the human remains occurring. The monument was excavated over seven field seasons and both wild and domesticated animals were present. Following the analysis of the faunal remains, evidence of feasting and sacrifice were observed. The presence of these activities as well as burial objects present within the mortuary monument suggests increasing social stratification among this population group.

Lubinski, Patrick (Central Washington University) and Thomas Hale (Central Washington University) [191] Identifying and Siding the Stylohyoid Bone for North American Artiodactyls

The stylohyoid is the largest bone in the hyoid complex surrounding the throat of artiodactyls. There is little published information to allow its identification to species or anatomical side. Our study examined comparative stylohyoid bones in order to provide criteria for taxonomic identification, using more than 350 animals representing 13 species present in the continental United States. Based on osteometrics and discrete features, the bone can be distinguished to species for most of these through an iterative set of comparisons, but with variable degrees of confidence. For example, a bone could be sorted into the small artiodactyl group based on maximum length with 99% success (n = 304), and a pronghorn specifically based on its S-shaped dorsal aspect with 99% success (n = 223). Other species, like small bovids and deer, are harder to separate with confidence, but fair results are obtained with some measures (e.g., deer species can be separated using anterior end width with 72% success in a sample of 76). Our study also extracted stylohyoids in place in order to provide criteria for siding, using 29 carcasses representing 8 species, and found it can be readily sided based on a marked concavity on the lateral side.

Lukas, Dominik (Department of Anthropology, Stanford University) and Claudia Engel (Department of Anthropology, Stanford University) [73] Changing Technologies, Changing Practices: The Transformation of the Çatalhöyük Research Database

Since its beginnings, the Çatalhöyük project has stood out as an early adopter of latest innovations in information technology and digital recording solutions. Consequently, a considerable effort went into keeping the technology infrastructure on site up to date, incorporating new developments, and ensuring compatibility of applications. A core component of the Çatalhöyük technology infrastructure is a central database which hosts textual and numeric records of the excavation. Excavation and Specialist teams enter data through highly customized desktop interfaces. As the teams’ research goals, interpretations, and practices evolve, the database developer generates the code to implement changing requirements in the interfaces—usually during the excavation season in a very short turnaround time. Over the course of the project each of these digital humanist developers has left traces not only in the featureset and functionality of the system, but also in the source code of the application itself. In this paper we will analyze this code with qualitative and Natural Language Processing methods. We will try to unravel how technological advances and ever evolving archaeological research practices are mirrored in the history of the Çatalhöyük central database code.

Lulewicz, Isabelle (University of Georgia), Victor Thompson (University of Georgia) and Thomas Pluckhahn (University of South Florida) [286] Shell Mound Architecture and Cooperative Mass Oyster Collection on the Central Gulf Coast of Florida, USA

Coastal fisher-gather-hunters often have a deep connection among their ritual practices, economic systems, and the built environment. Emerging trends and traditions of cooperation within forager communities can have lasting impacts on group social organization and can be instrumental in the development of early villages. The Crystal River region of the Gulf Coast of Florida, USA provides an interesting locale to explore the intersection between shell mound architecture and cooperative mass capture of estuarine resources. To do so, we combine our recent research on the temporality of village life and monument construction, habitat exploitation practices, and ethnographic example in order to model the emergence of cooperative...
systems in the context of these larger traditions (e.g., monument construction). The results from our recent research provide insight into patterns of behavior that are suggestive of habitual cooperation at multiple temporal and spatial scales.

[116] New Observations on Antlers from Chu Tombs
Lacquered artifacts unearthed from Chu state tombs represent the highest achievements of the lacquer industry in the Eastern-Zhou period (770–221 BC). Antlers form an important part of several typical Lacquered wood-wares unearthed from large and medium-sized Chu Tombs. Antler-wares mainly belong to three categories: 1) tomb-protecting beast (with two or four antlers inserted on the head), 2) lacquered wooden flying birds with tiger-shaped bases (with two antlers inserted on the bird waist), and 3) lacquered wooden crouching deer (with two antlers inserted). The antlers are identified mainly as sika deer, followed by David’s deer. Tombs with sika deer antlers were medium-sized tombs. David’s deer antlers were only found in large-sized tombs. The presence of David’s deer antler artifacts, especially adult antlers with many branches, may be related to the high social status of the tomb owners. The lacquered wooden-wares may have used real antlers because the Chu people esteemed deer. They thought antler was a symbol of strength and could be used to protect the tomb and keep evil out. Antlers may have also been a symbol of the wind that could guide the soul. I think these meanings may be connected with the natural phenomena of antlers annually shedding and regenerating.

[36] The Innovations that Traveled to the Philippines: An Approach to the Biological Conquest of the Islands (Sixteenth–Eighteenth Centuries)
Every process of discovery, conquest and colonization, regardless of its magnitude and historical implications, entails a transformation in those societies in which it takes place. The Philippines, as it had already happened to other parts of the world before, was no exception. The conquest of the Philippines Islands by the Spanish Monarchy supposed the transformation of a very important part of the indigenous population of the islands. In this occasion we studied the biological conquest of the islands and the impact between its inhabitants and its ecosystem. Analyzing those exogenous elements that, traveling on board of the Manila Galleon, contributed to the island’s life. That’s exactly what we call ecological impact of the conquest, derive of the introduction of new proceeding farming from Spain or from the Spanish American possessions, as well as agriculturalist and cattle raising new techins. The other subject of our study is the demographic impact that conquest and colonization processes had on the indigenous population. Not only because of the diseases transmitted to them, but also because of the forced movements of populations; as well as the European and African migration and its consequent miscegenation or mestizaje with the American indigenous population.

[83] A Quarter-Century of Exploring the Three Rivers Watersheds in Belize
The Programme for Belize Archaeological Project is situated in the heart of the Three Rivers Watersheds, drained by the Rio Bravo, Booth’s River, and Rio Azul/Blue Creek in northwestern Belize. These three river systems, along with groundwater, springs, and wetlands, nurture what is today the tropical rainforest refuge of the Rio Bravo Conservation Management Area, active farming communities, and long ago sustained multiple ancient Maya communities such as La Milpa, Dos Hombres, Chawak But’o’ob, Maax Na, Blue Creek, Grey Fox, and others. Comparatively little is known about tropical river systems in Central America. The Three Rivers have been an ideal laboratory in which to study the availability and quality of water for ancient Maya communities, the hydrologic advantages and challenges faced in the past, and to understand the sustainability of these resources for today’s inhabitants. This paper traces ancient Maya water use research undertaken over the last quarter century, and offers insights gained from...
multiple environmental methods and proxies, including water chemistry, sediment chemistry, geoarchaeology, and remote sensing studies including a 2016 lidar survey.

Lycett, Mark (University of Chicago), Andrew Bauer (Stanford University), Mannat Johal (University of Chicago) and Marco Madella (Universitat Pompeu Fabra, Barcelona, Spain) [325] Six Thousand Years of South Asia: Implications for Climate Modeling.
We review the archaeological evidence for land use patterning in South Asia over the past 6,000 years as part of a larger effort of the PAGES-supported Landcover6k and LandUse6k project to reconstruct global land use and land cover datasets for the purpose of improving models of anthropogenic land cover change used by climate scientists. Here, we use archaeological and paleoecological data from our study areas to trace land use shifts from the Southern Neolithic through the Middle or Preceramic Period and discuss their relationship to anthropogenic land cover change. Our data demonstrate an intensification and expansion of agricultural and pastoral land use during this period. We suggest that this pattern characterizes many regions of South Asia that these changes significantly altered both land cover and other environmental conditions during the mid to late Holocene.

Lyle, Robin (Crow Canyon Archaeological Center) [142] Two Episodes of Ritual Turkey and Dog Burials in Southwestern Colorado: A Case Study
Many instances of turkey and dog burials have been documented in the southwestern United States. Some are simple burials or discarded remains but some examples bear characteristics of deliberate sacrifice, arrangement and elaborate ritual interment. Excavations directed by D. M. Dove from 2008 through 2012 in Early Pueblo II period contexts at the large Champagne Spring site in Dolores County, Colorado, revealed two unprecedented examples of this latter type. On or near the floors of two pit structures were complete skeletal remains of multiple turkeys, dogs and other animal remains systematically arranged and covered with sandstone slabs and rich cultural deposits. Orientation and association of the various skeletons clearly suggests symbolic meaning in each episode, as does the sheer number of otherwise healthy individuals including; day old turkey poultts, puppies, a crow, cottontail rabbit, rattlesnake and several aged turkey hens with healed fractures. These two different episodes of elaborate, ritual burial occurred within a few meters of each other and a human generation apart but they both demonstrate significant, deliberate community scale sacrifice.

Lynch, Sally (McMaster University) [272] The Role of Social Memory in Everyday Bodily Practices of Pottery Production and Consumption during the Late Moche Period (AD 500–800) on the North Coast of Peru
Often the term “social memory” conjures up ideas of grand commemoration events such as statues, museums, large-scale construction and other public displays to remember the collective past. We must not forget, however, the seemingly mundane daily practices that help to create, maintain, and change society while simultaneously forming social identities. This study looks at the Late Moche period (AD 500–800) on the North Coast of Peru. It was a time of immense social, religious, and political change caused in part by environmental upheavals and foreign Highland influence. I propose to examine the role that bodily practices, in particular, pottery production and food consumption, have in the maintenance of a social past as well as future, particularly during periods of social unrest that characterized the Late Moche Period. The ceremonial center of Huaca Colorada in the Jequetepeque Valley provides ample evidence for both mundane daily practices, as well as more overtly commemorative and symbolic events of architectural reconstruction. This study will examine their intersection, as well as evidence of continuity and change in pottery production and food consumption that highlights the role of daily practices in the formation of social memory during the Late Moche period.

Lyon, Jerry (Tierra Right of Way Services, Ltd.) and Jeffrey Jones (Tierra Right of Way Services, Ltd.) [105] Cemeteries, Settlement Development, and Becoming Hohokam in the Northern Tucson Basin
The transition from hunting and gathering to increased reliance on farming and the subsequent development of distinct regional cultural traditions represent critical processes in the prehistory of southern Arizona. Previous research at the site of Valencia Vieja in the southern Tucson Basin suggests the development of a distinct Hohokam cultural identity began during the Tortolita phase (Red Ware horizon) when significant population aggregation originating in the Tortolita phase appear to foreshadow subsequent Hohokam developments. Recent excavations at Early Ceramic period sites (Dairy, Richter, and Lonetree-Redtail-Coachline) within a 4-mile reach of the Santa Cruz River in the northern Tucson Basin provide additional information on sedentism and the emergence of a distinct, local Hohokam tradition. This paper addresses Hohokam origins in the Tucson Basin by examining site structure, occupational histories, and settlement development at three important Early Ceramic localities, two of which were anchored to large, enduring cemeteries.

Lyons, Diane (University of Calgary) [161] Transferring Technological Styles: An Ethnoarchaeological Study of Marginalized Pottery Production in Tigray, Northern Highland Ethiopia
The transfer of pottery making skills and knowledge is well studied in Africa using the chaîne opératoire methodology. Chaîne opératoire is understood as a social practice in which technological choices are guided by social choices that potters learn as members of a potter community. The complement of technological choices of this group of potters creates a unique technological style. Africanists use technological styles to study the history of potter communities through time and space. But what happens if the learning network is transferred to other people? This paper presents results from a regional study of pottery production in northern Tigray. Contemporary pottery production is an economic strategy of very poor women, who are socially marginalized for practicing a despised craft. However, historians argue that blacksmithing and pottery making in the northern highlands were monopolized by a Jewish subgroup called the Beta Israel, who formed an endogamous caste. Most Beta Israel were evacuated to Israel during and at the end of Ethiopia’s civil war (1974–1991). Our study found a more complex social picture of pottery production than historians allow, and contributes to our understanding of the variability in the transfer of technological styles between diverse communities.

Lyons, Kevin (Kalispel Tribe of Indians) [350] Problematic Pixels: Prehistoric Residential Floor Recognition in the Pend Oreille Valley

Public archaeology, as constructed in the United States, is heavily invested in the efficient use of tax and rate payer moneys to identify archaeological sites. The form of this investment, typically, results in a well certified and experienced archaeological practitioner walking the land and/or systematically probing soils. Although well established, this approach is not without its conspicuous errors and project crushing missteps. With the recent proliferation of remote sensing datasets (e.g., lidar) and targeted use of additional methods, can site search failures be reduced and site discovery increase? If systematically applied upon a landscapescale, can such an approach improve needed efficiencies for both commercial and research oriented archaeology? The Kalispel Tribe shares its results of multi-modal search efforts for residential encampments and related phenomena on and adjacent to its reservation.

Lyons, Patrick (Arizona State Museum), Don Burgess (Arizona State Museum), Marilyn Marshall (Arizona State Museum) and Jaye Smith (Arizona State Museum) [390] Maverick Mountain Phase Ceramics from Point of Pines Pueblo: A Preliminary Report

Emil Haury’s1958 synthesis of the Pueblo III–Pueblo IV period (AD 1265–1450) archaeology of Point of Pines Pueblo, in east-central Arizona, is the American Southwest’s classic case study in how to reliably infer ancient migrations. Field school excavations conducted between 1946 and 1960 uncovered compelling evidence of immigrants from the Kayenta region of far northeastern Arizona and southeastern Utah. However, because the excavations at Point of Pines Pueblo have never been fully reported, the site’s ceramic assemblage is not nearly as well understood as it should be. Since 2012, a team at the Arizona State Museum (University of Arizona) has been studying the pottery from Point of Pines Pueblo in order to shed new light on the immigrant occupation. In this paper, we report on the analysis of dozens of previously uncatalogued reconstructible vessels from key contexts at the site. These objects provide insight into interaction between Kayenta immigrants and those who harbored them as well as architectural changes at the pueblo. They also represent critical data for understanding formation process at the site and refining its chronology. Important from a regional perspective, many of these vessels illuminate the development of Pinedale Style.

Lytle, Whitney (University of Texas at San Antonio) [187] Transformations within an Ancestor Shrine: New Discoveries from Group D—Xunantunich, Belize

The concept of transformation is expressed by innumerable cultures and has been explored by archaeologists across the globe. The ritual act is often represented in Maya iconography as rulers and religious practitioners exhibiting their power through the ability to change into their animal uays. However, like individuals, spaces can undergo a process of ritual transformation. This paper examines the subject of transformation and how it is demonstrated through imagery and space within a Classic period Maya ancestor shrine at the elite residential unit of Group D, Xunantunich. I will discuss preliminary analyses of crypts discovered during the 2016 field season coupled with findings from the 2012–2015 investigations and how they represent various manifestations of the transformation theme. First, the re-signification of the shrine from its original function within the Late Preclassic can be seen as an act of transformation. Second, various secondary burials and at least one primary individual were discovered within a crypt containing grave goods which I suggest were meant to transform the burial space into the watery underworld. Lastly, a more traditional representation of this ritual ability is expressed iconographically on two carved shell gorgets found in association with a buried individual.

This paper reviews current evidence for the origins of domestic cattle in China. We describe two possible scenarios: 1) domestic cattle were domesticated indigenously in East Asia from the wild aurochs (Bos primigenius), and 2) domestic cattle were domesticated elsewhere and then introduced to China. We conclude that the current zooarchaeological and genetic evidence does not support indigenous domestication within China, although it is possible that people experimented with managing wild aurochs in ways that did not lead to complete domestication. Most evidence indicates that domestic taurine cattle (Bos taurus) were introduced to China during the third millennium BC, and were related to cattle populations first domesticated in the Near East. Zebu cattle (Bos indicus) entered China sometime between 2000–200 BC, but much less is known about this species. The role of cattle as ritual and wealth animals seems to have been critical to their initial introduction.

With the emergence and development of composite tools in the Upper Paleolithic, adhesives became one of the most widely used materials by early human societies. Of particular interest is to know which animal/plant species were being exploited for glue manufacturing. The Houtaomuga site, located in northeast China, provides favorable materials for the identification of organic residues; and a few bone-handled microblades were collected from this site. In this study, we scraped micro adhesive samples from bone-handled microblades and carried out FTIR and proteomics analysis to determine the protein components and precise origins. The identified signatures from tandem mass spectra of doubly protonated tryptic peptides match most closely to known horse collagen markers, suggesting the adhesive was an animal glue made from horse parts. These results reveal the diverse utilizations of horses at the site, which provided not only meat and hides, but also parts for manufacturing adhesive.

Paleoethnobotany of Yangguanzhai  
[279] Yangguanzhai is a valuable resource for paleoethnobotanists to understand human-plant interactions in Neolithic northwestern China due to its excellent conditions for the preservation of macrobotanical materials. In recent years, several paleoethnobotanical studies on Yangguanzhai have been carried out on site, yielding many results that greatly contribute to our understanding of Neolithic agriculture in the region. Presented in this paper are the results of two systematic floatations conducted in the vicinity of Yangguanzhai. The first is from a well-defined Neolithic house feature, and the second is from a Neolithic moat. The authors utilized a combination of horizontal and vertical sampling strategies to enhance the interpretative value of macrobotanical remains during collection, and the resulting studies were the first intra-feature analyses on Neolithic plant materials conducted in northwestern China. Our results demonstrate that the human-plant interactions at a typical archaeological feature can go through various functional stages and vary spatially. These studies show that inter- and intra-feature relationships can provide substantial context for understanding the diverse trajectories through which plants and human cultures developed in the context of Neolithic China.

Characterization of Early Imperial Lacquerware from the Luzhuang Han Tomb, China  
[78] This paper focuses on presenting the characterization of materials from fragmented pieces of an imperial lacquer plate in the Luzhuang Han tomb, which dates to the early Western Han dynasty. Various noninvasive and minimally invasive techniques were performed, including optical and electron microscopy, XRF, Raman spectromicroscopy, FT–IR, XRD, and THM–Py–GC/MS. The lacquerware pieces consist of a five-layer structure, which includes (from the top): a red pigmented layer, two lacquer finish layers, a ground layer, and a canvas/wood foundation layer. The red layer consists of ground cinnabar mixed with urushi. The lacquer finish layers are made of urushi mixed with perilla or tallow tree oil, without any pigment. The ground layer is a mixture of organic materials including urushi, tree oil and amorphous carbon (possibly burned ashes) and inorganic fillers such as quartz, albite, and potassium feldspar. Urushi was also identified in the canvas/wood foundation layer. Though highly degraded, the canvas is probably made of hemp (bast fibers). The identification of high concentration of drying oil indicates an intentional addition of oil into the urushi to retard the rate of hardening and to increase gloss.

The Body as Machine, the Body as Commodity, and the Body as a Temple: Treatments of Enslaved African Laborers on Buena Muerte Sugar Estates in Cañete, Peru  
[348] From its arrival in Lima in 1709 until the abolition of slavery in 1854, La Orden de la Buena Muerte was among the largest slaveholders in the sugar industry of Cañete, Peru. Moreover, as an order explicitly founded to oversee the physical and spiritual well-being of marginalized communities, the Buena Muerte also played a critical role in public health programs throughout the region. These activities were grounded in fundamentally different, and often opposing, perspectives toward the treatment of persons of African descent. I argue that efforts to more fully understand the institution of slavery on Buena Muerte estates must account for the diverse economic interests and Christian values that shaped attitudes toward the treatment of enslaved African laborers. How did the Buena Muerte reconcile a model of exploitative control over the bodies, health, and standards of living of enslaved persons, with the ecclesiastical project of physical and spiritual salvation? What system of practices for controlling slave labor emerged from this negotiation, and how did it affect the health and well-being of the laborers themselves? To address these questions, I discuss preliminary historical and archaeological findings from ongoing research at one of the Buena Muerte’s sugar estates in Cañete, Peru.

Ochre Quarrying as Placemaking in British Columbia  
[216] In coastal and interior British Columbia, ochre was a key component of local traditional knowledge among hunter-fisher-gatherer communities. Ochre pigment quarries are found in alpine, lowland, and alluvial geologic deposits, and each are uniquely storied locations that carry ideas about history, tradition, and place. The procurement, trade, and use of ochre from each of those locations is deliberate, and embedded within a complex set of ideas and decision-making. Provenance-based analysis of ochre quarries and artifacts from associated archaeological sites has demonstrated continuity and change in the use of specific sources, preferential selection of some quarries over others, as well as variability in the extent and direction of ochre exchange networks.

Archaeology and Geomorphology of Paleo-Shorelines at Yellowstone Lake, Wyoming  
[140] Recent archaeological and geomorphological studies illuminate an understanding of paleo-shorelines along Yellowstone Lake, Wyoming. Current shorelines are not always adequate predictors of prehistoric archaeological site locations due to ever-shifting lake levels over the last 12,000 years. The 20-mile-long Yellowstone Lake is within a caldera and, thus, has experienced dramatic shifts in lake levels associated with volcanism. In addition, lake levels have changed greatly due to Late Pleistocene rebounding from isostatic depression and glacial melting. Until this year, archaeological survey along the eastern shore of the lake had failed to identify Paleoindian sites; however, recent surveys have identified Cody Complex cultural materials on Yellowstone Lake paleo-shorelines as much as 700 m interior from the current beach. In contrast, some paleo-shorelines in the southwestern portion of Yellowstone Lake are submerged under the current lake. This paper attempts to make sense of the information collected by geomorphologists and archaeologists to better understand and predict the locations of ancient sites around the various shorelines of Yellowstone Lake.

[176] The North Coast Prehistory Project of the National Museum of Canada

The objective of the North Coast Prehistory Project was to investigate the development of Maritime adapted cultures in the Pacific Northwest and the role of exchange systems in the subsequent development of stratified societies including advanced systems of trade and warfare based on Northeast Asian prototypes. Excavations of the extensive shell middens of the Prince Rupert Harbor yielded evidence of elaborate militarism along with extensive inland trade. The project worked closely with the oral history experts of the Gitksan/Wetsuweten Peoples in defining the network of trails that linked the communities of the Nass and Skeena watersheds with the adjacent coast and testing their knowledge archaeologically. It was never a primary objective of the North Coast Prehistory Project to excavate human remains from the shell middens in the Prince Rupert Harbor. Nevertheless, it was necessary to remove several hundred skeletons that had been buried within the houses excavated. Studies conducted on the burial materials provided new knowledge on cultural practices, especially warfare, but also on nutrition, periodic resource failures, pathological features. The information on the population that DNA studies provided for the large sample of human burials from sites in the Prince Rupert Harbor continues to provide new insights.

[367] Over the Mountains and through the Desert: Obsidian Use, Procurement, and Transportation in Northwest Colorado

Obsidian is a rare raw material in northwest Colorado. As no naturally occurring sources have been identified in the region, obsidian artifacts recovered at archaeological sites were likely brought in through exchange or direct procurement during seasonal foraging routes. Using X-ray fluorescence (XRF) analysis to identify obsidian sources, this poster addresses three questions related to obsidian artifacts found in the Colorado Bureau of Land Management, White River Field Office (WRFO): what obsidian source materials were used by past inhabitants of the WRFO, how did obsidian sources change over time, and how were these materials transported into the region? XRF data suggest obsidian artifacts recovered from within the WRFO came entirely from sources outside of Colorado, and that a correlation between certain temporal periods and source may exist. To provide a more robust understanding of the XRF data, potential overland travel routes are predicted through the calculation of least cost paths in ArcGIS. Site data collected by the Colorado Bureau of Land Management, in addition to an examination of ethnohistorical accounts, are compared to the predicted routes to assess the accuracy of the paths.

[231] Documenting Dietary Effects of Imperial Collapse and Drought: Bioarchaeology and Stable Isotope Analysis at Huari-Vegachayoq Moqo, Peru

This study examines the diets of 32 individuals who were deposited in the Vegachayoq Moqo sector at the site of Huari, the capital of the Wari Empire. The commingled skeletal remains date to the second half of the Late Intermediate Period (LIP), long after the empire’s collapse circa 1100 CE. This was also a time of an extended drought. The diets, reconstructed from carbon and nitrogen stable isotopes from bone collagen, are compared among the individuals and to those of earlier Wari populations to investigate the sequential effects of Wari imperial collapse and a long-term drought. When the results of the LIP individuals are compared to previously published data of 21 Wari-era inhabitants from the nearby site of Conchopata, their diets are significantly different. The LIP mean δ13C = −11.8‰, showing that carbon enriched foods like maize were still consumed, but this is significantly lower than the preceding Wari era, suggesting that less quantities of maize were consumed. The LIP mean δ15N = 13.0‰, which is significantly higher than the preceding Wari era, a change that might reflect the increased aridity of the LIP, manuring of crops, and/or starvation.

[221] Landscapes of Belief: Structured Religious Practice in Iron Age Central Eurasia

Realistic, symbolic, and metaphorical representations of animals (i.e., Animal Style Art), and associated themes (“griffins”/animal fusion, combat, geometric design within animal) depicted on artifacts attributed to Scythian, Saka, and Xiongnu, from Iron Age (ca., 1000–100 BC) north-central Eurasia are the focus of statistical analyses identifying structured usage among the regions, linked to religious beliefs. Common expression of symbolic subject matter and themes on artifacts is analyzed with Integrated Distance Analysis (IDA), a GIS-based approach. Religion, for this purpose a structured system of beliefs and symbols that permeate everyday life, expressed through symbols and metaphor on material culture compounded with mobile lifestyles are a direct link to landscape utilization to identify and study the structure and expression of religious belief on a continental scale, or macroscale landscape, in north-central Eurasia. This paper demonstrates evidence that widespread display of distinctive and predominantly animal iconography on artifacts associated with the Scythian, Saka, and Xiongnu is a primary line of inquiry for identification of the way Iron Age peoples in central Eurasia interacted between groups throughout the region and structured their lives.

[40] Silcrete from Nearby Sources Display Different Responses to Rapid Heating: Implications for Models of Early Human Heat Treatment

Heat treatment of silcrete in the Middle Stone Age of southern Africa has been taken to indicate cognitive complexity. This inference is based on the argument that silcretes require well-regulated heating and cooling rates to avoid thermal fracture. Alternative arguments have been made that silcrete can be heat treated with limited control over temperature gradients, and thus that heat treatment may have been a relatively simple process. These apparently contrasting positions elide the fact that different silcretes may respond differently to heating. To test this proposition, we replicated a series of past experiments in which silcrete blocks of specific size were heated rapidly to high temperatures. We used silcretes from two nearby sources on the south coast of Australia, and three from sources around the Middle Stone Age site of Varsche Rivier 003 (South Africa). Our results demonstrate sufficient variability in heating tolerance between sources that both the simple and complex models of silcrete heat treatment can be supported, albeit in relation to rocks from different sources. The results imply that when silcretes from multiple sources were used—as at Varsche Rivier 003—optimal approaches to heat treatment may have required the application of more than one method.

Mackie, Alexander (Hakai Institute), Nicole Smith (Hakai Institute), Colton Vogelaar (University of Victoria), Quentin Mackie (University of Victoria) and Joanne McSporran (Hakai Institute) [49] Coastal Settlement Patterns in British Columbia at the Pleistocene-Holocene Transition

In this presentation we explore how early Holocene shoreline settlement patterns in Haida Gwaii can be used to inform the search for late Pleistocene sites on the west coast of the northern British Columbia. The 11K to 14.5K cal BP shoreline on Quadra Island are located at elevations up to 180 m above modern. Low visibility necessitates focused investigations on these raised landforms in order to find early sites. We are applying our knowledge of the distribution of archaeological sites in Gwaii Haanas to Quadra Island. There are nearly 150 sites recorded in the intertidal zone of Gwaii Haanas, Haida Gwaii dating to 10,700 cal BP. Analysis of these data identified significant differences in settlement patterns between these early sites and those dating to the last two millennia. We also discuss whether early Holocene coastal settlement patterns may include a few long term residential sites from which people accessed many short term sites.

Mackie, Madeline (University of Wyoming), Todd Surovell (University of Wyoming), Robert Kelly (University of Wyoming) and Matthew O'Brien (California State University, Chico) [332] New Excavations at the La Prele Mammoth Site, Converse County, Wyoming

The La Prele Mammoth site (formerly the Hinrichs or Fetterman Mammoth) was discovered and initially excavated in 1987 by a crew led by Dr. George Frison. The remains of a single juvenile Columbian mammoth (Mammuthus columbi) were recovered along with a stone tool, a possible hammerstone, and a dozen pieces of debitage. Due to landowner dispute, no further work was completed on site for 27 years. In 2014 we returned to investigate the potential for intact deposits and settle the debate about cultural use of the mammoth. The last three field seasons have resulted in clear evidence of human activity associated with the mammoth. The fortuitous discovery of a chopping tool 12 m south of the mammoth bone bed in 2014 resulted in the identification of a secondary work area, the “Chopper Block.” This secondary location has produced multiple stone tools, hundreds of pieces of debitage, and artifacts never before seen in association with a mammoth in North America, including bone needles and an extensive ochre chert. The site offers the opportunity to better understand the activities which occurred at mammoth butchery sites during the Clovis time period.

Mackie, Quentin (University of Victoria), Colton Vogelaar (University of Victoria) and Daryl Fedje (Hakai Institute and University of Victoria) [49] New Approaches to the Underwater Archaeology of Hecate Strait, Haida Gwaii, British Columbia

Archaeological investigation of the possible coastal route into the Americas has always been hindered by sea level changes, including the drowning of much of the Pleistocene coastal plain. While it is now understood that significant portions of the coastal plain were never drowned, it is also clear that some of the underwater terrestrial landscape is intact and has archaeological potential. New approaches to the survey and modeling of paleocoastlines may increase optimism of finding underwater coastal sites. In this paper we discuss underwater research on the seafloor of Hecate Strait, near Haida Gwaii, British Columbia. Swath bathymetry reveals intact landforms up to 145 m deep, confirmed by grab-samples of in situ plants and intertidal fauna. Local archaeological sites put people on the landscape by ca. 12,700 cal BP, when sea levels were 100 m lower than modern, and bears and salmon are locally present by >14,000 cal BP. In this poster we discuss use of an Autonomous Underwater Vehicle to obtain high-resolution sidescan sonar of the seafloor. We also demonstrate some approaches in paleocoastal modeling which may help predict site location and recovery of archaeological materials from the deeply-drowned landscape.

MacLellan, Jessica (University of Arizona) and Daniela Triadan (University of Arizona) [236] Child Burials and Figurines at a Terminal Classic Maya Household, Ceibal, Guatemala

The ancient Maya center of Ceibal is known for a florescence during the Terminal Classic period (c. AD 800–900), a time when most cities in the region were in decline. Excavations at the Karinel Group, a residential complex, have focused on the site’s Preclassic origins. However, an elite household also occupied the area during the Terminal Classic period. The residents built four house platforms around a patio, had access to high-status goods, and took part in crafting activities. Along the centerline of the patio, they deposited a series of burials, mainly of children. These burials contained many grave goods, including ceramic figurines that functioned as ocarinas. Figurines have been found in two other child burials, and no adult burials, at the site. It has been observed elsewhere that Classic Maya figurines are frequently associated with women and children. These musical instruments shaped like human, animal, and supernatural characters may represent toys and educational tools, used for enacting intimate performances within the household. When compared to previously excavated burials at Ceibal, the Karinel Group burials demonstrate a flexible set of mortuary practices shared by elites during the Terminal Classic.

Macrae, Scott (University of Florida) [214] A Comparative Approach to Deciphering Past Agricultural Strategies in the Tropics: The Shared Trends of Resiliency, Vulnerability, and Complexity

Tropical environments are defined by a shared suite of climatic and environmental variables. These unifying characteristics led past archaeologists to delineate these regions as incapable of fostering state level civilizations. These interpretations presumed a lack of resources required to support agricultural production at the level obligatory for the urban centers that define states. Modern studies in tropical ecology question this perspective by identifying a high degree of localized resource diversity. A comparative study of how tropical societies fashioned their agricultural strategies to manage climatic and environmental conditions, while exploiting local heterogeneous resources, reveals how past peoples were able to cope with their surroundings while supporting complex tropical states. This will be examined in case studies from classical era Southeast Asia (CE 800–1400) and Mesoamerica (CE 250–900), drawing evidence from excavations, historical documentation, and observations of living systems. Following the research objectives of the Socio-ecological Entanglement in Tropical Societies project, the presentation will address resilient and vulnerable qualities within the agricultural methods employed. Results demonstrate a shared trend toward increasing complexity within the agricultural strategies of these tropical societies as they managed their environmental circumstances and supported state level populations with increasing social hierarchies.

Madsen, Alan, Sean Dolan (Los Alamos National Laboratory) and LeAnn Purtszer (Los Alamos National Laboratory) [366] Stump Holes and Soot Staining: A 15-Year Update on the Wildfire Hazard Reduction Project at Los Alamos National Laboratory

The frequency and severity of wildfires in northern New Mexico over the past several decades have increased, and wildfires often impact archaeological sites. In May of 2000, the Cerro Grande Fire burned approximately 48,000 acres of land in northern New Mexico including 7,650 acres within Los Alamos National Laboratory (LANL). Following the Cerro Grande Fire, wildfires continue to pose a threat to the Los Alamos community, LANL facilities, and cultural resources. In 2001, LANL implemented the Wildfire Hazard Reduction Project to reduce fuel loads (tree thinning) and to minimize impacts from future wildfires. A plan was implemented to survey burned and high risk areas, and mark all known and newly discovered archaeological sites for avoidance during tree thinning operations. Archaeologists surveyed approximately 7,800 acres and discovered 467 previously unidentified sites. Progress toward completion of site recording has been limited by budget, resources, and project load at LANL. As of 2015, 262 of the 467 cultural sites have been recorded. Sites consist of field houses, pueblos, cavates, rock art, trials, and artifact scatters ranging in dates from Early Archaic (5500 BC) to the Manhattan Project (1940s). This poster documents the work LANL archaeologists have completed so far.

Madsen, Christian K. (Greenland National Museum/National Museum of Denmark), Ian Simpson (University of Sterling), Michael Nielsen (University of Greenland) and Jette Arneborg (National Museum of Denmark) [190] On the Margins of the Marginal? Fringe Settlement and Land Use in Norse Greenland

Just before AD 1000 pioneer Norse hunter-farmers settled in Greenland and established what would be the extreme western outpost of Scandinavia and Europe for the next 450 years. The unexplained disappearance of this marginal medieval colony around AD 1450 has always puzzled researchers, as it posed a threat to the Los Alamos community, LANL facilities, and cultural resources. In 2001, LANL implemented the Wildfire Hazard Reduction Project to reduce fuel loads (tree thinning) and to minimize impacts from future wildfires. A plan was implemented to survey burned and high risk areas, and mark all known and newly discovered archaeological sites for avoidance during tree thinning operations. Archaeologists surveyed approximately 7,800 acres and discovered 467 previously unidentified sites. Progress toward completion of site recording has been limited by budget, resources, and project load at LANL. As of 2015, 262 of the 467 cultural sites have been recorded. Sites consist of field houses, pueblos, cavates, rock art, trials, and artifact scatters ranging in dates from Early Archaic (5500 BC) to the Manhattan Project (1940s). This poster documents the work LANL archaeologists have completed so far.

Magalhães, Marcos (Museu Paraense Emilio Goeldi) [62] A Cultura Tropical e a Origem da Antropização da Amazônia

Arqueólogos estão revelando que além de terem domesticado algumas plantas para consumo, como a mandioca, por exemplo, os indígenas teriam agido de modo a cultivar florestas inteiras! Além disso, pesquisadores de diferentes áreas do conhecimento estão confirmando que a formação de parte das florestas e biodiversidade amazônicas, é produto da seleção cultural de espécies. A consequência disto foi que, muito provavelmente, boa parte das florestas conhecidas como naturais seriam, na verdade, obra do engenho humano. Isto é, de origem antrópica. Em cavernas localizadas no topo da serra de Carajás existem evidências de que populações caçadoras-coletoras, que teriam chegado na Amazônia no início do Holoceno há mais de 11,000 anos, já exerciam impactos significativos sobre o ambiente. Em termos gerais, muito provavelmente, essas populações viviam da caça, da coleta, da pesca, do manejo e, posteriormente, também do cultivo de pequenas roças. O conjunto dessas ações vai constituir um processo civilizador de longa duração conhecido como Cultura Tropical. Foi durante a Cultura Tropical, portanto, muito antes das populações sedentárias horticultoras, que foi iniciado o manejo, a domesticação de plantas e, inclusive, a produção artesanal de cerâmica.

Magee, Shelby (University of New Mexico) [346] From Roads to Ritual: Comparing Logics and Scale of GIS Analyses of Inka Imperial Landscapes

During their expansion throughout the Andes, the Inka Empire restructured a cultural and physical landscape to meet objectives of logistical and ideological control over their subjects. While this process is embodied by archaeological features such as large-scale infrastructure and the strategic positioning of sacred places, interpreting these datasets require appropriately scaled analyses for which GIS is uniquely suited. In this paper, I explore this topic by comparing two geospatial analyses, each evaluating a different aspect of Inka imperialism. I first use a Least Cost Path Analysis (LCPA) performed on a segment of the Chinchaysuyu Inka road from Cuzco to Vilcashuaman in central Peru to inform how the Inka used roads as a means of imperial control on a regional scale. The second case study addresses ritual activity on a more localized scale with a Visibility Analysis (VA) from the
mixed Inka/local administrative center of Turi in northern Chile. This analysis scrutinizes the location of the surrounding non-Inkan sites’ ritual contexts to discuss where indigenous rituals were continued after the incorporation of the settlement into the Inka Empire and whether or not these ritual activities were performed out of sight of imperial authorities.

Magnani, Matthew (Harvard University)

Finding the Right Spot: Utilizing Historic Maps, Period Imagery, and Archaeological Data to Identify Aircraft Crash Sites within the Larger Battlefield Landscape

Identifying aircraft crash sites is a critical component of the mission of the Defense POW/MIA Accounting Agency. This paper uses several examples of aircraft crash incidents and illustrates the contextual use of multiple lines of data, such as historic imagery, GPS, period maps, and GIS for the effective location of individual crash sites across the greater battlefield landscape. This effort is undertaken to help address the goals associated with DPAA’s greater mission: the return of missing U.S. service members associated with past conflicts.

The Potential for Georeferenced Spatial Data on Coastal Erosion Sites
Coastal erosion sites contain the same complexity as any other site; however, the sequences are often truncated and the recovery conditions require adaptive approaches. Although these sites are eroding, there is a need for equal rigor in their recording. The coastal erosion site at Swandro, Rousay, Orkney, has been recorded using a variety of georeferenced datasets. This paper examines the potential of microanalysis of the 3D coordinate records of artifacts and georeferenced photogrammetry from a single building. The complex deposition sequence, together with the spatial distribution of artifacts within a Late Iron Age Structure, are explored using GIS. The deposits within the building indicate slag and other artifacts associated with metallurgy. The analytical potential for an integrated management using GIS is explored here. The potential that coastal erosion sites have for the understanding of formation and cultural interpretation at a micro-level is highlighted in this paper.

Mahoney, Maureen (Seminole Tribe of Florida THPO)

**Dating a Tree Island: A Comparison between Faunal Bone, Shell, Pottery, and Coprolites**

South Florida’s tree island hammocks are islands that were once completely surrounded by water and used as habitation areas from the Archaic period and beyond. Although many islands along the coast can be dated using marine shell, interior tree islands (such as those found on Seminole Tribe of Florida reservation lands) generally lack these artifacts making for a difficult dating strategy. This paper will focus on a comparison of dating material, including shell, pottery, faunal bone, and coprolites to determine the accuracy of results from each sample type. This analysis will prove important in determining the overall age of tree island archaeological sites located in South Florida, and provide unique insight into tree island formation processes.

**The Palace of Muweis and Its Medieval Necropolis**

Muweis is located in the Shendi reach, about 300 km north from the capital of Sudan, Khartoum. Its palace has been excavated by the Louvre Museum since 2007. It is part of the Meroitic Kingdom (350 BCE–350 CE), which covered an area of 1,500 km on the Middle Nile Valley, making it the most important political structure known in Sub-Saharan Africa until the nineteenth century. In 2008 a medieval necropolis was discovered among the remains of the palace, under the debris of a small house situated at the top of the mound sheltering the monumental building. Twenty-one graves were identified dating to the thirteenth century CE. The palace ruins give insight into the hierarchy (i.e., position) of the graves within the necropolis. Indeed, according to social status, the graves were dug in particular spots of the palace ruin. For example, grave F15, corresponding to the burial of the community leader, was placed at the very heart of the palace and covered by wooden beams, the only architectural feature recognizable in the necropolis. This presentation is dedicated to the archaeology and site description of this necropolis.

**Stable Isotopic (δ13C and δ18O) and Zooarchaeological Insights into Vertical Transhumance of Early Neolithic Domesticated Sheep and Goats in Southern Jordan**

Vertical transhumance provides livestock with consistent access to quality graze throughout the year and likely contributed to the intensification of livestock husbandry in the Near East over 10,000 years ago. Here, carbon (δ13C) and oxygen (δ18O) isotopic time series obtained from sequentially sampled domesticated and wild herbivore teeth recovered from late Pre-Pottery Neolithic B (ninth millennium cal BP) settlements, each located in the sharply divergent elevations of southern Jordan, were measured. Inverse cyclical variation visible in the carbon and oxygen isotopes of sequentially sampled sheep and goat teeth, and further calibration of sheep and goat δ18O values against those from aurochsen and gazelle, which track the oxygen isotopic composition of meteoric water and leaf water, respectively, reveal use of complex livestock husbandry systems that included vertical transhumance, stationary flock-keeping, and winter foddering. These isotopic data are then used to further inform zooarchaeological datasets from late PPNB settlements located in the Jordanian highlands and steppic margins.

Makowski, Krzysztof

**Religion and Power in the Middle Horizon: Castillo de Huarmey Imagery and Styles**

The idea that diffusion of a proselytizing religion is one of the main factors that generated the horizon effect follows the research on Wari and Tiwanaku phenomena since its inception. The seminal works of Dorothy Menzel have also convinced generations of scholars about the alleged relationship of these phenomena with the Wari Empire ideology and on the particular role that the sanctuary of Pachacamac fulfilled in this process. The analysis of rich ceramic and textiles from Castillo de Huarmey, the necropolis of high Wari elite and administrative center on the northern coast of Peru, built in the second half of the Middle Horizon (AD 800?–1000), contrary to expectations, does not offer any arguments to support this hypothesis. Despite the large number of fragments and whole pieces relating to probable local imitations of southern styles from the Wari nuclear area, the presence of characters and details typical for the iconography of Conchopata and Wari—the staff gods and winged characters—is rare in the elite funerary grave goods, with the
except for some textile and wooden objects, that were possibly imported. Very similar situation can be observed in Pachacamac funerary contexts and in post-Lima culture offerings.

Malainey, Mary (Brandon University) and Timothy Figol (Brandon University) [21] But Did They Eat Their Greens? Evidence of Plants in the Pottery of Northern Plains Bison Hunters and their Neighbors

Accounts of the amount of meat consumed by First Nations who relied on bison are spectacular; but, there are also reports of plant collection and use. The challenges and successes of using lipid residue analysis to detect plants in precontact Indigenous pottery are outlined. Fatty acid compositions of fresh roots, greens and certain berries form several distinct clusters when subjected to statistical analyses. Degradation processes arising from cooking and the passage of time tend to remove these differences. The presence of these low fat content plant products is typically indicated by residues with elevated levels of medium chain saturated fatty acids. The occurrence of plant sterols and characteristic distributions of triacylglycerols can provide additional support for these identifications. Lipid residue analysis shows that certain pots recovered from sites in the Northern Plains, adjacent parkland and southern boreal forest were reserved exclusively for plant materials. When combined with functional analyses, it is clear that certain Late Precontact Period vessel forms were more likely to contain only plant products. Lipid residues extracted from other vessels indicate plants were also prepared in combination with animal products.

Malcolm, Dee (Clark State Community College) [19] Incorporating Sex/Gender and Sexuality Studies into General Education Curriculum

When considering how to incorporate sex/gender and sexuality studies into college curricula, the question is: Where to start? In this paper, I argue that college and university programs should include content on the social construction of sex/gender and sexuality within general education courses. I will predominately focus on my work with Ohio community college students as a case study that has broader implications for general education outcomes. Pairing courses such as Sociology and Archaeology (as well as other social sciences) provides opportunities for the creation of learning communities to address social topics such as sex/gender and sexuality from diverse perspectives. Teaching across the curriculum enables an open dialogue to critically review the many causes of, and potential solutions for, inequality. Further, academic collaboration functions to create greater social awareness and understanding through the analytic process of intersectionality.

Maldonado, Blanca (El Colegio de Michoacán, A.C.) [164] Primary Copper Smelting in Mesoamerica: A Case Study from Central Michoacán

Copper was the main metal produced and worked in Mesoamerica, but data for premodern primary production and processing remain elusive. Systematic research at Itziparátzico, a Late Postclassic location in Central Michoacán, Mexico, has located evidence of copper production areas where concentrations of smelting slag were recorded. The absence of metallurgical materials other than slag (e.g., crucible fragments, mold fragments, stock metal, metal prills, failed castings, part-manufactured objects and spillages, etc.) around Itziparátzico indicate that only primary copper production had been carried out at the site. The analyses of slag samples corroborate that the production activities carried out at Itziparátzico involved primary smelting, and revealed a sophisticated smelting method, possibly involving the use of furnaces properly designed and built to provide reducing conditions during the refinement of copper ores. Recent archaeomagnetic dating of slags recovered from the area substantiate the Prehispanic origin of this technology.

Maldonado, Ronald (Westland Resources) [394] Long Day’s Journey into Night: Government to Government Consultation under Section 106 on the Navajo Nation

Section 106 of the National Historic Preservation Act of 1966, as amended requires that the Federal Agencies consult with American Indian Tribes on a government to government basis. There are numerous guidelines and trainings on how this should be accomplished under the law, but these do not consider the Tribal point of view. American Indian Tribes are sovereign Nations and expect to be treated as such, expecting long term relationships with Federal Agencies. During my tenure with the Navajo Nation, it was my job to build those relationships, by educating the Agencies and project proponents as to why the cultural resources were important to the Navajo People. These cultural resources were both on and off the Navajo Nation lands, so consultation could also include 22 other tribes who claim aboriginal use of Navajo Reservation lands and other Federal Lands. How these resources were managed was dependent on the relationships that had been built over the years.

Malfatti, Gina (College of Wooster) and Paul Nick Kardulias (College of Wooster) [90] Viking Age Grave Reentry within the Context of Mortuary Drama

The present study traces the history of grave manipulation and reentry in Scandinavia from the Stone Age through medieval times, but with a special emphasis on the context and implications of funerary activity during the Viking Age and the early medieval period. During this time span, the people of Scandinavia became a major force that reshaped the economic, political, and social structure of Europe. I examine the phenomenon of grave reentry and alteration within the framework of Neil Price’s (2010) idea of Viking Age “mortuary drama.” This study extends the idea of mortuary drama to the acts of reentry that may occur even centuries after the initial funerary performance. Particular emphasis is placed on boat and ship burials because they reflect the wealth and power of emerging elites. This study will discuss several sites including the Gokstad and Oseberg ship burials and the Valsgärde cemetery. The themes of space, monumentality, memory, and ritual all play a part in the theoretical perspective that the present study employs.

Malhi, Ripan (University of Illinois Urbana-Champaign) [176] Eight Years of Partnership with Coast Tsimshian First Nations on Genomic Research

In 2008 a partnership was established with the Coast Tsimshian to use genomics as a novel avenue of research to learn about the population and evolutionary history of these First Nations. Community based research methods were used as a way to establish research goals that were respectful and mutually beneficial to all parties. Through this partnership we have been able to gain insight into the present-day and ancestral Coast Tsimshian genetic structure. Specifically, we have demonstrated a close genetic affinity between present-day members of the Coast Tsimshian community and ancestors through paleogenomics analysis of human skeletal remains from the Prince Rupert Harbour region. We have also showed how ancient peoples of that

Knapping Flint on a Brush Hut Floor: An Example from Ohalo II, a 23,000-Year-Old Camp in Israel

Thousands of open-air campsites dating to the terminal Pleistocene and early Holocene have been recorded around the world. However, most suffer from significant preservation issues which limit available data on two levels: the general camp structure, and the details of each feature. The excellent preservation of the submerged site of Ohalo II (23,000 cal BP) provides an opportunity to analyze such a site on both levels. The focus of the paper is a flint assemblage (n = 5,621) from a fully-excavated brush hut floor serving as a case study for characterization and analysis of flint knapping activity. The assemblage was fully studied for all its components and the results were mapped and statistically analyzed for correlations between components. Furthermore, 62 flint specimens were refitted (including cores, debitage and tools). Two in situ and spatially distinct knapping/activity areas were identified, one of which was devoted to manufacture and/or retouching and/or storage of microoliths. Similar remains show that the same activities took place in other brush huts. Each floor was also rich with butchered animal bones, fish remains, and edible cereal grains. We conclude that each brush-hut appears to represent a household unit that included “indoors” tool preparation, maintenance, and maybe even discard.

Just a Scratch: An Experimental Application of Reverse-Microwear Analysis

In the summer of 2013 a thin piece of slate with peculiar, jagged grooves was recovered from the excavation of the Buzzart Dykes medieval park landscape in the council area of Perth and Kinross, Scotland. Unclear whether the grooves were natural or anthropogenic we employed a new method of examination, known as “reverse microwear analysis,” to understand what material made the scratches. A series of experiments were conducted where slate pieces were incised using a variety of different stone and metal artifacts. Using high resolution microwear images taken with a Nikon SMZ 800 stereoscopic microscope with a range of 20x–120x magnification, we compared our control group to the incisions present on the artifacts to try and determine the most likely method used to create these marks. The result was a new methodology for understanding the slate artifact as contemporary with the medieval park or an artifact of the pre-medieval landscape disturbed during the park’s construction phase. Furthermore, this methodology has applications for understanding artifact creation when there is discrepancy surrounding age, tool utilization, and artifact processing.

Introduction—Islands Connected or Unconnected: A Case Study of Malta

Islands gave birth to many cultural and economic adaptations in prehistory. After an introduction to the symposium, the paper will focus on the small archipelago of Malta, which demonstrates a particularly resilient trajectory of survival set against environmental and economic limitations that lasted millennia. Compared with the neighboring areas (Sicily, Sardinia, Italy) Maltese megalithic “Temple” culture presented an unparalleled c.1,500 years of unbroken development, and this paper discusses the factors that enabled a very small community to develop coping strategies more typical of advanced civilization than of Neolithic society. Recent intensive fieldwork of the FRAGSUS project (funded by the European Research Council) has revisited sites last examined a century ago, to sample chronological and paleo-economic data to reassess the apparent longevity of early Maltese cultures. The discussion will explore whether present data can demonstrate if these early peoples were as connected to each other through shared identities and exchange of material goods as we might expect in the relatively restricted space of the Mediterranean, or whether the emergence of disconnectedness is the outcome of close proximity and broadly similar shared origins.

Changing Social Spatiality in Mounded Funerary Landscapes

Funerary landscapes, as places where all fractions of society meet to honor the rituals of social and identity-building importance, can be used to attain an insight into group-specific attitudes toward spatiality. These attitudes allowed for people’s engagement with various elements of their environment as a means of deliberate creation of lasting ritual landscapes. However, social spatiality in funerary contexts is not static, but subject to changes in the group’s perception of both their landscape and their dead. Fifteen recently discovered tumulus sites in the region of Županjska Posavina in Eastern Croatia represent a unique ritual landscape and offer evidence for these changes which took place at the transition from the Middle to the Late Bronze Age. Ongoing excavations at one of these sites, Purić-Ljubanj, have shown that, while maintaining the most visible elements of the ritual during this period, the people have changed the inner architecture of the mounds and stopped the spreading of the cemetery by inserting the new mounds between the already existing ones. The results from these excavations may serve to determine how the reinterpretation of the ritual and the existing landscape may give rise to new forms of expression of local identity in prehistory.

Geoarchaeology of the Coffey Site, Northeastern Kansas: Implications for Finding the Material Remains of Paleoamericans in the Eastern Plains, USA

The Coffey site in the Big Blue River valley of northeastern Kansas is best known for its stratified Middle Archaic components. However, recent investigations at the site recorded stratified Late and Middle Paleoindian cultural deposits and what may be an Early Paleoindian or Pre-Clovis component in the late member of the Severance Formation, a Wisconsinan-age lithostratigraphic unit that occurs as a remnant beneath the T-1 terrace of the Blue River. The late member of the Severance Formation appears to span Marine Isotope Stage 2 and records valley activity just prior to and during cool and dry conditions that coincide with the accumulation of Peoria Loess and related eolian sand on the T-2 terrace and upland landscapes. This paper addresses the stratigraphic context of the Paleoindian components in the Severance Formation at the Coffey site and considers the potential for pre-Clovis cultural deposits in the Severance at Coffey and elsewhere in the Eastern Plains of the United States.

Between Farming and Hunting: Animal Exploitation in the Zacapu Basin, Michoacán, Mexico (AD 100–1450)

If the questions of herding or management of wild species have been regularly addressed in Mesoamerican zooarchaeology, cultural development is assumed to be essentially directed by agriculture. Indeed, the presence of only two widely recognized domesticated animals, the dog (Canis familiaris) and the turkey (Meleagris gallopavo), would have limited the growth of a more complex agropastoralism. However, the importance of nondomesticated animals and their interactions with the agricultural sphere may be underestimated. As demonstrated by ethnographic data, traditional Mesoamerican populations would obtain not only crops from cultivated fields, but small animals as well through a practice of so called garden-hunting. Based on the zooarchaeological study of three sites from the Zacapu Basin (Michoacán, Mexico), ranging from AD 500 to 1450, this presentation will explore the relationships between animal exploitation and cultural construction. We will show how exploitation practices evolve, following an increasing demographic pressure in the region, from an opportunistic hunting behavior to the development of garden-hunting and what seems to be the late adoption of the turkey as a new domesticated animal.

DNA Preservation in Archaeological Dental Calculus and Dentine

Ancient DNA provides unique insights into past human behavior, health, and evolution. Skeletal tissues (bone and dentine) and microbiome remains (dental calculus and paleofaces) can be rich sources of ancient biomolecules; however, inconsistent DNA preservation and variable environmental contamination pose major challenges in recovering authentic ancient DNA. Recent studies have suggested that dental calculus may provide a better preservation environment for ancient DNA than other skeletal tissues, but this hypothesis has not yet been systematically tested. In this study, we analyze the preservation of microbial and human DNA in 12 paired dental calculus and dentine samples from 6 archaeological sites (spanning 2950 BCE to 1900 CE) using a high-throughput metagenomics approach. We find that endogenous microbial DNA is typically more abundant and better preserved in dental calculus than in dentine, and we report differences in DNA preservation between oral-associated bacteria and archaea. By contrast, human DNA is typically more abundant and longer in dentine than in dental calculus, but there is also a higher rate of cytosine deamination damage in dentine, suggesting greater vulnerability to single-stranded DNA generative processes.

Understanding Pleistocene and Early Holocene Faunal Exploitation at Barrow Island, Northwest Australia

Barrow Island, located 50 km off the modern Pilbara coast, contains the longest and richest archaeological record of Pleistocene coastal settlement in northern Australia. During lowered sea levels of the Pleistocene, the island was part of the greater Australian continent. Archaeological survey has revealed an array of sites in cave, rockshelter, and open-air settings. The most diverse record has been recovered from a large limestone cave, where repeated visits began at c. 50 ka BP and continued until 7.5 ka BP, when increasing sea levels isolated the island from the mainland. Archaeofaunal records demonstrate that throughout this time, people visiting Boodie Cave exploited a combination of marine and terrestrial resources. Although medium and large-sized macropods are staple foods throughout occupation, various marine resources are found from the oldest deposits onward.
During much of the Pleistocene, prey consisted of medium-large terrestrial game and marine gastropods, but as the coastline neared the site, an increasingly diverse range of resources was consumed. This culminated in the early Holocene, when prey included over 25 species of vertebrates and 40 species of shellfish. These patterns likely reflect the changing role of the cave within the cultural landscape, rather than any dramatic shifts in resource exploitation strategies.

Manning, Sturt [81]

Prospects and Challenges for High-Resolution 14C Chronologies: New World and Old World Investigations

This paper will present some current work in 1) NE North America (northern Iroquoia), 2) NW Mexico, and 3) the East Mediterranean-Caucasus using radiocarbon (14C) dates integrated with archaeological/historical and/or dendrochronological information to try to achieve high-resolution chronologies via Bayesian chronological modeling. The paper will discuss and investigate the potential to achieve much greater precision which, through defining new chronologies, can in turn be transformative for archaeological and historical analysis. But the paper will also consider some of the problems or limitations in such work, and will review the conditions necessary to achieve robust, precise, and accurate chronologies for the past via radiocarbon and Bayesian chronological modeling.

Liminal Agents: Exploring the Social, Ritual, and Cosmological Aspects of Fishhook Manufacture in Middle Mesolithic Coastal Communities (8300–6300 BC)

This contribution aims to investigate the entanglement of environment, materiality, technology and cosmology in the Middle Mesolithic Stone-Age (8300–6300 cal. BC), of the North East Skagerrak area, Eastern Norway and Western Sweden, by focusing on the manufacture of bone-fishhooks. I argue that fishhooks are keys objects for exploring the worldviews of Middle Mesolithic coastal groups. Fishhooks were linked with daily subsistence, invested with much labor, and their manufacture entwined with the hunting of ungulates that provided the raw material. The process of producing fishhooks involved the transformation of living bodies into artifacts. Thus, I argue that these mundane objects were considered active agents in mediating the dangers and insecurities of an unpredictable “life aquatic.”

Manzanilla, Linda R. (U Nacional Autonoma de Mexico)

Xalla, Teotihuacán: A Multifunctional Palace for the Ruling Elite of Teotihuacán

In corporate societies such as Teotihuacán, it is not easy to detect the places where the ruling elite dwelt, made decisions, managed goods and labor, or participated in cult activities. Teotihuacán is very different from the Maya urban sites: no royal tomb has been found, rulers are not depicted or easily recognized. The corporate organization may have permeated the ruling elite, where a possible council of lords may have headed the Teotihuacán state. Xalla, with a surface of ca. 50,000 m², is located 235 m to the north of the Pyramid of the Sun. Since 1997, it has been under research by Linda R. Manzanilla; 15% of it has been extensively excavated. It may have been one of the seats of power for ancient Teotihuacán. The main plaza consists of four equivalent elevated precincts, one to each cardinal point, and set around a temple in the center. These four precincts had iconographical elements related to different deities, suggesting that the possible co-rulers may have been related to particular gods. The ruling elite of Xalla had embedded craftsmen located in Plaza 5: lapidary craftsmen, painters, garment-makers, carpenters, and perhaps also potters. Xalla has also a royal treasure of mica.

Prehistoric Pottery Production and Distribution in the Shkodër Region of Northern Albania

The aim of my poster is to present new provenience data regarding pottery sherds from several prehistoric archaeological sites in Shkodër, Albania. The pottery samples to be analyzed are from survey and excavation and were collected by the Shkodra Archaeological Project (PASH). Pots appear to have played important social and economic roles in Shkodër, but we do not yet know where they were made. Previous studies based on stylistic analysis refer to the large hill fort site of Qajtan as a center for pottery production during prehistory. My research tests this assumption using methods of petrographic analysis. Petrography points to multiple production centers and some limited ceramic exchange.

Marajh, Leah (University of Toronto)

The Socio-Ecological Entanglement of Water and Resilience in Past and Present Tropical Societies

Urban resilience and sustainability have gained increasing prominence in the literature as concerns regarding water resources and climate change continue to grow. Cities, particularly those in the midst of extreme urban development, are facing a wider range of stresses that call for greater enhancement of resilience techniques. This paper highlights the work of the Socio-Ecological Entanglement in Tropical Societies (SETS) project, whose goal is to investigate resilience and vulnerability within particular socio-ecological relationships among past tropical societies in South and Southeast Asia and Mesoamerica. The water management sub-project focuses on the availability, accessibility, and use of water resources. Stresses, such as climate change and increased urbanism, have created challenges to water conservation, both in ancient and modern times. An examination of these stressors on past water management in the SETS research sample, compared to those of the present-day, will provide insights and foster strategies toward the long-standing difficulties in producing “resilient cities” with greater levels of sustainability.

March, Ramiro Javier (UMR 6566 CNRS CREAAH [France])
Reconstructing the history of organic matter in archaeological context presents a challenge. Organic chemical signatures are the consequence of complex natural and anthropic processes that must be decoded in order to understand their hypothetical significations. This task follows different epistemological, methodological, and practical choices and needs to integrate knowledge from different disciplines. As a consequence, the characterization of the different molecules is related to the original question, the methods put in practice, and differential hypothetical environmental processes. For example, soils, ceramics or stones, may contain organic matter from different anthropic activities that can be unique or repeated. Further, these artifacts can subsequently be exposed to different kinds of natural interactions. Experimental approaches try to solve these difficulties but sometimes can lead to new and interesting questions about supposed paradigmatic explanations. We present here some case studies showing this complexity and their evolving answers.

[170] The Rise and Fall of the Bi-Headed Serpent: How Much of Late Lima Cultural Development Could Be Explained by an ENSO?
In the present paper, I will combine evidence of two sites: The Pachacamac Sanctuary and the domestic site of Late B, both in the Lurín valley in order to discuss the political changes happening in the central coast to the onset of the middle horizon. Asking how these political changes related with the climatic variation register for the area in both bottom sea and lake cores. I point out that this process of political centralization was contemporaneous with mayor climatic anomalies that have been proposed correspond of an ENSO. In specific, I will explore how the rise of a new political organization (called Late Lima) and their posterior dismiss related with this recorded climatic phenomena. At what level the transit of the Lima population at the Lurín Valley from independent communities under the Lima milieu, to be part of a local based Late Lima state. This state that finally disappear not leaving trace of occupation by the second half of the Middle Horizon. How much of these rise and fall of Late Lima was consequence of natural phenomena.

[85] A Bayesian Solution to the Controversy over the Identification of Bone Surface Modification in Paleoanthropology
Bone surface modification (BSM) remains a primary source of taphonomic inference in paleontological and archaeological contexts. However long-standing debates in BSM studies have undermined the utility of this approach. We use an objective machine-based learning algorithm rooted in Bayesian probability theory designed to quantify the level of uncertainty associated with a formal assignment of agent to individual BSM. Our multivariate Bayesian model, trained on large assemblages of experimentally generated BSM, accurately assigned agent of modification to an out-of-sample test with an average of 86.5% accuracy. Here we present the results of our updated probability model. We improved upon our existing model with the introduction of novel variables and an increased sample of experimentally generated training data produced by Nile crocodile feeding, spotted hyena feeding, large ungulate trampling, and human unmodified rock butchery. Here we also present the posterior distributions of model parameters associated with the morphology of individual BSM. Certain BSM attributes frequently associated with stone tool butchery marks (e.g., perpendicular orientation relative to the long axis of the bone, occur as a result of nonhuman agents of modification. Here we quantify the probability that key attributes are likely to occur with each respective agent of modification.

[329] Integrating and Disintegrating the North Acropolis of Yaxuna, Yucatán, Mexico
The North Acropolis of Yaxuna was the primary focus of ritual and administrative life at the site during the Classic period and functioned as a focal point for involving the local population in integrative activities. Yet architectural evidence suggests that this architectural complex changed in function over the course of its use. The acropolis was first built in the Late Formative and was modified up until the Late Postclassic. We argue that the changes we see in the architecture of this complex had to do with changing social and political relationships with other sites across the Maya lowlands just as much as they had to do with internal processes. In this paper we try and understand the types of activities undertaken at the acropolis through the analysis of material artifacts from a large trash pit associated with the complex. Copious amounts of ceramic, lithic, and bone materials, particularly from the Late and Terminal Classic periods, shed light on the types of activities undertaken at this group and help us contextualize processes of integration and disintegration.

Interweaving Colonial and Local Networks: Textile Production in Early Iron Age Iberia  
The role of textile production and consumption in the formation of Early Iron Age states in Mediterranean Europe has been often neglected in favor of other economic activities such as pottery making and distribution, as well as metallurgy. In the Western Mediterranean, connectivity has been mainly addressed through the study of Phoenician and/or Greek pottery in local settlements and vice versa. However, intensive production and consumption of textiles was at the heart of urbanization throughout the history of the world. Cloth was used as an ethnic and identity marker, as a tribute, as a trade product, and as an elite way of self-promotion, among many other things. Textile production and consumption are thus a fruitful venue to understand colonial relations in the region, as well as the interactions between both local communities and between them and the colonizers. In this paper, I focus on those interactions exploring several case studies of textile production in Iberia from the eighth–fifth centuries BC.

The Effects of Bilateral Asymmetry in Long Bone Length on Juvenile Age Predictions  
Diaphyseal lengths are routinely used to estimate age in juvenile skeletal remains. However, the effects of bilateral asymmetry in bone growth on the estimation of age have not been properly addressed. This study uses a sample of 26 individuals of known age (birth to 11 years) from the skeletal collection housed at the Natural Museum of Natural History and Science, in Lisbon, Portugal. Diaphyseal length of the humerus, radius, ulna, femur, tibia and fibula, were collected from the right and left sides. Differences between the sides were statistically significant for the radius, ulna and femur (p<0.009). Three age estimation methods were used to assess the impact on point age estimates. Overall, formulae provided by Cardoso et al. (2014) and Primeau et al. (2016) seem to overestimate age at death, more noticeably on the right side. Inversely, Stull et al.’s (2014) method always underestimates age, particularly on the left side. Although the side from which the bone was selected affects age estimates, these results suggest that selecting the appropriate age estimation method is more important.

Hinterland Causeways in the Maya Lowlands of Northwestern Belize  
This paper will present preliminary results of archaeological investigations concerning the spatial arrangement of hinterland causeways and their function within inter and intrasite exchange networks. This research is a subsidiary project of the Dos Hombres to Gran Cacao Archaeology (DH2GC) Project, a transsect settlement survey analysis of hinterland communities situated between the sites of Dos Hombres and Gran Cacao, in northwestern Belize. A primary goal of this research is to explore the role of causeways as conduits of market exchange linking the resource zones of highly dispersed populations in the periphery of centralized administrative centers. This will provide unique insight into the complexity of two way relations between administrative sites and hinterland communities. An understanding of interactions between these interdependent entities will allow for a clearer interpretation of sociopolitical and economic spheres of influence.

Chipped Tool Production and Exchange in Late Postclassic Tlaxcallan: Integrating Specialized Production with the Political Economy of a Collective State  
Archaeological and ethnohistoric research has demonstrated that political-economic strategies in Late Postclassic (AD 1250–1521) Tlaxcallan were highly collective. At the same time, recent cross-cultural research indicates that collective political structures are strongly correlated with internal revenue sources, or taxes and corvee paid by free citizens. Thus, we hypothesize that Tlaxcallcan political architects established internal revenue strategies to fund state activities. If this were the case, we would expect that goods were distributed through either large-scale redistribution or through open and competitive markets (as commodities). In this paper, we test this hypothesis by drawing on a dataset of roughly 5,700 obsidian artifacts yielded by excavations in two Late Postclassic residential terraces located within the city of Tlaxcallan. These data demonstrate that imported obsidian was widely used as a bulk economic resource. Thus, although obsidian was difficult to acquire due to Tlaxcallcan’s antagonistic relationship with the Aztec, the distribution of obsidian was not controlled for political gain (e.g., distributed as gifts through embedded exchange systems). Thus, this paper contributes to broader studies of economy in Central Mexico by illustrating alternative paths to production and exchange available to consumers.

Documenting Classic Maya Urban Landscapes: Comparing and Integrating the Results of Lidar and Topographic Survey at El Perú-Waka’, Petén, Guatemala  
Hidden by the dense forest canopy of the Petén, the size, shape and form of Classic Maya cities have remained difficult for archaeologists to document in their entirety. In recent years, however, the application of Light Detection and Ranging (lidar) technologies have enabled the rapid acquisition of topographic data for large swaths of the Maya lowlands. These previous investigations, primarily in Belize, Mexico, and Honduras, demonstrate, however, that the quality and required steps in processing and analysis of lidar data is highly variable, often dependent upon variations in vegetation
type and coverage. This paper examines the results of a recent lidar survey of the Classic Maya site of El Perú-Waka' located in the western Petén, Guatemala. Over the last 15 years El Perú has been subject of intensive and extensive topographic mapping and full-coverage survey. These “traditional” survey data provide a vital comparative dataset with which to examine the strengths and weakness of lidar data in the Petén.

Butterfly Imagery among the Classic Period Zapotecs of the Valley of Oaxaca

This paper explores the meaning of butterfly imagery among Classic period Zapotecs of the Valley of Oaxaca. Images of butterflies, or parts of their anatomy, sometimes appear on effigy vessels found in tombs. The effigy vessels represent rulers, or other individuals of high social-standing, as jaguars, owls or the Fire Serpent. I argue that rulers of Zapotec urban centers were perceived to have a number of specific naguales or alter-egos that constitute the moral basis of political power. The inclusion of butterfly elements in effigy vessels conveys the ruler’s faculty of transformation into his/her spirit companions.

There’s Sand in the Sensor! EO Approaches to Interpreting Delta-Desert Transitional Environments

The complex boundary regions between deltas and deserts pose particular difficulties for archaeological enquiry. In these regions, the dynamic interactions between aeolian and alluvial processes result in continuously changing hydrosocial landscapes that manifest over a range of spatio-temporal analytical scales. The wealth of tools, methodologies and theoretical approaches offered by the burgeoning field of remote sensing can help to deconstruct complex and often visually obstructed human geographical landscapes. Arid-margin EO approaches have increasingly incorporated multispectral imagery, thermal IR imagery, synthetic aperture radar (SAR), and high-resolution UAV-based photography and photogrammetry to deconstruct marginal and transitional landscapes, and to highlight the implications for those societies who inhabited them, as well as the modern-day researchers who seek to understand them. This paper presents a set of EO techniques to examine hydrosocial landscapes in the distal zone of the endorheic Murghab delta in Turkmenistan, and the potential to deconstruct these types of environments using aerial and satellite-based sensing techniques. Using an integrated approach, the paper evaluates the effectiveness of multispectral analysis, thermal imagery, landscape morphometry, UAV based imagery, classification algorithms and SAR data to develop an effective and transferable set of methods for examining these unique transitional zones.

Sourcing Lithic Raw Materials in the Namib Desert: Exploring Land Use and Technological Organization

Under a technological organization perspective, archaeologists seek to understand how prehistoric societies organized their activities across landscapes and how variation at individual sites articulates with changes in large scale land use systems. Lithic sourcing offers a powerful tool for testing hypotheses about technological organization and land use, but its application across the globe has, until recently, been hindered by expense and methodological difficulties. In this paper, we use pXRF and ICP-MS and the results of a two-year geological sampling survey to source a large sample of artifacts from three late Pleistocene sites in the Namib Desert. Our analysis shows that prehistoric groups who made very different types of stone tools also used the Namib’s landscape in different ways along a continuum of variability. Middle Stone Age groups appear to have focused subsistence activities in fertile river beds while Later Stone Age people appear to have had novel mobility patterns, exploiting coastal zones as well as much wider ranges in the desert. Our data provide some of the first empirical insights into land use and mobility systems employed by Upper Pleistocene populations in Southern Africa and have important implications for regional studies as well as the broader “MSA/LSA transition.”

I’m Your Huckleberry: Monitoring Impacts on Traditionally Utilized Food Sources of the Pomeroy Ranger District, Umatilla National Forest, Southeastern Washington

The utilization of traditional foods in the Columbia Plateau on ceded tribal lands is of great importance to present day indigenous communities within the region. Huckleberries (vaccinium spp.) are one of these highly valued traditional food stuffs among the Confederated Tribes of the Umatilla Indian Reservation (CTUIR) and the Nez Perce among others. However, the impacts of forest projects (i.e., logging, and prescribed burning) on this reserved treaty resource are poorly understood. Bearing that in mind, Umatilla National Forest Heritage staff members Jill Bassett, Allen Madril, and Will Marquardt; along with forest botanist Paula Brooks and professional photographer John Marshall, monitored 15 huckleberry patches in the South George Creek watershed west of the community of Anatone, WA, that were undergoing logging and prescribed burning treatment. Panoramic photographs were taken before and after treatment and 15 m transects were conducted to ascertain huckleberry cover, production, and canopy cover. Sites were visited before and after treatment and revisits are planned for the following five years. With this data, heritage staff on the Umatilla National Forest along with local tribes may be able to provide better recommendations regarding project impacts on an overlooked but vital cultural resource.

Chert versus Quartzite Edge Reduction Using a Mechanical Device and Its Relevance to Lithic Raw Material Variability, Selection, and Use

Lithic raw materials diversity in archaeological assemblages is used to address a multiplicity of fundamental questions concerning the evolution of human behavior. Technological systems are considered to be the result of conscious human choices, likely related to different types of rocks characteristics, performance and effectiveness. To test this model, we developed an experimental program using hand-knapped standardized blades on quartzite and chert in an upgraded version of a mechanical device, in order to improve experimental controlled conditions. The differences between the
performed in these two raw materials bring insights into why they systematically make two completely distinct tool kits in periods such as the Upper Paleolithic. [40]

The Challenges and Benefits of Comparing Archaeological and Oral Records
Archaeologists have referenced the oral record throughout the history of their research in Tsimshian territory. In this paper we frame our recent collaboration against this legacy and argue that that a symmetrical relationship is a necessary foundation for any conjunction between these complex datasets. Our collaboration recognizes the common history they represent, but also their different logical frameworks and empirical scope. In our context, the oral record was more complete, detailed, and comprehensive than the archaeological view of history. Thus, our first impulse toward history has come from indigenous sources, which subsequently framed our archaeological research questions. Our point of greatest overlap has been the macro-history of large-scale events, a subject covered extensively in the oral record and accessible via a regional view of archaeological data. We have consistently found that the oral and archaeological records conjoin when considered in this approach.

Accelerating History and Bayesian Models: The Rapid Emergence of Agropastoralism and the Tiwanaku State in the Lake Titicaca Basin, South America
Long-term cultural change can be nonlinear and punctuated by brief episodes of accelerating history. Such episodes, or emergent phenomena, have been described by a diverse set of theoretical approaches such as complexity theory, complex adaptive systems, panarchy, resilience theory, “eventful” sociology and archaeology, and the Annales School of History. These episodes can result in profound, lasting changes for large groups of people, but can happen too fast to be clearly documented without Bayesian models. This paper presents Bayesian models of two episodes of rapid change in the Lake Titicaca Basin in central South America, based on more than 250 radiocarbon dates. First, after millennia of foraging, agropastoralism emerged ~1590~1170 cal BC and remains the dominant economic adaptation today. Second, the Tiwanaku state emerged cal AD ~430~580, a primary state that grew to project a dominant hegemony in the central Andes for five centuries. In contrast to evolutionary expectations, the longue durée in the Lake Titicaca Basin was punctuated by brief episodes of rapid change. Bayesian models are the first step toward characterizing these episodes, detangling the synergistic interactions that generated them, and making comparisons to similar episodes in other parts of the world.

The Kleanza Approach: The Challenges of Working in Tsimshian Territory from a Cultural Resource Management (CRM) Perspective Working in Tsimshian territory as consulting archaeologists can be challenging at best particularly in recent years as a growing number of proposed development projects has put the Northwest Coast in the provincial and federal spotlight. As a company we strive to ensure our research objectives are guided by community heritage policies; however, given the nature of the business, we are influenced by our client’s requests, confidentiality, binding contracts, budgets, and provincial guidelines. Economic climates affect our competitive structure, staffing, salaries, and hourly charge out rates. It seems some consulting archaeologists prefer a simplified cookie-cutter approach collecting baseline data to satisfy research parameters outlined in a provincial permit. The challenge we face is how do we remain competitive but also remain in support of our local communities. Regardless of our intentions we are always caught in the middle between the client and community. We present a recent project in Metlakatla territory as a case study to examine how the work unfolded, and how the scope of work was influenced by the community, our client, and other stakeholders. We compare this to other projects we have completed in the region which have been collaborative and community based in our approach.

Creating, Enduring, and Transforming: Pots and People in Southern Taiwan
This paper seeks to reframe archaeological thinking on what constitutes “an object” and how such objects endure through time. I will consider the changing presence of pots among the Paiwan people of southern Taiwan over the past 2,000 years. The Paiwan are understood to have “lost their pots” at least 100 years ago, in the sense that they chose to stop making them. This “loss” is has been presumed to result from Chinese and Japanese colonial interventions during the nineteenth and twentieth centuries. However, newly emerging archaeological evidence from the Southern Paiwan Project directed by Prof. Maa-ling Chen suggests pottery production may have ceased many centuries earlier than previously thought. Although the Paiwan do not now make pots, and may not have made pots for quite some time, pots remain central to Paiwan ontology; how they understand themselves to be in the world and how they position themselves in today’s world. The continuing significance of pots, and their frequent incorporation into highly invisible public architecture, calls into question simple assumptions about “loss” and about the ways objects remake materially, and made meaningful as cultures transform. Provisioning and Agricultural Economy at Roman Gordian: Integrating Archaeobotany and Zooloarchaeology
Naomi Miller conducted extensive archaeobotanical research at the urban center of Gordian, in central Turkey, where she worked closely with zoooarchaeologist Melinda Zeder to publish an integrated study of diachronic change in agricultural economies and land use. One period, however, was not included in this study: Roman Gordian, when the once-large city became a small military encampment. Drawing on the foundational effort of Miller and Zeder, we couple archaeobotanical data with new zooarchaeological data (taxonomic composition, mortality profiles, prevalence of weight-induced pathologies, and biometry) in an effort to characterize the agricultural economy at the Roman military base of Gordian. We propose a model where the garrison developed durable social and economic relationships with rural farmers, who provisioned the site with wheat and young cattle, and local pastoralists, who focused on secondary products and provided mainly older caprines to Gordian. Economic risk was further managed by the garrison through household husbandry (of pigs and chickens), while environmental risks were managed by farmers using intensive irrigation but exacerbated by extensive pastoral production. Gordian, as a rare integrated faunal and botanical study of the Roman Near East, provides a model for further study of the Roman agricultural economy in the eastern provinces.
Mitigating Climate Change Impacts on Heritage Sites?
How fast do archaeological deposits, soil features and artifacts degrade? Is it possible to preserve archaeological remains in situ without significant loss of information potential? Climate change causing higher temperatures, increased and more concentrated precipitation events, changes from snow to rain, may lead to an irrevocable loss of information. Even small changes in the conditions of deposition, as caused by the global environmental development or local structural changes, may accelerate deterioration. This paper presents archaeological observations and results of paleoecological and geochemical analyses of archaeological deposits from two rural sites in northernmost Norway. These are combined with climate data and the first period of continuous monitoring of soil temperature, moisture and redox potential in sections. This data constitutes the basic research material for evaluations of conservation state and preservation conditions. The data has been collected in an interdisciplinary research project. The results have consequences for the heritage management of a large number of sites from all periods. Paleoecological analyses and redox measurements have revealed ongoing decay that might not otherwise have been detected. Decay studies indicate that both site types may be at risk with the predicted climate change. Some strategies for mitigation and management are suggested.

Native Science: How a Native American Understanding of Ritual as a Science Can Help Archaeological Analysis
In the last couple of decades, Native peoples across the world have become more vocal that indigenous rituals are not the result of religious superstition or mechanisms of social control, but the formulae of indigenous sciences. Ceremonies and many myths, they argue, have been mistakenly categorized as religious by anthropologists due to their baroqué appearance and our modern separation between nature from culture. Gregory Cajete and Leroy Little Bear have led the movement to recategorize rituals as scientific formulae—formulae that have long helped Native peoples survive by helping them understand, control and predict the world. However, few in archaeology have taken up the gauntlet. This paper addresses the background and philosophy that supports this conception of ritual, and attempts to apply it to better understand the archaeology of ritual monuments. While the ontological turn in archaeology has grasped the need to interpret archaeology according to the ontology of a given culture, it suffers from the same problem as analogical interpretation—models are imposed from a modern ethnographic group. However, if rituals are actually scientific formulae that define a culture’s understanding of the world, temporally precise ontologies can be exacted from them and used to interpret cultural actions.

Martin, Erik (University of Utah)
Form and Function: Projectile Point Morphology and Associated Faunal Remains at Four Eastern Great Basin Cave Sites
Spatial and temporal patterning of projectile point morphology continues to be a well discussed topic within the Great Basin. However, despite this attention, little progress has been made addressing the functional attributes of projectile points beyond the simple atlatl vs. bow dichotomy. Stratified cave sites offer a unique opportunity to study the relationship between hunting technology and prey choice through the analysis of projectile point characteristics and contemporaneously deposited faunal remains. This study examines several hypotheses related to ballistic performance, penetrative capabilities, and projectile morphology as related to prey size at four Utah archaeological cave sites: Danger Cave, Hogup Cave, Sudden Shelter, and Swallow Shelter. The study utilizes new and previously published faunal analyses in combination with landmark geometric morphometric analysis of a photographic database comprised of over 900 projectile points curated at the Natural History Museum of Utah.

Using Ancient Plant Macroremains to Understand Resource Consumption in the Past and Present
Many people recognize the need for markedly different mode of living amid a growing body of scientific evidence that the current world population is environmentally unsustainable. Exploring ancient foodways and landscape management techniques may improve our ability to imagine highly productive modes of food production and resource consumption dissimilar to that of our current global reality. Here, I show how a reconstruction of macrobotanical and faunal remains builds a narrative of anthropogenic forest development on a small island in Western Caribbean Panama during a period of rapid population growth and sociopolitical networking (ca. AD 500–1500). Using this example, we explore specific incremental changes that routine task performance and collective decision-making produce in vegetation and fauna, which in turn supported a growing human population of the past and remain visible in the archaeological record of the present.

Martin, Lois
Direction, Gender, and Cosmology in the Precolumbian Textile Technologies of Mesoamerica
Despite the paucity of actual archaeological textiles in Mesoamerica, alternative sources provide a picture of precolumbian textile technologies. These include: Colonial-era depictions and descriptions, tools, and especially continuities to ethnographic practice. Together, these reveal the centrality of textiles to these societies, and even hint at how textiles conceivably embodied and reflected indigenous cultural norms and notions. I argue that these sources suggest some hitherto under-recognized broad, underlying principles that emphasize opposition and complementarity. For instance, there are striking, regular consistencies in traditional gendered work, between the axis and gender of the body of the user and the tool in action. “Female and horizontal” are consistently counter-posed to “male and vertical” in all of the following: spindle whorl to circular shield; loom batten to battle sword; pick-up stick to digging stick; backstrap loom belt to burden strap. Moreover, just as Desrosiers (and others) have found consistent alternations between thread direction and gender in Andean garments, so, too, in Mesoamerica, warps ran horizontally on women’s skirts, and vertically on male loincloths.
While some scholars have proposed that every traditional cornfield reproduces Mesoamerican schemes of cosmic order, I will argue that hand-woven cloth—both past and present—traces cosmological outlines as well.

Martin, Simon (University of Pennsylvania Museum)

Copan in the Wider Maya World

The peripheral location of Copan has always raised questions about the ways in which it related to the core of the Maya world. Clearly Copan was no isolate in the Classic Maya tradition, divorced from developments elsewhere, but what did it continue to draw from the center and what were the mechanisms underlying those contacts? What do we know about the influence of centrally placed polities in this far-flung region, which held a symbolic status in the far east, but could never be a significant participant in the affairs of the core? This paper focuses on what we know of Copan’s foreign interactions, suggesting modes of interaction that extended over considerable distances, yet seemingly differed little from those between near-neighbors.

Bone Marrow as Part of the Local Cuisine at Fort St. Joseph, a French Fur Trade Post in Southwest Michigan

Analyses of the large faunal assemblage from the eighteenth-century Fort St. Joseph site (20BE23) in Berrien County, Michigan, are becoming more concerned with the question of “food or furs?” With over 70% of the identified animal remains coming from white-tailed deer, we are trying to discern whether broken long bones are the result of removal of marrow for subsistence, or if they may have also been used to prepare hides. In contrast to late prehistoric and early historic Native American sites in the Midwest, the best quality marrow bones—the metacarpals and metatarsals—are underrepresented at Fort St. Joseph. This suggests that the lower leg skeletal portions were purposefully collected and taken elsewhere. If marrow and bone grease were processed as part of the local cuisine, why are deer metapodial fragments so rare in the habitation refuse? Were marrow bones being used in addition to brains as part of the hide tanning process away from the site area that has been excavated?

Martindale, Andrew (University of British Columbia)

Building a Global 14C Database

Since the launch of the upgraded Canadian Archaeological Radiocarbon Database (CARD) in April 2015, CARD has expanded to contain more than 70% of the world’s online 14C archaeological dates across six continents. CARD’s transformation into a global repository raises concerns about access, security, protocols, management, capacity, and the prospects and long-term future of a single, comprehensive global 14C archaeological database. CARD is a template for that global database. Here we present a comparison of the world’s 14C databases and review their histories and capacities to situate CARD’s growth and capabilities. We identify the common elements for a universal data platform and argue that such an ambition should be a priority for researchers and 14C laboratories.

Repeat Photography and Cultural Resource Management: A Case Study from Glen Canyon, Arizona

Repeat photography, the collection of multiple photographs of the same subject from an identical location, is an effective technique for documenting the natural and cultural processes impacting archaeological sites, yet remains underutilized in cultural resource management. Analysis of repeat photographs may yield important data for understanding the processes affecting site integrity, which could result in improved site preservation and management. In this paper, repeat photographs collected over a twenty-year period are analyzed to assess the impact of high-flow experiments (HFEs), controlled water releases from Glen Canyon Dam, on an archaeological site located downstream in Glen Canyon. To conduct the analysis, I used Adobe Illustrator and Photoshop to document observed changes and estimate the percentage change between images using a grid intersect method developed by Hall (2002). The analysis demonstrates erosion caused by HFEs has decreased since 1996, likely resulting from a 200% increase in riparian vegetation along the terrace cutbank and changes in HFE management. These observations indicate repeat photography is a suitable monitoring technique for documenting the long- and short-term changes to archaeological sites and cultural landscapes, the results of which are easily discernible to resource managers and stakeholders.

Cosmogonía y ritualidad en contextos funerarios de Tamtoc, SLP, México

En antropología, la muerte es considerada un hecho universal con expresiones socioculturales fundamentadas en la cosmogonía de cada grupo humano, y es a través de los rituales funerarios que se marca la conexión simbólica entre la vida y la muerte, que se expresa tanto en el plano material-biológico (cadáver y lugar de destino final) como en el espiritual (trascendencias, creencias y escatología); en tanto que, la muerte, como hecho objetivo y como hecho cultural ritualizado, delimita el concepto de la vida y refleja la percepción y construcción imaginaria de un mundo paralelo ubicado en el más allá como una manera de resolver un problema esencial de la existencia humana. Así, el fenómeno natural de la muerte adopta un significado social cuyo sentido cultural lleva al plano de la valoración y respeto del ámbito sagrado-profano, configurando el orden religioso o la cosmovisión de las sociedades. Lo anterior motivó la inquietud de presentar este trabajo acerca de los distintos rituales funerarios que consideramos se llevaron a cabo en diversos sectores de la antigua urbe de Tamtoc durante el periodo posclásico (900 a 1521 d.C), como expresión particular de la cosmovisión de sus antiguos habitantes.

Rancho la Cueva: Agaves and Casas Grandes in a Cliff Dwelling

La Cueva is a cliff dwelling built by the Casas Grandes people in the Sierra Madre Occidental in Sonora, Mexico. It has been studied by the Sierra Alta de Sonora Archaeological Project with the aim of understanding the Subregional System on the mountains. So far, we have identified a protohistoric component and a prehistoric occupation from the Viejo and Medio Period (AD 900–1450). But the most relevant information is related with the mezcaleros knives, an industry well identified. At the site, we have evidence for the whole sequence of collecting, processing, and using agave. The presentation will describe this data.

Inter- and Intra-individual Dietary Variation among the Agro-Pastoralist Sai Island Meroitic Population

We examine inter- and intra-individual variation in diet among high-status individuals from an agropastoralist Meroitic burial population interred on Sai Island in modern Sudan. We use stable isotope data (δ13C and δ15N) from dentinal collagen, extracted from serial micro-sections of third molars, to reconstruct the diet of 10 individuals. We employ MixSIAR, a hierarchical Bayesian model for estimating isotopic mixing, along with a previously constructed isotopic food-web to reconstruct human diets. We find variation between individuals, and within individuals over the period of third molar growth (age 9–22 years), in the relative inclusion of C3 and C4 plant agricultural products, domesticated animals, and aquatic resources from the Nile River.

The Manteño of Coastal Ecuador: A Case of Territorial Expansion in a Diverse Environment

Inter- and intraregional expansion across a large geographically and environmental diverse terrain was a distinctive feature of the Manteño culture (1500 BP–1532) of coastal Ecuador. Using survey data collected by FAU Field School investigators, this paper explores the development of a large sociopolitical unit that encompassed diverse settlement types exhibiting a uniform ceramics. It is likely that this unit was described ethnographically as the Señorío de Salangome, one of at least four chiefdoms attributed to Manteño culture. The paper focuses on the process of territorial expansion of Salangome, implemented some 100 years prior to the arrival of the Spanish, a strategy that centered on the direct control of diverse environmental zones. The case of the territorial expansion of Salangome provides some direction toward an overall understanding of Manteño culture and its chiefdoms.

Internal Control and Management of Cultural Tangible Assets in Mexico: A First Step to Their Protection

Mexico is a country with a cultural heritage that has given him a unique identity. We have a wealth of collections ranging from the paleontological and archaeological, to the historical and ethnographic. These collections require a control that will allow both federal institutions and individuals to be aware of what they have under their care, as it is one of the serious problems they face today. One of the main objectives of this brief presentation will be: To give an insight into the control and management of collections in a general framework that will allow those responsible for guarding these tangible assets to know the existence of easy and practical ways to bring to fruition this task and ensure full compliance with the laws. At the same time, raise awareness among federal authorities and civil associations that they have in their hands the care and preservation of the cultural heritage of the nation.

Applied Ethnobotany in Arid Lands: The Importance of Time, Context, and Collaboration

This paper contributes to the field of applied ethnobotany, which focuses on the role that knowledge, institutions and cultural perspectives play in resource management and conservation (based on Cunningham). Through different case studies to understand how institutions and their use of wild desert plants, this paper stresses the importance of collaboration between disciplines, principally among biological and social sciences; and secondly between formally trained researchers, and local people and resource users. It also highlights the importance of employing archaeological data to better understand resource use through time and at various contexts. The ultimate goal is to achieve a sustainable use of the arid lands biodiversity today and
in the future. This effort is inspired by the example of Suzanne Fish and Paul Fish whom I have had the privilege of learning from. Where among many valuable lessons, community outreach and innovative archaeological research are central to their work. Therefore this paper is also a methodological contribution to the field of community archaeology, an archaeology that it is done by the people for the people.

Moving on from Movius: Recent Research in Pleistocene Archaeology in Myanmar

For many archaeologists, Myanmar is known as the place where Hallam Movius proposed the Movius Line as a result of his fieldwork in the 1930s. Movius proposed this line as a major cultural boundary of the Paleolithic era, with bifacial technology present in the west and north, but absent to the south and east. His line continues to have a major influence on contemporary discussions of human evolution in the Eastern Hemisphere. Motivated by debates about the line, and other questions about the place of Myanmar in the modern human colonization of Southeast Asia and Australia, I began...
fieldwork with local collaborators in Myanmar in 2016. In this talk I present results from the first research at Pleistocene sites in Myanmar since Movius’ expedition. I discuss the implications for the debates about the line, and about broad patterns of human evolution in Southeast Asia.

Inland Connectivity in Late Antique Mallorca (Balearic Islands, Spain)

The Balearic Islands lie in a strategic position within the Western part of the Mediterranean and played an important role in the trade routes crossing the Mare Nostrum. Therefore, connectivity of the island by sea has always been considered. However, inland connectivity has not been addressed in detail probably due to the lack of information on communication routes. The paper explores the inland connectivity of sites in the late antique landscape based in a combination of spatial analysis and field survey. Possible communication routes have been simulated using GIS by Least Cost Path Analysis. The archaeological and survey data of late antique sites in the Eastern part of the island have been examined in order to understand the location of the sites and its connectivity within the landscape. The results show that—even in a landscape where the knowledge of its communication routes is limited—a detailed study of the landscape and of the distribution of the sites, complemented with spatial technologies can help to advance an interpretative framework for inland connectivity in late antique Mallorca, an aspect relatively poorly explored so far.

Remote Sensing of Anthropogenic Vegetation in Sierra Sur, Oaxaca, Mexico

Geospatial technologies, such as remote sensing and LIDAR, have enabled archaeologists to capture high-resolution information about landscapes and settlement patterns thus contextualizing sites through a wider landscape perspective. These tools have also facilitated the detection of otherwise “invisible” archaeological sites through image or spectral analyses and other visualization techniques. This paper examines the performance of vegetation indices for the detection of anthropogenic vegetation from past human-environmental interactions and land use, using freely available satellite imagery of the Sierra Sur in Oaxaca. Concentrations of anthropogenic vegetation can be used as an indicator of past settlement activity in the absence of visible surface remains. Illuminating past activity patterns over wide geographic areas through the remote sensing of vegetation, findings from this paper can advance our methodological approaches to regional survey and mapping of the Sierra Sur.

Urban Carnivores, Rural Vegetarians? Faunal Discrepancies over Time and Space at Mayapán

A usually predictable attribute of Postclassic Maya settlements (in Belize and Yucatán) is the abundance of faunal remains relative to preceding Classic Period contexts. This discrepancy is not attributable to taphonomy or bone age, given the recovery of human bone from both periods and the abundance of fauna in even earlier Preclassic deposits. Robust forest environments, balanced human predation levels, and variable animal husbandry practices represent the best explanations for the wealth of Postclassic game. Yet, while urban Mayapán (within the 4.2 km² city wall) boasts dense deposits, peripheral Mayapán (outside the wall) does not, attesting to unequal access to animal resources according to residential zone and occupation. These new results suggest that animals served as more than generic “staples” among the commoner populace at the city and that politico-economic and social factors were at play. While urban conditions generally promote commoner wealth and economic interdependency at the site, farmers’ houselots in the periphery did not experience equitable benefits. In contrast, the scarcity of faunal resources at Terminal Classic households (in Belize and Yucatán) is most probably attributed to environmental or human-ecological stress.

The Early Intermediate Period Farmer’s Almanac: Coproducing Agriculture, Time, and Community on the North Coast of Peru

Previous research on plant foods and social memory in the Andes has primarily focused on ritual feasting among elite segments of society within the confines of exclusionary monumental spaces. However, it is vital to look beyond elite-directed activities and consider ritualized commoner and quotidian practices as integral to community building and memory making. This paper will demonstrate how domestic food production and consumption, the construction of agricultural landscapes, and wild plant collection in hinterlands are, indeed, also practices which coproduce collective conceptions of time, space, and social identity. Planting, harvesting, collecting, redistribution for tribute, processing, and consumption of plants were intrinsically associated with seasonal cycles and social events experienced by communities as a whole. We integrate paleoethnobotanical and geospatial data from two Early Intermediate Period sites occupied during both the rise and subsequent decline of the Virú polity on the North Coast of Peru. The urban Gallinazo Group site and administrative center Huaca Santa Clara provide interesting case studies for understanding place-making via the liminal spaces between core and hinterland within which agricultural production took place, as well as the social integration of community members through food-centric redistribution economies over several generations.

Matadamas Gómora, Diego (Proyecto Templo Mayor)
The Ometochtli Complex and Its Presence in the Offerings of the Great Temple of Tenochtitlan

In 1971, H. B. Nicholson classified the Mesoamerican pantheon of god’s by their symbolic elements and functions. One of the most important groups of this classification is the “Ometochtli Complex,” which is exclusively constituted of gods related to the most significant alcoholic beverage in prehispanic Mexico, the ocatl or pulque. This drink is created through the fermentation of the agave juice. Thus, pulque gods are easily identifiable due to key elements present in their attire. At the archaeological site of Templo Mayor, located in the heart of Mexico-Tenochtitlan, a significant number of excavated offerings includes many recovered artifacts related to the “Ometochtli Complex.” Thus, these offerings are associated with the principal imagery located at theedges of Tenochtitlán’s main temple. Some of the artifacts recovered in these offerings are connected to pulque and have a particular meaning by their relation to other elements composing the ritual deposit. This paper will show the importance and symbolic attributes represented by the gods of pulque in connection with the two most important Mexica gods: Tlaloc and Huitzilopochtli.

Studies into ancient DNA have advanced significantly in the last few years, but these have largely been absent in tropical environments. In the Caribbean, a number of questions still pertain as to the bioarchaeology of the indigenous precolumbian populations and the exact origin of these early inhabitants. Focusing on the skeletal remains of a late Saladoid population from Punta Candelero site (AD 640–1200), three correlated and simultaneous studies have been coordinated with the aim to investigate the archaeogenetics of the site, at the local burial and overall site context. This multidisciplinary investigation, combines the research into the human skeletal material at the endogenous trace human DNA and the microbial DNA. Complementing this study is the genetic research into faunal remains of companion dog burials of earlier cultural inhabitants. Procedures were conducted in a dedicated laboratory facility and concentrated on maternal inheritance (mtDNA) and microbial 16S rRNA typing, although extended genetic studies have been conducted in particular well preserved samples. The results, impact and significance of these studies to our understanding of the early peopling of the Caribbean, their well-being, life and origin will be presented. In addition, discussion on preliminary whole genome research, aspects and implications.

Mather, David (Minnesota Historical Society)[385] “Dear, Honored Guest”: Archaeological Models of Bear Ceremonialism in Minnesota

Archaeological expressions of bear ceremonialism in Minnesota include: ritual sites with dozens to hundreds of bear skulls, calcined fragments of burned bear paws, effigy earthworks, rock art and portable art. These were created by Siouan and Algonquian speaking peoples, including the Dakota and Ojibwe, who are still resident in the state. Some finds relate to the bear hunt, feast and funeral that are the focus of A. Irving Hallowell’s (1926) concept of bear ceremonialism. Others appear to represent rituals that are not documented in the ethnographic literature. Modeling, or connecting archaeological data with abstract theories, is used here to explore and interpret possible practices of bear ceremonialism in the state. Data sources include accounts of Minnesota bear ceremonialism from tribal elders and cultural anthropologists, archaeological contexts, artifacts and zooarchaeological analyses, and bear biology including comparative measurements of modern bear teeth of known age/sex to compare with archaeological materials. Resulting models include the concepts of bear graves and secondary burials, and seasonal connections between different types of rituals practiced by related groups, within and beyond the scope of Hallowell’s bear ceremonialism.

Matthers, Clay (Coronado Institute)[385] War and Peace in the Sixteenth-Century Southwest: Objected-Oriented Approaches to Native-European Encounters and Trajectories

Although conflict and conquest campaigns characterized many of the earliest encounters between Native and European groups in New Spain and La Florida, the transformation of objects, communities, and strategic policies in these areas was locally variable and changed dramatically by the close of the sixteenth century. Materials characteristic of these changes and variegated responses are found widely in the archaeological record of the American Southwest, but have seldom been explored for the insights they provide into broader anthropological themes such as resistance, exchange, and agency. While this study focuses on the fine-grained, contextual analysis of objects, its broader goal is to compare cultural trajectories at the regional and interregional scales, particularly the congruence and contrasts between the American Southwest and Southeast in the first century of New-Old World contact. Both areas transitioned from initial imperial strategies of acquisition and conflict, to policies of settlement and missionization by the end of the 1600s, and in both areas a similar suite of European objects was available. Nevertheless, the manner in which these objects were employed by Natives and Europeans varies significantly and in ways that reveal to us important aspects of the earliest Colonial encounters in North America.

Mathews, Darcy (University of Victoria), Joan Morris (Songhees Nation) and Reona Oda (University of Victoria)[77] Relatives of the Deep: Situated Knowledge and Archaeological Remote Sensing to Assess Climate Change Vulnerability at Tl'ches

Sellemah/Joan Morris, a Coast Salish Nation elder, was raised at Tl'ches, an archipelago of low islands in the Salish Sea of southwestern British Columbia. Islands are familial places in the Coast Salish world, the word translating to “relatives or ancestors of the deep.” Ongoing archaeological and ethnological research indicates this island ecosystem was shaped by millennia of resource management and subsistence practices. In 1957, a drinking water shortage forced residents to move to Vancouver Island—a move with disastrous implications for Sellemah and her family. Today, global climate change is threatening to impact the island chain at a time when Coast Salish peoples are returning to this ancestral cultural keystone place. To understand both the deep history of Coast Salish ecological management, and their future use of Tl'ches, we are using drone imaging to inventory intertidal archaeological and ecological features. Lidar digital elevation models are also used to map near-future sea level tidal heights associated with global climate change. Results indicate village sites and intertidal habitats will be profoundly affected by projected sea level change, necessitating the development of novel management regimes.

Mathews, Jennifer (Trinity University), John Gust (University of California, Riverside) and Scott Fedick (University of California, Riverside)[280] Twenty Years of Historical Archaeology in the Yaquiua and Costa Escondida Regions
Since the mid-1990s, members of the Yalahau and Costa Escondida projects have focused on historical archaeology in northern Quintana Roo. Our research has examined the remnants of the chicle (chewing gum), sugar cane and small-batch rum industries from the late 1800s. Although these sites are relatively recent, the production equipment and other artifacts have been picked through by later occupants, making it challenging to be able to reconstruct the historic record. In an attempt to overcome this obstacle, we have combined on the ground archaeology, with archival research and ethnographic interviews with local peoples as well as experts in commodity production. Through these combined methods, we have attempted to better understand the living and working conditions of Maya laborers, their foreign managers, as well as the production process for making chicle and rum in this remote region.

Mathwich, Nicole (University of Arizona) and Barnet Pavao-Zuckerman (University of Maryland) [285] Bureaucratic Reforms on the Frontier: Zooarchaeological and Historical Perspectives on the 1767 Jesuit Expulsion in the Pimeria Alta

The introduction of livestock to the Pimeria Alta (northern Sonora and southern Arizona), was one prong of Spanish imperial expansion into North America initiated largely by Jesuit missionization. Unlike other areas of North America, the missions in this region experienced an enormous bureaucratic transition following the expulsion of the Jesuits in 1767, and the subsequent arrival of Franciscan missionaries. Historians and historical anthropologists debate the social and economic impacts of this transition, but archaeological evidence has not been brought to bear on the issue or its consequences on the local landscape. This paper evaluates the ability of zooarchaeological, historical, and isotopic data to ascertain the impact of the bureaucratic shift on the landscapes of the Sonoran Desert. Animals like cattle, sheep, and goats have the ability to alter landscapes through grazing, and the stocking rates of these animals at the missions were linked to the relative stability and administration of a mission site. This paper examines range management strategies, and culling and butchering practices prior to and after the expulsion, and presents an archaeological framework for studying the shift in political ecologies in the region following the change in religious bureaucracy throughout the Spanish empire.

Matson, R.G. (University of British Columbia) and William Lipe (Washington State University) [142] Why Raise Turkeys in the Mesa Verde Region?

Lipe et al. (2017) present estimates of the costs of raising maize fed turkeys. Raising a turkey required approximately one-third as much maize as a Puebloan ate in a year. Here we present the probable reason for engaging in this costly behavior. Pueblo III Mesa Verdeans had a diet heavily dependent on maize and short on other protein sources. Most importantly, it was short on two essential amino acids, lysine and tryptophan. We begin by reconstructing the height and weight of Pueblo III Mesa Verdeans from their remains. We then produce estimates of calories consumed and compare this with the amount of calories and proteins provided by maize. Well-supported evidence indicates that 80% of both requirements came from maize. The amounts of lysine and tryptophan provided, however, are insufficient and beans and animal protein are the only constituents of Pueblo III coprolites with significant amounts of these amino acids. Yet the same evidence indicates that the amount of beans alone is inadequate and only small amounts of wild animal protein was consumed. In such a setting raising turkeys has obvious benefits. Matsumoto, Mallory E. (Brown University) [391] Molding and Stamping Hieroglyphs on Maya Ceramics

This paper examines the implications of mold-made ceramic texts for understanding Maya scribal practice and script ideology. Most studies of hieroglyphs on ancient Maya ceramics have focused on painted and incised vessels whose glyphic and iconographic contents were made by hand on an individual basis and often with a particular consumer in mind. In contrast, the molded texts addressed here consist of pre-formed hieroglyphs that were integrated into the vessel body itself, either by shaping all or part of the ceramic in a hard mold or by applying a stamp to its leather-hard surface. Previous theoretical work on reprographics suggest that written technologies can significantly influence the development of literary and intellectual culture, literary practice, ideologies of writing (e.g., Anderson 2001; De Weerdt 2011; Egan 2011; Eisenstein 1980). Furthermore, molded ceramic texts differ linguistically in manifesting more specific references to either the vessel or its user(s), more variability in content, and a more restricted temporal and spatial distribution than those with painted glyphs. More detailed study of this ceramic corpus promises to enhance our understanding of the relationship between the hieroglyphic script, writing technologies, and those who produced and interaction with the ceramic texts. Mattson, Hannah (University of New Mexico) [379]  
Beads, Myth, and Ritual Practice: Tracing Traditions of Ornament Use in Ceremonial Deposition and Costuming in the Northern U.S. Southwest
As early as the sixteenth century, Spanish explorers noted the abundance of turquoise and shell jewelry adorning the Pueblo residents of the Rio Grande Valley and southern Colorado Plateau. In addition to serving as aesthetically pleasing objects of bodily decoration, these ornaments figure prominently in Pueblo creation and migration stories and are vital to the performance of various ritual practices, including ceremonial dances and the making of offerings and prayers. Archaeological research reveals that some of these ornament traditions extend back over one thousand years to the earliest intensive agricultural occupations of the northern prehispanic Southwest, around AD 500 to 700. Continuities in the use of specific ornament materials and forms, particularly in ritual contexts, has implications for the persistence of certain ideological elements across time despite several episodes of dramatic population reorganization.

An Examination of Ancestry: Exploring the Peopling of the Americas through Paleoindian Cranial Indices in Comparison with the Howells Collection
The original peopling of the Americas has puzzled researchers for decades. While some evidence points to a single wave of migration, still other data suggest two or more waves. Their reasonable estimated arrival dates range from 14,500 to over 20,000 BP, although some scholars push back their arrival even farther. Drawing from archaeology, genetics, historical linguistics, and physical anthropology, the peopling of the Americas debate encompasses research from a wide range of experts. In this study, cranimetric data are examined by means of the cranial index, defined as the ratio calculated by multiplying the maximum width (XCB) of the head by 100, then dividing by the maximum length of the head (GOL). Cranial indices are known to vary between different regions of the world, suggesting that different ratios represent different geographic origins of peoples. I examine cranial indices from 12 individuals dating from the Terminal Pleistocene to the Early Holocene found throughout the Americas. These indices are then statistically compared to the 2,524 indices from 28 populations examined in the Howells Cranimetric Data Set using t-tests. Results of this test suggest morphological affinities between certain ancient and modern groups, offering insight into possible links between the two populations.

Exploring Occupation Patterns in the Lower Pecos and Central Texas Regions over the Last 9,000 Years Using Radiocarbon Dates
We use summed probability distributions derived from radiocarbon sequences as a gross measure of prehistoric occupation patterns for two regions in Texas. The first sequence consists of over 325 dates from the Lower Pecos Region, located along the Rio Grande and Pecos Rivers. The region has over 40 years of radiocarbon dating, with dates in this database coming from multiple excavation projects that were frequently focused on shelters and Texas. The first sequence consists of over 325 dates from the Lower Pecos Region, located along the Rio Grande and Pecos Rivers. The region has over 40 years of radiocarbon dating, with dates in this database coming from multiple excavation projects that were frequently focused on shelters and cave. The second dataset comes from the Upper San Antonio River area in Central Texas and reflects projects conducted since the late 1970s. This set has roughly 320 dates, with all dates coming from open sites. Focusing on the last 9,000 years, we compare the two regional sequences. Using the same calibration procedure, we isolate a series of differences in these distributions that do not seem to be adequately explained by sample bias (i.e., AMS versus conventional samples) or taphonomic processes related to different recovery contexts. While research is ongoing, these sequences may track regional hunter-gatherer occupation patterns, with differences providing opportunities to explore the impacts of other variables (e.g., climate/ecological shifts, disease) on each region.

Reevaluating the End of the Early Intermediate Period on the Peruvian Coast from the Perspective of the Lima Culture
El fin del Período Intermedio Temprano en la arqueología peruana ha sido cronológicamente ubicado alrededor del 600 AD y culturalmente es representado por el fin de culturas costeñas con Moche, Lima y Nasca. Alrededor del 600 AD hay evidencia de un evento extraordinariamente fuerte de El Niño, el cual ha sido registrado en sitios arqueológicos desde Piura hasta Lima. Este evento (o eventos), fue anteriormente interpretado como una importante causal de la caída de estas culturas costeñas, sin embargo, investigaciones más recientes, llevadas a cabo en diferentes partes de la costa peruana, vienen demostrando que los Moche, Lima y Nasca no se “extinguieron” en el 600 AD sino que siguieron existiendo hasta alrededor del 800–850 AD. No obstante, las características que presentan estas culturas costeñas después del 600 AD indican importantes transformaciones culturales y económicas que fueron implementadas por estas sociedades, en parte como respuesta a un escenario climático particular. Esta presentación analiza este escenario desde la perspectiva de la cultura Lima, en la costa central del Perú y propone la reconsideración cronológica para el fin del Período Intermedio Temprano.

Maxwell, Ashley (University of South Florida), Robert H. Tykot (University of South Florida) and Andrea Vianello (Independent Researcher)

The Romans and Byzantines in Veneto (northeast Italy), experienced invasions from a Germanic tribal group, the Langobards, in AD 567, with occupations lasting until the eighth century AD; however, Langobard diet and health are largely unknown during this period of transition. Information on Langobard diet and health is pertinent to understanding the political, economic, and social changes that occurred during the Langobard arrival and subsequent occupation. To address these questions, we focused on the seventh-century site of Sovizzo, an early medieval Langobard occupation located west of Vicenza. Sovizzo is an important case study because its location allowed the Langobards to secure large areas of farmland far from river systems that were used for Byzantine military communications. Excavations from 1985 recovered 175 individuals from earthen pits with grave goods indicative of social status (knives, bone combs, ceramics, and belt buckles). Of these, 50 adult individuals (25 males/25 females) were chosen for paleopathological and isotope analyses. Cribra orbitalia, dental pathologies, and trauma were recorded in the selected sample, with high rates of dental attrition, caries, dental calculus, and linear enamel hypoplasia’s suggesting a diet high in carbohydrates with hard fibrous foods. This was followed by isotopic and elemental analyses.

Maxwell, David (Simon Fraser University)

Beer cans have now been in use in North America since 1935, meaning that sites containing early beer cans have the potential for eligibility for protection in certain jurisdictions, such as California (where the California Environmental Quality Act requires the evaluation of materials greater than 50 years of age). This presentation will serve to clarify distinctive characteristics of beer cans produced prior to 1967, the current 50-year-old mark.

Manot 1 Calvaria and Aduma Skull: Are They the Same?
The Manot 1 calvaria demonstrates a mosaic of “archaic” and modern traits. Although the taxonomic significance of this combination of features is not clear, a similar combination of archaic and modern features exists in the fossil record across sub-Saharan African and the Middle East until after 35 kya. The aim of the current study is to examine the possibility that the Aduma skull, Ethiopia (60–90 kya) is the mother population that gave rise to the Manot Cave hominins. This was carried out by comparing the Manot calvaria size, shape and morphological features to that of the Aduma skull.

Weaving the Fabric of Society at Çatalhöyük: A Socio-Material Network Approach to the Study of Early Agricultural Settled Life, Social Structure, and Differentiation

The end of the Çatalhöyük Research Project’s (ÇRP) 25-year mandate and the consequent generation of large and unique datasets produced by the collaboration of excavators and the specialists labs provide an extraordinary opportunity to investigate patterns of early agricultural settled life, social structure and differentiation at an intrasite level through a synthetic approach capable of weaving together different data threads. In this study, a relational framework rooted in models of socio-material interdependencies is used to link the various ÇRP datasets (e.g., architecture, pottery, botanical remains, chipped and ground stone) and produce complex formal network models. Relational approaches are built on the observation that, instead of focusing on entities in isolation, analyzing the connections or the set of relations between them provides a much deeper understanding of the dynamics of social phenomena and in recent years have been increasingly recognized as a valuable methodological framework for investigating social linkages at Neolithic Çatalhöyük. Socio-material archaeological networks are used here as a way of mapping the cross-cutting and overlapping set of “flexible networks” that form the site’s social fabric. This methodology provides a way of elucidating social dynamics both synchronically and diachronically.

McCafferty, Geoffrey (University of Calgary)

Costume and Identity in Pacific Nicaragua
Sixteen years of archaeological research along the shore of Lake Cocibolca in Pacific Nicaragua has yielded a wealth of material culture relating to domestic practice and mortuary rituals for the period from AD 500 to 1250. Among these are numerous objects of adornment, such as pendants, beads, and ear ornaments. Additional costume information is found on small ceramic figurines, primarily of females with painted decoration indicating clothing, hairstyle, tattooing, and jewelry. Based on initial research we presented on the construction of identity from the Santa Isabel site. Now with another five years of excavation we are able to add new information from the sites of El Rayo and Sonzapote to contrast these contemporary sites to discuss regional variations in concepts of the “body beautiful.” Furthermore, changing styles from the late Bagaces (AD 500–800) to Sapoa (AD 800–1250) periods allows evaluation of ethnohistorical claims for ethnogenesis with the arrival of “foreign” groups with possible Mesoamerican origins.

McCafferty, Geoffrey [9] see Richey, Kate

McCafferty, Sharisse (University of Calgary) and Geoffrey McCafferty (University of Calgary) [209] Fringe Identities: Costume in the Mixtec Codices
The Mixtec codices depict costumes from Postclassic Oaxaca, including clothing, face paint, hairstyles, footwear, and jewelry. Contextualized in religious, military, and other social rituals, costume played an important role in framing the action as well as representing individuals in a variety of social identities. This paper focuses on styles and patterns of clothing as they were used to characterize gender, status, ethnicity, occupation, and religious and political roles. Specifically, we examine the extent to which costume communicates different aspects of social identity.

McCafferty, Ashley [290] Great Hungarian Plain Diet and Mobility through the Neolithic, Copper Age, Bronze Age, and Iron Age
The Great Hungarian Plain (GHP), which occupies part of Hungary and five surrounding countries, was a gateway to population influx and cultural admixture along the Eastern Steppe corridor. The GHP was a hub of cultural change, including a shift in settlement patterns, during the transition between the Neolithic and Copper Age and again during the Bronze and Iron Ages. This research uses stable isotope analyses to examine transformations in the GHP area and how these changes evolved over the course of a few thousand years. Isotopic analysis will provide evidence for subsistence strategies (carbon and nitrogen), answering questions about general diet and changes to diet through time. This approach will also provide data on the possible regions of cultural influence due to migration through the use of strontium isotopes. The isotopic data will help elucidate potential cultural dispersal patterns and the rate at which this occurred. Furthermore, the isotopic data will also help identify potential cultural evolution patterns and the rate at which this would have occurred.

McCafferty, Grant (Tulane University), Theodore Marks (University of Iowa), Andrew Schroll (Tulane University) and Jordan Krummel (University of Arizona) [210] Putting Southern African Rock Paintings in Context: The View from the Mirabib Rockshelter, Namibia
Various researchers have made great strides toward understanding southern African rock art through the exploration of the ethnographic and ethnohistorical records of San hunter-gatherer shamanism. In contrast, less attention has been paid to the archaeological context of the Later Stone Age (LSA) in which rock art was produced. This paper examines Middle Holocene rock paintings at the Mirabib rockshelter in the Central Namib Desert, western Namibia. Our fieldwork at Mirabib and our reanalysis of materials recovered during previous excavations present a striking picture of LSA foraging activities in this harsh desert environment. On the one hand, much of the archaeological record at Mirabib apparently relates to attempts at coping with extreme aridity at a site with no reliable water sources. On the other hand, the rock art imagery at Mirabib would seem to reflect a concern for rainmaking. Synthesizing this evidence, we offer some ideas about the role of the rock art production at Mirabib in the social systems of the hunter-gatherers who used the site. We argue that rock art was not passive wall decoration but was rather an instrumental part of social rituals aimed at the management of tensions arising among populations under stress.

McCarty, Sue Ann (University of Virginia) [356] Inter-Household Ceramic Motif Variation and Its Implications for Halaf Social Inequality at Kazane Hoyuk, Southeast Turkey
Intersite motif variability is understudied in a systematic way to understand the complicated design vocabularies, paint colors, textures and vessel forms of ceramics from the Halaf cultural horizon (5900–5350 cal. BCE/5200–4500 uncal. BCE), a culture-historical entity in the Late Pottery Neolithic of Upper Mesopotamia (southeastern Turkey, northern Syria and northern Iraq). Together, these motifs create an almost music-like multidimensional symphony of pattern including naturalistic figures that speak to the Late Neolithic political economy. At the largest known Halaf site—Kazane Hoyuk outside modern Sanliurfa, Turkey, inter-household ceramic variability was studied in order to determine if the famously rich painted motifs on vessels show signs of clustering in association with interior and exterior household spaces and, if so, what that motif distribution means in the context of social organization at the site. This is particularly relevant because social organization remains deeply enigmatic in the Late Neolithic; vessels that may have been associated with public feasting shed light on Halaf inequality and symbolic systems.

McCaulay, Brea (Simon Fraser University) and Mark Collard (Human Evolutionary Studies Program and Department) [287] A Test of Competing Hypotheses Concerning the Impact of Demography on Cultural Evolution
Recently there has been a surge of interest in the possibility that demography affects cultural evolution. Some authors have proposed that population size affects the appearance and retention of innovations and therefore influences the complexity of a population's cultural repertoire. Others have averred that it is not population size that drives cultural complexity but rather population pressure (the ratio of population density to the density of available resources). Still others have argued that population size may only have an indirect impact on cultural complexity. According to these authors, larger societies tend to have more specialization of tasks than smaller ones. Task specialization has the potential to affect the complexity of a population's cultural repertoire because individuals need not master all skills and can focus on learning a small number of more complex tasks. Here, we report a study designed to test among these hypotheses. We obtained from the literature data on technological complexity for a sample of small-scale societies. These data were combined with data for a number of independent and control variables. Subsequently, we used partial regression analysis and multiple regression to test the predictions of the three hypotheses. Our results do not support the hypotheses equally well.

[366] Land Use and Site Formation Processes of a Genízaro Land Grant: Recent Excavations at the Pueblo de Abiquiu, New Mexico

This paper will discuss the most recent excavations in the Genízaro Pueblo de Abiquiu, NM (est. 1754). Abiquiu, as one of the oldest and most successful Genízaro land grants, is a key area for better understanding the history and trajectory of Indo-Hispanic settlements in Northern New Mexico. Three distinct areas within the historical boundary of the land grant were excavated, representing domestic, defensive, and agricultural contexts. The paper will go over the excavations, ground-truthing GPR results, and highlight the ongoing collaborative process that has made this excavation a success.

McClung de Tapia, Emily (IIA-UNAM Mexico)

Domesticated Huauhtzontli (Chenopodium berlandieri Moq. ssp. nutallianae [Safford] Wilson and Heiser) in Prehispanic and Modern Mexico

Huauhtzontli, a cultivated chenopod widely distributed in the central highlands of Mexico, is generally believed to have been domesticated in prehispanic times. However, neither the timing nor the area of domestication has been clearly established. Morphometric analyses of modern fruits of the central Mexican subspecies of Chenopodium berlandieri and revision of archaeological specimens recovered from various excavations in the region suggest that domesticated fruits were not predominant, possibly until the end of the Late Preclassic period or later. Currently available evidence for archaeological remains of Chenopodium from the Teotihuacan Valley, Xaltocan, and San Gregorio Allapulco are discussed. Modern culinary traditions and their possible prehispanic counterparts are considered.

Coping with Conflict: Defensive Strategies and Chronic Warfare in the Prehispanic Nasca Region

Warfare was a significant sociopolitical practice throughout the Andes during the Late Intermediate Period (AD 1000–1450). A salient research topic within broader investigations of conflict is how populations cope with chronic warfare. This article utilizes statistical and GIS-based analyses of architectural features and settlement patterns to reconstruct defensive coping mechanisms among fortified settlements in the Southern Nasca region of Peru. Specifically, this research evaluates how populations deployed artificial defenses (fortifications), natural defensibility, and settlement placement to best protect themselves and critical resources from enemy incursions. Results demonstrate that slope was the most significant factor guiding the construction of intrasite fortifications. Patterns in intersite fortification were primarily driven by population size, whereby the smallest most vulnerable settlements constructed significantly more fortification features. Settlement patterns show that natural defensibility, large viewsheds, and proximity to economic resources dictated the selection of occupation locations. This research demonstrates that LIP populations made optimal trade-offs between competing defensive variables, revealing a pattern of complex and coordinated decisions directed toward regional defensive strategies.

The Obsidian Workshops at Late Classic Cotzumalguapa: Preliminary Technological and Sourcing Analyses

Scholarly understanding of the prehistoric economy of the Pacific Coast lacks the resolution afforded its Lowland counterpart. Analysis of the Obsidian deposits at Cotzumalguapa offer us a lens through which to bring our understanding of the prehistoric economy of the Pacific Coast into focus. Surface survey and excavations near the El Baúl acropolis revealed the presence of several obsidian dumps, the result of a large-scale lithic industry in the Classic Period site of Cotzumalguapa. Thus far, the debitage analyzed is almost entirely the result of prismatic blade cores reduction. Interestingly, however, neither nodules, nor decortication flakes, or even first series flakes and blades have been identified. Cores also occur in low frequencies and extant cores are nearly exhausted. These patterns suggest that obsidian was imported in the form of already reduced prismatic-blade cores as opposed to rough polyhedral cores or nodules. Preliminary visual analysis suggests the vast majority of the material from this deposit came from the Guatemalan Highlands sources of El Chayal and San Martin Xilotepeque. Although the debitage analyzed to date suggest blade production was the primary activity in the El Baúl group, there is also evidence of low intensity, projectile-point production.

McCrackan, Jennifer and Eric Weaver

Caves of the Badlands: A Geospatial Analysis of Cave Archaeology at El Malpais National Monument

The El Malpais National Monument located roughly 100 miles west of Albuquerque, New Mexico, borders the southern part of the San Juan Basin and the southeastern portion of the Colorado Plateau. The extensive geologic history of volcanic activity has created a seemingly hellish volcanic field rightfully named “the badlands” by Spanish explorers. However, the region is in fact home to a rich cultural history that heavily utilizes the natural environment, including its many cave systems. The lava flows themselves contain vast ancient trail systems that are poorly understood at present and have only recently become a topic of research. In the summer of 2016, locational data and assessment reports concerning the park’s over 400 recorded subterranean features were collected in order to produce a geospatial distribution map of those with archaeological significance. A preliminary examination of the distribution in relation to the park as a whole, as well as site comparisons by type and location are presented. This data will then be compared with prehistoric trail data collected from past archaeological surveys to assess a possible relationship between the caves and the trails.

McCray, Brian (Vanderbilt University)

Open Space and Restricted Action: Analysis of Intrasite Networks of Movement at Wimba, in the Northeastern Peruvian Montane Forest

In an area that has been considered marginal both geographically and in the narrative of South American prehistory, new research shows extensive settlement, landscape modification, and interaction between inhabitants of the eastern slopes of the Andes and their neighbors. The site of Wimba, located in the Amazonas department, in the northeastern Peruvian montaña—the tropical montane forest between the highland Andes and lowland Amazonian rainforest—is one of the best known archaeological sites located at the eastern edge of the Late Intermediate Period (ca. 900–1500 CE) Chachapoyas cultural region. New data collected by the Proyecto Arqueológico Wimba in 2016 sheds light on the site’s construction, duration of occupation, use, and abandonment. Through network analysis of architecture, ceramics, and lithics recovered from both open spaces and structures, this paper will examine how the built environment of Wimba structured movement, ritual, and politics. The paper will also consider the structure of movement throughout the region by comparing Wimba with nearby neighbors. These data reflect the role of Wimba’s inhabitants in local, regional, and interregional sociopolitical organization and intra- and/or interregional networks of interaction, roles that created and enacted a society that evades broad categorization as Amazonian or Andean.
McCurdy, Leah (University of Texas at San Antonio)

Solid Foundations: Practical and Symbolic Significance of Bedrock at El Castillo Acropolis of Xunantunich, Belize, in the Maya Central Lowlands

Not all excavations reach to bedrock. In the Maya Central Lowlands, exposing bedrock can be difficult due to the longevity of occupational sequences and the sometimes confounding presence of thick, seemingly endless Preclassic marl floors. In some cases, our ability to reach and examine bedrock helps us to consider early living and ceremonial spaces, masonry and structural techniques, as well as potential emic connections of natural limestone mountains and cultural manifestations of limestone temples. At the site of Xunantunich, Belize, we have evidence to support each of these considerations. In this paper, I focus on our findings of deliberately exposed bedrock during at least one building phase of El Castillo acropolis. I propose that the juxtaposition of exposed bedrock with a newly renovated temple structure above it, including an elaborate stucco frieze proclaiming divine and kingly prominence in the region, springs from the interconnectedness of the natural and built environments (as we distinguish them today) in the Maya worldview. The linkages of nature/culture in this example likely relate to messages of power and expressions of cosmology. Broadly, this case study resonates with cross-cultural questions about how humans conceptualize, interface with, and modify their surroundings.

A Method for Identifying Surface Scatters in the Jungles of Belize: A Case Study from the Medicinal Trail Community

The implementation of systematic surface collection on a grid within Operation 17 at the Medicinal Trail Community in northwestern Belize highlights the importance of surface collection to the fuller understanding of ancient Maya socioeconomics. Surface survey and collection at archaeological sites can lead to more precise interpretation of a site. However, jungle debris is often cleared from Maya sites with rakes, disrupting any surface collection before excavations begin. At Operation 17, care was taken not to disturb surface artifacts before excavation. Survey of surface scatter and further excavation of four of these units revealed that the surface and subsurface artifact concentrations were quite different. This poster looks further into the method of surface collection, and the kinds of information which can be learned from utilizing this method.

Spatial, Technological, and Functional Characteristics of Ceramics along the Southern California Coast

Prehistoric ceramics found across southern California have a discrete spatial distribution. While locally manufactured ceramics are common to the south and southeast of the Los Angeles River, prehistoric ceramic sherds are rare in deposits located to the northwest. This marked distribution is potentially explained through a few hypotheses. Populations to the north may have had access to resources necessary for pottery alternatives or may have differed in their settlement patterns, mobility, and/or subsistence practices. Alternatively, it is possible that ceramics are associated with distinct population histories and that the south is occupied with populations that are derived from the California desert. In this poster, I evaluate measurements of technological and functional variability of ceramic assemblages from deposits across coastal southern California to determine the degree of variation that exists in the use and production methods of vessel ceramics. After ruling out differences in surface age and deposition, if aspects of the environment are correlated with space, it is likely that vessel ceramics are tied to an ecological or economic feature of the environment. Alternatively, random variability across space potentially supports the hypothesis that population histories are largely driving the presence of pottery.

McGill, Kendall

Investigating Cedar Mesa (Utah) Settlement Pattern Behaviors Using Ideal-Free Distribution

Ideal-Free Distribution (IFD), a behavioral ecology theory, has been increasingly adopted by archaeologists to address questions about the relationship between settlement distribution, environment, and economy. In an anisotropic environment like Cedar Mesa, IFD theorizes that individuals would arrange themselves across the landscape according to habitat suitability and occupy the highest ranked regions first to maximize benefit to the individual. The Ancestral Pueblo of Cedar Mesa subsisted on a maize-based diet and it has long since been assumed their dietary reliance on dry-farmed maize yields resulted in residence location selection driven by access to agriculturally productive land. Analyzing archaeological site data and digital environmental datasets with IFD provided an opportunity to reexamine the settlement patterns of the Ancestral Pueblo on Cedar Mesa and the potential influence of additional environmental variables. In addition to proximity to arable lands, IFD predicts that occupants would select residential locations that reduced transportation costs to essential resources, such as water, wild foods, and fuel. This presentation shows the results of habitat suitability calculations and assesses the degree to which IFD predictions align with settlement pattern behaviors on Cedar Mesa.

Responding to Burning Libraries

Rising sea levels, increasing storminess, melting glaciers, rising soil temperatures, and increased wildfires are all increasingly affecting archaeological sites worldwide. Accelerated destruction of sites with organic preservation poses a dual threat to global and local cultural heritage and to archaeological evidence that is becoming recognized as key global change data. As archaeologists increasingly participate in local, national, and international efforts to promote genuine long term sustainability we also recognize that our “distributed observing network of the past” is rapidly being destroyed by accelerated environmental change. Many local responses to these challenges are being mounted by archaeologists and host communities, but there is an urgent need for coordination and collaboration on a wider scale to share resources, pool expertise, and identify and disseminate best practice. The threat posed to both heritage and science provides an opportunity for enhanced cooperation among resource managers and local residents as well as outreach to the wider public. This session is sponsored by the SAA Climate Change Strategies and the Archaeological Record Committee and by the IHOPE

The Sky Is Falling: Site Formation Processes at Woodpecker Cave, Johnson County, Iowa

Woodpecker Cave is a small, limestone rockshelter occurring on a drainage of the Coralville Reservoir in Johnson County, Iowa. The site was originally excavated in 1956 by Warren Caldwell and has been the home of the University of Iowa archaeological field school from 2012 to 2016. The University of Iowa excavations identified Late and Terminal Woodland materials with a high concentration of roofspall contributing to the archaeological deposits. When combined with recent terrestrial LiDAR scans of the rockshelter, the roofspall data provide insights into the site formation processes occurring at Woodpecker Cave. Roofspall morphology and the fabric of the archaeological deposits are the focus here to better understand how active formation processes occurring within the rockshelter have influenced the human occupations of the site.

Buck-ing the Trend: Surprising Species Identifications of Archaeological Bone Points Using Zooms in Deer-Dominated Faunal Assemblages

Fragmented and worked bone continues to be problematic for accurate identification using traditional morphology-based analyses. In this study, we apply a number of ZooMS (Zooarchaeology by Mass Spectrometry) techniques for the identification of bone points from two precontact Iroquoian village sites in southern Quebec, Canada. The predominance of white-tailed deer in the mammalian faunal assemblages of both sites, combined with the approximate size of the original bones, led to the initial assumption that the majority of the bone points found were likely to have been made of this animal. A preliminary nondestructive study of two of these points, first reported at the 2016 SAA conference, revealed the unexpected species identification of bear. Further testing of additional points from the sites has revealed a wide variety of surprising species, rather than the expected result of deer. These identifications highlight the importance of biomolecular techniques, such as ZooMS, in providing reliable and accurate species determinations, particularly for worked bone. It also provides a cautionary tale in applying general faunal assemblage assumptions to worked artifacts, which has implications for the interpretation of species-specific importance.

McGuire, Randall (Binghamton University)

How Modern Boundaries Blind Us to the Precolumbian Known World: A View from the Southwest/Northwest

Archaeologists live in a North America divided by lines. These lines include the borders of nations, the boundaries of states and provinces and the limits that we as archaeologists have drawn around culture areas. These lines affect in subtle and complex ways, how we frame questions, how we define the boundaries of our studies, what journals we read, what colleagues we talk to, where we go to school and dozens of other aspects of archaeology. Most if not all of these lines had no meaning for the ancient peoples of the continent. Nowhere is this clearer than in the Southwest of the United States and the Northwest of Mexico. Here archaeologists have traditionally drawn a hard boundary between a Southwest and a Mesoamerican culture area. The national border between the United States and Mexico has aided and abetted in this conception. International, collaborative research has allowed archaeologists working in northern Mexico to transcend both the political border and the cultural areas. The result of this research has been a more dynamic, integrated and expansive understanding of interregional interactions on a continental scale.

The Role of Portable Rock Art during the Northern California Archaic Period

One of the largest and oldest portable rock art assemblages identified in North America has been documented in the upper reaches of the Sacramento River in Northern California. This florescence of stylistic activity, commencing as early as 6,000 years ago, appears to be a symbolic manifestation of group identity and a harbinger of the rise of social and territorial complexity in this region. In this paper we explore the linguistic, social, and ecological variables that may have given rise to this burst of symbolic expression.

What Doña Ana Phase and Modern Jackrabbits (Lepus californicus) Can Tell Us about Climate Change in the Southeastern Southwest

This paper documents the environmental conditions of the Tularosa Basin/Hueco Bolson during the Late Formative Period in the Jornada Mogollon Region of the U.S. Southwest by comparing stable carbon isotope values of black-tailed jackrabbits (Lepus californicus) from archaeological site LA 12361 to modern jackrabbits in southern New Mexico and west Texas. Recent research by Stephen Smith and his collaborators provides evidence that carbon isotope values of jackrabbit bone collagen produce an effective proxy for the plant communities, and by extension the environmental conditions, within which these herbivorous animals lived and foraged. Knowing this, it is possible not only to understand jackrabbit diet and environmental conditions in prehistory, but also to compare dietary and environmental proxies with modern jackrabbit stable carbon values to document how the environment has changed since the thirteenth century. A comparison between archaeological and modern jackrabbits provide a deeper temporal context for understanding climate change in the Tularosa Basin and Hueco Bolson. Additionally, a discussion of the utility of stable hydrogen isotope analysis for differentiating between jackrabbit diets biased toward either C4 or CAM plants will be presented as a method to increase interpretive precision of dietary and environmental variability.

The Maritime Fur Trade before the Maritime Fur Trade on the Pacific Coast of North America
The maritime fur trade on the northwest coast of North America (ca. AD 1778–1850) was a historically consequential process that unfolded throughout the Indigenous territories of the Pacific coast. Tens of thousands of astronomically valuable sea otter pelts were traded by Indigenous chiefs with visiting ship captains, who then transported these pelts across the Pacific and sent profits home. The massive wealth generated by this colonial trade encircled the globe but also amplified existing political dynamics within and between Indigenous communities that continue to have political and ecological reverberations today. While this iteration of the “maritime fur trade” is well documented, much less is known about how this short-lived trade was preceded by thousands of years of intensive occupation, use, and political control of the coast, including the role of otters in Indigenous hunting traditions and governance as well as the material culture of adornment and trade. This presentation reviews the zooarchaeological evidence from sea otters from hundreds of archaeological settlements along the coast and sketches some historical ecological hypotheses about the former abundance of this iconic marine mammal species, whose populations are recovering and once again exerting impacts on coastal ecosystems and the maritime foodways of Indigenous coastal communities.

McKee, Brian (University of Arizona) and Christopher Taylor (EcoPlan)

Shadows of War, Shadows of Peace: Sites from El Salvador’s Civil War
The Salvadoran civil war, fought from 1980 to 1992, devastated the country and left 75,000 to 100,000 people dead. Much of the worst fighting was in the northeastern department of Morazán. Numerous battles were fought there, where several terrible civilian massacres occurred as well. Through much of the war, northern Morazán was a primary stronghold of the FMLN guerrillas. The poster examines two civil war sites in northern Morazán. The first, Cerro Pelón—the northern spur of Cerro Gigante—was one of three neighboring mountains involved in numerous battles, especially in the early 1980s. Features there include foxholes, trenches, an air raid shelter, a fortification wall, and a bomb crater. The second site is related to the disarmament of the FMLN following the signing of the Chapultepec Peace Agreement in January 1992. Shipping containers monitored by U.N. observers, as well as by representatives of both sides, were used to deposit arms prior to their being decommissioned. The study integrates interview data and historical resources with the archaeological remains to elucidate the nature of the war and the succeeding peace.

McKenna, Moriah (Connecticut College) and Anthony Graesch (Connecticut College)

The now-forested New England landscape has been shaped substantially by long-term human activities. Partitioned by thousands of miles of stone walls, the young and dense woodlands visible today are a consequence of intensive clear-cutting and farming activities in the eighteenth and nineteenth centuries. In this study, we apply the theory and method of landscape archaeology to the study of farming practices at an eighteenth-century, 49-acre colonial farmstead in southeastern Connecticut. We present data collected with an array of methods—lidar, penetrometry, archaeological reconnaissance, subsurface testing, vegetation survey, and aerial photography—that, when combined, provide a fuller synthesis of humans’ uses of landscape. We highlight, in particular, the results of pedestrian survey, and we show how typologies of stone concentrations and stone wall barways may be productively linked to variability in routine agricultural practices across farmstead fields. When aggregated in a GIS, these data not only shed light on relationships of past land use to contemporary plant communities, but they also provide a spatial and economic context in which to consider the roles of slavery and indentured labor on early colonial farms.

McKillop, Heather (Louisiana State University)

Underwater Transect Excavations, Sediment Coring, and Remote Sensing at the Paynes Creek Salt Works
Following the discovery and mapping of over 100 salt works in a shallow, salt-water lagoon system, a collaborative, interdisciplinary research project was initiated with funding from NSF to examine the ancient landscape, sea level rise, use of the wooden buildings for salt production and as residences, and reconstruct the underwater sites using 3D GIS. Sediment coring across the lagoon system identified red mangrove peat, an indicator of actual sea level rise, as well as a plethora of pollen that revealed changes in vegetation patterns. An automated research vessel imaged the seafloor, along with air photos from a drone framing the underwater sites in the modern mangrove ecosystem. Transect excavations through wooden buildings and across open areas indicated the buildings were associated with salt production, with little activity outside buildings. A lagoon lab set up on the edge of underwater sites was used to sort, record, and analyze briquetage and other artifacts. Selected salt-water saturated artifacts were 3D scanned in the evenings at our base station and returned for storage underwater. Exhibits featuring 3D printed replicas of artifacts from the Underwater Maya project were established working with local stakeholders.

McKinney, Caroline (University of Florida), Sarah Hlubik (Rutgers University) and David R. Braun (George Washington University)

Applications of Multipsectral Imagery to the Archaeology of Human Origins
Multispectral imagery is a powerful tool for various disciplines that use landscape scale spatial patterning to understand and identify underlying geochemical variations. Paleontologists have used multispectral imagery in numerous locations; however, it has not been extensively applied in the study of archaeological sites associated with human fossil localities in East Africa. Extensive geological exposures combined with laterally expansive volcanic ashes in the Turkana basin make this an ideal location to apply this technique. Here we present a study using 2-m resolution multispectral imagery (provided by the GeoEye Foundation) to investigate the location and patterning of archaeological sites in the Okote Member (1.6–1.39 Ma) of the Koobi Fora Formation in an attempt to identify potential archaeologically productive sediments in the Karri region of the Turkana Basin. Our results indicate the potential of this technique for identifying certain features of the archaeological record but also that difficulties associated with applying this technique in a geologically heterogeneous environment. This research was supported by the National Science Foundation International Research Experience for Student program (OISE-1358178 and 1358200).
McLaren, Duncan (Hakai Institute), Daryl Fedje (Hakai Institute), Gitla Elroy White (Central Coast Archaeology), Seonaid Duffield (University of Victoria) and Alisha Gauvreau (University of Victoria) [49] Archaeological Investigations of the Intertidal Ecotone on the Central Pacific Coast of Canada

On the outer central Pacific coast of Canada, the intertidal zone is a highly productive ecotone that lies between temperate rainforest and marine biomes. The tide comes in and out over five vertical meters twice every day. While the tide is out, our research teams have been investigating archaeological aspects of intertidal strata, artifacts and features. Stratigraphically the intertidal zone provides a window into the late Pleistocene archaeology of the region. Our subsurface testing into beach deposits has uncovered preserved late Pleistocene strata with associated flakes, cores, projectile points, wood chips and human footprints. Some early Holocene assemblages have also been found which include animal bones accumulations and lithics. A variety of petroform features are prevalent on beaches in front of later Holocene shell middens including canoe runs, circular meeting places, cleared trails and activity areas, fish traps, and clam garden walls. Overall, archaeological investigations in the region point to the long-term importance of the intertidal ecotone as a place for focused and intensive land and resource use as well as social interaction.

McLaughlin, Rowan (Queen’s University Belfast), Katrin Fenech (University of Malta), Rory Flood (Trinity College Dublin), Michelle Farrell (Queen’s University Belfast) and Ronika Power (University of Cambridge) [133] Rhythms of Stability and Change in the Central Mediterranean

This paper explores changing patterns of isolation in prehistoric island societies, and their ongoing connections with the wider world. The case study is the expansion of agriculture in Southern Europe in the sixth millennium BC, and subsequent landscape and cultural evolution in the Maltese archipelago. This was a series of maritime events, establishing connectivity between Mediterranean islands whose inhabitants’ ‘Neolithic package’ lifeway permitted high-density settlements in small islands. In Malta, where unique Neolithic art and architecture ultimately flourished, farming was established by 5500 BC, and some enduring stability ensued. But there was limited continuity—sudden change occurs in the archaeological record of various timeframes, as do phases of potential abandonment—although these are difficult to resolve using archaeological data alone. Paleoenvironmental evidence is therefore used to fill the gaps. Indeed, AMS 14C dating has revealed that episodic rhythms of stability and change were commonplace in prehistory. The timing and magnitude of these events in Malta explored in this paper, revealing an island world whose cultural responses to the challenges of prehistoric life were precipitated on the archipelago’s unique intersection of isolation, size, and available resources.

McLay, Eric (University of Victoria) [334] Ancestral Landscapes of the Salish Sea: Exploring Inland Shell Middens, Social Memory, and Coast Salish Narratives

This paper will explore indigenous and archaeological ways of understanding “inland shell middens” in the Salish Sea on the Northwest Coast, British Columbia, Canada. Archaeological evidence suggests inland shell middens represent depositional practices that may have embodied new strategies of social memory and ritual practice beginning in the Marpole Phase (2400 to 1200/1000 cal BP). To move beyond the deeply plumbed Northwest Coast ethnographic literature to interpret the archaeological past, ethnographic research will draw upon dialogues with descendant Coast Salish peoples today about how their ontologies, cultural beliefs, values, lived experiences and daily practices associated with the ancestral dead and nonhuman beings and ancestral objects powerfully shape Coast Salish understandings of their own settlement history.

McLoester, Madeleine (University of Chicago) and Mark Schurr (Notre Dame) [102] Middle Grant Creek: A Rare Example of a Single Component Huber Phase Site on the Illinois Prairie

Our understanding of the protohistoric Huber phase is limited by our small sample of sites from this complex period. We present preliminary findings from the summer 2016 excavation at the Middle Grant Creek (MGC) site at Midewin National Tallgrass Prairie in Wilmington, IL. The site is a well-preserved single component Huber phase, warm weather camp that survived historic farmsteads and the construction and abandonment of an Army arsenal. MGC expands the sample of Huber sites and provides needed data on lifeways during the final period before European arrival. We expect data from MGC to help refine our understandings of seasonality, mobility, and site types of Huber communities as well as inform possible down-the-line impacts of the fur trade. As one of the few single component sites in the region, data also help us untangle relationships between the multiple late prehistoric communities in the region and refine existing regional typologies.

McManamon, Francis (Center for Digital Antiquity—ASU) [18] Online and In-Person Professional Training for Archaeological Data Management and Digital Curation

This presentation describes a series of professional training workshops created by the Center for Digital Antiquity that are designed to introduce archaeologists to the basic aspects of managing and curating digital archaeological data. In the last quarter century, the creation and use of digital data in archaeological investigations has become routine. Documents, images, datasets, and geospatial data in modern archaeology are now nearly always in digital formats. Research projects, CRM firms, public agencies, and individual scholars who conduct archaeological investigations use a variety of computer systems for collecting, describing, analyzing, and reporting their data. However, the curation of these digital data once a project is completed often is overlooked as an important action and seldom treated with the same rigor as the data creation, description, and analysis. The Center for Digital Antiquity was established to improve the curation of archaeological data so that it can be more easily discovered, accessed, and reused. One of the most common challenges of carrying out this mission is the lack of understanding in the archaeological community of good digital data management and curation practices.

[47] New Radiocarbon Dates and Methods for Elucidating the Extent and Timing of Use for Intertidal Fishing Features on the Northwest Coast

Acquiring accurate and precise dates for archaeological materials and features is fundamental for investigating human history on the Northwest Coast (NWC) of British Columbia, Canada. Remarkably few radiocarbon dates for intertidal features exist in the literature, and they are only associated with features that yield objects which can be directly dated, such as fish traps containing wooden stakes. Various numerical and relative dating techniques have been applied to other types of intertidal features, although these methods cannot constrain intricate temporal variations. Thus, wooden stake features provide some of the best opportunities to evaluate how the intertidal zone on the NWC was used and managed by people during the late Holocene. In this study, we present 99 new calibrated radiocarbon dates from intertidal fishing features on the NWC that define spatio-temporal trends related to the extent and timing of use for such features.

[71] Tracing Pathways of Power, Identity, and Landscape at Río Amarillo, Copan Valley, Honduras

During the Late Classic period, the ancient community of Río Amarillo was actively engaged in the politics of the city of Copan, whether willingly or not. Some have suggested that the fertile bajos of the Río Amarillo East Pocket may have produced food for the city to its west, ameliorating shortages that could have arisen due to its rising population. Archaeological research conducted by the Proyecto Arqueológico Río Amarillo, Copan (PARAC) since 2011 has recovered information regarding both the relationship between Río Amarillo and Copan, and the relationship between Río Amarillo and its environment from the Late Classic to the Postclassic period. The presence of Copan’s power within the town of Río Amarillo is most visibly evidenced by a seventh-century altar that mentions Ruler 12, and later by the construction of a building bearing mosaic sculptures linked to Ruler 16. Both this latter structure and a censter lid found by PARAC recall the founder of Copan’s Maya dynasty, K’inich Yax K’uk’ Mo’, who was clearly revered by at least some portion of the Río Amarillo population. Analysis of sediment and botanical samples has also provided insight into the types of crops grown around the site and consumed by its inhabitants.

[375] Uintah Basin Basketmaker II Anthropomorphic Style: Antecedent and Ancestral to Classic Vernal Fremont Style Rock Art

In his recent analysis of petroglyphs in the Uintah and San Rafael zones east of the Wasatch Mountains, Keyser (2016) identifies a subset of Fremont style figures as “solidly pecked trapezoidal body style Fremont.” In this paper, I expand upon Keyser’s analysis by adding to this stylistic repertoire a set of anthropomorphic figures that are largely similar to, but lack Classic Fremont diagnostic features, such as homed or winged headaddresses, or body decorations, such as necklaces. Rather than fitting the category of Classic Fremont, I argue that this small assemblage represents a transitional or bridging style linking Eastern Basketmaker anthropomorphic style (Durango, Colorado and Los Pinos, New Mexico zones to the south) and Classic Fremont style in the Uintah Basin (specifically the Cub Creek and Cockleburr Wash, Dinosaur National Monument area). I interpret this evidence of stylistic continuity, correlated with the presence of early maize (AD 250–400) in the Uintah Basin (Talbot and Richens 1996; Ortman and McNeil 2015), to suggest that Kiowa-Tanoan speaking EBM maize farmers from southwestern Colorado migrated to the Cub Creek area where they reproduced EBM solidly pecked trapezoidal style which was antecedent and ancestral to the Classic Vernal style.

[380] “Why those old fellas stopped using them?” Spiritual and Ritual Dimensions of Stone-Walled Fish Trap Use Among the Yanyuwa of Northern Australia

Archaeological approaches to stone-walled tidal fish traps of Indigenous Australians focus on the technology and subsistence, with chronological development linked to demands of increased food production associated with demographic change and social intensification. For the Yanyuwa “Saltwater People” of tropical northern Australia, old stone-walled fish traps found within the intertidal zone are associated with the creative acts of ancestral spirit beings. As such, these fish traps are imbued with spiritual potency such that use requires specialized ritual practices (involving ochre and smoke) by senior men who also prescribe who can and can’t use the traps and eat the resulting catch. Today these traps lie dormant, not because the demand for fish has decreased but because of the demise of old highly initiated men of Law. These senior men not only possessed the requisite ritual knowledge to repair and activate the traps but also the specialized social and political knowledge to ensure adherence to strict and religiously codified laws and rules governing fish catch consumption among the community. The Yanyuwa teach us that socioreligious factors may be of equal or greater importance than socioeconomic factors in understanding why peoples of the past decided to use and disuse fish trap facilities.

[287] Additional Statistical and Graphical Methods for Analyzing Artifact Orientations and Site Formation Processes from Total Station Proveniences

The orientations in three dimensions of clasts within a deposit are known to be informative on processes that formed that deposit. In archaeological sites, a portion of the clasts in the deposit are introduced by non-geological processes and these are typically systematically recorded with total stations. In assessing archaeological site formation processes, the raw data plus the R code to implement these methods and those already described in McPherron (2005) will become open access to help further their use in assessing archaeological site formation processes.

McPherron, Shannon P. [38] see Lin, Sam
Bones, Beads, and Birds: Determining Cultural Affiliation of Skeletal Remains and Artifacts from Casuarina Mound, Brevard County, Florida

Efforts to repatriate Native American human remains and artifacts are of immediate importance to American archaeology. Excavated in the early twentieth century, Casuarina Mound (8-Br-0122) was first dated to the Malabar II period (750-1565CE) by Irving Rouse in his 1951 publication A Survey of Indian River Archaeology, Florida. Historical accounts describe the removal of at least 112 skeletons and numerous funerary objects from three successive interments. A small subset of this material was donated to the Peabody Museum of Natural History at Yale University. Here, we document all human skeletal material and funerary objects from Casuarina Mound present in the collection. Represented mainly by cranial material, the individuals comprise a range of age/sex classes and present indicators of life history, health, and disease associated with cultural biomarkers. The funerary objects, despite being only a fraction of that removed from the mound, are strong indicators of cultural identification. Our documentation of Casuarina Mound human remains and artifacts at the Peabody Museum may reconnect contemporaneous elements and objects housed at disparate institutions. Such analyses contribute to the determination of ancestry and tribal affiliation using replicable and verifiable methods, and connect institutions and indigenous communities through scholarship and consultation.

Shifting Domestic Economies at Postclassic Period Moxviquil: Insights from Ceramic Petrography

This poster presents evidence of a singular Late Archaic period habitation feature. Recent compliance excavations conducted at site LA 45730 along the Pecos River east of Carlsbad, New Mexico, have provided rarely seen evidence of occupation in the Permian Basin. A small pit structure exposed in a highly eroded floodplain terrace provides an opportunity for further insights. Few such structures have been fully documented in this region. Material remains recovered from the pit structure provide evidence for utilization of locally available riverine food sources. Intramural features show evidence for structure support posts and there is also evidence of internal storage and possibly a prepared floor. Artifacts recovered in association include two diagnostic Late Archaic projectile points. The orientation of these and other flaked-stone tools suggests intentional placement according to the cardinal directions and are postulated to represent ceremonial abandonment of the structure. This site provides valuable data for interpreting Late Archaic lifeways in the Permian Basin. This poster aims to highlight these findings and to bolster an otherwise poorly represented dataset for the Late Archaic in southeast New Mexico.

McTavish, Rachel (University of Wisconsin-Milwaukee) and Corey Hoover (University of Wisconsin-Milwaukee)

A Holistic Investigation of Economization at a Late Prehistoric Village in Northern Illinois

The economization of lithic raw materials for Late Prehistoric groups in the midwestern United States has long been the subject of research. This research has often focused on explaining aspects of either technological or subsistence changes, such as the shift to agriculture (e.g., Bamforth 1989; Cobb 2000; Emerson, et al. 2000; Emerson and Titelbaum 2000; Jeske 1990, 2000). This project uses the underlying framework of economization used by these lithic studies and applies it to faunal remains, ceramics, and lithic assemblages from a single site in northern Illinois, the Washington Irving Site (11K52). The site dates to circa AD 1100-1440 (Jeske 2000). This study uses an ArcGIS spatial analysis of the distribution of the assemblages from the site to identify activity areas and discard patterns that are essential for understanding the economizing behavior used at the site. This study uses a multipronged approach to provide a holistic interpretation of changes to diet, settlement, intergroup relations and technology that were established throughout the Midwest during this period.

Archaeofauna and Archaeobotany studies in Northwestern South Asia: Past, Present, and Future

Both Zooarchaeological and Paleoethnobotanical studies have been carried out on animal and plant remains from archaeological sites in northwestern South Asia for at least a century. These investigations, while providing important insights into the hunter-gatherer and agropastoral economies of the region, have lagged behind those carried out in other parts of the world in both quantity and quality. Indigenous practitioners of both subdisciplines are few, and interest in these aspects of archaeology is poorly developed locally. Studies by non-indigenous practitioners have also been limited and reports of analyses slow to be published. In this presentation I highlight reasons for these shortcomings—both institutional and intellectual—and discuss the promise for future work in the region.

Shifting Domestic Economies at Postclassic Period Moxviquil: Insights from Ceramic Petrography

Building a Virtual Bridge Connecting Indian Himalayan Archaeology with a Virginia University and the World

The Virtual Curation Laboratory at Virginia Commonwealth University (VCU) in Richmond, Virginia, and the Archaeology Department of Hemwati Nandan Bahuguna (HNB) Garhwal University, in Garhwal (Srinagar), India, have partnered to create three-dimensional (3D) models of artifacts and sculptures from the trans-Himalayan region of northern India. Many of these items are on display in the HNB Garhwal University Museum of Himalayan Archaeology and Ethnography. This partnership seeks to preserve these items, make them more widely available to researchers, and raise public awareness of the cultural heritage of the state of Uttarakhand. VCU students are drawing on 3D printing to create an exhibit that showcases this heritage to their fellow students and faculty.

Discussant
The Early to Late Postclassic Period transition brought substantial changes to the political and economic organization of many regions of Mesoamerica. For the networked polities of highland Chiapas, these changes included substantial decreases in population at existing monumental centers; the establishment of new political centers in several principal highland valleys, and the establishment of an expansionary Chiapanec state in the Central Depression, centered on the city of Chiapa de Corzo. This paper examines the evolution of domestic economic organization at the highland political center of Moctezumil throughout the Postclassic period. In particular, we focus on changes in the production of utilitarian ceramic wares in Moctezumil’s domestic assemblages, including vessel forms, clay sources, firing techniques, and tempering processes. Ceramic petrography highlights the technological choices made by household producers of ceramic vessels throughout the Postclassic period. Most strikingly, we observe shifts in the acquisition of resources, including clays and nonplastic inclusions such as sand, volcanic ash, and crystalline calcite. A contrast in the production techniques for the dominant medium- and coarse-wares in Moctezumil’s domestic assemblages may suggest multiple, contemporaneous production communities within the local area.

[105] **Social Inequality and Food Storage at Hohokam Platform Mound Sites in the Phoenix and Tonto Basins**

Some social theorists contend that the critical threshold in the development of complex, ranked societies is the emergence and institutionalization of inequality, or a formalized hierarchical organization that is inherited and reproduced. One pathway that elites take in establishing and institutionalizing political power is by attaining control over the economy. A key strategy of establishing economic power is to mobilize and store food surpluses. For the prehistoric Hohokam of southern Arizona, social and ideological inequalities appear to have peaked at platform mound sites during the late Classic period (ca AD 1300–1450). Some platform mounds in the Phoenix and Tonto Basins include rooms with large storage capacities, including structures with granary pedestals. These pedestals are the remains of beehive-shaped adobe storage features. The included storage pattern has been bolstered by the recent discovery of several large, stone-paved granary pedestals within an atypically large room in the compound of the Lower Santan Platform Mound in the Gila River Indian Community. This room provides evidence that food surplus was stored in a limited-access context, and further supports the contention that Late Classic period Hohokam platform mound communities had established complex internal ranking and institutionalized leadership positions.

Medina, Paulo (Boston University)

[386] **Demystifying Southern Lowland Chultunes: The Ritual Space Hypothesis**

This investigation’s working hypothesis is that chultunes, manmade subterranean features, served as ritual spaces in the southern Maya lowlands. The hypothesis is an outgrowth of my grounding in cave archaeology. Ethnographically, even subterranean features used for utilitarian activities, such as mining, come to have sacred meaning and this phenomenon can be documented in ethnohistoric sources. However, my hypothesis has not been tested. Dennis Puleston argued for a utilitarian function of chultunes based on his perception of these features occurring exclusively in rural areas while others have argued for their more frequent location in cenitones. I will conduct a preliminary examination on the spatial distribution of chultunes and their relationship with other architectural features at various sites and make a connection between chultunes and caves.

[135] **Proto-Tarascan Uacusecha Metallurgy: Issues about Technological Transition and Lost Techniques**

Within the large and rich vein of archaeological studies on Western Mesoamerican metallurgy (ca. AD 800–1500), a large body of literature is devoted to the metal production of the Tarasco Kingdom (AD 1420–1522), since by AD 1450 this became the most important center of pre columbian metalworking. Indeed many scientific studies have focused on the material and the technological aspects of Tarascan metal artifacts, particularly of copper and copper alloy bells. In comparison, little is known about Uacusecha metalwork—identified as the predecessor of the Tarascan—an approach that offers to provide knowledge on a key and yet poorly documented phase of middle Western Post-Classic Metallurgy. This paper follows recent advances in Uacusecha metallurgy by presenting further results of an interdisciplinary scientific research based on the use of diverse analytical techniques (OM, XRD; SEM-EDXRF) on a small metal collection recently discovered in Malpaís Prieto Archaeological Site, near Zacapu, Michoacán, Mexico. As a result, this paper presents a groundbreaking pilot study that discusses issues about technological transitions and lost techniques of Western metallurgy, which included the production of copper, copper alloys and silver artifacts.

[252] **Hallazgo de la Tumba de Miguel de Palomares**

En el año 2016 el Programa de Arqueología Urbana (PAU) del Instituto Nacional de Antropología e Historia (INAH), llevó a cabo excavaciones frente a la Catedral Metropolitana de la Ciudad de México. Además de encontrarse vestigios arquitectónicos de la época virreinal, se descubrió una lápida mortuoria con un epitafio alusivo al canónigo Miguel de Palomares. Al continuar con la excavación, se localizó un entierro secundario que debe corresponder al personaje mencionado en la lápida. En esta exposición nos referiremos a este hallazgo y su importancia no solo por ubicarse en el período virreinal temprano sino también por tratarse del descubrimiento de los restos del canónigo que formó parte del primer cabildo eclesiástico de la Nueva España. Los estudios continúan; diferentes especialistas que colaboran en esta investigación, realizan análisis osteológicos, radiológicos, moleculares, de isótopos y genéticos, que serán complementados con la investigación histórica de archivo para corroborar la identidad del canónigo, así como para dar a conocer los aspectos biológicos y las circunstancias en las que vivió dicho personaje.

Meehan, Pascale (University of Colorado, Boulder)

[82] **Examining Rural Responses to Political Collapse: The Early Postclassic at Monte El Santo, Oaxaca, Mexico**

Recent archaeological research at the site of Monte El Santo, Oaxaca, Mexico, examines how the rural community of Monte El Santo responded to the political collapse of the Río Viejo polity during the Early Postclassic Period (800–1100 CE). The collapse ushered in important changes for the coastal inhabitants of the Lower Río Verde Valley—the site of Río Viejo experienced a sharp decline in population, and a newly formed population center at San Marquitos grew to rival Río Viejo in size. While previous research at Río Viejo has demonstrated that after the political collapse site residents were able to produce and manage surplus cotton and gain greater access to long-distance goods, research at Monte El Santo explores the degree to which people in rural communities responded to these changes. This presentation will discuss research of domestic contexts at Monte El Santo. This research, which is ongoing, will help determine how rural actors engaged with the changing political, economic, and social climate of the Early Postclassic. These data will be compared to those from Río Viejo in order to discuss whether the post-collapse economic opportunities available to inhabitants at Río Viejo also existed for those at Monte El Santo.
Megarry, Will (Queens University Belfast), Gabriel Cooney (University College Dublin) and Rob Sands (University College Dublin) [376]  
A Multiscale Landscape Approach to the Production of Polished Stone Tools in Neolithic Shetland  
The Shetland Archipelago at the very north of Scotland contains one of the best preserved Neolithic stone tool quarries in Western Europe. Recent fieldwork by the North Roe Felsite Project (NRFP) has considerably advanced our knowledge of this quarry landscape and the production of polished stone axes and Shetland knives. The NRFP has explored the landscape dynamics of this activity on a range of scales; from regional geological survey and workshop prediction using multispectral satellite imagery, to the intrasite distributions of artifacts and debitage, and targeted excavation of quarry pits. While felsite dykes are present throughout the quarry complex, definite evidence for quarrying is only visible at certain locations. Excavation has shown that quarrying methods and intensity of extraction differs between sites. The process of felsite extraction, and the possible local and regional networks used for its distribution across the archipelago, are explored in this paper. Using landscape modeling techniques the location of the quarries are explored with particular focus on the visual and spatial relationship between the quarry pits and their landscape, and between the quarry landscape and the wider region.

[280] Consumer Culture at the Nineteenth-Century Maya Refugee Site at Tikal, Guatemala  
In the mid-nineteenth century, Maya refugees fleeing the violence of the Caste War of Yucatán (1857–1901) briefly reoccupied the ancient Maya ruins of Tikal, Guatemala. These Yucatec-speaking refugees combined with Lacandon Maya, and later Ladinos from Lake Petén Itza to form a small, multilingual village in the sparsely occupied Petén jungle of northern Guatemala. The following paper will discuss the recent archaeological investigation of the historic refugee village at Tikal, with a focus on the recent villagers may have been trading to obtain such goods, such as tobacco and other jungle products. As will be demonstrated, despite its remoteness from urban centers, the Tikal Village was well connected to trade networks of surrounding societies, demonstrated by the quantity and diversity of foreign items found in their homes and in vast midden deposits around this short lived community.

[71] Political Dynamics and the Organization of Chert Production in the Copán Valley  
This study focuses on the social aspects of craft production among outlying populations of the greater Copán Valley of Honduras during the Late Classic to Early Postclassic transition (AD 800–1200). Lithic data from four valley sites including Rastrojón, Río Amarillo, Quebrada Piedras Negras, and Site 29 are compared to elucidate raw material procurement strategies and methods of chert reduction by local producers. Interesting differences emerge among the sites concerning changes in raw material procurement and technological strategies during a period of proposed Copán expansion and subsequent waning of political presence. A full sequence of production activity was more frequent at sites like Río Amarillo but not others—a trend that appears to increase during later occupations of the Early Postclassic and suggests intensified crafting practices at this locale. Thus, this study adds to a growing body of intraregional investigations of the Copán hinterlands by highlighting varied strategies of craft production during times of pronounced political change.

[13] Of Mud and Magnets: Archaeometric Prospection at the Site of Altica  
The Formative Period site of Altica in the Pátiallache range poses many problems when designing an excavation strategy. Three millennia of erosion, and centuries of chisel plowing have eviscerated the site, removing any traces of architecture and in situ remains above the tepetate (local bedrock). As such, in the early stages of the Altica Project, the primary concern was the detection and identification of sub-surface features. The simplest way to do this would be using geophysical apparatuses such as ground-penetrating radar or an electric resistance meter. Although it is located at the top of a hill, strong, frequent localized rain frequently flooded the terraces of interest for days on end, making it impossible to detect subsurface features using the aforementioned methods. Because of these limitations, we were forced to exclusively use magnetic gradient prospection—with largely successful results—to detect sub-surface pits. This paper will discuss the method used, the various difficulties encountered during prospecting, and the results of the magnetometric study.

[171] The Pre-Aksumite to Aksumite Transition in Eastern Tigrai: Ceramic Evidence from Ona Adi  
The Pre-Aksumite to Aksumite transition (PA-A transition) is critically important for the culture history of the Horn of Africa. This period in Western Tigrai (400/300–150 BCE) represents a cultural break between the Sabaeans-influenced Pre-Aksumite period (800–400/300 BCE) and the predominantly indigenous kingdom of Aksum. Pre-Aksumite and Aksumite polities in Western Tigrai were not directly related and marked by significant sociopolitical change. The emerging picture of the PA-A transition in Eastern Tigrai differs from that observed in the Aksum region, based on continuity in site occupation and minimal Sabaean influence. Although Sabaeans were present in Eastern Tigrai, their socioeconomic impacts may have been minimal or indirect. Moreover, recent surveys have found that a hierarchical political system was in place during the Aksumite period. Analysis of Ona Adi ceramics are revealing patterns of continuity and gradual change in the distribution of decorations including incisions, black topped, notches on the lip and grooved decorations. The PA-A transition also witnessed the appearance of new styles such as punctuated and corrogated vessels. Additional work is needed beyond Aksum-Yeha to explore the regional implications of the PA-A transition.

Melendez, Juan (Washington University in St. Louis)
To date, nine greenstone mosaic masks (GMM), recovered in eight royal and one elite interment, have been found in association with other grave goods belonging to ancient Maya individuals from Tikal, El Zotz, and El Perú-Waka'. Nearly 1,000 tesserae compose these nine GMM, however to date it is unknown what the mosaic masks originally looked like as these were found unassembled. Nonetheless, prior to carrying out preliminary reintegration and restoration projects, a manufacturing study was deemed necessary. This paper presents the technological analyses carried out to determine the material of the tools used to create each tessera. This analysis is based on scanning electron microscope (SEM) observations of selected sectors of the tesserae. By comparing the SEM observations of contemporaneous greenstone materials obtained from experimental archaeology processes, I expect to identify manufacturing signatures that could suggest one or multiple traditions of GMM production. In addition, the contextual information of the GMM that could provide insights about the sociopolitical dynamics in the Central Maya Lowlands during the Early and Late Classic periods (AD 350–750) will be covered in this paper.

[23] The Manufacturing Traces of the Turquoise Objects and the Lapidary Technology from Chaco Canyon: An Experimental Archaeology Approach

There are thousands of turquoise objects found in different sites of the American Southwest, and Chaco Canyon, New Mexico, is known as one of the principal areas that concentrated most of them. Unfortunately, most of the researches about these stones had been focused on their symbolic meaning, morphology, provenance, trade and use, but very few study their manufacturing traces and the organization of their production. In this paper, we will present a technological/traceological approach to analyze and characterize their manufacturing techniques through the employment of Experimental Archaeology and Scanning Electron Microscopy (SEM). The comparison of the turquoise assemblages from different contexts and sites located at Chaco Canyon shows relationships with the lapidary tradition of the American Southwest, but with a particular technological pattern that differs with other turquoise objects from New Mexico. With these new data of the geography of the manufacturing techniques, it is possible to appreciate new nodes of interactions and trends of circulation of the turquoise pieces (raw materials, blanks, and finished objects) among the sourcing areas, the workshops, and the final consumers.

[35] Settlement and Rituals: The Red Deer at Late Mesolithic and Early Neolithic Settlement Sites in Southwest Norway

The red deer is one of the most common motifs at several Late Mesolithic rock carving sites along the coast of southern Norway. It is assumed that this animal was both an important food resource as well as an object of rituals and religious beliefs during this period. The focus of this paper will be to examine how the red deer appears in different contexts at settlement sites during the Stone Age, and to explore how these contexts reflect diverse activities, including rituals and ceremonies. Our knowledge about how animals have been a part of rituals at Stone Age settlement sites is very limited because of bad preservation for bones. Recent excavations of three adjacent settlement sites from Rogaland in southwest Norway have however produced new insights. The sites are dated to the latter part of the Late Mesolithic and the Early Neolithic, around 4000 cal. BC. The preservation conditions were unusually good and around 50,000 fragments of bones were recovered. The great majority of these bones are from red deer. This paper aims to explore entanglements between people and red deer and the diversity of structural remains and material culture springing from this in the late Mesolithic.

Meloche, Chelsea (Simon Fraser University)

[247] Finding Skeletons in Our Closets: Legacy Collections and Repatriation

Contemporary standards of collections management ensure that materials collected during archaeological fieldwork are well documented, provenienced, and catalogued within a database for future research purposes. These standards have come to be crucial to contemporary archaeological practice, however, this was not always the case. Historically, certain objects were often considered more important than a collection as a whole. This resulted in poorly documented collections, with miscatalogued, incorrectly provenienced, or missing items. Since they continue to occupy a large part of contemporary repositories, these so-called legacy collections present a unique set of collections management issues. Their minimal standards of documentation become particularly problematic in the context of repatriation requests. This presentation will examine these issues in the case of the Rickley collection at the University of Windsor. By recounting the excavation, curation, rediscovery and repatriation of the collection, I will present this case as an example of the complications that can arise when legacy collections become the focus of a repatriation request. In doing so, I will reflect on the implications of dealing with historical collections in contemporary repatriation cases, the current efforts underway to address these issues, and the importance of addressing both the existence and future of these oft-forgotten collections.

[331] Identity and Offerings in the Southern Peruvian Andes: A Comparative Study of the Painted Tablets and Discs Tradition of the Arequipa region, Southern Peru

Inka and Spanish imperial projects in the Andes frequently targeted local beliefs and ritual practices, albeit in dissimilar ways. Understanding the effects of imperial projects is not possible without a clear sense of the local ritual landscape and its (in)compatibility with state religions and other practices spread across state networks. The painted tablet and disc tradition of the Arequipa region in the Southern Peruvian Andes offers a particular case for studying local and regional rituals and identity. Although it has been primarily treated as pre-Inka in previous scholarship, recent evidence from Andagua complicates this picture, raising questions not only about Inka religious expansion in the region, but also potential obstacles for Spanish evangelization practices. Drawing from archaeological and historical research, the painted tablet and disc tradition presents an important prism to examine how rituals inform identity and are manifest in humans’ relationships with the landscape amid non-state and colonial contexts.

[182] Izapa and Highland El Salvador: Terminal Formative and Classic Period Ties

This paper explores coastal and highland interaction in southern Mesoamerica between coastal Chiapas and highland El Salvador. Published accounts of Salvadoran excavations have reported that ties between highland Salvadoran sites and Mesoamerica declined at the close of the Formative period with the eruption of the Ilopango volcano. The dating of the Ilopango eruption has since been updated, and a renewed look at interaction between these
zones is necessary. This paper reviews archaeological evidence including ceramics, burial and offering traditions, construction techniques, and monuments, to highlight similarities between the sites of Izapa, Chalchuapa, and Quelepa before and after the Ilopango eruption. Ties between Izapa and Chalchuapa are especially strong. These links suggest greater cultural continuity in both regions during the Terminal Formative to Early Classic transition than has been presented in past reports.

Méndez, César (Dpto. Antropología-Universidad de Chile), Antonio Maldonado (CEAZA-Universidad de La Serena), Andrés Troncoso (Dpto. Antropología-Universidad de Chile), Amalia Nuevo Delaunay (Dpto. Antropología-Universidad Alberto Hurtado) and Sebastian Grasset (Independent-FONDECYT #1170408) [143] Human Responses to Holocene Aridization South of the Atacama Desert (31° to 32° S), the Meaning of Differences in Landscape Use The geographical band between 31° and 32° S, from the Pacific to the Andes, lies in the southernmost part of the semi-arid north of Chile, south of the Atacama Desert. Multidisciplinary research to the north and south of the Choapa River’s mouth is uneven, thereby in need of new data for understanding the relative intensity of the human traces across the landscape and the human interactions with environmental changes. Currently, the combined pollen records in the coast and highlands indicate arid phases between 7800–6200 and 3500–2200 cal BP. Though the archaeological radiocarbon record spans the Holocene, changes in its distribution across the landscape coincide with these time intervals and with other minor changes. The few excavations in rockshelters north of the Choapa River’s mouth have yielded dates on features and bioarchaeological material precisely within specific time gaps of the nearly-continuous record south of this area, built on coastal shell-middens and inland open-air sites. These preliminary collations posit sampling biases versus climate change as alternative mechanisms influencing the past human spatial distributions. Assessing human responses to environmental change in the margins of the desert should prove useful for the broader understanding of landscape use and its variation throughout the Holocene. FONDECYT #1170408; #1140837.

Mendez-Quiros, Pablo (Universidad Autonoma de Barcelona) [134] Redes viales y prácticas de movilidad en los Valles Occidentales meridionales, área Centro Sur Andina En este estudio proponemos una reconstrucción de la red vial de los Valles Occidentales meridionales. A partir de un trabajo de análisis e interpretación de imágenes satelitales. Esta red estuvo organizada sobre la base de diez rutas troncales, diecisiete nodos de primer orden y siete de segundo orden. Analizamos el funcionamiento del sistema de senderos, caminos y poblados durante los periodos Intermedio Tardío y Tardío y su relación con prácticas de movilidad diversas y convergentes. Discutimos en esta ponencia las estrategias de movilidad de las comunidades agricultoras y agro-ganaderas que habitaron en la costa, valles y sierra, planteando la existencia de una movilidad generalizada y multidireccional que ha sido invisibilizada bajo una visión hegemónica de la existencia de un sistema de transporte y comunicación vía caravanas.

Menocal, Tatianna (Desert Research Institute) [367] An Overview of Cultural Resources Monitoring at the Nevada National Security Site An integral component of the cultural resources management program at the Nevada National Security Site (NNSS) is the monitoring of cultural resources that have been determined eligible to the National Register of Historic Places (NRHP). The Desert Research Institute periodically conducts field evaluations of these cultural resources in order to document their condition and note any deterioration due to natural processes or unauthorized activities. NRHP eligible properties at the NNSS include prehistoric and historic archaeological sites as well as historic buildings and structures. A few of these resources are inspected annually, while others are selected from a list of NRHP eligible properties and are monitored at longer intervals. The NNSS cultural resources monitoring project is a long-term endeavor and provides a photographic and written record of these cultural resources through time and serves as an indicator of the overall effectiveness of the National Nuclear Security Administration Nevada Field Office’s NNSS cultural resources program. This poster presents an overview and results of cultural resources monitoring at the NNSS with case studies of the different kinds of cultural resources found there.

Menon, Jaya (Presenter) [167] The Materiality of Domestic Space: Indor Khera, North India, 200 BCE–500 CE Most State and University-sponsored excavations in India have tended to focus on public and elite spaces, in keeping with nationalistic aims of projecting a grandiose view of the past. This has led to the inevitable marginalization of nonelite domestic spaces. One of the few cases of household archaeology in the Indian subcontinent has come from Indor Khera in the Upper Ganga Plains in northern India. Archaeological data recovered during the excavations has given valuable information on the intersecting histories of ordinary houses and households dated between 200 BCE and 500 CE in this peripheral neighborhood in a small town. The current paper is an attempt to assess and map the materiality of everyday practices of a household through a micro-study of a single house, analyzing through its various episodes of construction, use, alterations, and adjustments, the patterns illustrative of an everyday life. It is possible to do a “close reading” of the excavated data (micro-stratigraphies, features, and contextually recovered artifacts,) within a house, that will enable the identification of the location and nature of individual activities undertaken by ordinary people, as well as the flexible and changing uses of space over time.

Mentore, George (University of Virginia) [384] The Angel of History and the Paradise of Progress in the Scholarship of Peter Roe In honor of the innovative contribution by Peter Roe to the ethno-archaeological research on Amazonia, my paper will focus on the indigenous knowledge forms which invert our own logos about material objects. Roe’s early willingness to allow indigenous thought to impact our scientific interpretations was well ahead of its time. Today, we on the ethnographic side of Amazonian scholarship, have little difficulty speaking in terms of the
"social life of things." Yet, even beyond, the legitimacy of the "social" within the discipline, we still retain reservations about going all the way into Amerindian thought processes to speak about the "truths" of shared subjectivity between things, animals, and humans. What happens to our modernist interpretations of studied artifacts when we extend to them the vital existence we claim only for us humans? Would they radically transform archaeology? Would we change our view of humanity? How much of a threat to current modern politics and laws of national heritage would such an altered position produce? The answers to these and other relevant questions will be posed within the paradigm of a concern for the "aesthetic," an attitude of scholarship Peter Roe long advocated for anthropological research.

*Craft, Commerce, and Community at Kolomoki: Domestic Craft Producers in the Woodland Period of the American Southeast*

Archaeological considerations of craft production and specialization in the Americas has often focused on elaborate prestige goods crafted from exotic materials. Less frequently studied is the potential for specialized production of mundane household goods. Recent research from the Southeast suggests that intensive production of such items was occasionally practiced at the household level among Middle and Late Woodland period (ca. 200 BC–AD 1000) societies, which generally lacked centralized political authority and hereditary inequality, features typically associated with economic specialization. Investigations at Kolomoki, a large Middle-to-Late Woodland mound and village complex in southwest Georgia, have produced evidence for intensive crafting within domestic contexts at a scale implying production for distribution and use beyond the household. Here I review the evidence for craft specialization and exchange from Kolomoki and attempt to situate it within an exchange network predicated upon periodic ritual gatherings associated with Swift Creek and Weeden Island interaction. I argue that periodic convergence at Kolomoki and other mound centers temporarily brought together individuals from various ecological and geological zones, providing an outlet for craft producers and visitors to exchange raw materials and finished goods.

*Reimagining the Colonial Encounter through Gitxaala Eyes*

Archaeology on the north coast of British Columbia has focused on three zones of attention: Namu, Haida Gwaii, and Prince Rupert Harbour. These loci have created a kind of orthodoxy that, while reasonable in certain aspects, has unduly shaped contemporary political interactions between First Nations and the state. This paper draws from an Indigenous intellectual framework (that has appropriated the tools and techniques of anthropological archaeology) to challenge and redefine the orthodoxy view of the Tsimshianic north coast. By focusing on the intersection of archaeological record, settler-capitalist ships' logs, and Indigenous historical narratives this paper argues that the current archaeological understanding of the north coast of BC is serious flawed and mired within a contemporary political economic struggle whereby the state has preferentially allied with some regional First Nations to the detriment of others.

*Geomorphic and Isotopic Indicators of Anthropogenic Change from Holocene-Length Alluvial Deposits in the Rio Blanco Watershed*

Several compendia have illustrated the reach of conventional approaches to exploring the origin of omnivorous diets. Included are the cost of developing large brains and bodies; tooth size/shape, enamel thickness, wear; and the chemical signal from diet on bones/teeth. Over the last decade, new interpretations of human origins have proposed a long history of fire dependence, suggesting humans are biologically adapted to cooked food. However, these studies have not provided direct indication of eco-niche exploitation, plant utilization, or what food was processed with stone tools. The context of hominin activities at Olдуvai Gorge (Bed I and II) is revealed through macrobotany, ethnoarchaeology, and the analysis of pollen, phytoliths, and biomarkers. However, no studies explore the human ecology, dietary dimension, and functionality of Acheulean technologies as seen through direct evidence in the form of plant residue that may still reside on stone tool surfaces. We present lithic residue indicating:

- Proximity of wetlands/plant resources.
- Bark, resin, and lignified tissue deposited on hand axes.
- Bifaces preserved starches from underground storage organs, and some legumes. Phytoliths on hand axes derived from cork.
- Resinaceous material attached to scrapers.
- Scrapers trapped starches from the rhizome of Typha capensis.
- USO epidermis is attested by root bacterial fibrils.

*Geomorphic and Isotopic Indicators of Anthropogenic Change from Holocene-Length Alluvial Deposits in the Rio Blanco Watershed*

Recent geoarchaeological investigations in southern Belize have focused on the Paleoleindian to Archaic site of Tzib'te Yux located in the Rio Blanco watershed and dating between 3000–12500 BP as well as adjacent river terraces. Landscape-level vegetation changes are apparent within the area in the form of forest clearance by 5000 BP. Evidence of pedogenesis derived from four years of excavations and sedimentation rates established through modeling and high-precision 14C AMS dating have produced an erosional history of the wider watershed reflecting the extent of land clearance throughout the Holocene. Combined with compelling evidence for contemporaneous human occupation, these data facilitate an assessment of geomorphic, and ecological change with underlying climatic, geologic, and anthropomorphic drivers. Stable carbon isotopic signatures of insoluble components of soil organic matter (SOM) reveal the impact of human occupation on vegetation regimes within the Rio Blanco watershed with 513C values of humins and humates reflecting a C3 dominated landscape prior to a rapid shift of up to 4‰ following the introduction of C4 crops (maize) to the region. Values remain at relatively less negative values through the Classic Period, declining only after the abandonment of nearby Maya polities.

**Hitler’s Fortress Builders: The Use of Nondestructive Testing to Quantify the Differential Treatment of Laborers on Second World War Alderney**  
World War II left behind archaeological evidence of an impressive magnitude on the British Channel Islands, and today many of these features lay untouched. It was throughout my master’s research at Glasgow University in 2013–2014 that I developed a project to enhance our archaeological understanding of these concrete relics. Using a specific set of methods, I was able to accurately and nondestructively test the compressive strength of several concrete features. Combining this raw data with the available historical material, I was able to show that features constructed by professional German engineers were markedly stronger when compared to features constructed by poorly treated conscript laborers from Eastern Europe and the Soviet Union. Overall, this discovery served as a means to quantify the extreme dichotomy in the living and working conditions of these labor classes, while simultaneously refining a methodology that could have important implications for historical archaeology.

**Timing of Stress Episodes at Houtaomuga: Neolithic and Bronze Age Comparisons**  
The unborn and minimally worn anterior teeth of 48 individuals from Neolithic and Bronze Age levels of the Houtaomuga site in Jinlin Province, China were examined macro- and microscopically for location on the labial surface of lines of Enamel Hypoplasia relative to the cementoenamel junction. From estimated ages of enamel formation across the tooth crown surface, ages of occurrence of stress exposure were calculated. Variation in timing of growth cessation and recovery from birth to six years, as recorded in the enamel of the anterior dentition, is explored within the cultural and environmental contexts of two distinct subsistence economies: the Neolithic based solely on hunting-gathering-fishing, the Bronze Age with millet cultivation added to the basic h/g/f economy. This study examines the bioarchaeology and life histories of young children across dimensions of time, environment and subsistence in Northeast China.

**The Impact of Experience and Flake Attributes on Carcass Processing Time and Efficiency during Actualistic Early Stone Age Butchery**  
Actualistic butchery often investigates the relationship between tool characteristics and butchery behavior but rarely considers individuals’ butchery skill. Therefore idiosyncratic behavioral differences may confound analyses of butchery time or efficiency. Here, two novice butchers used replicated Oldowan flakes on 40 domestic goat limbs to examine how tool attributes affected processing time and efficiency during defleshing and disarticulation, and whether a learning curve impacted butchery performance as individuals gained experience. Neither butcher displayed significant temporal trends in defleshing efficiency (weight of meat defleshed per unit time) or disarticulation time (number of seconds required to separate joints) during the experimental series, however rank-order correlation indicates a significant positive trend in hindlimb defleshing efficiency through time for one individual. Two-way ANOVA shows hindlimbs were butchered more efficiently than forelimbs, but both butchers were similarly efficient. In contrast, disarticulation took significantly longer for one butcher, but forelimb and hindlimb disarticulation times were similar. Flake length, width, longest cutting edge length, and weight were positively related to defleshing efficiency, and negatively related to disarticulation time. Overall, bigger flakes were better for disarticulating limb joints and quickly removing meat, and these patterns were not obscured by increasing butchery experience. Supported by NSF awards 1358178 and 1358200.

**Legal Premises Involved in the Archaeological Registry**  
The paper we present reveals the legal basis of the Mexican cultural heritage public registry and the consequences of the relation it sustain with its statements and academic interests involved in the description of archaeological materials. Accordingly, the real work begins of typology, chronology and cultural classification, associated with the sites and related archaeological materials, as well as, its preservation status. All this information is stored, organized and published, in a strong database system, also designed to provide indicators to enhance the policies for heritage protection, based on real data. It’s important to stress the relevance of developing a systematic, homogeneous and standardized database designed, according to Registry Law parameters. This National Public Registry database is being inputted by curators and academic researcher contributions, ensuring certainty about archaeologic goods, it’s amount, localization and academic assets for the future planning projects.

[222]  
**Evidence of Diet and Food Consumption from Chavin de Huantar during the Middle and Late Andean Formative (1200–550 BCE)**  
Excavations carried out at the Wacheqsa sector at Chavin de Huantar identified archaeological contexts from the Middle Formative (1200–900 Cal BCE) and Late Formative (900–550 Cal BCE). In this paper we present preliminary results of starch analysis carried on in culinary equipment (ceramics) retrieved from domestic occupations from the Middle and Late Formative periods and a large midden, originated from the discard of feasting remains during the Late Formative period. Microbotanical analysis performed on the ceramic assemblage retrieved in these spatial units revealed a variety of plant food resources. Two types of maize, wild grasses, chile peppers, and allluco were identified. Maize was overwhelmingly the most common taxon present, and some granules exhibited signs of grinding, boiling, and possibly fermentation, which could be indicative of chicha consumption within the Wacheqsa sector. This evidence may suggest patterns of consumption among the spatial units identified as well as vessel use specialization for food production, having at the same time implications in food procurement and resource management strategies.

[339]  
**Bison Ecology and Precontact Human Land Use at the Promontory Caves**  

Promontory people were proficient bison hunters with a sophisticated understanding of bison ecology. In contrast, modern researchers know relatively little about precontact bison ecology in the Great Basin. We combine botanical analysis of dung and isotopic analysis of various substrates (dung, hair, hide, bone) to reconstruct ancient landscapes and bison behavior during the Promontory occupation. Carbon isotope compositions indicate that a C3-dominated environment existed at the Promontory Caves during the Late Prehistoric human occupation, and botanical analysis provides evidence for the specific plant taxa present. Most bison procured by Promontory people consumed C3 diets. However, one sample of moccasin leather had an anomalously high δ13C value, indicating significant C4/CAM plant consumption. Select specimens from Franktown Cave (Colorado) and Ross Rocks Shelter (Wyoming) also had unusually high δ13C, suggesting the possibility that occasional bison were procured on long-distance scouting expeditions or other forays to the south and east. We use isotopic and botanical evidence to evaluate this hypothesis and alternatives such as (1) trade, (2) occasional migration of bison from distant locations, and (3)(atypical consumption of locally-available C4/CAM plants, perhaps during times of stress. We also discuss the implications of our data for hunting and land use among proto-Apachean groups.

Metz, Micca (Cardno)

After the War: An Analysis of the Mortality of American Soldiers from the Last Century

This historical archaeological analysis examines differences in the age of mortality for U.S. Army personnel who fought for America in the last 100 years. This study centers on the historical data gathered from historic mortuary monuments and compare that data with contemporary mortuary monuments. Specifically, I focus on the timing of death for returning veterans and the increased occurrence over time and by war, as reported by Veterans Affairs (2016). The data are separated by years of service, following major wars or known conflicts where American Army personnel were engaged, looking for a trend in (a) which conflict produced the most post war casualties, (b) the number of years following the end of the conflict when the deceased died, and (c) the age of the soldier at their time of death. This investigation examines the pattern of altered mortality during the last 100 years of Seattle-based soldiers.

The Rapid Generation and Visualization of 3D Timelapse Reconstructions of the Excavation at the Paleolithic Site Arma Veirana in Italy

Arma Veirana is a Middle/Upper Paleolithic cave site of the Maritime Alp's of Liguria, Italy, which has the potential to offer insight into the interaction between Modern Humans and the Neanderthals. Preliminary excavations have shown a continuous occupation between the Middle and Upper Paleolithic time periods, yet the complexity of the cave morphology and geology have made it difficult to isolate erosion as well as environmental and non-natural factors to understand the full image of hominin interaction and prehistoric life. In this paper, we propose a novel method to rapidly combine and visualize timelapse photogrammetric and LIDAR data of the cave excavations. This method enables archaeologists to evaluate and analyze the layers and artifacts of the excavation within the context of the cave. Through a better understanding and visualization of the cave excavation over time, it is expected that this method will further link micro and macro factors of the site, which would otherwise not have been as apparent.

Examining Variable Funerary Practices at Pottery Mound, New Mexico

Pottery Mound (LA 416) is a Pueblo IV village located on the Rio Puerco in central New Mexico southwest of the modern city of Albuquerque and was occupied from the mid-fourteenth to mid-fifteenth centuries. This site is most notable for its abundance of local and nonlocal ceramic types and elaborate kiva murals (Schafaesma 2007). Excavations at Pottery Mound took place during several University of New Mexico (UNM) field schools under direction of Frank Hibben and later Linda Cordell between the 1950s and 1970s. The recovered skeletal sample, curated at the Laboratory of Human Osteology (Maxwell Museum of Anthropology, UNM) comprises about 175 individuals of all ages, which exhibit evidence of a variety of different funerary practices which remain poorly understood. This study examines the Pottery Mound osteological collection for biological information (including age, sex, and pathology) and taphonomic evidence of mortuary practice. These data are then compared to the archaeological context the burials were discovered in such as provenience, orientation, position, and affiliated funerary objects. Then both archaeological and osteological data are analyzed for patterns to address potential biological and/or cultural factors that may explain the variability in funerary practices in Pottery Mound.

Meyer-Lorey, Robin (UCLA)

Economic Intensification in Old Kiyangan: Global Interaction and Intraregional Trade Understood through Trade Ceramics

Access to imported goods by premodern societies implies economic intensification and long distance trade and interaction. Investigations in the Old Kiyangan Village (OKV), Ifugao, Philippines, have indicated that Southeast Asian and Chinese trade ceramics began to influence social interactions as early as 600 years ago. This presentation reports on our work in OKV that highlights the role of outside trade in the development of social differentiation in the region. We focus on the period before and during Spanish contact in the Philippines, drawing materials from around the end of the thirteenth century to circa AD 1800. Spatial and temporal analysis of trade ceramics (stoneware and porcelain) in Old Kiyangan Village can answer our understanding of the availability of these prestige trade ceramics to different members of the community as well as the role of the ceramics within the community. These insights reveal more about the ways in which individuals at OKV taking part in intra- and interregional trade networks may have consciously or unconsciously altered the availability and significance of prestige goods such as trade ceramics in their own community.

Meyers, Maureen (University of Mississippi)

Shell Bead Production at a Southern Appalachian Mississippian Frontier

Frontier areas differ from non-frontier areas in multiple ways; one is by a more intense degree of interaction with other cultures. To successfully settle a frontier area, frontier groups must not just interact but also socially integrate with other groups. Craft production is one way social integration occurs. At the Middle Mississippian-period Carter Robinson site, there is evidence for the production of shell beads. This paper presents this evidence, which includes all stages of shell bead production, shell waste, drills, and flake tools, and discusses how shell bead production may have acted as an integrative mechanism at this Mississippian frontier.

Salud y adaptación al medio en San Mateo Atenco y Santa Cruz Aitzapan (ca. 200–1000 dC)
El estudio de la salud en el pasado utilizando restos óseos humanos está constreñido a una serie de limitantes, durante las exploraciones arqueológicas no se logran recuperar el total de los esqueletos que deberían representar a la población, sin embargo cada colección ósea representa un fragmento de la historia de vida de las personas que allí vivieron; se estima que un aproximado del 15 por ciento de los individuos presentan alguna señal de enfermedad, que bien puede ser de origen traumático, degenerativo, metabólico o infeccioso. En las últimas décadas ha surgido el interés por el desarrollo de técnicas moleculares que coadyuven en la identificación de los agentes infecciosos, sin embargo las condiciones de conservación de los materiales no siempre se prestan para este tipo de estudio de ahí que la paleopatología siga validándose del análisis morfoscópico para la identificación de las enfermedades en el pasado. En el presente trabajo nos dedicamos al análisis de las lesiones observadas en 82 individuos, 20 corresponden al sitio de San Mateo Atenco (SMA) y 62 a Santa Cruz Alizapán (SCAT) para tratar de recrear las condiciones de vida de los aldeanos asentados en las ciencias del Valle de Toluca.

Human Activity Accelerating the Rapid Desertification of the Mu Us Sandy Lands, North China: Evidence from Micro-Charcoal Assemblages

Over the past several thousand years, the arid and semiarid regions of China have experienced a series of asynchronous desertification events in its semiarid and sandy desert areas, but the precise identification of the driving forces of such events has remained elusive. Identified are two rapid desertification events (RDEs) at ~4.6 ± 0.2 ka BP and ~3.3 ± 0.2 ka BP from the JJ Profile, located in the eastern Mu Us Sandy Lands. These RDEs appear to have occurred immediately following periods of persistent frequent and intense fires based on the micro-charcoal assemblages. We argue that such fire patterns, directly linked to an uncontrolled human use of vegetation as fuel, played a key role in accelerating RDEs by ensuring that the land surface was degraded beyond the threshold required for rapid desertification. Today, the Mu Us Sandy Lands are an important agropastoral transition zone and a powerful ecologically-protective screen preventing the incursion of deserts from the south and east. According to this analysis, future major ecological rehabilitation should focus on improving vegetation coverage and avoiding fire hazards to reduce the risk of desertification. The micro-charcoal might be considered as an important proxy for investigating the fire process and ancient human activities.

Ascendancy through Ancestry: Evidence of Late Classic Sociopolitical Change at the Ancient Maya Site of Pacbitun, Belize

The ceremonial architecture of Pacbitun’s epicentral plaza was recently discovered to have underwent a drastic early Late Classic (AD 550–700) transformation. The assemblage, originally designated as a Southern Lowland architectural archetype known as an E-Group complex, was uniquely modified physically and adopted an intensive mortuary practice that seemingly altered the group’s function. The inclusion of several Late Classic elite interments suggests that Pacbitun’s ceremonial assemblage had begun to function as another Southern Lowland archetype known as an eastern shrine. Continuing with this investigation, the next task would be to identify what this archetypal conversion might signify for the site. To do this, it will be important to understand what the E-Group and eastern shrine archetypes are thought to represent in Maya society. It will also be important to understand how the meaning of ancestor veneration evolved through time. This paper will detail the projected significance of both archetypes and explain the sociopolitical motivation behind placing ancestors into these structures. I plan to demonstrate that the conversion of Pacbitun’s most time-honored, sacred monumental public work would have had tremendous communal and ministerial ramifications and may suggest the site was experiencing sociopolitical change in the Late Classic. Agelah and the Powershot: Digital Possibilities for Alternate Ways of Knowing in Archaeology

Digital recording methods offer a range of new means of collecting, organizing, and presenting archaeological information, which lead to new ways of thinking about the past. Capitalizing on the intuitive design of digital technologies additionally creates the potential for communities whose voices have been missing from the past to create their own proceedings. In this paper, I draw upon my experiences experimenting with multimedia recording strategies at Petra, Jordan and at Catalhoyuk, Turkey, in order to create opportunities for locally hired site workers on these projects to participate in excavation documentation. The photographs they created, especially, reveal ways of understanding the linkages between modern and ancient peoples, places, and objects that diverge from the normally assumed boundaries and relationships captured in archaeological recording. The affordances of digital technologies articulate with the specific archaeological expertise of site workers and the unique interpretive approaches of nonspecialist communities and gives rise to transformative ways of seeing and knowing the archaeological record. I will also discuss the limitations of the intuitive character of digital technologies, examining how the knowledge required to master these tools can work to exclude particular voices, though in different ways than previous recording technologies have done in the past.

Mickleburgh, Hayley

Modeling Skeletal Disarticulation: Using Actualistic and Comparative Taphonomy to Improve the Analysis and Interpretation of Human Burials

Skeletal disarticulation patterns can be diagnostic of environmental conditions (e.g., water flow), animal behavior (e.g., scavenging), and/or human action (e.g., intentional displacement of bones), aiding the reconstruction of the events that formed a burial feature. In archaeoanthropology, a model of the “natural” or “common” sequence of disarticulation of the human skeleton at the joints has served as the basis to distinguish “natural” bone displacement from human intervention. This model is derived from archaeological observations and actualistic studies of animal taphonomy, and thus lacks verified actualistic data on human skeletal disarticulation. This paper discusses the preliminary findings of controlled, actualistic experiments in human decomposition and skeletal disarticulation, undertaken at the outdoor human decomposition facility of the Forensic Anthropology Center at Texas State University. This project aimed to document soft tissue decomposition and bone disarticulation in five willed donated human bodies. Displacement of the body (parts) and bones over time was captured and movements quantified using 3D photogrammetry. Ultimately, this research aims to assess the
existing model for the “common” sequence of human skeletal disarticulation. Ongoing research using a larger sample aims to investigate the potential effects of specific variables such as body mass, body position and mummification on joint disarticulation.

*From Flame to Flowers: Moths and Butterflies in the Codex Borgia Group*

Butterfly imagery in the Borgia Group shows how these volatiles were classified in Postclassic Central Mexico. They are grouped with birds among the 13 “lords of the day” in the Codex Borgia, and they sometimes seem to be interchangeable with moths, especially in imagery of the Fire God. Another god, Ehecatl-Quetzalcoatl, is associated with images of “army worms” devouring maize, symbolizing the caterpillar stage of a moth that distributes its eggs in the wind. Butterfly symbols are naturally linked with flowers that nourish butterflies. This is especially notable in representations of Xochiquetzal and Xochipilli, two deities who wear butterfly face paint and have names incorporating the word flower. Seasonal patterning is also evident in imagery of flowers and butterflies associated with the rainy season in a unique narrative section of the Codex Borgia.

*Sociocultural Anthropology’s Engagement with Archaeology and Indigenous Frameworks*

As archaeologists seek out new ways to engage with indigenous frameworks, people, and communities, sociocultural anthropology can engage and advance the conversation in several ways. Archaeologists and sociocultural anthropologists commonly work with the same communities, on the same issues, but on different time scales. Long term research with the Upper Skagit tribe of Washington State, undertaken collaboratively with archaeologists and community members, reveals sets of social tensions of considerable time depth. These include the relationship between stratification and egalitarianism; water and land; and centralization and isolation. These sets of irresolvable contradictions are seen in mythology, in ethnohistory, in the ground, and in contemporary social relations. These insights are only visible through the use of multiple methods that foreground indigenous frameworks.

*Landscape Survey of Potential Combustion Features at FxJj20 Site Complex in Koobi Fora, Kenya*

Previous research in the Koobi Fora Formation, Marsabit District, Kenya identified nine delineated areas where the sediment was lithified and rubefied. These features derived from the excavation of the archaeological site of FxJj20-Main in the Lower Okote Member, which dates between 1.5 and 1.64 Ma. Previously, similar features in archaeological sites have been recovered with material that exhibit evidence of having been exposed to high temperatures. These features are discrete, isolated, circular, and noticeably different from surrounding tuffaceous silt. The spatial distribution of these features was mapped on an ancient landscape. Twenty-five total potential combustion features were identified and associated artifacts and fossils were recovered at 12 of these. The spatial distribution of the potential features indicated possible environmental influences on location and clustering of the features. The frequency of these features distinguishes this area from other parts of the ancient landscape. IRES grants from the U.S. National Science Foundation supported this research.

**Miller, D. Shane (Mississippi State University)**

*The Warfare Paradox, or All Quiet on the Western Tennessee Valley Archaic*

The complex hunter-gatherers of the Middle and Late Archaic periods in the Tennessee River Valley of the American Southeast are well-known for displaying evidence of intergroup violence, including scalping and trophy taking. On the other hand, these time periods are also known for the emergence of exchange networks centered on items including bone pins and bifaces. I argue that the co-occurrence of exchange networks and intergroup violence was likely the result of iterated “live and let live” or “tit for tat” strategy for coping with increasing demographic pressure.

**Miller, Heather (University of Toronto)**

*Invisible Value: Steatite in the Faience Complexes of the Indus Valley Tradition*

Faience (composition, frit or siliceous paste) was widespread, special, and yet everyday across much of Eurasia for well over a millennium, yet hardly known today. These materials were made with many different recipes and production methods, but there is an unusual, apparently unique, variation in faience composition for some objects in the Indus. Some siliceous paste objects include steatite fragments, invisible on the surface and requiring laboratory analysis for detection. These could be production additions for strength or similar purposes, or they could relate to a different kind of materiality, either for religious meaning, as in some modern uses, or a symbol of Indus identity/unity, as in other uses of steatite during the Indus period.

Statistically Limiting the Error Associated with Old Wood in Archaeological Dating: A Case Study from the Kuril Islands

This paper introduces a method for probabilistically narrowing carbon 14 date ranges on wood charcoal samples by computing the likelihood of selecting a specific tree-age in a random sample of charcoal. Archaeologists and others often build chronologies on fragments of wood that are of unknown age prior to the death of the tree. Here we examine a way in which these sources of error could be mitigated through statistical analysis of tree growth rings. As a case study we analyze specific tree species represented in samples collected by the Kuril BioComplexity Project.

Theoretically Informed Isotope Analysis: Human-Animal Relationships at Fishbourne Roman Palace

Stable isotope studies have become common-place in archaeological investigations of human diet and mobility, often underpinned by small comparative studies of associated animal remains which are generally utilized as baseline data. However, the value of moving beyond such anthropocentric studies and of analyzing animals in their own right is becoming increasingly recognized. Detailed research on animal diet and mobility is enhancing our understanding of animal management and patterns of procurement but there is scope to consider isotope data in more theoretically informed way, to examine broader issues of human-animal relationships in the past. To highlight the benefits of a human-animal studies approach to isotope analysis, this paper will present the results of an investigation focused on the high-status site of Fishbourne Roman Palace in England. It will explore how incorporation into the Roman Empire inspired new relationships between people, animals, and their environments.

Miller, James (Indiana University of Pennsylvania)

Porcelain and White Salt Glazed Stoneware at Hanna’s Town

Previous archaeological investigations at Hanna’s Town have involved locating the homes within the town and locating the fort. My research involves analyzing Porcelain and White Salt Glazed Stoneware to determine if there is a spatial pattern across the site. This may shed light on wealth distribution at historic Hanna’s Town. Detailed analysis of decorative mold will also provide insight on trade patterns and economics of the colonial frontier in the late eighteenth century. Historic Hanna’s Town, in existence from circa 1769 through 1790, was located near present day Greensburg, Pennsylvania. Hanna’s Town, the first English county seat west of the Allegheny Mountains, rivaled Pittsburgh at the time, and included around 30 homes, a jail, and three taverns. In 1782 a combined British and Seneca force attacked and burned the town except for the fort and two structures. They also massacred livestock and targeted homesteads in the surrounding area. In 1969 the land was purchased by the Westmoreland Historical Society and archaeological investigations of the site began that year as well.

Miller, Kye (PaleoWest Archaeology)

Red Ware and Migration in the Northern San Juan Region: A View from Pit Structure Architectural Practice

Previous researchers have proposed that early red ware traditions in southeast Utah (i.e., Abajo Red-on-orange) represent an intrusive practice in an area generally dominated by black-on-white ceramics. This red ware “intrusion” has previously been interpreted as possibly representing the in-migration of southern groups into southeast Utah and southwestern Colorado. Using the communities of practice approach, this paper characterizes pit structure architectural practice in relation to technological style in the northern San Juan region during the Basketmaker and early Pueblo periods to explore migration and social identity among early Pueblo residents of southeast Utah and southwestern Colorado.

Miller, Mary

Technologies of Replication in Maya Figurines

Among the class of Late Classic Maya figurines generally considered to be from the Island of Jaina, molds were used to form entire objects as well as individual body parts. Molds may also have been taken of one finished figurine in order to generate a new object that would be slightly larger than the original, sometimes resulting in cascading generations of related works. Production techniques of the ceramic mold may also have been deployed for individual body parts, particularly the human head. In this investigation the nature of assembly, the use of molds for both body parts and whole figurines, and the subtle differentiation of related works, will be evaluated.

Miller, Naomi (Univ of Pennsylvania Museum and ISAW)

Social and Spiritual Landscapes in Ancient Mesopotamia

Ethnobiologists have demonstrated that shared human cognitive processes generate cross-cultural regularities in how people categorize the natural world. The human ability to recognize taxa means that plant and animal classification is not totally arbitrary. In addition, ancient people would have had place-specific knowledge of the particular plants and animals living in the territories they frequented. Representations of plants and animals in relation to each other in a landscape therefore reflect an understanding of the “natural” world, but the meaning of the compositions is not necessarily self-evident. Archaeobiological data, ancient texts, ethnographic analogies, and plant and animal morphology and distribution are brought to bear in the analysis of two iconic objects of ancient Mesopotamia, the Warka Vase and the so-called Ram in the Thicket. In both cases references to plants and animals are brought to bear in the analysis of the composition of the Warka Vase and the so-called Ram in the Thicket.
highly productive maize on fertile soils, and the storage and redistribution of cereal maize and bitter manioc flour, created new forms of territorial expansion during the last 3,000 years, eventually reaching the Andean foothills, southern Brazil, and the Caribbean islands.

Miller, Sarah [224] Heritage Monitoring Scouts (HMS Florida): Engaging the Public to Monitor Heritage at Risk
Along Florida’s 8,000 miles of shoreline, nearly 4,000 archaeological sites and over 600 recorded historic cemeteries are at risk from coastal erosion and rising sea levels. The matter remains complex in Florida where despite the 20% higher rate of sea level rise compared to the global average, “climate change” remains politically taboo. This paper will outline ongoing efforts to engage the public in monitoring coastal sites and the creation of the Heritage Monitoring Scout (HMS Florida) by the Florida Public Archaeology Network (FPAN) as well as discuss outcomes of the first annual “Tidally United: Cultural Resources Shoreline Monitoring and Public Engagement Summit” as FPAN plans for a second summit in June 2017.

Miller, Stephanie (University of California, Riverside) [329] The Ghost of Functionalism
This paper considers the assumptions, limitations, and greater implications that a theory of integration-disintegration has for analyzing social change across space and time. It reviews the historical foundations of the concept of integration as it emerged in enlightenment social theory and considers how the concept of integration has been repeatedly and uncritically co-opted into various discourses of archaeological theory. An alternative framework for thinking about social change will be offered and the context of the Yaxuna-Coba causeway will serve as an example to illustrate the various strengths and weaknesses of these different approaches for positing possible pathways of economic development.

Miller Wolf, Katherine (Indiana University East) [276] Curating Large Skeletal Collections: An Example from the Ancient Maya Site of Copan, Honduras
Bioarchaeologists draw data from the detailed study of human remains from archaeological contexts. The information embedded in the skeleton provides a powerful window into prehistory; informing us of past lifeways, health/disease, diet, kinship, migration, and conflict. The intimate relationship between the living and the dead is necessarily imbued with respect and an ethical responsibility to properly handle and curate the remains of those that we study. However, the conservation of skeletal collections may be hindered by a myriad of challenges at various scales including bureaucracy, unstable political climates, insufficient funding, missing field documentation, inadequate laboratory space, or a lack of basic necessities like storage containers or shelving units. Here, I will present the process and results of a decade-long project devoted to the conservation and re-housing of the Copan skeletal collection. The human remains curated at the Centro Regional de Investigaciones Antropológicas include more than 1,000 individuals excavated by various archaeological and rescue projects over the past 125 years. Special focus will be paid to the logistics of implementing a large-scale conservation project considering possible pitfalls and solutions, especially in a tropical climate. Finally, recommendations will be offered to prevent problems before they arise both in field and laboratory methodology.

Millhauser, John K. (North Carolina State University) and Lisa Overholtzer (McGill University) [209] Mixed Metaphors and Mixed Media: Using Commodity Chains and Commodity Circuits to Better Understand Aztec Textile Production
Archaeological and ethnohistoric investigations of Aztec textile production have shown how women’s labor and domestic economies were intertwined with the imperial political economy. However, remarkably little attention has been paid to the people involved in affiliated industries—like cotton growers, dyers, and spindle-whorl-makers. Material evidence of these people is often ephemeral or isolated, but it is available. In this paper, we draw on theories of commodity chains and commodity circuits to unite these data and show why attention to these affiliated industries matters. The metaphor of the chain draws attention to the social and economic dependencies linking people along a production sequence: links that often correspond to physical places like markets, workshops, and farmlands. Commodity circuits draw attention to flows of goods that are nonlinear and multidirectional, to goods that intersect and are bundled together in these flows, and to the flexibility of the meaning and value of these goods. Applying these ideas to Aztec textile production expands our view beyond one segment of society, singular relationships, and finished products. These ideas also direct our attention to variation in terms of work and dependence among the individuals, households, communities, and regions that were linked together by textiles.

Milligan, Jennifer (PaleoResearch Institute, Inc.), Linda Scott Cummings (PaleoResearch Institute, Inc.), R. A. Varney (PaleoResearch Institute, Inc.) and Gina Laurin (Denver Art Museum) [191] pXRF at the Museum: Nondestructive Elemental Composition Analysis of Collection Objects
Applications for X-ray fluorescence Spectrometry as an analytical tool in anthropologically related disciplines continue to expand. Museum staff are charged with the amazing, yet daunting, task of housing, preserving, researching, and showcasing our most valued cultural treasures, and this versatile tool can help. As a nondestructive technique for investigating elemental-based aspects of material culture, handheld XRFs are an effective analytical option for museum collections. A handheld XRF was used to implement museum studies focusing on the presence of heavy metals such as arsenic, mercury, and lead associated with pesticides and elemental composition of pigments. Multiple collection methods were employed to identify elemental signatures from portions of non-homogeneous samples including ethnographic objects, paintings, furniture, and figurines. This poster highlights the resulting datasets with attention to semi-quantitative analysis of elements likely associated with poisons, as well as elemental presence/absence related to pigment composition and identification.

Milliken, Ian (Pima County, Arizona Cultural Resources & Historic Preservation Division), Jerome Hesse (SWCA Environmental Consultants), Suzanne Griset (SWCA Environmental Consultants) and Doug Gann (Archaeology Southwest) [59] Tracking the Footprints of Early Agricultural Farmers in Tucson, Arizona
Located at the confluence of the Rillito and Santa Cruz Rivers in Tucson, Arizona, archaeological excavations discovered an ancient agricultural field and canal irrigation system that contained human footprints belonging to an estimated 7 adults and 2 children, and 1 set of canine prints. These fields...
and footprints date between 1000 and 500 BC. This exceptional discovery drew worldwide media attention and required an innovative and collaborative approach to data acquisition and interpretation. This paper provides information related to how the fields and footprints were discovered and the unique series of events that led to their remarkable preservation. We’ll discuss the collaboration of multiple institutions to document and interpret the footprints within their context of the agricultural and canal irrigation system, using silicone casts of individual footprints, gait analysis, ingress to egress tracking analysis, 3D modeling, soil geochemistry and micropaleontological samples, and the results of the implemented analyses.

“Mind the Gap”. Social Networks and Chaco Migration Scenarios

Migration plays an important role in archaeologists’ reconstructions of the origins and development of Chaco society. Scenarios include migration from the northern San Juan to Chaco Canyon and other southern San Juan settlements in the ninth–tenth centuries; from Chaco to the central San Juan in the eleventh–twelfth centuries; and from the central San Juan to Chaco Canyon in the twelfth century. To evaluate possible migration pathways we compiled a database of 1.8 million ceramics from 340 Chacoan great houses and large-scale religious structures, and chipped stone from a subset of these buildings. We apply social network analysis to evaluate the dynamics of intersite relations from AD 800–1300 using a consistent method for dividing assemblages into 50-year intervals. We further assess the directionality and strength of ties by analyzing ceramic technological attributes—including carbon paint, smudging, slip color, and temper types—supplemented by lithic raw materials tied to subregional sources. Results indicate a prominent social gap between the southern and northern San Juan until the eleventh century; stronger and earlier ties of Chaco Canyon great houses to those south and west of the canyon; and the establishment of a prominent network pathway along the Great North Road in the early 1000s.

[91] Comparing Traditional and Photogrammetric 3D Model–Based Measurements of Lithic Artifacts

We assess how photogrammetry and three-dimensional (3D) model-based measurement approaches compare to traditional approaches of lithic analysis. Photogrammetry is a novel, inexpensive and accessible method of producing models of lithics. However, it is unclear how the rate of inter-observer measurement errors of 3D models produced through photogrammetry compares to that of traditional approaches. Here we analyze flakes from Salado period archaeological sites in the Tonto Basin, where interactions among villages and the production of lithic tools are well understood. Features of flakes are assessed using traditional qualitative assessments and caliper measurements. Then, the same flakes are analyzed using photogrammetry modeling software to produce a digital model of each artifact that allows for quantifiable characterization of minute details through data mining techniques. The reliability of both methods in terms or inter-observer accuracy, and in their ability to capture changes in knapping strategies within Tonto Basin are assessed statistically.

[84] A Brief Introduction to the Sonoran Desert Fish

While Suzanne and Paul Fish are endemic to the Sonoran Desert, they have been invasive in other regions of the World. The hybrid vigor from combining Paul’s Michigan foundation with Suzy’s Texas background added to their wide spread geographic range of experiences. As well, an enduring monogamy, not well-known for this species, contributes to their impressive contributions in archaeology. Here, we briefly explore the natural history of this unique team.

Minor, Elizabeth (Wellesley College)

The funerary equipment of the Classic Kerma elite community included sets of ceramic vessels accompanying the primary deceased and sacrificed individuals. Stacks of beakers were placed in communal areas of graves, suggesting that the vessels were intended for group use in the afterlife. Graves with extraordinary organic preservation include woven giraffe-hair implements placed near the vessels. In comparison with ethnographic examples, these tools are beer strainers. Two graves also had vessels with preserved beer mash. Beer provided an important source of nutrition in Nubia, as in Egypt, and ancient Nubian beer is notable for containing natural tetracycline. The placement of communal beer vessels and drinking equipment in elite graves demonstrates the social nature of imbibing alcoholic beverages in the Classic Kerma culture. The beer stored in larger vessels was strained and then served to others in smaller beakers. This process of consumption acted to reinforce the social relationships between the participants. In death, these relationships were manifested through the coercion of individuals to be sacrificed to accompany the burial of the primary deceased individual. The
carefully arranged beer equipment was brought into the mortuary context, ready to be tapped to continue to commemorate these relationships in perpetuity.

[365] One Site, Multiple Histories: A Study of the Numerous Phases of Habitations at Fort Caswell

This study explores the archaeology of tourism through an examination of the multiple habitations of Fort Caswell, situated on the southwest coast of North Carolina. The brick fortification was built in the 1830s. Subsequently, it served as a U.S. Army installation from 1861 to 1945. The site has undergone extensive reconstruction due to its strategic geographic location at the mouth of the Cape Fear River, changes in function and ownership, and damages due to severe weather and war-related activities. The Baptist Assembly of North Carolina purchased the fort and its surrounding buildings in 1949, and since then has used the property as a retreat center and camp. Systematic excavation of the site since the early 2000s has produced a large assemblage of artifacts. The material retrieved during work at the fort includes items of very recent vintage. I discuss the importance of including artifacts form modern occupations in the consideration of the history of the site. Additionally, I consider the implications of excavations in which artifacts from recent habitation levels are regarded as trash and discuss how this behavior can dramatically change one’s perception of an archaeological site.

Minturn, Penny

[41] Planning for the Battlefield

The Defense POW/MIA Accounting Agency (DPAA) is tasked with recovering missing military personnel from conflict areas all around the world. In the past we have dealt most often with individual ground losses, expedient burials, and aircraft crashes. But soon we will be confronting the daunting, and very different, responsibility of the recovery of multiple individuals from battlefields. Battlefields differ from our “standard” excavation sites in many ways, namely, the number of casualties, the size of the site, the presence of enemy combatants, the length of time of battle, movement of troops, and complex formation processes during and since the battle. It will not be efficient or successful to approach these sites with previous recovery techniques. This paper lays out a recovery plan for approaching battlefield archaeology, given the unique constraints DPAA deals with, as well as highlighting the unique and vast resources from which we can draw.

[326] Patrones Funerarios en 3 sitios del Departamento de Managua, Nicaragua

En esta ponencia discutimos un hallazgo muy importante para la arqueología de Nicaragua, en lo que respecta a patrones funerarios del Período Tempisque terminal y posiblemente Bagaces inicial. El hallazgo fue realizado a 18 kilómetros al sur de la ciudad de Managua, el mismo comparte algunas similitudes con otros sitios de la ciudad de Managua, pero con notables diferencias en lo que respecta a ensambajes cerámicos y al mismo tiempo en los patrones funerarios en sí; por ejemplo, en Ticuantepe, aparentemente se practicó el sacrificio humano en el cual la mujer debía acompañar al jefe o principal al más allá; en el sitio Los Martinez-La Chureca se practicaron dos patrones; el entierro primario y el de cremación; en el sitio Las Delicias, también en la costa del Lago de Managua a la altura del aeropuerto internacional A. C. Sandino el patrón practicado fue entierro primario y secundario. Todos del período Tempisque terminal y/o Bagaces Inicial.

[88] Reflectance Transformation Imaging: A Unique Approach for Imaging Use Wear on Obsidian Artifacts

Use-wear analysts use various methods of imaging in order to identify patches of wear on stone tool surfaces. Obsidian, however, creates several imaging roadblocks for use-wear analysts who often depend upon light microscopy for their analyses. The integration of scanning electron microscopy (SEM) has led to the generation of results from obsidian objects as it removes interference from color, surface reflectivity, and transparency. Yet SEM also has several drawbacks for use-wear analysts, namely cost of running the analysis and lengthy processing time. In recent years, Reflectance Transformation Imaging (RTI) has gained traction as an imaging method that can reduce interference from variables such as sheen and transparency. This makes RTI well suited for imaging obsidian artifacts. Use of RTI for identification of wear features remains relatively unexplored. RTI is a fast process that uses inexpensive components to produce high-quality, two-dimensional results. This poster presents preliminary results from a study designed to identify wear use on obsidian artifacts imaged via RTI. I demonstrate how RTI provides a potential complimentary imaging method that can be applied to problematic raw materials for the identification and analysis of wear features.

Miszaniec, Jason (Department of Anthropology, University of California, Davis)

Contemporary economic and subsistence fisheries are a significant resource in Norton Sound, Alaska. Artifacts and faunal remains recovered from test excavations at the Shaktoolik Airport site (NOB-072) demonstrate that indigenous peoples have been fishing in the region for at least the last millennium. We aim to trace the regional development of fishing strategies, and how they were influenced by demographic and climatic changes by comparing over ten thousand faunal remains collected in situ and from bulk soil samples from three discrete cultural occupations: 1)Thule/Nukleet, AD 1000–1400; 2) Yup’ik, AD 1400–1800, 3) Inupiat, AD 1800–1900). An analysis of early Thule assemblages will shed light on the development of Yup’ik coastal and riverine adaptations. Preliminary data indicate that fish counts as well as species-richness increased from early to late Yup’ik occupations and subsequently declined during the historic Inupiat habitation. Hunter-gatherer fishing economies represent a specialized subsistence strategy. The stability and predictability of fish is attributed to increases in populations as well as higher degrees of sedentism. Because of its technological investment and demographic implications, tracing the origins and development of fishing economies is of key interest in coastal archaeological research.

[250] Using Multiple Techniques to Assess the Crop Marks of Early Medieval Barrow Cemeteries in Scotland
This paper will show how using multiple techniques will refresh our understanding of crop mark sites, which is imperative for their protection and preservation. This work comes out of a research project looking at barrow cemeteries in north and east Scotland, the wealth of aerial archive was reviewed and explored through multiple methods. Rectifying and transcribing the aerial APs was one aspect, but ground survey picked up newly identified upstanding barrows at multiple sites. The results extend the time-depth of the barrow landscape, and allow us to better understand this fragile archaeological resource.

[271] The Spread and Development of Iron Technologies in China
Iron production in this paper is divided into two types: wrought iron and cast iron. Wrought iron was spread through the Eurasian grasslands to China two times; at the middle of second millennium BC and ninth to eighth century BC. At the later time, wrought iron daggers with golden or bronze handles spread to northeastern China. After wrought iron arrived in the Central Plains of China where bronze working was developed, there was the invention of cast iron technology. Development of cast iron technology of the Central Plains was accomplished by de-carburization to produce iron tools. On the other hand, in the Great Wall Region and the Eastern Tibetan Plateau wrought iron technology spread from the Eurasian grasslands. The diffusion route of wrought iron in these areas is affirmed by the chronology of the bimetallic dagger with a three pronged design. Wrought iron technology spread from northwestern China through the Eastern Tibetan Plateau to southwestern China. Finally, wrought iron technology spread to South-East Asia.

[214] Socio-Ecology and the Sacred: A Comparative Study of Historic Natural Sites in Tropical Asia
Within the complex socio-ecological systems of South and Southeast Asia, ancient sacred natural sites were created by and imbued with cultural and ideological values; these were seen as liminal spaces or threshold environments. In this context, sacred natural sites act as transitional landscapes between the human and nonhuman worlds in ancient and modern times. This sub-project involves examining the roles of sacred natural sites in each of these three early state formations from 800–1400 CE: the Chola (South India), the Sinhalese (Sri Lanka) and the Khmer (Cambodia). Several ancient sacred natural sites around the world are active parts of societies today, and the ones chosen for this study span several categories, including sacred mountains, rivers, forests, and caves. Using the paradigms of entanglement theory and resilience theory, this sub-project analyzes the importance of sacred natural sites as socio-ecological integrative mechanisms within a comparative model of the Charter States present in South and Southeast Asia. The results of this transdisciplinary research can help inform us of the cultural factors and broader practices in the conservation of endangered natural sites and also provide more holistic alternatives to the problems of urban sprawl in the states of our contemporary globalized civilization.

Moe, Jeanne (Project Archaeology-BLM)
[97] Archaeological Inquiry and Integrating Science and Social Studies: A Research Opportunity
Educators have long claimed that traditional school subjects should be integrated while archaeologists praise the ability of their discipline to bridge the divide between science, social studies, and many other subjects. While everyone seems to think that interdisciplinary teaching and learning is important and highly desirable, very little research has been conducted on students' conceptual understanding of the relationship between science and social studies. In a case study, I assessed students' understanding of interdisciplinary learning through archaeological inquiry and found that they were confused about the nature of both science and social studies and the relationship between the two. Additionally, I found that very little research on conceptual understanding of interdisciplinary science learning has ever been conducted. The preliminary findings from the case study and the lack of research point to a promising area for future research of prime relevance to archaeology education.

[69] Networks of the Dead: Exploring Patterns of Homogeneity and Diversity in the Precolonial Caribbean Using Network Analysis
The precolonial Caribbean shows great diversity in burial patterns across time and space, making the interpretation of funerary behavior very complex. While some broad trends in funerary practices have been noted, a simple assessment of the frequency of different burial practices in the region reveals a range of body positions and body treatment, as well as burial location and grave goods. In this paper we use statistical and network explorative approaches to map these variable practices. A 2-mode network analysis will be used to visualize large-scale differences between various temporal and
regional divisions in the data-set. These overarching patterns will be further elucidated by a number of micro-networks centered on individual burials and their cross-connections. Our application of network approaches to funerary data bring to light some important considerations for assessing homogeneity and diversity in the funerary record, and showcases another avenue for network applications in archaeology.

[394] Displays of Identity: A Community-Engaged Approach to Studying Identity through Photo Diaries

This study is part of a larger research project, which looks at displays of social identity and the effects of influence from outside contemporaneous groups in precolombian Peru. In studying past communities, we look beyond our own interpretations of “who” we perceived people to be and begin asking questions that reveal who they thought they were and how they chose to advertise that to those deemed “other.” The nature of this research requires working closely with contemporary local communities who remain tied to their prehistoric landscapes and understanding the affects that may have on how they perceive themselves today. To this end, a community-engaged study on the advertisement of contemporary identities was conducted in the agropastoral town of Cosma, situated in the Cordillera Negra at the headwaters of a branch of the Nepeña Valley. Participants from the Cosma community created photo diaries during the 2016 field season, where they were able to take photos they believed best represented who they were within their community. This paper will present on the methods we utilized, the issues and problems we encountered, overarching themes represented in the photographs, and the preliminary results of this pilot study within the Cosma community.

Molist, Miquel (UA/B/Spain), Josep Bosch (Museu de Gavà), Anna Gómez (UA/Spain), Silvia Calvo (UA/Spain) and Mònica Borrell (Museu de Gavà)

This paper presents a synthesis regarding the exploitation of the variscite mineral in the prehistoric mines of Gavà, Spain, as well as the manufacturing of ornaments and their dissemination during the Neolithic period. Special emphasis will be given to the results of the latest research in both the mineralogical characterization and archaeological interpretations derived.

[179] Identifying the Quintessence of Olmec Centers in Formative Olmec

In the early twentieth century, the discovery of the Olmec colossal heads associated with San Lorenzo, La Venta, and Tres Zapotes led to the early designation of these three sites as the triadic centers of Olmec civilization, implying a level of cultural uniformity. Subsequent archaeological investigation has shown that the three centers, each with a distinct but overlapping chronology, share few commonalities in layout, artifact assemblage, or sculpture style. Indeed, the heads themselves demonstrate distinctive regional styles and configurations of display, underlining the many differences between the primary centers of the Olmec heartland. Given these disparities, is it possible to speak of the quintessential Olmec site? What clues might remain to signal those aspects of Olmec places considered most cherished or significant by their ancient inhabitants? This paper will explore the construction of Olmec landscapes in relation to the regional geographies—specifically places of convergence, emergence, and hierophany. Rather than a single site serving as a model for other Olmec centers, the Olmec quintessential place is suggested by the way all three Olmec centers engaged with regional topography through practices of gathering, rituals of pilgrimage and deposition, tensions between the seen and unseen, and manifestations of the animate landscape.

[102] A Comparative Ceramic Analysis of Motifs from Three Sites in the Cambria Locality, Minnesota

The Cambria phase (AD 1050–1300) is an archaeological complex primarily centered on the elevated terraces of the Minnesota River in south-central Minnesota. Cambria phase pottery demonstrates technical and stylistic influences from several different late prehistoric cultural traditions, including Mississippian, Plains Village and Late Woodland. Cambria ceramics are currently classified as part of the Initial Middle Missouri Variant, but certain affinities are evident between the grit-tempered, rolled rim ceramics of the Cambria phase and the Powell-Ramey series at the Middle Mississippian site of Cahokia in west-central Illinois. However, the nature and degree of the relationship between these cultural areas has never been defined clearly. In order to identify the range of variation within Cambria ceramics, a comparative attribute analysis was completed using ceramic assemblages from the Cambria, Price and Owen D. Jones sites, which are collectively referred to as the Cambria Locality. This paper presents the results of a motif analysis that categorized individual design elements and identified four design field patterns. The results are interpreted at multiple levels of analysis, but primarily are focused on contextualizing intersite motif and design field variation in a micro-regional context within southern Minnesota. In addition, possible extra-regional origins of certain motif packages are discussed.

[350] Interpreting a Deserted Medieval Village through Geophysical Data

Ground-penetrating radar is often used as a way to collect from reflections from buried features, which are then processed into colorized horizontal amplitude maps to visualize these features in the horizontal plane. While this is a good way find and visualized features in “batch mode” there are other less commonly employed methods to process the data. The Castles in Communities project in Ballintubber, Ireland, project has collected GPR datasets from multiple years to produce standard GPR images, integrated with magnetic gradiometer maps and three-dimensional isosurface renderings. In this way very different types of features, both architectural and agricultural are visible in large areas outside the castle walls. This shows where the medieval village was located, as well as other associated structures and agricultural fields. In addition within the castle walls a number of buildings, a church and other work areas, now totally invisible on the surface, have been identified. A number of these archaeological features have been excavated to confirm and refine the geophysical results.

Mongélo, Guilherme [327] see Watling, Jennifer

Monks, Gregory (University of Manitoba)

The Nuu-chah-nulth (Nootka) of Canada’s west coast are renowned ethnographically for their cultural practice of open ocean whaling. Research in the last decade has shed light on the preferred species, the ecological reasons why whales were pursued, the antiquity of whaling, and the economic and social implications of whaling. Most of this research has been substantive and methodological in nature with only modest attention to theoretical issues. In this paper, I take a Human Behavioral Ecology perspective on Nuu-chah-nulth whaling and offer analyses of the practice from both optimal foraging and costly signaling perspectives. I conclude that these perspectives are complementary and provide a more complete understanding of the practice than would one or the other perspective alone.

Monroe, Cara (University of Oklahoma-LMAMR), Fernando Villanea (Washington State University-School of Biological), Eric Lenci Jr. (Muwekma Ohlone Tribe), Alan Leventhal (San Jose State University-School of Social Scien) and Rosemary Cambra (Muwekma Ohlone Tribe) [92]

Ancient Human DNA Analysis from Central California: Interpreting the Penutian Migration through Genetics.

Mitochondrial DNA (mtDNA) data was collected from over 300 individuals to further understand the hypothesized spread of Penutian populations from the Columbian Plateau into Central California around 5,000 BP. While living and ethnographic Ohlone groups—specifically in the San Francisco Bay area—speak Penutian languages, it is unclear what effect immigrating Penutians speakers had on existing Hokan populations between 2500–3000 BP. Distinct maternal lineages that belong to either immigrating Pro-Utian speaking peoples, or to Hokan populations who lived in the area for more than 7,000 years, have been identified and indicates intermarriage post-migration. Bayesian analysis further suggests a major population expansion within the region.

Whole Vessel Caches: A Comparison of Offerings at Cerro de la Virgen with Lower Rio Verde Valley Public Space Offerings

Previous archaeological excavations in the lower Rio Verde Valley in Oxaca, Mexico, have provided evidence for communal ceremonies since the Late Formative (400–150 BCE). The Terminal Formative (150 BCE–250 CE) period saw a continuation of communal ceremonies at hinterland sites along with the emergence of the region’s first polity, Rio Viejo. The maintenance of these practices in the hinterland during the increasing urbanization occurring at Rio Viejo suggests their importance in community identity. These ceremonies included mortuary rituals, feasting, and public offerings. This presentation will focus on public offerings primarily by presenting data from Cerro de la Virgen, one of several secondary centers. Three seasons of fieldwork at Cerro de la Virgen have demonstrated a marked affinity for the emplacement of offerings, especially whole vessels, on a scale not seen in other secondary centers in the lower Rio Verde Valley. The data from Cerro de la Virgen will then be compared with public offerings at other secondary sites in the region.

Paradox No More? Postclassic Mazapa and its Regional Context

During the 2014 through 2016 field and laboratory seasons of the RRATZ Project, the archaeological site of Mazapa was recorded, mapped, and its pottery and obsidian artifacts analyzed. These efforts reveal that Mazapa, located near Chonegal, Veracruz, is one of the largest Late Postclassic sites known for the southern Gulf lowlands. It contains approximately 170 structures that range from low housemounds to platforms measuring 7 m high. Although sizeable Postclassic settlements have been documented for the western Tuxtla to the immediate southeast, and the Mixtequilla region to the northwest, only ephemeral contemporary occupations had been previously identified in this intermediate region. Preliminary understandings of the site suggest that it shared features with both adjacent regions. Landform modifications around the periphery of the site core may have given it a defensive advantage characteristic of its contemporaries in the uplands, its ceramic assemblage shares greater affinities with sites to the west (despite differences based on local clays), and obsidian materials reflect broad temporal trends of the Late Postclassic. This paper presents the results of field and laboratory investigations, and comments on the impact this new information has for the regional Postclassic archaeological context of the broader southern Gulf lowlands.

Montenegro, Alvaro and Scott M. Fitzpatrick [296]

Environmental Influences on the Prehistoric Movement of Modern Humans through Wallacea

Archaeological evidence for early population dispersals from Sunda to Sahul extends back to at least 50 kya in Australia and between 42–40 kya in Timor-Leste and Sulawesi. An increasing number of sites dating to between ca. 41–14 kya on these and other islands such as Halmahera suggest that modern humans were becoming more proficient and spatially expansive than once believed. What were the prime variables environmentally, socially, or climatically that may have influenced these movements during the Late Pleistocene? In this paper, we examine how and why these groups dispersed across this region during different intervals of time, taking into consideration the presence of now-submerged islands, winds, currents, and climatic (seasonal and other variability) processes. The results have implications for modeling colonization routes and estimating seafaring capabilities during the initial stages of Sahul occupation.

Underwater Archaeological Surveys in Shakan Bay, Southeast Alaska

The coastline of southeast Alaska was submerged by post-Pleistocene sea level rise from at least 16,000 cal BP until it stabilized about 10,600 cal BP. The submerged continental shelf was modeled using bathymetry and other data to identify areas exhibiting high potential for the occurrence of archaeological sites. Two seasons of underwater archaeological survey have been conducted at this location (NSF OPP–0703980 and 1108367), using multibeam sonar, side-scan sonar, sub-bottom profiler, real time video from remotely operated vehicle (ROV), and sea floor sampling using a van veen grab sampler and sediment screening. This data has produced a detailed overview of Shakan Bay, located on the northwest corner of Prince of Wales Island.

Beneath the Blue-Green Trees: Understanding the Built Environment of Yaxox through Lidar Analysis

The Upper Belize River Valley hosted a high density of ancient Maya settlement from the Early Preclassic Period onward, supported by abundant fertile alluvial floodplains. In addition to the handful of major civic-ceremonial centers spread along the valley, the region also sustained numerous middle-tier administrative, ceremonial, and residential locales. The site of Yaxox, strategically situated at the confluence of the Macal and Mopan rivers, provides an intriguing example of a minor civic-ceremonial locale. Despite the perceived minimal nature of the center, Yaxox features certain architectural elements—such as sacbeob, reservoirs, and a ball court—commonly attributable to larger polities within the valley. Although the site remains understudied, the acquisition of aerial lidar for the region in 2014 allows for the remote analysis of the middle-tier center and its associated built environment. This paper focuses on the utilization of spatial information to analyze the natural landforms and archaeological landscapes surrounding Yaxox. These data will aid in the determination of the relative chronology, role, function, and extent of the site and provide a deeper understanding of the relationship between the middle-tier loci and other, larger surrounding centers such as Cahal Pech, Buenavista del Cayo, and Baking Pot.

Rain Petition Rituals and Offerings in Mesoamerica: Archaeological and Ethnographic Research

This paper examines two ritual expressions: the offering 102 of the Aztec Great Temple of Tenochtitlan (1436–1502) and the “promise” to the Santa Cruz or rain petition ceremony in Temalacatzingo, Guerrero, Mexico (2007, 2008, and 2010). It analyzes the consumption of botanical materials, such as copal resin, amaranth seeds, ahuehuete branches, yauhtli flowers, guajes and beans in both rituals. It identifies similarities in the way those materials were used, and proposes that this fact demonstrates cultural continuities in religious life of ancient and contemporary Nahua peoples of central Mexico. It argues that both ritual expressions rendered worship to rainy and fertility goddess: Tláloc and Tlatoque in the past, Santa Cruz in the present. In this context, the botanical materials functioned not only as presents to the deities but also as representations of the natural factors (mountains, rivers, land and clouds) related to fertility in Mesoamerican religious tradition. The cultural continuities are explained as a consequence of persistence of agriculture of temporary, especially maize production, as the main economic activity, and the survival of ancient religious ideas and symbols.

Montgomery, Lindsay (University of Arizona)

Multivocal Landscapes: Mapping Mobile Ontologies onto the Northern Rio Grande

Forming a strategic corridor from the Southwest to the Plains, New Mexico’s northern frontier was an important site of cross-cultural interaction during the colonial period. It was on the fringes of the Spanish Empire that Hispanic, Pueblo, Ute, Apache, and Comanche groups converged, generating new cultural identities and materials in the process. While archaeologists have long been interested in the particular ways in which Pueblo groups conceptualized and marked this region, the rich and diverse ways in which mobile groups have engaged with the Rio Grande landscape is less well-known. Through a discussion of the archaeological remains of Ute, Apache, and Comanche groups I will explore the unique ways in which mobile groups make and mark space. Structuring this discussion is the belief that movement is the essential thread which binds together the social, economic, and spiritual worlds of mobile societies both in the past and in the present. As an indigenous ontology, mobility has important implications for how we as archaeologists interpret spaces, places, and things.

Moonkham, Piyawit

Mythscape: An Ethnohistorical Archaeology of Space and Narrative in the Northern Thai Cultural Landscapes

A thousand-year-old narrative of the Naga in northern Thailand relates how the town known as Yonok came to be destroyed (by an earthquake) after its ruler became unrighteous. Regardless of this divine retribution, the people of the town chose to rebuild. Local chronicles and written documents show that people in the region continue to practice and believe in the narrative today. The Naga is seen as the guardian of the land. It is also seen as the creator and protector of rivers, lands, villages, and towns. In addition, there are more than a hundred archaeological sites spread throughout the Yonok ancient town indicate that people remained and revived settlements after the earthquake. This paper argues that the Naga myth is an agentic source for people to initiate action and performance. The myth is also used as referential knowledge by local people to modify physical landscapes, and guide their decisions over what might be called a mythscape, the ways in which people have learned to understand and interact with the surrounding environment. Mythscape is also a tool by which people act and reimagine their space as communal monumentality.

Moore, Christopher (University of Indianapolis)

Interacting in Cramped Spaces: Material Culture and Identity at the Mission San Joseph de Sapala

Accounts by sixteenth- and seventeenth-century explorers, missionaries, and government officials clearly illustrate the considerable amount of variability in indigenous cultures, ethnics, and traditions found throughout the Southeast at contact. Beginning in the mid-seventeenth century, many of these formerly dispersed groups began to coalesce around mission communities in modern Georgia and Florida. The historical narrative of the contraction and eventual destruction of the Spanish mission system in Florida describes numerous towns and communities from the mainland aggregating for a time on Sapelo Island, the site of the Mission San Joseph de Sapala. This paper investigates Mission period ceramic variability in an effort to evaluate the degree to which interactions in mission communities is reflected in the diversity of ceramic attributes.

What’s in a Dress? An Archaeological Collection of Kapa Cloth from Nineteenth-Century Nu‘alolo Kai, Kaua‘i Island, Hawai‘i

Anthropological discussions of gender and sexuality in colonial-era Polynesia have often focused on the introduction of Western clothing styles and the relationship between changing modes of dress and the negotiation of new social identities. Because clothing is highly perishable, however, there have been few opportunities to address this topic through the archaeological record. My paper presents an analysis of an exceptionally well-preserved collection of archaeological cloth from Nu‘alolo Kai, Kaua‘i Island, Hawai‘i. This collection contains fragments of imported fabric and Hawaiian barkcloth or kapa from a site occupied until approximately 1850. Kapa and foreign cloth were found together in the site’s uppermost layers. One remarkable piece of painted kapa was sewn into a sleeve, possibly as part of a missionary-style dress. This paper suggests that the introduction of new styles of dress in Hawai‘i was more complex than is often understood. While Hawaiians at early nineteenth-century Nu‘alolo Kai may have incorporated Western clothing into their daily routines, they also continued to make and use kapa. In fact, kapa manufacture, particularly the incorporation of foreign elements, may have served as one way for kapa makers to negotiate local systems of meaning in an environment of rapid social and cultural change.

Beyond Iron Age “Towns”: Examining Oppida as Examples of Megasites and Low-Density Urbanism

The question of whether Late Iron Age oppida in Europe were truly “urban” has dominated debate over these sites since the nineteenth century. Oppida, however, have been surprisingly absent from comparative urban studies, despite increasingly nuanced perspectives on the nature and diversity of the urban phenomenon. In particular, Roland Fletcher’s suggestion that oppida might be examples of a range of alternative urban-like centers has been largely ignored by scholars of the European Iron Age. The increasingly complex nature of many oppida makes it a pertinent time to assess Fletcher’s...
claims and examine whether oppida can be compared to low-density urbanism elsewhere in the world. Using specific case studies, this paper argues that oppida did, in fact, share characteristics of low-density urbanism and that this is likely to be due to the negotiated nature of power in Iron Age societies.

Using Archaeological and Genomic Data to Investigate the Evolutionary History of Celiac Disease

The Neolithic Transition brought with it a number of changes in the relationships that people had with animals, plants and pathogens. Increasing proximity to domesticated and commensal animals, and, larger, denser communities shifted the disease ecologies of these communities and resulted in an increasing number of disease vectors. I use ancient and modern DNA to look at the effects that these new dietary and epidemiological trends had on people in the past and the genomic legacies of the Neolithic Transition today. This talk will focus specifically on Celiac Disease, an autoimmune disease resulting in life-long gluten-sensitivity. It is estimated that between 1 in 100 and 1 in 300 people worldwide live with this disease, which, if untreated may result in gastrointestinal and central nervous system stress and iron deficiency anemia. While clinical and global health efforts have increase awareness, diagnosis and treatment, many questions remain about the evolutionary history of this disease. Combining archaeological and genomic data can begin to address questions about the history of Celiac Disease.

Sedentism and Plant Domestication: Northwest Amazonia

Two different scenarios have been proposed to explain sedentarization and the transition from foraging to sedentary societies. In the first a key resource or a combination of resources allows the stability of the population giving rise, over time, to sedentarization; in the second, a population concentration caused by an external change such as drastic climatic fluctuation or regional population increase with its concomitant social problems force the adoption of a sedentary way of life. In these scenarios plant domestication and the adoption of agriculture has been underlined; a good example of this is the interpretations of the archaeological record of the Levant. Yet, while Amazonian paleobotanical record shows a robust processes of plant domestication and plant experimentation, the archaeological record, particularly in the northwest Amazon, is very poor in examples of early sedentism associated with the adoption of agriculture. This paper explores the relationship between plant domestication and sedentarization in Amazonia.

Excavations in Cacatoltepexi Cave, Chiepetlan: Paleoindian Enigma and Late Postclassic-Early Colonial Transition

Cacatolutepexi Cave, located near the town of Chiepetlan, is notable for its depictions of what appear to be deer being chased by humans done in white paint. Excavations in the cave uncovered evidence of use in the Late Postclassic-Early Colonial periods. An unexpected find at the back of the cave was an enigmatic deposit of calcium carbonate filled with chert debitage and animal bones, which returned radiocarbon dates around 9800 cal BC.

Land Snails and Archaeology on the California Channel Islands

Land snails have the potential to address a variety of archaeological concerns, including the identification of paleolandsapes and paleoclimatic conditions. Such studies demonstrate how non-marine mollusks can be employed to infer changes such as seasonal and long-term precipitation rates and anthropogenic land use alteration. Although land snails are abundant in Channel Island sites, they are often ignored. In this paper, we utilize land snail remains from three archaeological sites on San Nicolas Island and a rockshelter site on San Miguel Island to address specific questions about past human activities and settlement patterns throughout the Holocene. Multiple land snail taxa including Micrarionta opuntia, Helmithoglypta ayressiana, and Xerorionta sp. were identified and quantified in this study. Our results suggest that land snails can be used to clarify stratigraphic ambiguities in the archaeological record, especially patterns caused by short-term occupation/abandonment cycles. Furthermore, our study suggests that the native people of San Nicolas Island incorporated land snails into their ritualized activities and ceremonial events.

Moran, Kimberee S. (Forensic Outreach)

In 2009 the National Research Council released a damning report on the state of forensic science in the United States. The end result has been a six-year mission to develop national standards and best practice for the myriad of forensic specialties. Coordinated by the National Institute for Standards and Technology (NIST), scientific working groups (SWGs) brought together practitioners, academics, and other stakeholders from around the country to draft documents defining standard terminology and operating procedures. Despite stalled legislation, a national Forensic Science Standards Board was established in 2013 and it was announced that the SWGs would be dissolved and reformed as the Organization of Scientific Area Committees (OSACs). The aim of the OSACs is to, once-and-for-all, create the standards for their disciplines. While many forensic fields have a well-established history within the SWGs and now OSACs, crime scene investigation has traditionally been overlooked in the quest for standards. Finally, in 2015, over a year after the formation of the OSACs, NIST announced the formation of a CSI OSAC that included two members from the archaeology community. This presentation will provide an update on the progress of the CSI OSAC and the road ahead.

[285] The Archaeology of Ecological Imperialism in Central Mexico

In the 1960s and 1970s, cultural anthropologist Roy Rappaport criticized the effects of the West on the developing world. Well before Crosby popularized the term, Rappaport labeled this process “Ecological Imperialism” to clarify the unequal relationship between the needs of an empire and environments it absorbs. Rappaport wrote when scientists were beginning to observe global ecological degradation, but anthropologists had yet to develop a historical perspective. Over the past decade, archaeologists have demonstrated ecological degradation also has a history: past states and empires dramatically altered their environments. Archaeologists also recognized that such environmental impacts constitute legacies that shaped the political economies of the two imperial systems built different systems of environmental interaction. But they greatly influenced each other in negative and positive ways. A consideration of both are necessary to understand the long-term consequences that continue to be inherited into the present systems of global Ecological Imperialism.

[8] Where Did the Sacrificial Subjects Live? An Oxygen Isotope Study of Individuals Sacrificed by the Aztecs during the Late Postclassic Period

We present preliminary interpretations of the residential patterns of Aztec sacrificial subjects from the Templo Mayor of Tenochtitlan and the Templo R of Tlatelolco (present-day Mexico City) who died during the Late Postclassic period (AD 1400–1519). The study uses oxygen isotope analysis of bioapatite phosphate to assess whether these individuals lived in the Valley of Mexico during the last years of their lives or were brought in from distant Aztec provinces. Tissues analyzed also include individuals from a local residential burial site in nearby Ecatepec, which provides a local phosphate oxygen isotope baseline. We find that, besides a few interesting cases, the majority of the sacrificial subjects (children and adults) resided in the Valley of Mexico prior to being offered to the Aztec gods.

[82] Flora, Ethnoecology, and Foodways in the Land of the Sky

Analysis of botanical residues recovered from the Río Verde Valley has yielded a wealth of information about activities of ancient inhabitants. Data from this paper were derived from large-scale excavations at the Terminal Formative urban center of Río Viejo, and the Terminal Formative outlying sites of Cerro de la Virgen and Loma Don Genaro. Evidence of agricultural practices as well as the collection of wild and fallow-dwelling plants have been revealed through charred seeds and other macrobotanical remains. The recovered archaeobotanical specimens indicate the use of several typical economic species, as well as a range of uncommon plants that may have been used for various purposes including fiber, medicine, and ornament. Moreover, the distribution of species across each site informs understandings of spatiality in terms of distinctiveness or overlap of activities taking place at individual loci. The diversity of practices represented by the botanical remains adds nuance to traditional paradigms of Formative Period foodways and ethnoecology in the region.

[231] Cultural Interaction and Fueguian Islands Archaeology: Discussing Middle and Late Holocene (50º–55º South Latitude, Chile)

The Fueguian archipelago, dominated by three major islands, namely Tierra del Fuego, Dawson, and Navarino, is located namely at southermmost end of South America and was peopled by hunter-gatherer societies from c. 10,500 BP to the twentieth century. Sea coastline areas have evidence of specialized marine adaptation since c. 7,000 BP, including navigation. Ethnohistoric and ethnographic records account for an overlapping network area of three groups: Selk’nam land hunters and Alacaluf or Kawésqar from central-western Patagonia and Yámana or Yaghan, south of the Beagle channel, the latter two groups being defined as specialized maritime nomads. The use of the subsistence dichotomy between terrestrial/marine and pedestrian/canoe has limited research hypothesis and the comprehension of the archaeological record. We present a broad comparison of cultural interaction data from the Middle and Late Holocene archaeological record is developed, focusing on lithic/bone technological traits (e.g., Levalllois core reduction method) and raw material distribution (e.g., obsidian and Miraflores rocks).

[99] From Serial Specialist to Cereal Specialist: Managing Hunting and Husbandry in the Context of the Terminal Pleistocene-Early Holocene Fitness Landscape of North China
Recent reconstructions of terminal Pleistocene-early Holocene settlement and subsistence patterns in northern China indicate that the intensive yet highly mobile hunting pattern that developed during the Younger Dryas as a way of mediating the increased temporal and spatial patchiness of the terminal Pleistocene resource base was maintained and even facilitated by early experiments with farming millet in the early Holocene. The long-term viability of this novel adaptation was evaluated in the context of other adaptations that first appeared in the region in the Early Holocene. Within this framework of competing adaptations, it is argued that though mobile hunter-farmers may have initiated the adoption of agriculture multiple times across northern China in the terminal Pleistocene, this lifeway was ultimately outcompeted by a less mobile, more agriculturally-dependent adaptation that could support greater population densities in the early and middle Holocene.

[323] The Vestments of My Mysteries: Craft Production and the Ritual Economy at Iron Age Gordion
The Terrace Building Complex at the Iron Age site of Gordion in Turkey has been called the most complete picture of organized textile production at a Mediterranean palatial center. Artifactual analysis of the numerous textile tools discovered in the Terrace Building has provided a foundation for ambitious models of the Phrygian political economy: it's been suggested that textiles produced in this "industrial quarter" were intended as payment for the Phrygian army, or tribute. Analyses of the individual "workshop" units of the Terrace Building, however, does not necessarily support the notion that the complex was built as a workshop exclusively for such politico-economic ends. Rather, the wide range and spatial arrangement of the myriad non-textile-related finds in this monumental building indicate that these were multipurpose units. The straightforward models derived for identifying craft specialization and characterizing its relationship to social and political organization are, in the case of Gordion, insufficient. I draw on the emerging theory of the ritual economy to explore connections between the production zone of the Terrace and the wider cultural and political landscape of Early Phrygian Gordion in order to derive a more culturally embedded model for the relationship among craft activity, social capital, and economic value.

Morgan-Smith, Maggie (University of North Carolina at Chapel Hill)
[280] Ours and Theirs: Chapels and Community Dynamics at Rancho Kiuic, Yucatán, Mexico
Drawing on recent excavation and oral history data from the site of Rancho Kiuic, this paper will compare information related to two chapels located within the community. Formerly known as San Sebastián, the community functioned from the late Colonial to National periods as a ranching operation occupied by several generations of Maya-speaking landowners and laborers. Though the two chapels (Capillas I and II) share a number of structural and temporal characteristics, their respective locations, assemblages, and oral histories suggest that they served different sectors of Rancho society. I argue that differences in the uses and material signatures of these two chapel complexes lend insight into community dynamics, specifically related to socio-economic distinctions among the Rancho's population.

[125] Ceramics and Society within the Late Classic Motul de San José Polity: A Multidisciplinary Perspective
Over the past 15 years, Late Classic ceramics from Motul de San José and surrounding sites in the Central Petén Lakes area have been subjected to a variety of technical analyses. Modal and petrographic analyses of ceramics from sites throughout the Motul area have been used to explore intra-polity patterns of production and exchange for both elite and mundane vessels. At the same time, Instrumental Neutron Activation Analysis (INAA) has been conducted on sherds from Motul to define production and exchange patterns for the well-known Ik' corpus of feasting vessels, and has elucidated elite social networks between centers across the southern Maya lowlands. In this paper, we combine the various lines of technical research and present new INAA data from a constellation of nine sites—from modest farming hamlets to a major trading port—within the Motul polity. Using this extremely robust dataset, we reexamine ceramic production and exchange between Motul and its satellite centers. We also consider how the larger Motul polity, through the perspective offered by the various smaller sites, was incorporated into larger, interregional interaction spheres.

[260] The Galick Site: Initial Investigations at a Precontact Site on the Vermont Shore of Lake Champlain
The Galick site, located at the southern terminus of Lake Champlain, has long been identified as a potentially critical context for examining the precontact occupation and ecology of the southern Lake Champlain basin. Both its position at the confluence of local and interregional transportation networks and its setting within an area of remarkable biological diversity highlight the Galick site’s potential importance to foragers and early farmers operating along the southern shores of Lake Champlain. In 2016, the South Champlain Historical Ecology Project conducted the first intensive archaeological investigations at the Galick site and began delineating what appears to be a major multicomponent campsite. This poster presents the initial results of 2016 research and provides an early outlook on the Galick site’s potential significance within the larger Lake Champlain basin.

**The Number of Distinct Elements (NDE): An Alternative Measure of Faunal Abundance**  

NISP (Number of Identified SPecimens) and MNE (Minimum Number of Elements) are frequently used as measures of anatomical abundances in archaeology. Recent experimental results suggest that NISP provides estimates of skeletal abundances that are less robust than those based on MNE. However, our analysis of paired NISP-MNE data shows that MNE is prone to inflate the representation of rare parts. Moreover, MNE is known for being severely impacted by aggregation methods. These fundamental problems considerably limit the value of MNE as a measure of abundance. This paper introduces an alternative counting method called the Number of Distinct Elements (NDE). This new metric focuses on the occurrence of predetermined, invariant landmarks tallied on mutually exclusive specimens. Preliminary experimental results suggest that NDE counts are robust predictors of faunal abundances. Moreover, the NDE approach eliminates the long and tedious task of spreading and drawing specimens to identify fragment overlap. Furthermore, NDE values are additive and easily calculated. For these reasons, the NDE approach constitutes a compelling alternative to MNE in the analysis of faunal patterns.

**The Exchange of Ground Nephrite Celts across the Rocky Mountains**  

Nonlocal nephrite (jade) artifacts are reported from archaeological sites in northern and central Alberta and are derived from nephrite tool producing areas in southwest British Columbia. This is evidence of trade extending more than 800 km distant across the Rocky Mountain divide. We provide results from a variety of nondestructive techniques (portable X-ray fluorescence, X-ray diffraction, and near-infrared spectrometry) to determine the geochemistry and mineralogy of nephrite ground stone celts found in Alberta, and to associate those individual artifacts with documented celtproducing areas in British Columbia. The accurate identification of nephrite can reveal significant cultural relationships that involved long distance exchange of raw materials between occupants of Alberta and British Columbia. The rarity of nephrite celts in Alberta and comparison of their morphology with those from British Columbia suggests that nephrite celts were primarily prestige-related tools in Alberta.

Morison, Melissa (Grand Valley State University)  

**Taking Out the Trash: Resilience and Reuse in a Late Roman Urban Space**  

This paper presents analyses of Late Roman pottery from the Gymnasium complex at ancient Corinth, Greece. Ceramic vessels from well-stratified deposits in multiple functional areas of the complex, dating from the late fourth through late sixth centuries CE, provide evidence for patterns of community structure and adaptive capacity over a period of significant socioeconomic change. An analysis of the Gymnasium ceramic assemblage reveals significant shifts in Corinth’s engagement with pan-Mediterranean trade networks, a repurposing of a significant civic complex, and related shifts in attitudes toward trash disposal, ritual, and pollution (both physical and otherwise). These changes in the conception and use of space within and adjacent to the Gymnasium complex, occurring over two centuries—from the “collapse” of the Roman Empire through the subsequent transition to the new structures of the early Medieval (“Late Roman”) period—help to expand understanding of the role of large, diverse, multicultural urban centers such as Corinth in mediating regional response to larger-scale processes of cultural transformation.

**A Correlation Analysis of Expedient Stone Tools and Faunal Remains at the Tule Creek (CA-SNI-25), San Nicolas, California**  

People have utilized stone tools for food procurement, manufacture of utilitarian and nonutilitarian goods, and self-defense for thousands of years. On the California Channel Islands, both formal (curated) and informal (expedient) stone tools have been observed in the archaeological record. Tule Creek (CA-SNI-25) is a large multicomponent site located on an uplifted marine terrace on the north coast of San Nicolas Island, outermost of the California Channel Islands. Humboldt State University and California State University Los Angeles (CSULA) conducted open-area excavations to investigate the cultural significance of the site and to find intact features. Formal and expedient stone tools were recovered from these excavations along with numerous features, bone and shell tools and ornamental, and extensive faunal remains. In this paper, we present the results of a correlation analysis of the expedient stone tools and the faunal remains found at the Tule Creek site. Our results suggest that there are no statistical correlations between the distribution of expedient stone tools and faunal remains at Tule Creek. This analysis allows for the further understanding of the roles that expedient stone tools performed on an island environment.

Morrison, Alex (International Archaeological Research Institute) and Melinda Allen (University of Auckland, Department of Anthropology)  

**Examining the Causes of Migration into East Polynesia: A Bayesian Chronology Perspective on the Ideal-Free Distribution Model**  

The colonization of the islands of East Polynesia was one of the most rapid and expansive migratory events in human history. While extensive research focuses on determining the chronology of East Polynesia colonization, far less attention has been placed on elucidating the processes that influenced this migration. The Ideal Free Distribution Model of human behavioral ecology has proven useful for exploring a range of issues regarding colonization and mobility in varying ecological contexts around the globe. In this presentation we use the Ideal Free Distribution Model to generate prediction about the factors that influenced movement out of West Polynesia into East Polynesia. As context for the study, we begin by reevaluating the suite of initial radiocarbon dates for East Polynesia using a Bayesian calibration framework. We then revisit West Polynesian archaeological assemblages dating to the time period directly preceding the colonization of East Polynesia and review the archaeological evidence for inland settlement, increased competition, and emerging status differentiation. These results are integrated into a Bayesian chronological model and compared statistically with our estimate for East Polynesian colonization. Finally, we address a set of hypotheses based on the Ideal Free Distribution Model in light of our results.

Morrison, Blythe [122] see Riggs, Charles
Morrison, Kathleen (University of Chicago) [325] LandCover6K: Using Archaeology to Improve Climate Models

This paper introduces LandCover6k, an international collaboration dedicated to reconstructing Holocene land cover (vegetation) and land use on a global scale. Throughout the Holocene, human land use has led to changes in vegetation as well as having other effects on global climate. These effects are typically modeled (anthropogenic land cover change models, ALCC) using limited historical information, with the results of such models used in climate models. Existing ALCC models differ significantly, however. LandCover6k aims to contribute to climate modeling efforts by aggregating archaeological, historical, and pollen data on a global scale.

Morrow, Sara (University of Notre Dame) and Meredith S. Chesson (University of Notre Dame) [207] Networks of Material Mediation: Shopkeepers in Rural Community Social Dynamics

While archaeological research has explored the flow of trade and exchange of manufactured goods between rural communities, regional market towns, and urban centers, less attention has been given to the way that rural shops and shopkeepers played a significant role in the accessibility and distribution of material goods in local economies. Focused on the emergence of rural shops in Western coastal Ireland and islands of Inishark and Inishbofin, 1840–1905, this study will contribute to an understanding of how rural communities created and maintained local shops through tumultuous and stable periods of economic transition. Rural communities, in particular islanders, without the institutional support of the national government or mainland banks, forged unique pathways to acquire shop capital, import vital goods and supplies to communities, and make payments to urban wholesalers. Recent excavations by the Cultural Landscapes of the Irish Coast Project on Inishark and Inishbofin, combined with records of wholesale distribution networks in historic shop ledgers and oral history, will further an understanding of how rural, and at times isolated, communities mitigate their material status through unique forms of entrepreneurship and community cooperation.

Morse, Charles (University of Notre Dame) and Meredith S. Chesson (University of Notre Dame) [191] Bodies, Bowls, and Burial: New Perspectives on the Bab adh-Dhra’ Mortuary Assemblage

Though death may seem an instantaneous experience, the treatment of death by a mortuary community provides implications for activity and identity that stretch far beyond a stilled heart. Archaeologically, we can use evidence associated with mortuary practices to inform us about lifeways and beliefs of the interred and the community at large. Mortuary contexts from the Early Bronze I (3500–3100 BCE) at Bab adh-Dhra’ provide just such an opportunity. The site, situated in the Southern Ghor region of Jordan near the Lisan Peninsula of the Dead Sea, presents a diverse burial assemblage associated with shaft tomb burials. By conducting a comparative analysis of the mortuary materials that focuses on the appearance and treatment of atypical goods—including basalt bowls, maceheads, figurines, and wood objects—compared to more ubiquitous materials—osteological remains, ceramics, and beads—we can gain insight into their notions of value. By investigating their concepts of value in this assemblage, we provide a better understanding of complex practices for a site that showed a marked investment in a cemetery location before their later shift to settlement at the site.

Morton, Shawn (University of Calgary) [337] The Symbolic Centre: The Preclassic Legacy of Yaxnohcah’s E-Group

For nearly 2,000 years, the E-Group at Yaxnohcah served as this city’s spiritual and administrative heart. From the early facet of the middle Preclassic through the Terminal Classic, as the rest of the site grew, morphed, and ultimately fell into disuse, this group continued to be remodeled, refurbished, and rededicated. Further, in a stunning testimony to social memory, and after a period of clear abandonment, it became the focus of Postclassic activity that included the erection of a diminutive stela. In this paper I explore the broader significance of this group within the context of the Preclassic Central Karstic Uplands and contemplate Yaxnohcah’s lengthy presence in this region from the perspective of this early base.

Moses, Sharon (Northern Arizona University) [107] The Multivocality of Firearm Materials among the Captive Africans of the Hume Plantation, Georgetown, South Carolina 1790s–1860s

This paper will discuss firearm materials and related artifacts found in the slave quarter of the historic Hume Plantation, a rice producer in the South Carolina low country from the late eighteenth century until the Civil War. Due to the historical context of violent outbreaks in the region including a murder at a neighboring plantation, it would seem that firearms and materials that could be used for weaponry would be highly prohibited among the enslaved. Yet, archaeological and zooarchaeological evidence suggests that firearms and related artifacts were not only present but that they were used in a variety of ways including as trade goods, as materials for making other items, and as status symbols. This paper introduces LandCover6k, an international collaboration dedicated to reconstructing Holocene land cover (vegetation) and land use on a global scale. Throughout the Holocene, human land use has led to changes in vegetation as well as having other effects on global climate. These effects are typically modeled (anthropogenic land cover change models, ALCC) using limited historical information, with the results of such models used in climate models. Existing ALCC models differ significantly, however. LandCover6k aims to contribute to climate modeling efforts by aggregating archaeological, historical, and pollen data on a global scale.

Moses, Victoria (University of Arizona) [127] The Many Roles of Roman Dogs

The Romans had a strong interest in the natural world. Their relationships with animals extended from animals as food source to animals as exotic curiosities and everything in between. Dogs held a complicated position for the Romans, filling a wide range of roles. For example, dogs could be companions, war weapons, street cleaners, or victims of sacrifice. This variety shows how dogs were conceptualized sometimes as individuals and pets, sometimes as pests, and other times as powerful and almost magical beasts. This paper explores many of the roles of dogs in the Roman world using zooarchaeological and textual evidence. The main focus is the use of puppies and dogs in medicinal and religious rituals.

Moss, Madonna (University of Oregon) [77] Did Tlingit and Haida Eat Sea Oters during the Precontact Period? An Issue of Intellectual Property and Cultural Heritage

In recent years, zooarchaeological studies have been designed to address a variety of issues in conservation biology, but rarely has zooarchaeology been used to document cultural practices that are currently under public scrutiny. Use of sea otters is part of Tlingit and Haida cultural heritage. Conducted with Sealaska Heritage Institute, this project attempts to show how laboratory analysis of archaeological collections can document butchery and processing practices that have direct implications for issues of contemporary wildlife and ecosystem management and sustainable harvesting by Alaska Natives. Sealaska Heritage Institute is sponsoring this study because it seeks to increase scientific knowledge and make it available to local resource users. Sealaska also aims to educate the larger public about the long-term relationships Tlingit people have maintained with sea otters and other wildlife.

Eating Like a Bird: Millet in Iron Age Italy—Economic, Political or Identity Choice?

Recent research reevaluating the evidence for consumption of millet in Archaic and Roman Italy indicates that its role has been underestimated. New findings from Iron Age and Archaic contexts at the Latin settlement of Gabii clearly support a more nuanced and complex situation than the one portrayed by ancient Latin authors and modern scholarship alike. The recovery of significant quantities of millet at Gabii is in sharp contrast with the absence of this crop in similar contexts from Iron Age Rome. These patterns suggest interesting implications for the understanding of the cultural and political landscape of central Italy during the Iron Age. Issues of identity, economic practice and sociopolitical interactions in a period of rapid transformations toward urbanism are here presented.

Moutsou, Theodora (University of Cyprus)

Using pXRF to Unravel Raw Material Choices in Early Holocene Lithic Assemblages from the Island of Cyprus, Eastern Mediterranean

This poster presents the preliminary results of an extensive geo-chemical fingerprinting program using pXRF that was undertaken on a large and diverse lithic collection that included three different raw materials, namely obsidian, carnelian and picrolite. Specifically, the project investigated the use of these three raw materials in Early Holocene lithic assemblages—stone tools and ornaments—from the island of Cyprus, eastern Mediterranean. Obsidian, carnelian and picrolite have been defined as the three rare rock types that found their way to Cypriot assemblages that date between 12,000 and 5500 cal BP. Interestingly, two of them reached the island via a sea-crossing whereas picrolite albeit insular is a rare resource. Contrary to previous work that examined only a small proportion of obsidian or picrolite (but not carnelian) collections from the island’s early sites, this project used HH pXRF to analyse all the artifacts made on these materials with the aim to establish a) numbers of utilised sources and, b) patterns of source preferences. The overall aim is to address the extent and directions of human interactions in the eastern Mediterranean and the reasons behind the choice of the above raw materials over the locally available options.

Authentication of Museum-Curated Tsantsas Utilizing Next Generation Sequencing Technology

The Shuar, native to Northern Peru and Southern Ecuador, prepared shrunk heads to serve as trophies following battle, in response to their cultural beliefs. Inauthentic human shrunk heads (tsantsas) were prepared in a precise manner and exhibit key morphological characteristics. Forgeries, including primates and inauthentic human preparations, were marketed to tourists and private collectors to profit from the “savage” image surrounding the Shuar. Inauthentic shrunk heads were prepared in a nontraditional manner; however, key morphological characteristics may be present highlighting the need for DNA analysis to provide further discrimination. Species identification was conducted to identify a head as human, sloth, or primate. Genetic markers were analyzed using next generation sequencing to determine the provenience of the shrunk heads, as a means of authentication, since forgeries are often European, while tsantsas are of South American ancestry. Maternally and paternally inherited DNA was also analyzed to determine the potential relatedness among authentic tsantsas, due to the taking of women following battle. This method of analysis can be applied more broadly in forensic science to cases involving the identification of human remains and the illegal sale of antiquities on the black market, threatening cultural preservation.

Moyes, Holley (University of California, Merced)

Mapping Caves: Telling the Story

Maps are symbols. While we often think of them as representations of the real world, they are in fact interpretations of the space no matter how accurately and precisely produced. Maps tell a story—YOUR story. Maps make an argument. No two people will map a space in exactly the same way and no two stories will be completely alike. While some researchers are primarily concerned about precision and accuracy in representation, others focus on more humanistic, sensory, or phenomenological elements. Caves are particularly difficult to represent because of their topographic complexity and differ significantly from built environments because their natural organization is not based on a social logic. These problems exist not only with caves but also with all complex spaces in both how to map and what to map. The 3-dimensionality of the space and how one experiences it exacerbates representational challenges, particularly when using Geographic Information Systems or other 2D or 2.5D programs. In this paper I discuss methods in cave mapping using examples from ancient Maya cave sites in Belize. I suggest that rather than thinking of archaeological maps as a form of scientific data creation, we envision them as telling a story of the cave.

The Pragmatic and Epistemological Challenges of Collaborative Research

Chair

Moy, Rachel [309] see Jones, Terrah

Mover, Steve (Fitchburg State University, Fitchburg) and James Blish (Middlesex Community College, Woburn)
This paper outlines some of the lessons learned from more than a decade of working with the Hassanamisco Nipmuc of Massachusetts. During the course of this evolving collaboration there have been many epistemological and ontological challenges. Chief among these has been finding common ground between the questions pursued archaeologically and those that hold relevancy for indigenous peoples. Rather than seeing these as contrasting purposes the Hassanamisco Woods Project has found productive ways of joining these into a common purpose. What has emerged is an archaeology that in many respects is traditional in focus that combines sound empirical research with a pragmatic philosophy that sees value in practical outcomes. The result has been a highly productive, socially satisfying collaboration that has been embraced by Nipmuc elders and youth alike. It has also resulted in a series of joint publications as well as book length manuscript that is in progress.

Mueller, Natalie [174] The Role of Ritual in Early Food Producing Economies: Seed Keepers and Seed Exchange in Ethnography and in the Archaeological Record of Eastern North America

The ethnographic record is replete with examples of farming societies for whom the maintenance and exchange of seed stock was imbued with ritual significance. Seed keeping is often an institutionalized role for families or individuals: a matter of pride, as aspect of identity, and a heavy responsibility. The establishment of these rituals and institutions may have been crucial to the domestication of annual plants and the development of food producing economies. What would seed keeping and seed exchange rituals look like in the archaeological record? The presence of ‘precocious domesticates’ in clearly ritual contexts is one possible archaeological correlate. I present evidence of anomalously early domesticated erect knotweed (Polygonum erectum L.) from a Middle Woodland mound in Kentucky (Walker-Noe 15GD66) and suggest directions for further research.

Mueller, Raymond, Jessica Hedgepeth Balkin (University of Colorado, Boulder) and Arthur Joyce (University of Colorado, Boulder) [82] Agricultural Productivity of Four Different Physiographic Zones in the Lower Río Verde Valley, Oaxaca, Mexico: Using the Current Landscape as a Means to Facilitate an Understanding of Past Productivity

As part of the larger Río Verde Settlement Project (RVSP), soil sampling of different physiographic zones was conducted during the spring of 2016 in the lower Río Verde Valley. The major goal of this sampling program was to assess variation in soil fertility across the region, as related specifically to maize agriculture. The lower Verde Valley was broadly divided into four physiographic zones (floodplain, coastal plain, piedmont, and secondary valleys). Previous studies identified the floodplain as the most agriculturally productive zone, but only broad-based environmental data were previously available. Our study sought to capture large-scale soil variation between physiographic zones as well as smaller-scale variation within each zone. Samples were therefore taken in different microenvironments within each physiographic zone. Efforts focused on surface soil samples, but paleosols were also sampled whenever possible to calibrate for changes in landscape fertility between the prehispanic past and the present. Samples were tested for several major chemical indices representing requirements for maize agriculture (e.g., phosphorous and nitrogen levels as well as CEC). These data will be used to develop a GIS model of agricultural productivity in the lower Verde Valley and to help explain diachronic changes in settlement patterns.

Muir, Robert, Jesse Morin (K’omoks First Nation [staff archaeologist]), Hilary Pennock (Simon Fraser University), Sarah Dougan (Simon Fraser University) and Wedlidi Speck (K’omoks First Nation [cultural advisor]) [46] The Pentlatch Pebbles: Incised Stones from an Ancient K’omoks Village Site in Courtenay, British Columbia

Recent excavations at the K’omoks First Nation ancient village site at Pentlatch resulted in the discovery of 122 incised pebbles and small cobbles. Such artifacts are very rare in the Pacific Northwest, with only one other comparably large assemblage having been reported at Tse-whit-zen in Port Angeles, Washington. The incised stones from the Pentlatch site were found throughout the site area and from all stratigraphic contexts, spanning (at least) several hundreds of years of occupation; nonetheless the artifacts display remarkable consistency in design elements and motifs. The most common motif, described by us as “parted hair and braids,” bears striking resemblance to ethnographic imagery of young women participating in a traditional puberty ritual. This interpretation of the motif is explored and evaluated by drawing on traditional knowledge of K’omoks Nation community members and ethnographic literature from the Salish Sea region.

Mullen, Alice (University of The Witwatersrand) [28] Significantly Differentiated Figures: Understanding Difference through the Construction of Personhood in the Southern African San Idiom

Within the corpus of San rock art in the South African Drakensberg Mountains is a category of highly embellished, oversized anthropomorphic figures termed Significantly Differentiated Figures (SDFs). Such images have previously been interpreted as San ritual specialists’ conceptualization of themselves, in metaphor, as a result of the arrivals of African farmers and European colonists. This paper, drawing on new data gathered during surveys of the Matalele region in the Eastern Cape, South Africa and the Sehlabathebe National Park in Lesotho, shifts focus from broad discussions on the embodied experiences of ritual specialists to the significance of individual SDF images within the region. A newly identified site is to be sampled for dating, with a view to challenging interpretations of SDFs as a recent phenomenon in the history of San rock art production. Examination of ethnographic texts relating to San personhood highlights the construction of identity through a network of relationships between human and nonhuman beings existing both in the mundane and spiritual universes of San peoples, offering insight into why certain nonhuman features may have been incorporated into these highly distinctive figures and what message they may have conveyed to subsequent viewers.

Mullen, Kyle (University of Kentucky) [320] Dune Settlement in the Wake of Tres Zapotes

As the Tres Zapotes polity’s economic and political power diminished in the Early Classic, the eastern lower Papaloapan Basin (ELPB) became a political frontier as sites in this contested region strengthened ties to both Classic Veracruz and Central Mexico. It is during this time that a series of near-coastal palaeodunes and estuarine lakes see an increase in occupational intensity. The ecological diversity of the dune landscape provides a unique setting to explore how the intersection of environmental, political, and economic factors impacted settlement patterns in the region through time. Over the course of field seasons in 2014 and 2015, 17 km² of systematic pedestrian survey was conducted on the dune landscape. Through the analysis of architecture and surface artifacts, this paper sheds light on the processes that brought people to the dunes during the Classic Period, in the wake of Tres Zapotes’ decline.
Müller, Peter (Leibniz-Center for Tropical Marine Research [ZMT], Bremen, Germany), Philip Staudigel (University of Miami, Rosenstiel School of Marine), Sean Murray (University of Miami, Rosenstiel School of Marine), Hildegard Westphal (Leibniz-Center for Tropical Marine Research) and Peter Swart (University of Miami, Rosenstiel School of Marine)

Impact of Prehistoric Cooking on Proxy Signatures in Shell Midden Constituents

The analysis of geochemical proxies in skeletal remains has become a standard tool in shell midden research. Sub-seasonally resolved proxy records provide information about environmental and anthropological aspects such as ancient climate conditions, fishing and foraging seasonality or site occupation pattern. However, as subsistence was the primary purpose for fishing activities in most prehistoric cultures, it is likely that many shell midden constituents such as cooking prior to deposition, potentially altering their geochemical proxy records. To study the impact of prehistoric cooking methods on such proxy records, we exposed modern bivalve shells (Mercenaria campechiensis) to different prehistoric cooking treatments. Afterward, we analyzed shell mineralogy, conventional oxygen and carbon isotopes, various element/Ca ratios and their clumped isotopic composition. Our data clearly show that all prehistoric cooking methods cause an alteration of most paleoenvironmental proxies and in particular the oxygen and clumped isotopic signatures even without a conversion of the initial aragonite into secondary calcite. Thus, depending on the cooking method, pre depositional heating might have introduced considerable errors into previous paleoclimate studies using shell midden constituents. Furthermore our data show that clumped isotopes can be used to clearly detect and differentiate between different cooking methods.

Experimental Analysis of Late Paleoindian Bone Tools at Bull Creek in Oklahoma

Summer of 2016 excavations at the Late Paleoindian campsite, Bull Creek, in the panhandle of Oklahoma resulted in unique bone tool discoveries. Within a bone pile butchering feature, containing ribs and a vertebral column, a mandible tool was found in situ wedged into the head of a rib. The mandibular notch appears to have been used to pry the rib heads from the spinal column with the coronoid process and condylar process imbedded around the rib head. In addition to the mandible a scapula tool of unknown purpose was also discovered. Through the means of experimental archaeology, we used cattle bones to re-create the bison tools and experimented with their potential functions.

Artifact Geographies of the Viking Age

The hair comb is one of the most commonly recovered bone artifacts from early medieval sites in Northern Europe, particularly in Viking-Age Scandinavia. Beyond the bone hair comb's association with technological innovation, it acts as a powerful proxy for urbanism, human migration, and long-range trade in Viking-Age towns. Yet despite this prevalence, the bone hair comb remains understudied in recent years and few multi-site syntheses have been undertaken. Existing studies have focused on the stylistic and technological aspects of combs rather than the raw materials used in their manufacture. This is largely due to unreliable methods of raw-material identification for highly worked bone objects. Zooarchaeology by Mass Spectrometry (ZooMS) is a low-cost and minimally destructive proteomic technique which has been successfully applied in the identification of such raw materials. By producing a "peptide fingerprint," ZooMS can distinguish between the antler of biogeographically discreet deer species from which comb crafting components are sourced. Through the application of ZooMS to the analysis of bone hair combs, our study further characterizes the technological innovations and population dynamics of the Viking Age. This paper introduces a new project that will undertake such analyses across Viking and medieval Northern Europe.

Munro, Kimberly (Louisiana State University)

Persistence and Material Mnemonics in the Cosma Basin: 5,000 Years of Ritual Enactment in the Upper Nepeña River, Peru

The Cosma Complex is located in the Cordillera Negra at the headwaters of the upper Nepeña River Valley, Ancash Peru. Fieldwork conducted between 2014–2016 documented repeated reconstruction episodes associated with the reuse of monumental ritual architecture originally dated to the Late Preceramic (3000–1800 BCE). By the Early Horizon infant remains and other offerings were placed into earlier architectural contexts as a final capping episode on at least one mound. As settlement patterns shifted, a third mound was constructed along an adjacent ridge-line. Based on the abundance of cooking treatments, we analyzed shell mineralogy, conventional oxygen and carbon isotopes, various element/Ca ratios and their clumped isotopic composition. Our data clearly show that all prehistoric cooking methods cause an alteration of most paleoenvironmental proxies and in particular the oxygen and clumped isotopic signatures even without a conversion of the initial aragonite into secondary calcite. Thus, depending on the cooking method, pre depositional heating might have introduced considerable errors into previous paleoclimate studies using shell midden constituents. Furthermore our data show that clumped isotopes can be used to clearly detect and differentiate between different cooking methods.

Early Human Control over Ungulate Taxa in the Southern Levant

An expanding catalog of faunal assemblages spanning the Late Epipaleolithic through Pre-Pottery Neolithic (PPN) periods in the southern Levant points to growing human control over taxa that eventually become domesticated (wild goat, wild pig and wild cattle). This change in human-animal relationships occurs several centuries if not millennia before full-fledged management and domestication are visible in the archaeo-zoological record. We explore this shift by referencing data from 10 faunal assemblages spanning the agricultural transition and by the Early PPNB (10,5000–10,2000 cal. BP) that document the beginning of a trade-off between intensive human hunting evidenced by a broad array of animal taxa and resource depression, and ungulate taxa that are ultimately domesticated. We focus on local conditions that led to a reconfiguration of human-wild animal relationships and the nature of the interaction. Finally, we situate the southern Levant into its larger setting in Southwest Asia by emphasizing an increasingly protracted and multinational picture of animal domestication and the importance of local ecology and regional social networks in facilitating the exchange of knowledge and possibly animals. Early evidence for new human-animal relationships prior to full-fledged animal management encourages reevaluation of what should be considered wild within the wild-domestic continuum.

Munson, Jessica (Lycoming College) and Lorena Paiz Aragón

Ceramic Variation and Ritual Behavior at Altar de Sacrificios, Petén, Guatemala

Located at the headwaters of the Usumacinta and the confluence of the Salinas and Pasión Rivers, Altar de Sacrificios is uniquely positioned with strategic access to points far beyond its sandy shores. Despite the geopolitical importance of this site, Altar has not featured prominently in recent narratives about the political history of Classic Maya society. After more than 50 years, a new phase of archaeological investigations seeks to bring Altar out of the shadows and reevaluate this city’s role and contributions as a place for exchange, innovation, and social interaction within the Maya lowlands. In this paper, we analyze the contents of ritual deposits excavated by Harvard University (1958–1963) and the current Altar de Sacrificios Archaeological Project (ALSAP) to gain a better understanding of the diverse ritual practices performed within this community. In particular, we focus on the variation of ceramic vessels recovered from cache deposits and burials to map out Altar’s sphere of influence and interaction during the Late Preclassic to Classic period transition.

Murakami, Tatsuya (Tulane University), Shigeru Kabata (Universidad de las Américas Puebla) and Julieta López (Universidad Nacional Autónoma de México)

Architecture and Urban Transformation in Formative Central Mexico: New Findings from the Tlalancaleca Archaeological Project, Puebla

Tlalancaleca was one of the largest settlements before the rise of Teotihuacán in Central Mexico and likely provided cultural and historical settings for the creation of Central Mexican urban traditions during later periods. Yet its urbanization process and architectural traditions remain poorly understood. Our research over the last five field seasons indicates that Tlalancaleca was urbanized during the Middle Formative period (ca. 650–500 BC) and experienced large-scale urban transformations during the Late Formative (ca. 500–100 BC) and a subsequent and final urban expansion during the Terminal Formative (ca. 100 BC-AD 200/250). This paper presents preliminary results of excavations, which were carried out at monumental structures at Tlalancaleca. It discusses the construction techniques used for talud-tablero facades (a combination of sloping walls and vertical panels) and the temporal relationship between the introduction of the talud-tablero style and the urban development. Preliminary analysis suggests that the talud-tablero was introduced sometime during the Terminal Formative period and was associated with urban expansion before the abandonment of the site.

Murguía Hernández, Ana Iris (Universidad Juárez del Estado de Durango)

La Feria Colonial: Flow and Exchange of Products in the Nueva Vizcaya in the Eighteenth and Nineteenth Centuries

The trade network in the colonial era formed a great circuit that used communication paths. El Camino Real de Tierra Adentro was used to transport the products sold through fairs that were established at strategic points in the New Spain. Kingdoms away as was the Nueva Vizcaya had people who used to travel these roads annually to bring their products and other materials to get points not only of the New Spain, but also from Spain and the Philippines. The circuit of fairs and marked trails around these strategic points show how the flow and exchange of goods between the various kingdoms of New Spain and the Metropoli worked.

Murphy, Beau (University of New Mexico) and Cristián González Rodríguez (Universidad de Chile)

A GIS Analysis of Production Areas, Ritual Spaces, and Socioeconomics at the Mixed Inka-Local Administrative Center of Turi, Northern Chile

While anthropologists are often concerned with profiling the socioeconomic character of the cultures they study, this task can be challenging for archaeological researchers investigating long-abandoned settlements. Intrisite socioeconomic reconstructions in particular may depend upon such factors as the accurate detection of specific production activities and the partitioning of architectural features into socially informative categories. This paper presents a case study on this topic wherein GIS is used to quantitatively define production loci and evaluate the spatial organization of architectural groups. The distribution of production materials across the site surface of Turi, an Inka administrative center in Northern Chile, are first evaluated to define specific production loci. These data are paired with a typological assessment of Turi’s ritual structures, known as chullpas, to elucidate differences in social identities across the settlement. Integrating these datasets with several additional GIS-based analyses supports the authors’ advancement of preliminary hypotheses regarding the settlement’s socioeconomic organization. Results indicate a complex imperial-local political economy operating upon a community of “neighborhoods,” whose chullpas evidence distinct social associations. These results are contextualized within Inka studies and the general application of GIS to resolve site-level socioeconomic data, and the efficacy of the utilized analytical units and methods are further discussed.

Muro, Luis (University College London) and Lorena Paiz Aragón

Using Computerized X-ray Tomography to Track Rates of Agricultural Domestication Using Seed Coat Thickness

Pulses were an important crop in human prehistory. Tracking traits of domestication in pulses has been limited in the past due to poor preservation of diagnostic features of domestication. Traditionally, morphometric techniques have focused on changes in seed size. The authors measured horsegram (Macrotyloma uniflorum) from South Asia, dating from the Neolithic (2000 BC) to the Early Historic Period (AD 400–700), which showed an increase through time with domestication. This is in juxtaposition to other pulses such as lentils from the Near East that show a slower and gradual increase in size without a clear leveling off after the Neolithic. To understand these differences in pulse domestication trajectories another trait of domestication was studied. Decreases in seed coat thickness have been an assumed trait of pulse domestication. We measured seedcoat thickness in horsegram from southern India dating from 4000 and 3200 years BP with computerized X-ray tomography using the UK Synchrontron. It was the first time archaeological pulses have been successfully imaged. We discovered different grades of testa thickness over time, which suggests this trait is not under the control of a single underlying genetic factor. Thus, synchrontron technology offers new possibilities into nondestructive, high resolution imaging to investigate specific archaeological issues.
Murphy, Joanne (University of North Carolina Greensboro)  
**Ritual and Tombs around the Decline and Collapse of the Pylian State**
The palatial society of the Greek Late Bronze Age collapsed around 1200 BC. There were signs of widespread mass destruction throughout Greece and several of the palaces and settlements were abandoned. Two of the largest palaces, however, Mycenae and Tiryns in the Argolid, showed evidence of rebuilding of houses in and around the palaces after the first major destruction fire. The century after the initial destruction of the palaces was a period of turmoil and filled with more devastating fires at the palaces. In contrast to this image from the Agolid, the post-destruction occupation of the Palace of Nestor in southwestern Greece was limited to small areas in the palace that survived the fire. Despite the lack of evidence for habitation in the area, several of the tombs, which are the primary evidence of ritual during this period, were used after the collapse. This reuse of the tombs, some of which had not been used for several generations, begs the question of the relation of ritual to the collapse of the society and its role in attempts at stability and regeneration in a period of turmoil.

**The Colony of a Colony? The Establishment of Plantations in Dominica, c. 1730–1763**
This paper draws on archival documents held in Dominica, France, and Martinique in order to trace the establishment of a plantation economy that was integral to—yet technically outside the sphere of—French colonial rule in the early modern Americas. Prior to the end of the Seven Years’ War in 1763, European settlement in Dominica was formally prohibited by a series of treaties. Yet surviving notary and Catholic parish records reveal that in the middle decades of the eighteenth century, a number of families from northern Martinique established mixed subsistence and secondary export plantations in southern Dominica, thereby extending their kinship and commercial networks beyond the boundaries of French rule. These settlements, while illegal, were key to spreading and modifying practices of plantation agriculture, slaveholding, and trade already established in neighboring colonies. Adopting a micro-historical approach, the paper reconstructs the familial, social, and economic networks that linked the French colony of Martinique to the neutral island of Dominica, and argues that the labor of enslaved people in this seemingly peripheral island helped fuel the growth of the French Atlantic economy.

**Hand Ax Function at Shishan Marsh-1: Preliminary Results of an Experimental Use-Wear Analysis**
Although hand axes are one of the longest lasting and most iconic stone tools in the Paleolithic, little experimental work has been done to inform archaeologists about hand ax function. The research presented here explores hand ax function using low powered microscopy and an image-based GIS approach. Thirty-two hand axes were created with chert collected from outcrops in the region surrounding Shishan Marsh-1. For the purpose of this study, the researchers focused on experiments involving subsistence activities such as butchery, plant and shellfish processing, and digging. Prior to use, the edges of the experimental hand axes were examined for knapping traces using a Wild M420 Makroskop and photographed at 72x. Blind tests were employed with instructional guidelines to help standardize recording procedures and increase the accuracy of the methodology. The results of the edge damage distribution analysis of the prehistoric hand axes were then compared with the results of the experimental collection. This research has implications regarding hand ax function, hominin tool use in a desert refugia, and provides future directions in experimental protocol.

Murray, Sarah (University of Nebraska–Lincoln)  
**New Technologies in Feature Recording for Archaeological Surveys: Potential and Challenges**
Archaeological landscapes are complex three-dimensional environments, containing not only cadastral survey units and evidence of sites in the form of artifact scatters, but also anomalous topographical features and standing architectural remains of a variety of periods, types, and states of preservation. The time-consuming nature of careful architectural recording and the difficulty of acquiring the high-quality geodata required for a proper architectural survey in the remote countryside have long obviated the possibility of recording most of these three-dimensional features with any kind of precision or detail as part of intensive survey projects. However, recent advances in computing speeds, 3D data acquisition techniques such as lidar scanning and photogrammetry, and mobile RTK DGPS technology have made it not only practical, but relatively easy and efficient, to record architectural features with unprecedented thoroughness, speed, and accuracy in the field. In this paper I review the utility of these new methods for architectural recording in the context of survey projects, consider how they have the potential to change the way we analyze features and landscapes both in the field and in the lab, and critically examine the logistical challenges of data archiving and dissemination that such developments will entail.

**A New Look at Camp Organization in Open-Air Late Pleistocene Sites in the Southern Levant**
A wealth of Late Pleistocene–Early Holocene open-air camp-sites is recorded around the world. However, in sites predating the use of stone for construction, central features such as huts and their floors are rarely preserved. Thus, the documentation of site structure and the identification of past activity areas are limited to hearths (when preserved) and their environs, and to distribution patterns of cultural remains. The focus of this paper is selected sites from the Mediterranean Levant, analyzed on two levels, namely, the camp level (general size and layout) and the feature level (type, size and contents of floors, hearths, etc.). The case studies used here include Ohalo II (ca. 23 ka, no stone construction), Neve David (ca. 16 ka, some stone construction), and el-Wad terrace (ca. 15–13 ka, intensive stone construction). The analysis results illuminate some changes through time, with certain
innovations in each period. By ethnographic analogy, we suggest that the observed changes show local continuity on the one hand and increasing cultural complexity with reduced nomadism on the other. Thus, our results provide new insights into the cultural process leading to the establishment of permanent settlements and later to the formation of the first Neolithic villages.

Naglik, Matthew (University of Michigan) and Parrish Wright (University of Michigan) [132] A Roman “House”? A New Model for Understanding the Origins of the Roman Gens

Debate concerning the development and origins of the Roman kinship group known as the gens has a long and contentious history. Theses questions, however, necessarily move beyond the primary textual evidence, the standard resource for such studies. Different heuristic models must be utilized to take advantage of all available data, whether it be textual, archaeological, or via ethnographic comparison. I propose the concept of a “house society” as developed by Lévi-Strauss and taken up by numerous scholars since as one useful tool. Such a consideration allows for the expansion of the concept of Roman kinship beyond the traditional genealogical focus on patrilineal relationships to other types of relatedness within the system. It also reinforces the dynamic nature of the gens as it evolves within a larger sociopolitical framework. A further benefit is the spatialization of the gens, reconnecting kinship to the physical landscape and reintroducing available archaeological data. Evidence from the community of Gabii and nearby Osteria dell’Osa reveals a social organization present in Latium which may have led to the gentilic system. Finally, this model reconnects the Roman gens with the larger world of anthropological kinship studies, allowing for more sophisticated cross-cultural comparison and hypothesis formation than currently occurs.

Nagle, Arianna (University of Victoria) [263] Estimating Ancient Urchin Size on the West Coast of Vancouver Island

Archaeological remains of sea urchins along the Northwest Coast have not been a subject of concerted archaeological research, but have the potential to provide new insights into Indigenous marine subsistence practices, and the complexities of precontact First Nations’ ecological roles within the marine ecosystems they inhabited. The focus of this report is to investigate the importance of red sea urchin (Strongylocentrotus franciscanus) size in the archaeological record at the sites of DFSh-7 (Huul7ii) and 93T (Hup'kisakku7a) in the area that is now called Barkley Sound. I discuss the potential for preserved urchin hemipyramids (an element in urchin jaws) to predict ancient urchin body sizes. To this end, I measured a series of urchin hemipyramids and test sizes to improve on an existing regression based method for estimating archaeological specimens in Barkley Sound.

Nahil, Emmett (Boston University) and Mary Clarke (Boston University) [392] Maya Monument Production: Techne and the Birth of Meaning

Analyses of sculptural practices of the Ancient Maya have centered on the final stages of production, namely the identities of sculptors, the locations of production, and the techne of sculptural practice. While the contributions of these analyses cannot be contested, there remains a poorly resolved understanding of when in the process of sculpture limestone gains its cultural significance. This paper presents data from recent excavations at a quarry workshop at Xultun where a stela still attached to bedrock was uncovered. Our analysis of this discovery provides a glimpse into the first stages of monument production, such as stone selection and removal, as well as the beginnings of cultural practices often associated with the use life of a stela.

Nakamura, Oki [211] Rethinking Local Differences in Burial Customs in the Final Jomon Period

Previous studies have discussed burial customs and society of the Kamegaoka culture in the final Jomon period (around 3200 to 2500 cal BP) as a single unit of similar local societies in the northern Tohoku district, extending around 220 km from north to south and around 180 km from east to west. In contrast, geographical clustering with delaunay triangulation, my new spatial analysis using GIS, reveals local scale differences in burial customs in terms of shapes of burial pits, grave goods and red pigments. As a result of the analysis, it is possible to distinguish at least 12 local units of burial custom in this district. There is an uneven distribution of jadeite beads, which are considered as an indicator of social stratification in the Jomon period, between areas. Furthermore, there are different levels of varieties in shapes of burial pits. These results imply that local societies had different levels of social inequality or complexity, and different social or symbolic meanings of burial customs, which leads me to propose an alternative understanding about local meanings of burial systems.

Napolitano, Matthew (University of Oregon) [180] Colonization of the Land of Stone Money: Resolving the Unclear Origins of Early Settlements of Yap, Western Caroline Islands

The prehistoric colonization of remote islands in Micronesia represents some of the most significant series of diasporas in human history. While archaeological and genetic research is shedding new light on the origins and timing of what were clearly multiple and chronologically disparate entries into the western and eastern Micronesian archipelagoes, many of these colonizing ventures are poorly understood. This is particularly true of Yap in the Western Caroline Islands. Unlike the Palau and the Mariana island groups, where robust archaeological and linguistic datasets reveal a relatively clear picture of settlement between ca. 3500–2800 cal BP, limited investigation and conflicting lines of evidence archaeologically, linguistically, and paleoenvironmentally, have resulted in significant gaps in our understanding of human settlement in the western Pacific. Identifying sites in Yap pre-2000 BP, alluded to by paleoecological data, has great potential for altering existing models of colonization and long-distance interisland interaction in Remote Oceania. This paper presents the results of the first systematic archaeological survey on Yap dedicated to identifying evidence for colonization.

Napolitano, Matthew [4] see Hill, Mark
This investigation is an archaeological analysis of the lower Rimac River Valley, located in the Peruvian Central Coast, where several irrigation channels that were originated from the river allowed the cultivation of a great extension of land in this valley. The objectives of this study were to establish the occupation sequence and settlement pattern in those artificial valleys in precolonial times and their relation with this irrigation system. Modern and old maps and aerial photos were used in order to examine and make a map of the area before the modern expansion of the city during the twentieth century that destroyed the precolonial irrigation systems and numerous archaeological sites. The investigation also comprised the analysis of colonial documents from the sixteenth to the early nineteenth centuries, trying to establish the political and territorial organization of the indigenous population in the late precolonial period. Part of this investigation was submitted as a PhD thesis at the University of Calgary in 2013.

In Moquegua the monumental provincial center of Cerro Baúl was ritually abandoned circa 1050 CE. It is at this time that Wari affiliated occupation of the sacred summit ended and production of imperial Wari goods ceased in the region. This evidence does not indicate that the empire collapsed at this time, but instead suggests when Wari officials chose to withdraw from this frontier region. Why did they leave? In this paper we discuss the changing population dynamics in Moquegua at 1050 CE and how a number of factors may have undermined the legitimacy of Wari elites, who relied heavily on ritual and supernatural sanction to dominate the valley. We describe the nature of Wari ritual practice in previous periods and how it may have been a key strategy in Moquegua for incorporating local, subordinate elites. Yet, by 1050 CE much had changed. Settlement patterns shifted and alternative environmental response to changing climate, confirming observations from other disciplines that the magnitude of modern impacts exceeds past temporal and spatial patterns. The corresponding impact on archaeological resources is great, requiring a renewed effort to document threatened sites while also working with local and state governments to develop mitigation strategies. The Middle Atlantic Archaeological Conference (MAAC) has supported the creation of the "Climate Change Response Network for Mid-Atlantic Heritage Resources," which acts as an online archive of survey and salvage projects. A result of this project is the recognition that archaeologists in the region have monitored sea level rise for decades, their work providing a unique framework for the modeling and prediction of future impacts. The network highlights the predicament of archaeology in this time of climate change: accelerated research and discovery in the face of catastrophic loss.

In this study we analyzed (71) samples comprised of various types of speleothems (Stalactites, stalagmites, flowstones, cave pearls) collected in various locales in Belize (Macal, Barton Creek, Pine Ridge, Roaring Creek, Cave’s Branch, and Sibun Valley). Our samples came from two separate expeditions, the Belize Valley Speleothem Project provided by Dr. Holley Moyes (U.C. Merced), and Xibun Archaeological Research Project provided by Dr. Polly A Peterson. Our results indicate that INAA can be useful in profiling the variation within samples from the same cave; and the variability between different caves, thus making INAA a viable method of sourcing lithic materials.

Since the late 1960s, flotation has been used to extract macrobotanical remains from soil. Machine-assisted flotation is a popular method; however, very few publications discuss the logistics of designing and constructing such a machine (notable exceptions include Hunter and Gassner 1998; Nesbitt 1995; Pearsall 2015; Shelton and White 2010). Flotation machines are often built in the country of research. The availability of local resources impacts the design, construction, and operation of a flotation machine. This paper aims to provide guidelines and considerations for fellow archaeobotanists and archaeologists who are contemplating building a flotation machine, while providing examples from the author’s own experience in southeast Arabia, specifically northern Oman. This paper covers pragmatic considerations during the design phase, practical suggestions for sourcing material and physically constructing a machine, and, finally, discussions on the role of local engagement. Using southeast Arabia as an example, this paper explores how continuous integration of local community members into archaeological research has fostered long-term and sustainable community engagement.

The occurrence of "foreign" ceramic materials as well as the breakage and transport of speleothems during ancient Maya cave visitations have become an increasingly well-documented phenomenon (Brady et al. 1997). This phenomenon has raised several questions such as the spatial and temporal extent of these interactions, practices, meaning and specifically what does all this tell us about the relationship between Maya polities and proximal or distant caves. Geochemical analysis of geological samples by Instrumental Neutron Activation Analyses (INAA) is a very common and reliable practice. In this study we analyzed (71) samples comprised of various types of speleothems (Stalactites, stalagmites, flowstones, cave pearls) collected in various locales in Belize (Macal, Barton Creek, Pine Ridge, Roaring Creek, Cave’s Branch, and Sibun Valley). Our samples came from two separate expeditions, the Belize Valley Speleothem Project provided by Dr. Holley Moyes (U.C. Merced), and Xibun Archaeological Research Project provided by Dr. Polly A Peterson. Our results indicate that INAA can be useful in profiling the variation within samples from the same cave; and the variability between different caves, thus making INAA a viable method of sourcing lithic materials.
Since the beginning of archaeological research, style has been used to characterize and define numerous aspects of social interaction and complexity, including communities of practice which structure ways in which elements of material culture are transmitted. The persistent transmission of knowledge through time and space implies a long lived community of practice. Chupadero Black-on-white, produced in central and southeast New Mexico, was possibly the longest lived of all the Black-on-white wares and the most extensively exchanged. Yet for all of its longevity and ubiquity in the Southwest, the design style, based on morphology and painted decoration remain constant. In this research, I conduct an attribute analysis of decorative design and morphology of Chupadero in order to assess to what degree, if any, change in style occurs. I explore the geographic dimensions of this long-term production and the long-distance exchange of Chupadero Black-on-white. I then discuss the communities of practice, collective memory, and the communities of identity implied by this long term production, which started in the late Pueblo II period. Finally, I discuss the implications of the production of this ware in the context of exchange in the greater Southwest.

During the fourth millennium BC a number of considerably big settlements have developed in the territory of modern Ukraine, thus constituting the biggest sites in Europe at that time. Mostly investigated only as single entities these “megasites” have never been considered thoroughly as part of the whole landscape of Trypillia settlements. Some scholars have argued that these could have been examples of early formed urban centers (aka “proto-cities”), others, instead, proposed that these were big villages without a clear social hierarchy visible in site organization and structure. This paper will present the spatial quantitative analysis of the whole database of known Trypillia sites and will propose a new perspective of seeing the megasites as locations for seasonal gatherings rather than permanently occupied urban-like central-places. Moreover, and more generally, the paper represents an attempt to exploit the great potential of large datasets to answer “bigger” research questions without getting lost in dry and meaningless numbers and statistics.

Neeley, Michael (Montana State University) and Steven Swinford (Montana State University) [151] Complete Vs. Broken: Exploring Assemblage Variation in Two Natufian Sites from Jordan

Archaeological sampling of lithic assemblages is an important process for characterizing the makeup and range of variability of these materials. These characterizations often focus on complete pieces due to the greater number of variables that can be recorded and the uncertain utility of incomplete data. But do complete pieces adequately characterize assemblage variability? Are these samples capturing the same range of variation found in broken pieces (e.g., proximal pieces)? This paper explores variation in metric measurements (e.g., width, thickness) of blades/bladelets from two Late Natufian sites in west-central Jordan. First, we attempt to address the question of how many pieces are necessary to encompass the range of variation within the assemblage (a sampling problem). Should assemblages be sorted or stratified by certain variables beforehand or are random samples sufficient? Second, are measurements of complete and proximal pieces representative of the same population or does a focus on complete pieces yield a sample significantly different from the proximal blade population? Preliminary results indicate differences between the two samples and we address the ways in which assemblage characterizations can be biased by sampling and a focus on limited classes of material.

Neff, Hector (California State University–Long Beach), Sachiko Sakai (California State University–Long Beach), Brendan Culleton (Penn State) and Douglas Kennett (Penn State) [182] Late Formative Through Early Classic Occupation History in Eastern Soconusco

Neff, Hector (California State University–Long Beach), Sachiko Sakai (California State University–Long Beach), Brendan Culleton (Penn State) and Douglas Kennett (Penn State) [182] Late Formative Through Early Classic Occupation History in Eastern Soconusco

Deposits in the mangrove zone south of Izapa have abundant debris from salt and ceramic production, consistent with pyro-industrial specialization based on fuel wood and other resources. These archaeological deposits are also relatively intact, and thus they offer the opportunity to test hypotheses about demographic trends derived from more chronologically ambiguous deposits of the coastal plain and piedmont. A regional demographic bottleneck has been suggested for the Early Classic, when survey data indicate virtually no one was living on the coastal plain. This contraction may have started even earlier, since prevailing interpretations suggest a peak in monumental activity at Izapa during the Late Formative, with no new sculptures erected during the Terminal Formative. In the mangrove zone, demographic contraction seems to begin around AD 1, and there is very little use of the zone during Early through Middle Classic times. Thus, the trajectory of industrial activity on the lower coast seems to follow Izapa and coastal plain population trends. This paper presents stratigraphic evidence, chronometric dates, and ceramic data that support this interpretation of the Late Formative through Early Classic occupation history.

Neff, Hector [81] see Lohse, Jon

It has long been claimed that the Jomon-era cultural and ritual system was probably replaced by a new early farming cultural system (Yayoi Culture) brought by immigrants from the Korean peninsula. Recently, however, Japanese archaeologists have been working to determine the variability of ritual practices in each region of the Japanese archipelago. This paper analyzes the transformational process of ritual items (e.g., clay figurines and stone implements) of the Tohoku (northeastern part of main Island) region in the first millennia BC, in which the Jomon cultural ritual system entered its final phase on the main island of the archipelago. Based on this case study, I am proposing a revised model of the social process which transformed the ritual system from that of a hunter-gatherer to an agricultural society.

Negus Cleary, Michelle (University of Sydney AUSTRALIA) and Elizabeth Baker Brite (Purdue University) [25] Kalas and Urbanism in Western Central Asia

Kalas (qalas), as iconic fortified enclosure sites, were nodes within dispersed and low-density settlement patterns of Central Asian oases. The largest kalas functioned as the equivalent of urban centers for mobile, agropastoral societies. A complex and diversified system of agropastoral subsistence and production strategies were employed within the oases in response to extreme climatic and environmental conditions. This paper will focus on the transition from the Late Antique to Early Medieval periods in the oasis of Khorezm that saw major changes occur in the Khorezmian settlement pattern. Kala sites were abandoned, some were reused for different activities, and new kalas were established on smaller scales. The hydrological system underwent major changes, with some new areas of the oasis being occupied. There were far fewer large enclosure sites, and this period saw a modification of the kala as a type and the beginnings of centralized urbanism with the Arab conquests of the eighth century AD. Groups with different socioeconomic organization inhabited the oasis and constructed different types of sites. This paper will examine themes of permanence, tenure, abandonment, mobility, and decentralization.

[59] *Entangled Prehistories: A Physics Idea and Culture Change in Chaco Canyon*

Recent work by physicists on “entangled histories” offers archaeologists an alternative perspective for studying prehistoric culture change. The conventional wisdom of archaeology’s contribution to the broader discipline of anthropology is its ability to study change over long spans of time. In recent years, archaeologists have done this using increasingly precise dating techniques combined with processual, multi-scalar, and comparative approaches. The concept of entangled histories expands this repertoire. It says that any entity’s past cannot be described by a single chronology. Rather, the past is created by multiple chronologies intertwined with each other. This paper assesses the utility of this idea of entanglements for studying prehistoric culture change in Chaco Canyon, New Mexico.

[17] *Decolonizing Archaeological Methodologies: The Making and Remaking of Research Practices with Tribal Communities*

Archaeological research has traditionally been a top down scientific process of knowledge production with little involvement from the descendant communities whose cultural resources and heritage are under investigation. With the incorporation of feminist, postprocessual, postcolonial, and Indigenous theories in archaeology, the discipline has become more accessible and accountable to publics and communities outside of the specialists who conduct archaeological research. In this presentation, I will outline the approach to Indigenous archaeology that I developed in collaboration with the Federated Indians of Graton Rancheria for my dissertation research at Tolay Lake Regional Park. This approach involved establishing and adhering to core research values and working with tribal committees to ensure that the research is relevant and worthwhile to the tribe. I will show through this case how research that is coproduced with Indigenous communities can lead to richer understandings of the past and how the products of this research can positively impact the lives of many different peoples today.

[47] *Caught between a Rock and a Soft Place: Using Optical Dating to Date Ancient Clam Gardens in the Pacific Northwest*

Rock-walled archaeological features are notoriously hard to date, largely because of the absence of organic material for radiocarbon dating. This study demonstrates the efficacy of dating clam garden walls using optical dating, and uses optical ages to determine how sedimentation rates in the intertidal zone are affected by their construction. Clam gardens are rock-walled, intertidal terraces that were constructed and maintained by coastal First Nation peoples to increase bivalve habitat and productivity. These features are evidence of ancient shellfish mariculture on the Pacific Northwest and, based on radiocarbon dating, date to at least the late Holocene. Optical dating exploits the luminescence signals of quartz or feldspar minerals to determine the last time the minerals were exposed to sunlight (i.e., their burial age), and thus does not require the presence of organic material. Our optical ages suggest that clam garden walls on Quadra Island, British Columbia, were built incrementally within the last two millennia, and increased sedimentation rates in the intertidal zone by up to fourfold. The dating of rock-walled marine management features such as clam gardens and fish traps can lead to significant advances in our understanding of the intimate relationships that Indigenous peoples worldwide developed with their seascapes.

[61] *The EAFWG and Multi-scale Analyses of the Use of Fauna during the Archaic Period in the Interior Eastern Woodlands*

The formation of the Eastern Archaic Faunal Working Group (EAFWG) has brought together zooarchaeologists responsible for the analysis and interpretation of a large number of significant faunal assemblages from Archaic period sites. Our collaboration has led to the preservation of nearly 60 significant faunal datasets from 21 archaeological sites in several areas of the U.S. interior Eastern Woodlands in the Digital Archaeological Record (tDAR). This collection of datasets has been integrated using tDAR ontologies, which allow us to compare and combine datasets created in different formats by different researchers. After addressing the comparability of these datasets, we are examining research questions that have broad significance to understanding the Archaic Period. Temporal and spatial variability in reliance on aquatic resources by Archaic peoples has long been noted, and differences have been attributed to environmental variability and climatic change, to patterns of population growth and aggregation, and most recently to cultural preference, practices and interaction. The EAFWG tDAR collection of datasets allows us to explore differing use of aquatic resources.
as well as how these contrasts relate to potential causal factors at local, subregional, and regional scales. Our research provides important perspectives on the natural and cultural landscapes of the Eastern Archaic.

Newlander, Khori (Department of Anthropology & Sociology, Kutztown University) [79]
Using Sourcing Studies to Examine Paleoindian Lithic Technological and Socioeconomic Organization in the Great Basin
In many regions of the world, archaeologists use sourcing studies to document patterns of toolstone procurement and conveyance that, in turn, inform their understanding of prehistoric lithic technological and socioeconomic organization. This is certainly true of Charlotte Beck and George T. Jones’s research in eastern Nevada, where the sourcing of obsidian, andesite, and dacite artifacts has figured prominently in their study of Paleoindian lifeways. In this paper, I briefly reflect on Beck and Jones’s contributions to sourcing methods and their use of sourcing studies to examine Paleoindian lithic technological organization and mobility. Recently, I worked with Beck and Jones to develop an analytical protocol for sourcing chert artifacts in eastern Nevada, as the next step in the lithic analytical program they started thirty years ago. Thus, I conclude by describing the potential for chert sourcing studies to augment the understanding of Paleoindian lithic technological and socioeconomic organization Beck and Jones have built based on the sourcing of volcanic artifacts.

Newman, Sarah (James Madison University) [392]
First Steps and Finishing Touches: Imaging Techniques and Ancient Maya Bone Craft Production
Although archaeology focuses on the things that endure, the means by which we study those things is constantly changing. Recent technological developments have revolutionized how we assess chronology, our abilities to identify smaller and smaller traces of organic and inorganic residues, and the ways we share our data among ourselves and with the public. This presentation details a series of imaging techniques, used alone and in combination, that reveal details of ancient bone crafting methods, often at new scales or from new perspectives. I review the contributions of microscopic and macroscopic imaging, Reflectance Transformation Imaging (RTI), and 3D modeling software (such as Agisoft PhotoScan) to understanding ancient Maya bone crafting practices. Seeing ancient things in new ways highlights not only specific production methods, but also the specialized knowledge and practiced skills required during hunting, butchery, crafting, and finishing to transform parts and pieces of animals from dietary resources to raw materials and from skeletal elements into finely crafted bone tools or ornaments.

Bioarchaeological Conservation and Ethics in Mainland Southeast Asia
This paper identifies the ethical and conservation challenges of working with skeletal remains from mainland Southeast Asia, a region including Thailand, Cambodia, Laos, Vietnam, and Myanmar. Due to the increasing political rest experienced over the past decades, researchers have had better opportunities to work in these countries, with relatively easier access to appropriate permissions to excavate archaeological sites. The firsthand accounts of bioarchaeological research conducted by the authors, including current field and laboratory analysis issues will be discussed. Some of the challenges within local bioarchaeological practice include the development of local expertise, limited finances, challenging environmental and storage conditions, a lack of resources and specialized equipment, and restricted access to materials and sites. These concerns can limit the methods available for the analysis of human skeletal remains in this region, sometimes hampering chances for publication with the expectation of the use of new technologies in bioarchaeology. For example, the practice of display of human remains in open-air museums, and local museums run by the local communities in Southeast Asia will be discussed. This presentation also identifies several examples of recent challenges with bioarchaeological ethics, including exporting bone samples for analyses to other international universities.

Ng, Laura [36]
Transnational Linkages: The Archaeology of the Late Nineteenth- and Early Twentieth-Century Chinese Railroad Workers
Archaeological studies of Chinese railroad sites in the American West tend to be site-specific and rarely position material assemblages in a global or diasporic context where both people and goods moved back and forth across the Pacific Ocean. This paper examines how transnational frameworks can help archaeologists better interpret the material culture found at Chinese railroad sites by drawing on the fields of Asian American studies and historical archaeology.

Managing Cultural Resources within Protected Areas
A goal for cultural heritage management is to advance the comprehensive preservation, conservation and management of cultural resources, defined as the broad array of stories, knowledge, people, places, structures, objects, and the associated environment that contribute to the maintenance of cultural identity and/or reveal the prehistoric, historic and contemporary human interactions with an ecosystem. Involving the state and local community in regular management, activities, and projects should always be an important part of a national government’s goals and objectives. Community support, or the lack thereof, can make or break a project, but public involvement benefits both the government and the community. The public often has misconceptions about what archaeology and historic preservation really entail, and utilizing local volunteers and state government representatives exposes the public to what the field is really about, helping to bridge the gap between the agency and concerned community groups.

Nicholas, George (Simon Fraser University)
Significant differences exist between Western and Indigenous societies, and their respective knowledge systems, worldviews, modes of explanation, conceptions of time, and nature of material culture. Acknowledging these is essential to making sense of contemporary claims around Indigenous cultural property, especially in museum settings. For many indigenous peoples, cultural property was and is defined and enacted in daily life (objects may be animate), with distinct expectations and responsibilities for what is considered proper care of objects and information. Importantly, the division of property into “tangible” and “intangible” forms may be unfamiliar, indeed even artificial or unnatural when applied to indigenous contexts. This presentation focuses on the benefits of, but also ethical and intellectual property concerns about the display, use, storage, replication of indigenous heritage in museums, including 3D scanning and printing, “virtual repatriation,” and other new technologies.

Nichols, Deborah (Dartmouth College)
Interaction was important early in the development of complex societies during the Formative period in Mesoamerica. Despite its small size, Altica was integrated into Early-Middle Formative exchange networks as it obtained some ceramics, obsidian blades, and ornaments of exotic stone and exported Otumba obsidian that began to circulate widely at this time. There likely were other early villages within proximity to the Otumba source engaged in procuring obsidian for trade to other sites, but Altica is the only one so far identified. We discuss our multi-technique approach to composition analysis of Formative ceramics and obsidian. To place Altica in a regional context, a goal of the project is to develop a compositional data base, not just for Altica, but for the Basin of Mexico and for Central Mexico more generally. This represents one of the largest compositional studies for the Formative period in Mesoamerica. Our goal is to develop a foundation for subsequent researchers to build on.

Nicodemus, Amy (University of Wisconsin La Crosse) and John O’Shea (University of Michigan)
Pecica Șanțul-Mare (Romania) was a major trade center during the Middle Bronze Age. Its inhabitants participated intensively in regional and extra-regional exchange networks, bringing a range of utilitarian and prestige goods into the Lower Mureș valley. The quantity and diversity of imported items at Pecica far exceeds that of contemporary settlements in the region, with goods often by-passing other Mureș Culture communities along the major trade routes. Pecica also appears to have had preferential access to some valuable extra-regional raw materials, such as unworked Baltic amber and marine shell. Not only did Pecica serve as an entrepôt, but it was also a major producer and exporter of prestige items, including fine metalwork and composite ornaments prominently displayed by elites and local leaders. Control over these exchange networks was critical to Pecica Șanțul-Mare’s role as a regional center, serving as a gateway community to the Lower Mureș region. However, it did not develop gradually into this major economic node over time. Rather, control of regional trade was a significant consideration for its establishment, especially for mineral resources upriver in the Transylvanian highlands.

Nicholas, Richard (California State University Los Angeles), Anthony Morales (California State University Los Angeles) and Melanie Saldana (California State University Los Angeles)
Analysis of Ground Stones Found at a West-Central Mojave Desert Rockshelter Site
CA-SBR-14 is a rockshelter site located in the South Range of Naval Air Weapons Station (NAWS), China Lake in the west central Mojave Desert. Subsurface investigation of the site has provided important contextual data that challenges previous interpretations of prehistoric use of the area. Artifacts collected include milling slabs on the surface of the site, fire-affected fragments that were recovered from subsurface test units, and three handstones that appear to have been deliberately placed with other artifacts in an unusual feature. Analysis of collected ground stone flakes provides possible evidence of ground stone manufacture. Compared with plant and coprolite data, this poster provides important insights into prehistoric food processing at the site.

Nicolay, Scott (University of California, Merced)
Over, Under, Sideways, Down: Cave Shrines and Settlement in Southwest Prehistory
Although evidence for the use of caves and earth openings as shrines in the North American Southwest begins in the Pleistocene, this practice intensified greatly after the development of agriculture. Many of the region’s major shrines appear divisible into three categories: controlled shrines, to which access was restricted by surface architecture; contested shrines, which were located equidistant between two or more surface sites; and remote sites, which may have marked cultural boundaries. Cave shrines may have defined both center and periphery of settlements. If so, this practice represents another parallel between paradigms of cave ritual in the Southwest and Mesoamerica.

Nicolaic, Erica  
Consumption Patterns of a Pre-World War II–Era Japanese American Community on Terminal Island  
Transmigration and diaspora are topics which archaeologists have recently begun contributing to in more detail (Lilley 2004, Ross 2010, 2011). These concepts assert the fact that cultural interchange exists when immigrant or migrant communities settle in new lands, and rejects the idea of homogenization, acculturation, or complete resistance and can be addressed in archaeology via consumption. Consumption patterns, though seemingly unimportant, have the ability to shed light on almost every aspect of life: social, economic, and cultural (Deetz 1996; Praetzellis and Praetzellis 2001; Scatchel 1992). Studying immigrant and migrant communities via consumption gives the ability to contribute much to the theory of transmigration and diaspora and the broader understanding of immigrant and migrant communities in the United States (Voss and Williams 2008). The proposed research consists of an archaeological study of the pre-World War II–era Japanese-American community at Terminal Island in Los Angeles and investigates the Japanese-American experience in order to understand the ways this community interacted with each other and their neighbors economically, socially, and culturally.

[115] Artificial Cranial Modifications of Human Remains from Archaeological Sites in China  
This paper explores artificial cranial deformation from two archaeological sites in China. Jilintai cemetery (2500–2000 BP) is located in Yili region, northwestern Xinjiang, and Yingpan cemetery (2000–1500 BP) is located in Yuli county, northeastern Xinjiang. A total of 253 crania (202 from Jilintai and 51 from Yingpan) were examined in this study. Crania were measured according to the Standards Book, and 11 angles and 6 indices were calculated. Statistical analyses include discriminant function analysis and the one-way ANOVA test. The results show that 23 crania (female = 10, male = 13) were deformed in Jilintai. In contrast at Yingpan, 22 crania (female = 15, male = 7) were deformed. The interpopulation comparison shows that all crania from both sites exhibited circumferential modification, indicating a similar cultural tradition. The significant differences between modified and unmodified crania were on measurements of cranial length and breadth, and angles of the vault, while there are no significant differences in facial morphology. The intra-population comparison suggests that generally females display more pronounced deformation than males. In addition, individuals with deformed crania possess more prestigious burial goods, especially females, than those with normal cranial morphology. This may suggest that individuals with deformed crania enjoyed higher social status in their community.

Nielsen, Axel (CONICET Argentina)  
[134] In the Middle of Nowhere: Internodal Archaeology and Mobility in the Southern Andes  
"Internodal archaeology" contributes to research on social processes through the study of the areas between nodes, i.e., places where human activities tend to cluster (sites or densely settled areas, depending on the scale). By focusing on the material traces directly generated by people’s movement, this approach holds great potential for addressing questions regarding who traveled across regions and why. These possibilities are illustrated through research conducted in three internodal areas of the Atacama Desert (the coastal stripe, the Upper Loa River, and the high Andean lakes). It is argued that interregional mobility during late prehispanic times involved—at least—three practices with different agents, i.e., coastal individuals visiting the interior, local and foreign pastoralists traveling with caravans in different directions, and task groups from communities of the Loa river basin moving to the high puna in the summer. We discuss here the goals and archaeological signatures of each one of these mobility patterns.

Nielsen, Jesper (University of Copenhagen)  
[288] An Army of Winged Souls: Butterfly Iconography in Teotihuacán  
In no other culture in ancient Mesoamerica do we find butterflies represented as frequently as in the iconography of the central Mexican metropolis of Teotihuacán (c. 0–600). Appearing in mural art, painted on stuccoed tripod vessels and in the shape of clay adornments attached to incense burners, these winged creatures undoubtedly held a special place in Teotihuacán worldview and religion. Interpretations of butterfly symbolism at Teotihuacán is often based on analogies with Late Postclassic Aztec culture, emphasizing the belief that butterflies are related to the souls of deceased warriors. In this paper I examine Teotihuacán butterfly iconography in the perspective of one of the greatest natural wonders of the Americas—the yearly return of billions of monarch butterflies to the central Mexican highlands—and I suggest that this spectacular phenomenon played a central role in the initial development of the idea of the transformation and return of the dead in the shape of butterflies.

Nielsen, Kristina (University of California, Los Angeles)  
[347] Aztec Aesthetics: Historical Reconstructions and Contemporary Cultural Recovery Movements  
Since the 1960s, Mexicayotl communities—or communities focused on Mexican Indigenous revivalism—have pursued an Indigenous cultural recovery. In the United States, these efforts have gained traction among Danza Azteca communities who increasingly employ prehispanic flutes, rattles, and other Mesoamerican instruments in their rituals and performances. Danza Azteca communities have been drawn on the lines of inquiry that parallel those of Robert Stevenson (1968:17, 18), including the study of archaeological artifacts; the study of texts, documents, and iconography from Central Mexico; and the study of contemporary practices in Indigenous communities that are viewed as survivals from prehispanic times. In this paper, I outline contemporary methodologies employed by these communities that have resulted in discoveries parallel to those in music archaeology. Drawing on nearly two years of fieldwork with the Los Angeles Danza Azteca community, I examine the intersection of reconstruction as an academic historical study vis-a-vis recovery. This paper offers insights into the growing phenomena of an “Aztec aesthetic” and highlights shared challenges faced by archaeologists and Danza Azteca communities.
Nielsen-Grimm, Glenna, Richard Terry (Professor Emeritus of Soil Science, Dept. for Plan), Bryce Brown (Brigham Young University), Deanne Matheny and Ray Matheny (Professor Emeritus, Department of Anthropology, Br) [229] Residue Analysis for Cacao in Southeastern Utah Ancestral Puebloan Ceramics, Montezuma Canyon, Utah In 2009, theobromine, a biomarker for Theobroma cacao, was found and reported in an analysis of cylindrical vessels from Chaco Canyon, New Mexico (Crown and Hurst 2009). Washburn’s positive results from ceramics recovered from Brew’s excavations at Alkali Ridge, Utah (Washburn et al. 2013) dating to the Pueblo I period, pushed the time depth of cacao use centuries earlier than the findings from Chaco Canyon. They suggest cacao was brought from the south as a journey food and later used as a food drink (Washburn et al. 2013:2012). They found theobromine/caffeine signatures in Abajo Red-on-Orange and other ceramics. Recent research (Crown et al. 2015) suggests the prehispanic Southwest use of cacao and holly-based drinks. Since 2013, we have tested ceramics from excavated locations in Montezuma Canyon, Utah, and an early collection of whole vessels from the Natural History Museum of Utah. We have positive results from residue tests of gray ware vessels, black-on-white bowls, redware bowls, and mugs. We believe we have developed procedures that address contamination of objects selected for residue analysis. Implications of this research are useful to researchers considering trade with, and influence of, prehistoric Mexican cultures on prehistoric Southwest populations.

Niespolo, Elizabeth (UC Berkeley), Warren Sharp (Berkeley Geochronology Center), Christian Tryon (Department of Anthropology, Harvard University), Tyler Faith (School of Social Sciences, University of Queensland) and Todd Dawson (Department of Integrative Biology, UC Berkeley) [371] Using C and N Stable Isotopes in Ostrich Eggshells to Develop Paleoenvironmental Records for Late Pleistocene East African Rockshelter Sequences The Middle to Later Stone Age transition in East Africa ~30–60 ka has been hypothesized as a response to increased resource risk due to cooler, drier Late Pleistocene environments with greater short-term variability. Local paleoenvironmental records are needed to test such hypotheses. Ostrich eggshell (OES) fragments are common in African archaeological sequences, are amenable to 14C and U-series dating, and their δ13C and δ15N values are known to correspond to the C isotopes of vegetation and mean annual precipitation, respectively. Here we show that primary stable isotope compositions are preserved in dated OES from GvJm-22 rockshelter at Lukenya Hill, Kenya, and Kise II, Tanzania for at least 50 ka. Mean 513C and δ15N values from ~14–3 ka at both sites indicate wetter environments during the African Humid Period, as expected. Prior to 14 ka, mean δ15N values at Lukenya Hill show an all wetting trend for the past ~50 ka, while at Kise II, precipitation oscillated, with a dry period during MIS 2. These results suggest distinct paleoenvironmental trends through time at sites separated by only ~300 m elevation, 3° latitude, and 350 km distance, suggesting a more complex mosaic of environmental change in the area than regional/global records resolve.

Nieto, Rubén (Universidad Nacional Autónoma de México) [145] La cerámica engobe naranja grueso de Santa Cruz Atizapán: Examen integral de un indicador arqueológico del intercambio durante el Epipaleolítico (ca. 650–900 dC) Durante el periodo Epipaleolítico, la cuenca del Alto Lerma experimentó una intensa interacción con distintas regiones, que le permitieron acceder a materias primas y productos necesarios para la subsistencia. Entre los productos que se han reconocido como evidencia de la relación señalada, destaca una cerámica que presenta características singulares como un engobe distintivo cuya superficie aparece craquelada. Se caracteriza a su vez por una pasta burda, laminada y con textura porosa y, especialmente, una gran cantidad de inclusiones de partículas de colores blanco, negro y café. Como se ha comprobado, esta ceramicá se ha detectado en numerosas regiones y, particularmente, en el valle de Toluca aparece en contextos arqueológicos de los finales del Clásico y llega a su máxima presencia para el Epipaleolítico. Los exámenes mediante técnicas físico-químicas han permitido identificar componentes que sugieren como posible procedencia la región de Ixtapan Tonatico, lo que podría vincularla a la producción y distribución de sal.

Nims, Reno (Portland State University) and Virginia L. Butler (Portland State University) [228] Sablefish (Anoplopoma fimbria) and Human Ecodynamics at Tse-whit-zen and the Salish Sea Zooarchaeological evidence from Tse-whit-zen indicates that juvenile sablefish, or black cod (Anoplopoma fimbria), played an important role in the village’s economy for ~2,200 years, but sablefish is scarcely mentioned in previous Northwest Coast archaeological research. The near-total absence of this species from other coastal sites in the Salish Sea cannot be explained by postdepositional destruction, screen size, sample size, or differences in zooarchaeological identification criteria. Thus, the pattern of uneven sablefish representation is likely related to social and ecological factors, which we explore in this presentation. We make synchrohnic and diachronic comparisons of sablefish abundance and body-size in two well-studied contexts, including two plankhouses, to investigate the ways that sablefish fit into the economy and social life of Tse-whit-zen. We also suggest that wider patterns of sablefish representation in the Salish Sea reflect changes in the biogeochemistry of sablefish over time.

Nimura, Courtney (University of Oxford) [28] Ships and Feet in Scandinavian Prehistoric Rock Art Scandinavian rock art was created from the Late Neolithic through the Early Iron Age. The majority of these images were produced in the Bronze Age—a period when postglacial isostatic uplift altered much of the Scandinavian coastline. Although the lexicon of rock art motifs is diverse in Scandinavia, this paper will focus on two key figurative motifs: ships and human feet. It presents results from two different studies. The first is a Scandinavian-wide GIS-based analysis that explores the distributions of ships, and considers their relationship to both the societies that made them and to changing coastal environments. The second presents new data collected during fieldwork on feet images at two sites: Järrestad in southern Sweden, and Boglùsa in central Sweden. These two projects employ different methodologies, yet they can both be used to pose a series of questions regarding the meaning and potential significance of human feet and ship motifs. A wide range of ideas and interpretations are explored, from visual punning to solar alignments to relationships with the changing environment. These interpretations are then connected to other rock art in the region and to theories of Bronze Age worldviews.

[187] (Re)Creating Monumental Space: The Everyday Use of Plaza Space at Aventura, Belize, from the Terminal Classic to Late Postclassic
During the comprehensive survey of the Maya city of Aventura, Belize, the Aventura Archaeology Project (AAP) identified 29 structures located within the confines of the site’s largest monumental plaza, the A Plaza. While Maya plazas tend to be open places for ritual performance and/or market exchange, the structures in Aventura’s A Plaza, constructed with "seemingly" no regard to the orientation and layout of the site’s other monumental architecture, suggests the possibility of an alternative narrative for some Maya plazas. A preliminary analysis of artifacts recovered from the site suggests that its occupants shifted regional connections during the Terminal Classic Period (post-CE 750), from the west (the Petén) to the north (the Yucatán). These connections were maintained through the Late Postclassic Period (ca. CE 1500) and provide insight to the construction of structures within the preexisting monumental space. This paper offers a preliminary discussion of the structures located within the boundaries of Aventura’s A Plaza. In doing so, this paper considers the everyday meanings of recreating or ritualizing the site’s monumental space within the backdrop of the social, political, and cultural changes that are occurring from the Terminal Classic to Late Postclassic periods.

[396] The Arrival of Belief: Religion and Art at the Extremities of the Silk Roads, AD 500–800
Most studies of Silk Road connections between East Asia and Europe focus on exchanges between China and the Roman and Byzantine worlds. In Japan however the eastern Silk Road terminus is regarded as Nara where the Imperial Palace gathered a wealth of treasures from Central Asia. At the other end of Eurasia, silk and Buddhist images discovered in northeastern Europe testify to the Silk Road’s significance beyond its commonly-accepted western terminus. This presentation seeks to insert these outlying regions into the Silk Road narrative by focusing on Japan and the British Isles, examining the role of religion and art in the period of great trans-continental change following the collapse of Roman and Han empires. Between the sixth and eighth centuries AD, Buddhism became established in the Japanese archipelago, stimulating the coalescence of indigenous beliefs into what became known as Shinto. Meanwhile, at the other end of Eurasia, Christianity spread through the British Isles, absorbing many elements of Celtic and Saxon spirituality. The arrival of these continental religions coincided with other important changes, including the demise of mound tombs as energy was redirected toward temple building in Japan and church building in Britain, closely related to the emergence of new nations.

Nixon-Darcus, Laurie (Simon Fraser University)

A morphological investigation of grinding stones recovered from the Northern Ethiopian site of Mezber revealed changes through time that likely were made to increase efficiencies. The need for efficiency may have been due to increasing needs (e.g., larger populations), an increasing reliance on grains in the diet, a desire to reduce grinding times). Through the phases at Mezber the archaeological evidence suggests a change in the quantity of grinding stones. The growing numbers of recovered grinding stones during the Middle Phase may also reflect increasing needs for the types of reasons suggested above. As the numbers decline in the Late Phase, there may have been a reduction in need for grinding, perhaps due to out migration from this rural area into more populated town areas. The grinding stones found at Mezber also reflect multifunctional tools used to grind both domestic grains and imported grains, as evidenced by different surface textures and starch grain analysis.

[199] Globalization in Southeast Asia’s Early Age of Commerce and the Contributions of Maritime Archaeology
Globalization has become a central concern of anthropology, and recently scholars have debated its definition, origins, and social implications. For example, some contend that it is a process associated with modern times while others argue that the first long-lived networks involving regular, trans-regional trade emerged between East Asia and the Mediterranean around AD 1000, and even earlier with other regions. It has become increasingly evident, based on a growing corpus of data, that long-distance economic and social interactions were very important in the ancient world in many different regions and had transformative effects on the communities involved. In this paper, we will examine current debates surrounding globalization and discuss how shipwrecks and other maritime archaeological sites can be used to investigate this phenomenon in East and Southeast Asia during the late first to mid-second millennia AD. In particular, we will highlight the Java Sea Shipwreck, a twelfth–thirteenth-century trading vessel thought to have been sailing from China to Java when it foundered in the Java Sea.

We evaluate the sensitivity of handheld X-ray fluorescence (pXRF) analysis in reliable identification of geological sources of copper artifacts with varying levels of corrosion. As part of a larger project, we analyzed 52 copper artifacts and dozens of copper samples from known geological sources with Laser Ablation-Inductively Coupled Plasma-Mass Spectrometry (LA-ICP-MS) (Hill et al. 2016), and analysis of the same source samples with pXRF. In both of these previous analyses, we have achieved a reclassification success rate; in fact the pXRF performs better on source samples than the LA-ICP-MS when raw data are the input (Hill and Nolan 2015). Here we apply this direct comparison to artifacts from Scioto Valley Hopewell sites. Each artifact and each source sample were measured with both instruments. We compare the classification of each artifact to likely geological source group among the two methods in order evaluate the reliability of pXRF as an independent tool for identifying the likely geological source of copper artifacts in archaeological context. The ability to successfully employ pXRF on copper artifacts opens new avenues of exploration to include large and fragile objects that are not normally amenable to LA-ICP-MS analysis.
Valley. The recognition and proper identification of these Browns Bench variants may be informative to archaeologists attempting to understand lithic reduction strategies, trade and exchange, and human mobility in the intermountain west.

Archaeologists have chemically distinguished the vitreous stone of the Rogerson Formation of southern Idaho, northeast Nevada, and northwest Utah as the Browns Bench Toolstone Source. Recent geologic research into the Rogerson Formation reveals that the deposits are much more variable than archaeologists recognize. Multiple potential toolstone beds with unique properties are present within the formation. This material is referred to as ignimbrite by geologists though some of it has the visual characteristics of obsidian, while other components appear similar to rhyolite. This paper outlines the variation in position, quality, character, and chemistry of the toolstone components of the Rogerson Formation in the Salmon Falls Creek Valley. The recognition and proper identification of these Browns Bench variants may be informative to archaeologists attempting to understand lithic reduction strategies, trade and exchange, and human mobility in the intermountain west.

Located in the northern Petén, Guatemala, the Maya site of Naachtun has been investigated since 2010 by a pluri-disciplinary French-Guatemalan team. Some of its goals aim to reconstruct the political history of the site and its spatial evolution through time, and to understand the management of local resources and the impact of anthropic activities on the landscape. Archaeological and environmental excavations and studies have been carried out in the city center and surroundings areas while a pedestrian survey has been conducted on a 2 km² zone centered on Naachtun with the purpose of understanding the settlement patterns—in particular the “rural” settlement—at a larger scale, resource management in relation with the different bajos closed to Naachtun, and the agrarian strategies adopted out of the city center. In this contribution, we will present the first results and interpretations of the LIDAR dataset with a focus on methodological aspects and comparisons with the traditional pedestrian survey program.

The widespread Birnirk culture is considered the source of the Thule and modern Inuit peoples across the arctic, based largely on legacy data from the 1930s to 1960s. Nonetheless, the archaeology of the Birnirk culture is understudied, with a 1970s archaeofaunal study near Barrow framing the culture as ringed seal specialists who depleted local seal populations and were forced to migrate northward. This proposition is called into question by our excavation of two houses in 2016 at Cape Espenberg that provides detailed evidence of Birnirk subsistence pursuits and allows comparisons with subsequent Thule occupations in the area. The focal resources for both time periods are drastically different. Dating ca. AD 1000–1250, the Birnirk faunal assemblages represent broad-based economies dominated by caribou and fox, along with seal. Just a century later, AD 1350–1450, a Thule occupation had an extreme focus on seals—over 80% of the identified fauna. The cause of this shift in resource focus is still under investigation, but may represent the immigration of Siberian peoples into Alaska. This change may also reflect the forcing of climate or ecosystem dynamics, coupled with the responses of social systems, as mediated by technology and ideology.

Deep Histories from Shallow Sites: Archaeological Investigations of Later Sites in Eastern Dibouti

Today, the Afar Region of East Africa is known for barren landscapes and some of the hottest average temperatures in the world. However, archaeological and climatological evidence suggests that over the last 3 million years the region has also exhibited temperate Savannah climates. This paper presents new archaeological data that chronicles the Oldowan through Islamic periods at the eastern edge of the Rift Valley. It begins the project of describing how deep historical processes intersected with the Islamic World along the Dibouti Coast.

Norman, Garth (ARCON, Inc.) [301]
Mesoamerican Contact on the Southwest Northern Frontier

Research by ARCON, Inc. over the past two decades, using multidisciplinary archaeology research tools and interregional comparative research, is providing regional boundaries to help construct histories of ancient people. The role of cultural exchange is becoming more apparent with intellectual data for exploring the rise of high civilizations in ancient cultures. A variety of research discoveries includes ancient turquoise trade between Mesoamerica and the Southwest (turquoise trace analysis beginning with the Toltecs), the Maya 260-day calendar, astronomy observatories, geometry and standard measure in art, architecture and sacred site planning. Sites studied include Baker village, Nevada, Parowan Gap, Paragohon Village, Capital Reef, and Rochester Creek, Utah. Mesoamerican comparisons include the sites of Izapa and Teotihuacán, Mexico.

Norman, Scotti (Vanderbilt University) [331]
Defining Identity during Revitalization: Taki Onqoy in the Chicha-Soras Valley (Ayacucho, Peru)

Investigations into Early Colonial Period status and identity of New World indigenous people have focused on assemblages of Spanish and indigenous goods in domestic and public contexts (Deagan 2003, Rice 2012). These studies have investigated how access to new goods and foodways may have reflected status among indigenous people, or how use of these imports in specific contexts were markers of changing identities. This paper presents excavation results at Iglesiachayqoq (Ayacucho, Peru), an Inka settlement where inhabitants participated in a 1560s revitalization movement called Taki Onqoy. In this movement, Andeans rejected Spanish cultural traditions in favor of a return to local deity worship. Rather than strategically exploiting Spanish goods as a marker of status, some inhabitants of Iglesiachayqoq actively rejected these imports in order to reaffirm their indigenous identities in the face of mass death, labor demands, and religious change. Utilizing ceramic, faunal, and spatial data, I argue that the presence of Spanish goods in specific households cannot be fully understood merely as rejection or acceptance vis-à-vis resistance or accommodation. Instead, patterns of use at Iglesiachayqoq were complicated by indigenous actors who were caught between outwardly conforming to Spanish mandates while simultaneously maintaining local identity through Taki Onqoy practices.

Armchair Archaeology: GIS-ing the 1733 St. Jan Slave Rebellion

The 1733 St. Jan Slave Rebellion in the Danish West Indies was an ephemeral event, from an archaeological perspective. Lasting only 8 months and diffused across the 20-square-mile island, the rebellion lacks a traditional archaeological signature even from battlefield methodologies. However, it is useful to apply archaeological questions to topics that are difficult to approach through dirt and shovel. This paper will discuss the application of GIS methods to analyze the slave rebellion from multiple temporal vantage points, including social conditions leading up to the rebellion, the events of the rebellion as it unfolded, and how the reorganization of the island in the aftermath of the event can be seen spatially.

Norwood, Alexandra (Arizona State University) [353]
Formal Open Space at Teotihuacán

The lack of large plazas at Teotihuacán has led archaeologists to claim that Teotihuacán was a city with very little public open space. There are, however, many smaller assembly areas distributed around the city. The Teotihuacán Mapping Project identified a large number of “plazas” in the city but the criteria were subjective and the data were never analyzed. I have filtered these data by applying a more formal definition of plaza than the initial field criteria used by the Mapping Project. After evaluating the public open spaces identified in Teotihuacán, I compare the level of spatial access to plazas for neighborhoods throughout the city. I also analyze the level of access residents had to markets and temples. Finally, I compare the amount of open space and number of plazas at Teotihuacán to other Mesoamerican cities to see where Teotihuacán fits in the spectrum of open space abundance and distribution in Mesoamerica. These results provide quantitative data on formal open space in Teotihuacán for the first time and will enable a broader integration of open space into examinations of both daily and ritual life in Teotihuacán.

Novak, Shannon (Syracuse University) [31]
Corporeal Congregations and Asynchronous Lives: Unpacking the Pews at Spring Street

This paper seeks to expose the “fallacies of synchrony” that often accompany the analysis of human remains. In approaching a cemetery, for example, we all too easily think of the bodies there as a “community,” even when they belong to different generations or geographic contexts. This simple point has major implications, especially for the bioarchaeology of urban landscapes. Here, chronologically disparate elements accumulate in vast mélanges, offering innumerable examples of the “non-contemporaneity of the contemporaneous,” an idea developed by Karl Mannheim (1928) and Alfred Schutz (1967) and now extended to archaeology by Gavin Lucas (2015). To escape the fallacies of synchrony and explore the shifting rhythms of city life, I turn to the case of the Spring Street Presbyterian Church in Manhattan. When the church burial vaults (ca. 1820–1850) were unexpectedly unearthed in 1967 and now extended to archaeology by Gavin Lucas (2015). To escape the fallacies of synchrony and explore the shifting rhythms of city life, I turn to the case of the Spring Street Presbyterian Church in Manhattan. When the church burial vaults (ca. 1820–1850) were unexpectedly unearthed in 2006, they seemed to represent a ready-made “congregation.” Yet Spring Street was actually a “catchment zone” of mingled and mangled temporalities. Though placed together in death, the bodies there had only occasionally crossed paths in life. By following some of their traces to and from the site, we may come to understand what it means to gather, work, and worship together in a society of strangers.

La arquitectura como indicador de integración social en la región de Yaxuná

Las investigaciones realizadas en Yaxuná y parte de su área circundante han mostrado un complejo panorama que se manifiesta en el número y variedad de asentamientos prehispánicos, así como en la coexistencia de patrones y elementos culturales de diverso origen. Partiendo de que la
archaeological project targeted on the material dimension of smoking practices in public parks of Santiago. We analyze how the material information available for study may not survive excavation intact. In a lab setting, photogrammetry and construction of 3D models of skeletal elements shows promise for augmenting and preserving teaching collections and rare materials. However, correct implementation of these techniques requires some degree of training and skill, as well as means to curate the large data files they produce. This paper will explore the potential positive and negative aspects of implementing digital curation methods for skeletal elements as well as data generated from osteological analyses. Ethical considerations will also be discussed.

Novakowski, Joshua (California State University, Chico), Chrissina C. Burke (Northern Arizona University) and Caitlin M. H. Bishop (Northern Arizona University)
[161] Zoological Analysis of Dog Pathology in the American Southwest: A Case for Interpreting Dogs as Companions as Opposed to Beasts of Burden
This presentation provides an update on prehistoric Southwest dog pathologies from the Museum of Northern Arizona’s curated faunal collections. Our zooarchaeological analysis of healed cranial lesions and tooth wear has not only expanded on earlier research accomplished in previous years but it has redefined the prehistoric dog’s role in the agricultural Southwest. Typically, domesticated dogs are identified as beasts of burden, which has inhibited sufficient and further analysis of the relationship between humans and dogs. Our research identifies that a lack of postcranial healed fractures and tooth wear evidence for dogs consuming human-like diets indicates that these animals may have been close companions of humans. In addition, the pathologies present on these canids convey a more dynamic and complex relationship between humans and dogs in the Southwest, one that had not previously been addressed by archaeologists. By combining zooarchaeological analysis with a chronology based on associated ceramics, we are able to describe the life of dogs in the Southwest in a more holistic manner. This information allows us to expand our understanding of how dogs were treated in Northern Arizona and creates a better potential to connect archaeological research with the interests of the public.

[121] Middle Pleistocene Lifeways in the Azraq Oasis, Jordan
This introductory paper to the session on research underway at the Shishan Marsh I site in the Azraq Oasis, Jordan presents an overview of the results of our paleoenvironmental, faunal, lithic and site formation analyses. A model of targeted and repeated use of the marsh is suggested. These results are situated within their historic and regional contexts and their implications for understanding the capabilities of Middle Pleistocene hominins are also considered.

Nowell, Sarah (University of Montana) and Ashley Hampton (University of Montana)
[50] The Bone Tool Assemblage from Housepit 54 at Bridge River
Excavations of Housepit 54 in the Bridge River village recovered an immense amount of cultural material that has contributed to a better understanding of the lifeways of its past inhabitants. The faunal assemblage contains a number of items tentatively identified as bone tools. This poster outlines the results of research aimed at understanding the effects of taphonomic and cultural processes associated with the formation of bone tool assemblages. Implications are drawn regarding activity variation across and between floors.

Nowlin, Jessica (Center for Archaeological Research, University of Texas at San Antonio)
[166] An Inland Response to “Orientalization”: Funerary Ritual and Local Practice in Central Italy
Greater trade and connectivity has often been associated with changes in cultural practice. This is particularly the case for the Orientalizing period for which the traditional view holds that objects, ideas and practices from the eastern Mediterranean exerted tremendous influence on local Italian communities during the eighth and seventh centuries BCE. This paper articulates the subtle differences between the presence of imported objects, changes in material culture, and changes in cultural practice for two inland sites within the Apennine region of the Abruzzo. It examines funerary assemblages from the necropoleis of Fossa and Campovalano through multiscalar bootstrap resampling of grave goods. The results show that although both communities experience increased connectivity during this period, the number of imported objects does not necessitate a change in funerary ritual. The frequent presence of imported buccero at Fossa shows strong ties with Etruria, but the local Iron Age funerary tradition was maintained. At Campovalano, although the number of imported objects is low, local ceramics and metal wares were employed within a new funerary practice of banquetting. Through this examination of local responses within the Italian interior, it further demonstrates importance of contextualizing the impact of greater foreign contact with an understanding of practice.

[246] Archaeology of Smoking Behaviors on Public Parks of Santiago, Chile
Cigarettes are the most numerous, ubiquitous, and tolerated form of trash on the urban landscape (Graesch and Hartshorn 2014:1). This statement has special meaning in Chile, leading country in cigarette consumption in the continent, especially between women and youngsters. Current approaches in the study of this phenomenon are based on interviews, but no material study has yet been conducted. Considering the differences between people’s discourses and actions, along with the abundance and high rate reproduction of cigarettes in the urban landscape, archaeology may provide an alternative approach to assess the smoking behavior(s). On this basis, it is a fertile ground for developing a study with a contemporary archaeological scope, particularly considering that the main weakness of tobacco consumption programs is monitoring. In this paper we present the results of an archaeological project targeted on the material dimension of smoking practices in public parks of Santiago. We analyze how the material information

[230] An Andean Mountain Shrine: The Case of Balconcillo de Avillay, Huarochiri (Lima, Peru)

One of the characteristics of ritual practices in the Andean Society is the presence of shrines in top of mountains related to local deities. These shrines formed part of ancient cultural landscapes that involved settlements, farmlands, cemeteries, and even complex road systems. Most of these ritual spaces are not regularly present in the archaeological record, yet they are frequently mentioned in ethno-historical accounts. This study presents a preliminary analysis of a shrine located in the top of a mountain between two archaeological sites: Balconcillo de Avillay and the Inka Road of Nieve–Canturillas. This shrine presents defined and complex architectural features shown by the presence of red wall painting and a large system of platforms that surround the top of the mountain. The shrine is also related with funerary structures associated with the site of Balconcillo de Avillay, a Late Intermediate site in the Upper Lurin Valley, in the Central Coast of Peru.

[328] The Current Work of “Sistema de Registro Público de Monumentos y Zonas Arqueológicas e Históricas” in Mexico

Not long ago a public register of moveable and immovable goods of Mexican cultural heritage was implemented. This system has been changed and modified to improve it. In general terms, the “Sistema Único de Registro Público de Monumentos y Zonas Arqueológicas e Históricas (SURPMZAH)” consists of an identification, description, and finally the assignment of an official number to the piece to assist in the recovery of the object if stolen. I believe the system has unsuccessfully transformed and ask the following question: Does the “Sistema Único de Registro Público de Monumentos y Zonas Arqueológicas e Históricas actually work? I suggest some ideas:

- Should the collections be verified frequently
- Dissemination between the investigators and general public
- The Register should be realized by each of the INAH delegations of Mexican Republic.

Núñez-Regueiro, Paz (Musée du Quai Branly, Paris) and John Janusek (Department of Anthropology, Vanderbilt University)

In the context of a pluridisciplinary mission organized by the French government in Chile, Argentina, Peru, and Bolivia in 1903, archaeological excavations were conducted in the monumental site of Tiahuanaco by the naturalist Georges Courty. During his three-month stay, he conducted extensive fieldwork in the Akapana mound, the Sunken Temple, the Kalasasaya, and the Chunchukala and Putuni structures. The material corpus unearthed is estimated to consist in over 1,400 artifacts, later divided between Bolivia and France. Courty also brought back to Paris a map of the ruins and excavations, some stamps and drawings, and a set of 61 photographs. Yet he failed to publish his results. Very early on, he was criticized for his lack of rigor and the destructions on the site, leading to a black legend of the French mission that prevails up to now. Our research aims at reasssembling the material archives of Courty’s work, following step by step his excavations and associating his observations with the current state of knowledge. We also review the objects held at the Musée du Quai Branly and the Museo Nacional de Arqueología, in an attempt to contextualize part of the collection, with a special emphasis on stone sculpture.

[48] The Search for the First Americans on Oregon’s Submerged Landforms: New Methods and Upcoming Research

Until recently, the search for Pleistocene-aged sites along Oregon’s coast has been mostly limited to subaerial landforms. In 2017 however, the search for early sites will reach past the subaerial and to Oregon’s outer continental shelf. These search efforts will be guided by using a GIS-based model that predicts the former potential of reconstructed late Pleistocene-aged coastal landscapes. We review our modeling methodology and how ecological aspects of Oregon’s coastal landscapes may have changed from the LGM to 12,000 cal BP. We also discuss upcoming fieldwork activities and research goals in the study of Oregon’s ancient submerged terrestrial landscapes.

[252] Mortuary Archaeology, Burial Practices, and Defining the Prehistoric Funerary Landscape on the Sunshine Coast, British Columbia
The ancestral burial practices among the peoples of the northwest coast of British Columbia have been well studied and documented by academics, heritage resource management professionals, and the First Nation Communities. Recent systematic surveys from archaeological impact assessments within the Sunshine Coast have yielded previously unidentified funerary archaeological features including various funerary petroforms atypical to this region. My aim is to revisit and define the types of archaeological features associated with burials and funerary rites that occur within the Sunshine Coast. Using existing research and examining the results from recent studies involving mortuary archaeology features on the Sunshine Coast, and northwest coast, I aim to explore and redefine what comprises the prehistoric funerary landscape.

O'Boyle, Robert (University Of Montana), Erich Longie (Spirit Lake Oyate, Tribal Historic Preservation) and Dianne Desrosiers (Sisseton Wahpeton Oyate, Tribal Historic Preservation)

Working Together to Save Our Culture: Creating a Tribal Register of Historical Places

Not long ago, the Spirit Lake Oyate and Sisseton Wahpeton Oyate were a single band, part of the Dakota Nation, living in the homeland we had occupied for millennia. Manifest Destiny, greed, and racism led to war and the establishment of reservations. Over the decades, the U.S. government separated within our people as they divided the land for settlement. Today, we are working together to bring our people back together based on the places that matter the most. Together the Spirit Lake Tribe and the Sisseton Wahpeton Oyate have collaborated with Heritage Consultation Solutions, the North Dakota State Historic Preservation Office, the Montana State Historic Preservation Office, and the Iowa Department of Transportation to develop the establishment of the Tribal Historic Preservation Registers on our Reservations. A Tribal Historic Register affords us proper participation in the national and state historic preservation programs—based on recognition of tribal sovereignty and respect for tribal cultural values. Developing a tribal register give us a powerful tool in preserving our culture. In addition, it has a strong spiritual component, which takes into consideration our practices and knowledge recognizing cultural and sometimes religious significance of places, and also properly records, preserves and stores this sensitive information.

Chemical Residues in Ceramic Household Containers of Santa Cruz Atizapán Site in the Valley of Toluca, Mexico

The results of analysis of chemical residues are presented in a set of 2469 samples of archaeological ceramic artifacts: 434 foreign vessels (Kabata 2010), 452 samples of various types of local vessels (Pérez 2002, 2009), 480 comales (Terreros 2013), 470 pots, pans, 334 cazuleas, 140 braseros, and 159 sahumadores. The containers correspond to the Late Classic and Epiclassic lakeside site occupation of Santa Cruz Atizapán, in Mexico State. Residues of protein, carbohydrates, fatty acids, phosphates, and carbonates were identified following the protocols used by the Laboratory of Archaeological Survey of UNAM (Barba, Ortiz and Pecci 2013; Barba, Rodriguez and Córdoba 1991). The analyses were registered due to the chemical enrichment resulting from normal and recurring use.

O'Briant, Kevin M.

Make History: Public Archaeology as a Way of Life

Archaeologists, historians, and other scholars in the heritage sector share a responsibility to public interpretation, education, and the dissemination of our current understandings of the past often while challenging myths and dominant histories that clash with those interpretations. Use of dense academic jargon in archaeological publications represents a significant barrier to public engagement with our work, and narrow specializations prevent us from deploying our investigative tools to illuminate the past in our own local regions and communities. This presentation highlights ways to engage the public in our own communities through heritage tourism, school outreach, adult education programs, plant identification walks, and neighborhood archaeology projects. By literally digging in our own backyards and leveraging peer-reviewed journals, student papers, and the “gray literature” generated by local cultural resource management projects, we can educate our friends and neighbors about the value of archaeological research methods, interpret the histories and prehistories of the landscapes we inhabit, and counter the erasure of indigenous people from local historical narratives.

O'Brien, Matthew and Danny N. Walker (University of Wyoming)

Communal Hunting and Teasing Out Signs of Cooperation in the Past

Communal hunting represents an intensification on particular prey species requiring significant cooperation and coordination, but identifying the social organization of this extinct mode of terrestrial hunting in North America leaves inquiries relegated to evidence derived from archaeology and ethnohistory. One tangible line of evidence used to identify social interaction between participants in hunting activity has been meat sharing. Yet observing meat sharing in the archaeological record has been stymied by the small scale of archaeological excavations and taphonomic processes that have destroyed functional evidence or obscured provenience. The Protohistoric Site of Eden-Farson provides a rare opportunity to examine meat sharing practices within the context of communal hunting. Past excavations revealed at least 10 discrete households with discrete refuse discarded within each of the structures and a well preserved faunal assemblage dominated by at least 174 Antilocapra americana. Faunal analysis established contemporaneity among households and identified the distribution of hunt proceeds among the participating families. In addition, X-ray fluorescence analysis on 50 obsidian tools with household provenience highlights the variation in procurement of obsidian through trade or direct procurement. These independent lines of evidence provide a more complete picture of Shoshone communal hunting participation as well as its organization.

Reconstructing Household Units Using Census Data and Plans
This paper will present the benefits and limitations of incorporating census data in the analysis of household units in San Juan, Puerto Rico, to archaeological investigations. The objective of this research is to study part of the population that resided in four streets, located west of the Cathedral in the capital of San Juan during 1910. The Cathedral Ward was selected with the understanding that the area was associated to elite residents since the sixteenth century. Specifically, this research is focused on studying the information recorded in the census form, which includes: professions and trades, race, nationality, family relationships and civil status. The Porto-Rico Board of Fire Underwriters plan from 1921 was used to identify the types of structures within these streets, the lot distribution, and number of stories for the buildings. By combining these sources, it was possible to reconstruct the number of families living in those streets, as well as social status. This analysis and interpretation allowed a layer of information to be added to the history of the building and the streets, which in turn can be correlated to existing archaeological data from completed projects.

Ochoa Castillo, Patricia

Contribuciones científicas de un coleccionista: Francisco Plancarte y Navarrete y el Preclásico

Las colecciones arqueológicas del Preclásico del Altiplano Central que se encuentran depositadas en el Museo Nacional de Antropología son una fuente de información fundamental para el conocimiento de este periodo, además de ser las más numerosas y completas en su tipo, ya que incluyen tanto las que proceden de las grandes excavaciones realizadas hace décadas (aunque desafortunadamente constituyen un porcentaje menor), como aquellas colecciones que llegaron al museo por adquisiciones diversas como donaciones y compras, formas que fueron comunes y legales antes de la Ley Federal sobre Monumentos y zonas arqueológicas, artísticos e históricos (Dario Oficial de la Federación de 6 mayo de 1972), que reguló estas actividades; así como decomisos y canjes entre museos. Por lo anterior, es de gran necesidad y responsabilidad extraer la mayor información posible de estas colecciones, en este caso particular del Museo Nacional de Antropología, ya que son colecciones que forman parte esencial de nuestro conocimiento sobre el Preclásico. Un conjunto que destaca entre éstas, es la colección que atesoró el Obispo Francisco Plancarte y Navarrete, personaje nacido en la segunda mitad del siglo XIX y quien fuera pionero en el conocimiento sobre el Preclásico.

Ochoa-Winemiller, Virginia (New Jersey City University)

Ethnoarchaeology, Domesticity, and Place-Making among the Maya

Using an ethnarchaeological approach, this paper explores the nature of the domestic built environment of rural Yucatán. Data from four Maya communities is used to assess the various mechanisms involved in the design and use of household architecture and test the assumption of cultural continuity in Maya housing from the ancient past to modern times. Geographic Information system-based analysis revealed spatial variations in number, shape, and construction materials of structures. Assessment of qualitative data showed a pattern of bounded extended families involved in the building of structures and space organization to establish a sense of community reminiscent to the sixteenth-century Cah.

Measuring Human Impacts on Islands Relative to Size

Archaeological research on islands worldwide demonstrates that initial colonists exerted substantial environmental impacts on local ecologies, ranging from the extirpation of native species to landscape modification. The degree of impact was dependent on a host of variables, including the kinds and number of introduced plant and animal species, the remoteness of settled islands, and extent of interaction between discrete landmasses. Yet, there is still much to learn about the consequences of human impact on different islands through time. Here we summarize current knowledge and analyze how ancient human impacts differentially affected islands of varying sizes across the world’s major island regions of the Pacific, Caribbean, and Mediterranean. Using principles derived from island biogeography, we compiled a database of archaeological instances of impact that include: 1) extinction and extirpation rates of native biota; 2) introductions of exotic species; 3) changes in floral and faunal biodiversity; 4) cases of landscape change directly related to human influence; and 5) the triggering of trophic cascades. Our results suggest that, while broad patterns are evident, the complex, localized interplay between humans and island ecosystems is less dependent on purely physiographic factors (here, island size) and more dependent on specific cultural trajectories of regional populations.

Gone Fishing: Evidence for Wide-Ranging Marine Exploitation in the Initial Settlement of Island Southeast Asia

“Fishing is much more than fish . . . It is the great occasion when we may return to the fine simplicity of our forefathers” (Herbert Hoover, Fishing for Fun and to Wash Your Soul, Random House, 1963). In the vast oceans separating continental Sunda and Sahul are more than 17,000 islands that make up the Wallacean Archipelago. Lying to the east of Huxley’s Line, these islands are characterized by unbalanced and depauperate terrestrial faunas but support some of the world’s most biodiverse marine ecosystems. While permanently inhabited today the size of many of these islands would seem to preclude occupation in the absence of agriculture or translocation of animals. Here we discuss recent excavation results from Eastern Indonesia which demonstrate the technological innovations and specialized marine adaptations which allowed wide-ranging exploitation of diverse marine resources, enabling persistent Pleistocene occupation on these small islands.

Natural Disasters and Interregional Interactions: The Establishment and Maintenance of Long-Distance Connections beyond the Northern Plains

Some 7627 calendar years ago, the Plinian eruption of Mount Mazama prompted small, dispersed bison hunting groups to abandon temporarily their traditional homelands and seek refuge among their distant relatives in the east. During their stay, they established new social ties and learned new technologies such as the use of stone boiling to extract nut oils. Returning to their homeland, they adapted this technology to extract bone grease and produce pemmican. As a reliable, storable, portable, and nutritious foodstuff, pemmican provided food security for the Northern Plains groups and gave them a valuable trade good to exchange with their eastern and western neighbors. As such, this natural disaster initiated a series of practices designed to maintain and expand the social safety net instituted during a time of need. From the simple exchange of goods and information to the development of extensive trade centers, the bison hunters and their neighbors established an ever-expanding network where economic, social, ritual and historical practices evolved in tandem with local developments. The objective of this presentation is to explore these developments in long distance interactions through time.

Journeys of Our Ancestors: Ceramic Colorants and Their Role in Understanding Migration in the American Southwest

Culturally defined color, and the technology used to produce it, is a hallmark of ceramics produced in the American Southwest prior to European contact. This characteristic (among others) was utilized to initially name, define and describe archaeologically recovered ceramic wares (e.g., Colton and Hargrave 1937; Fewkes 1898; Kidder 1931; Shepard 1931). The integration of conservation science and materials science approaches to this research is crucial to reveal nuanced interpretations of cultural and artistic motivations in production, which are key features toward understanding migration—particularly as colorant chemistry is related to culture, technology and condition. Further, technological advances in nondestructive analysis—including portable XRF—enable data collection from sample sets where NAGPRA, preservation and other concerns eliminate the possibility of destructive sampling. This paper reports results used to reconstruct manufacturing technologies to fabricate visually similar colorant layers associated with Hopi Sikyatki Polychrome and other Jeddito Yellow Wares, as well as highlights the effective use of portable XRF in identifying Point of Pines Polychrome and Gila Carretas Polychrome glaze-paint technologies. They provide insight into the transmission of people, material culture and technology across the landscape.

Hunting and/or Gathering: Gender and Fishing Practices in Polynesia

Fish and fishing occupy an intersection between meat and not-meat, hunting and gathering. As such, it does not fall into a clean division of labor by gender. Fish were acquired, processed, and distributed according to distinct sociocultural and sociopolitical codes of conduct that could result in death if not properly carried out: either accidental death from ciguatera toxicity or execution as punishment for breaking kapu/taboo. Tuna is well-known to be one of the most prized animals in Polynesian culture, and as such, is often studied in attempts to add political, economic, and ritual nuance to understanding foodways patterns. However, other fish should be given analytical consideration beyond being lumped together as reef fish. The pufferfish is one of the most commonly recovered fish specimens in archaeological contexts due to the exceptionally durable nature of its mouth bones. It has also ethnographically been noted as a fish that can be “gathered” by women and children due to the ease in collection once stunned, which is a stark contrast to the tuna hunts that men embarked on. This paper seeks to engage in a discussion about gender and fishing in Polynesia via the archaeological evidence from a site on Mo’orea, Society Islands.

Protecting Our Fossil Fuel: Bone Dates, Date-Assessment Protocols, and the Need for a Worldwide 14C Database

Large datasets of bone 14C dates are the foundation of integrative research in Late Quaternary faunal paleoecology, biogeography, paleogenetics, responses to environmental change, extinction occurrences and rates, and roles of climate and humans in the extinction process. This research requires strict date-assessment protocols including knowledge of material dated, taxon, sample chemistry, fraction dated, isotopic and C/N values. Currently, however, using 50+ years of 14C dates and implementing date-assessment protocols is difficult because a) the number of dates produced by different methodologies and technologies is large and have variable accuracy probabilities, b) date records are scattered in a plethora of publications and reports, and c) dating methods and sample characteristics remain poorly reported. Additionally, data are difficult to obtain from labs because of a) privacy agreements, b) incomplete record keeping, and c) record loss as labs close. We illustrate these difficulties and the urgent need for a 14C database and by a) noting variability in age estimates resulting from different dating methods, b) a brief critique of recent megafauna extinction research, and c) radiocarbon lab responses to information requests associated with this critique. Without a worldwide 14C database, integrative research, strict date-assessment criteria, and proper evaluation of interpretations are nearly impossible.

Oliver, Jeff (University of Aberdeen)

On Grounding “Margins” and “Marginals”: With Brief Visits to the Bennachie Colony (Scotland) and New Iceland (Canada)

Marginality is a perennial trope within the literature of settler societies. This paper is concerned with how people, past and present, become caught up with labels of “marginality,” among other forms of “identity history.” The theory is grounded in what are potentially conflicting ideas: one that places emphasis on fluidity and change, the other which takes a firm materialist stand. The apparent impasse is resolved by clearly identifying contexts—both material and historical—where temporary stabilities are achieved in the way people relate to each other and to the things around them. Such an approach helps ground our understanding of how “margins” and “marginals”—and host of other distinctions besides—become stuck and unstick. Our first stop is the uplands of mid-nineteenth-century Northeast Scotland, and the Bennachie Colony, where high rents and rationalized farming practices transformed wage-laborers, by turns, into “squatters” and “proletarian heroes.” Our second stop is turn-of-the century Manitoba, where settlers could be singled out as “undesirables” in one context but exhibiting widely shared values in another. How can this be? The answer lies at the juncture between people and things. As ever the devil is in the detail.

Oliver, José R.

Communities, Practices, Identities, and Transmission in the Orinoco River Valley: Inferences and Deductions from the Perspective of Mixed/Hybrid Ceramic Technologies and Styles

One salient feature of most precolombian ceramic complexes/traditions defined for the Orinoco Valley (Venezuela) is the prevalence and persistence of a minority of potters whose technology and/or style is in sharp contrast to the remaining and numerically dominant (normative) ceramic assemblage. Additionally, technological and/or stylistic elements that seem to originate or relate to separate ceramic traditions are often found “mixed” in the same potsherds or found in the same stratigraphic context. The traditional culture historic-centered, normative approach has struggled to account for such “atypical” minority wares and hybrid ceramics, usually relegating their presence to diffusion, without considering the diverse social dynamics and processes of transformation and agency entailed in “diffusion.” This paper addresses the question of whether current concepts of community and “practices,” and modes cultural transmission do provide a more productive and rigorous framework for the classification, analysis, and interpretation (deductions, inferences) of such persistent phenomena of ceramic hybridity, mixing, and convergence than the traditional normative cultural approach did. Underlying it all, is the question the identity (or is it plurality of identities?) of the potters and their users as expressed through ceramics.

Olsom, Sandra

Advanced Imaging of Saudi Arabian Petroglyphs: How Science Informs Art

How petroglyph images are recorded in the field is instrumental for analysis, archiving and publishing data. Being prepared to implement multiple advanced imaging techniques provides numerous advantages. Because lighting conditions, preservation and manufacturing techniques vary from one petroglyph locality to the next, having the flexibility to apply different imaging options as appropriate greatly facilitates data retrieval. Many archaeological projects require that the bulk of the image analysis is done after returning from the field, and it may be difficult, costly, or even impossible to revisit sites, so initially capturing the maximum amount of information is critical. Keeping a well-organized digital archive when different techniques are employed is also critical. Better imagery greatly enhances the readers’ comprehension of the scientist’s publications. Developing a website that shares images with colleagues around the world promotes new collaborations and accelerates scientific progress. In this study, high-resolution gigapan panoramic photography, reflectance transformation imaging, 3D laser scanning, and illustration directly from digital photos using a professional pen tablet are discussed. The examples given are from an ongoing research project over much of western Saudi Arabia, where a wide temporal range is represented and styles of creating the art vary from one region to the next.

Olson, Jan (University of Alberta)

The Heat of the Night: Ritual Purification and Curing in Mesoamerica

While daytime is often reserved for fairly mundane activities, most archaeological questions have focused on this time period. A wide variety of activities though cross the day into the nighttime, or occur only after dark. It is during the night when Mesoamericans re-created much of their mythology in ritualistic acts. This paper explores the use of household temazcales as nightly ritual spaces. These saunas were not only found in large communal spaces, but also in households. For what were the household temazcales used? Which goddesses added meaning to their practices? Interpretations from ethnohistoric and archaeological sources brimming with images and statements will help to elucidate these questions; fieldwork will add observational data.

Olson, Kyle (University of Pennsylvania)
Formation and Transformation of Communities in Prehistoric Khorasan

This paper evaluates the previously proposed sequence of transformations in prehistoric social organization in Northeastern Iran (Khorasan) using geospatial analysis of settlement distributions. The proposed sequence begins with agricultural villages during the Neolithic and Early Chalcolithic, transitions to craft-producing towns during the Late Chalcolithic and Early Bronze Age, culminates in a process of proto-urbanization and the emergence of state-like structures during the Middle Bronze Age, and subsequently collapses at the end of the Bronze Age, resulting in the “abandonment” of the region until the Middle Iron Age. Several explanations have been invoked to explain the transitions in this sequence, including migrations, shifting long-distance trade routes, the exhaustion of productive resources and climate change. In this paper, I present the results of a settlement pattern analysis of data generated through synthesis of legacy surveys in GIS and visual inspection of satellite imagery. This analysis focuses on several key variables, including measures of site size, morphology, landform correlations, clustering, hydrological potential, estimation of territorial boundaries, and relationships to modeled transportation corridors. The results of this study help us to operationalize the concepts of “community” and “social organization” in this region and evaluate the validity of the proposed culture-historical sequence.

Olszewski, Deborah (University of Pennsylvania) and Brenda Baker (Arizona State University)

The Later Stone Age in the Fourth Cataract Region, Sudan: Lithic Assemblage Features at ASU 09-02

Later Stone Age (LSA) foragers in the Middle Nile Valley had relatively mobile lifeways that included use of pottery. Distinguishing LSA from Neolithic ceramics is difficult due to continuity in styles, an issue that extends to lithic assemblages. Lunate microliths and scaled pieces and use of flint and quartz as main lithic raw materials span both periods. We examine the lithic assemblage at ASU 09-02, a LSA site in the Fourth Cataract region of northern Sudan. Situated on a terrace north of the Nile River, radiocarbon dates between 10,600 and 9500 cal BP indicate occupation(s) in the earliest Holocene. ASU 09-02 also yielded ground stone tools, bedrock grinding slicks, and a cluster of 25 pits within sedimentary bedrock. Lithics were obtained from surface collection and excavation. Analysis shows that flint (58.4%) and quartz (22.9%) predominate. Results support previous observations that emphasis on blade/bladelet production (10.5% surface and 5.5% excavation) may be one characteristic of the LSA compared to the Neolithic. Slight flint and quartz patination also may distinguish lithics from the two periods. These attributes depart from the traditional way of differentiating chronological periods, which cannot be applied here due to similarities in the tool components.

Ceramic Chronology and Current Visions of the “Terminal Classic” and Collapse in the Southern Maya Lowlands: A Brief Desultory Philippic

Recent popular interpretations have proposed that the “Terminal Classic” in the southern lowlands was a gradual transition or slow multi-stage process or that many ninth and tenth century centers continued to prosper; or even have proposed a “What collapse?” scenario. Yet systematic site by site review of ceramic chronologies and evidence reveals that these characterizations and, indeed, the whole debate are poorly informed due to errors in ceramic typologies and limited understandings of the nature and complexity of the ceramic record, especially regarding the many Fine Paste ceramic types. Site level interpretation is hindered by insufficient excavation of stratified middens and minimal lab time. This generates long, undivided and incoherently defined “Terminal Classic” phases, overreliance on “the last dated monument” and elite iconography, and selective use of disparate data, which together create a Rorschach Test for any favored model or correlation. Corrective measures require more refined ceramic chronologies and careful intersite comparisons based on reorientation of resources to middens and lab work. On a positive note, by piecing together evidence from ceramic work that does meet high standards, a more convincing picture of ninth and tenth century landscapes may be beginning to emerge from the methodological fog.

O’Neil, Megan E. (Associate Curator, Art of the Ancient Americas, LACMA)

Collaborative Research on Maya Ceramic Vessels at LACMA

This paper features the Maya Vase Research Project, a collaboration of LACMA’s Conservation Center and the Art and the Ancient Americas Program, which is studying Classic-period Maya ceramics in the LACMA collection. The project’s first phase was to perform digital technical imaging, comprised of photography in different regions of the electromagnetic spectrum, starting in the visible and expanding from X-rays to the Infrared, including ultraviolet visible induced fluorescence. Digital rollout photography also was done in the visible and infrared ranges, which in combination yield false-color infrared images. The research team examined the objects and technical images to determine avenues for further analysis, particularly concerning hand-building and decorative techniques. For example, conservation scientists use multiple analytical tools (e.g., XRF, FTIR, SEM, and cross-section) to examine pigments and stucco. Our research combines such study of materials and techniques with art historical, epigraphic, and archaeological analysis, considering, for instance, artists’ choices of materials and manufacturing techniques in relation to the objects and images they created. We also explore how this evidence may shed light on artistic process and collaboration, relations with other media such as mural painting, and artistic innovation and exchange between the Maya region and Teotihuacán.

Development of Maritime Networks and Human Migration in Wallacea and Oceania during Neolithic to Early Metal Ages

The Austronesian expansion both in Island Southeast Asia and Oceania after the Neolithic times is one of the famous cases of human maritime colonization and adaptation in the world. This paper explores the evidence of Neolithic to Early Metal-aged maritime networks and maritime adaptation in East Indonesia or northern part of Wallacea based on our recent excavations in Northern Maluku and Central Sulawesi as well as some other latest archaeological outcomes in Island Southeast Asia. We summarize the excavation results, explore their implications for reconstructing maritime networks and adaptation, and then also discuss the possible human colonization and interisland networks between Island Southeast Asia and the Pacific Islands mainly Near Oceania after Lapita times.

[338] The Hyena Ecology during the Late Pleistocene of the Levant: Manot Cave (Israel), a Case Study
Manot Cave is situated in the western Galilee hills of Israel. Excavations have been conducted since 2010 in 12 different areas, yielding a rich archaeological record attributed mainly to the Early Upper Paleolithic period (46–33ka). Area D is located in the main hall of the cave on top of the western talus less than 15 m from the assumed cave entrance. The upper sedimentological layer is about 80 cm thick and contains flint items, bones, coprolites and stones. The Area D ungulate-dominated faunal assemblage was studied in detail to determine the accumulation agent/s and shed light on the occupation of the cave by humans and carnivores. No evidence of in situ human activities was identified, pointing to the presence of artifacts as a result of slope sliding. The accumulation of bones and coprolites seem to have occurred in situ by animal activities. Our taphonomic results match the known criteria for a Hyena den: Crocuta crocuta bones with juveniles among numerous coprolites and high proportion of gnawing marks on ungulate bones. Therefore we suggest that Manot Cave served alternately as humans’ shelter and hyena den. Following this, insights pertaining to the spotted hyena’s ecology in the late Pleistocene Levant will be described.

[113] Artifact Density and Predictive Modeling in Old Kiyangan Village
This presentation explores the possibility of predicting house pad footprints in the Old Kiyangan Village, Ifugao, Philippines by looking at the density of artifacts in upper levels of excavation units. Knowing the artifact density in upper levels would help future excavations at the Old Kiyangan Village site when digging new units. I hypothesize that there would be a higher artifact density between 30–50 cm below datum in each trench, which are on the edges of a house platform. In addition, I also argue that there will be a positive correlation with the relative density of artifacts in the upper levels to the density of similar artifacts in deeper levels. To test this hypothesis, I used the site accession record to calculate the estimated artifact density of earthenware ceramics between 30 and 50 cm below datum. To calculate the density, I divided the total mass of the recovered earthenware ceramics in the relevant depth range by the estimated volume of sediment removed from those levels. Results of this analysis were then correlated with the presence or absence of intact earthenware ceramics—infant burial jars that indicate the center of a house platform.

[222] From the Sky to the Andes: Intersection between Traditional Survey and Satellite Multispectral Analysis
In recent years, the use of multispectral imagery has become increasingly important in archaeological research, site detection, and classification of site functions. As the use of these images becomes more common, we must test their accuracy in order to assess their utility and potential problems with their uncritical application. In this presentation we examine the advantages and limitations of using multispectral imagery as a general survey tool. First, we use multispectral imagery from the region of Huarochirí in the Peruvian highlands to conduct a preliminary analysis of the landscape using ENVI software to identify and classify agricultural landscape features and other archaeological sites. We then compare the results of this analysis with areal data collected through traditional pedestrian survey techniques. This methodological exercise allows discussion of the ways traditional field methods and newer technologies can complement one another and ways archaeologists can be more critical in using multispectral imagery. In the case of the Peruvian highlands, critical evaluation of the utility of multispectral imagery for reconstructing archaeological landscapes is particularly important because the highlands’ difficult topography can pose challenges to traditional pedestrian survey, limiting the representation of these landscapes in archaeological research.

[340] Bears and People: From the Wilderness to Dancing
There has been a very strong relationship between human societies and the brown bear (Ursus arctos) in many different places and cultures. The bear has had multiple roles in European societies, from the ancient (and modern) epitome of the wild, through religious symbol to the arenas of the Roman Empire, and their later use as entertainment. At what point does the bear’s position change in society from an animal to be feared, to one to be mocked? In terms of captive management, a fully grown bear would require considerable space and food. How and where were these captive bears kept? Did they survive into adulthood, and what is the evidence for taming? These issues will be examined here using evidence from zooarchaeology, material culture, and iconography.

Ortega, Allan (Centro INAH Quintana Roo), Rosa Maria Flores Ramirez (Centro INAH Colima) and Andrés Saúl Alcántara Salinas (Centro INAH Colima) [183] Life Conditions in Human Skeletal Samples from Colima and Quintana Roo, Mexico: A Comparative Analysis across Time

Life conditions of agrarian populations in Mesoamerica changed during the cultural periods. Scholars have seen a stature decrease and a pattern of increase of the morbidity indicators across the time (De Ángel 1996; Márquez et al. 2002). The aim of this paper is to compare skeletal stress indicators between Maya (Quintana Roo) and West Mexico (Colima) settlements to evaluate life conditions, similarities and differences from 200 to 900 BC. These settlements share modes of production and weather conditions. Differences are in landscapes. We analyzed cribra orbitalia, hyperostosis porotic, dental tartar and caries, enamel hypoplasia lines, and periostitis in tibia in adults (more than 15 years old) of both sexes by region study (Colima: two archaeological sites and 35 females and 15 males, and Quintana Roo: 18 sites, 25 females and 17 males) and by chronology (Preclassic and Classic). We conclude that Colima’s Preclassic females show more indicators of unspecified infections than Quintana Roo’s. During Classic times, males and females of Quintana Roo show more stressful conditions than Colima’s samples. The landscapes and social organization are possible explanations for these differences.

Ortiz, Jose Raul (University of Arizona), Takeshi Inomata (University of Arizona) and Barbara Arroyo (Proyecto Arqueológico Kamilaljuyu) [81] Bayesian Analysis and Chronological Revisions in Southern Mesoamerica

The application of Bayesian analysis on radiocarbon dates from key sites in southern Mesoamerica has contributed to chronological revisions, which are leading to a reevaluation of social processes among major political centers. Main challenges in this analysis include long occupation and mixing of old carbon in construction fills; poor preservation in the tropical environment; and the paucity of short-lived plant remains. Key steps in our application of Bayesian analysis on Mesoamerican archaeology are: first, to identify and eliminate problematic dates in new and existing datasets; and, second, to test different scenarios regarding stratigraphy, radiocarbon dates, and ceramic phases in order to reach the most appropriate interpretation.

Ortiz, Laura (Proyecto Templo Mayor), Julia Perez (Proyecto Templo Mayor), Ximena Chávez (Proyecto Templo Mayor) and Emilio Ibarra (Laboratorio de Paleoetnobotánica y Paleoambiente I) [174] The Meaning of Plants around Death: The Case of Offering 149

Each offer in the Tenochtitlan Sacred Enclosure is the representation of a microcosmos that can be understood through the analysis and interpretation of each one of its compounds. An important part of them are the vegetal microremains, floral remains that did not endure through the pass of the time for its own organic nature but that in the Aztec period had multiple meanings that allowed them to be an frequent material of offering. The Offer 149 is an exceptional case up to the moment, not only for the wealth of the materials, which include braziers, olive seashells, flint knives, bone awls, copal, obsidian objects, bone remains of snakes and birds. The presence of two infants decapitated and dismembered are the elements that give a relevant meaning to the discourse of the offer. The quantity and the excellent conservation state of the pollen remains, identified as part of the Cheno-Am pollinical group, can be indicative of the intentional deposition of these plants that keep a strong symbolical meaning, possibly making an allusion of the child’s sacrifice because it is a special consecration offer. In this paper we will present the preliminary results of the pollinical content of the Offer 149.

Ortiz-Diaz, Edith [135] The Periphery Gold Production Areas of Oaxaca: Tradition and Distinctiveness

In no other part of Mexico have been found so many gold objects as in Oaxaca. The Mixtecs and Zapotecs from central Oaxaca created amazing pieces with such great mastery as well as in the aesthetic and technological aspects. The Oaxaca artisans worked principally with gold and silver. The mineral needed in order to make these objects was relatively abundant in Oaxaca. Nevertheless, outside the realm of the Central Valleys of Oaxaca and the Mixtec area, mineral resources existed in most of the state and many groups created metal objects. One of these areas is the northern sierra of Oaxaca.

Ortman, Scott G. (CU-Boulder)

Thinking Exponentially: Settlement Scaling and Archaeological Data

Archaeologists are used to thinking linearly, where sample measures can be well-characterized by a mean, a standard deviation or a proportion. Settlement scaling theory requires us to think exponentially, where all these summary measures change with the scale of the settlement from which they derive. This sounds like a big problem, but once one gets used to it many traditional concerns about the quality of archaeological data turn out to not be all that important, and the archaeological record becomes a strong resource for the investigation of human societies as complex systems. In this paper, I consider the ramifications of thinking exponentially for the data requirements of scaling research in archaeology. I discuss issues related to the development of population proxies, the way error in measurement works at logarithmic scales, and the variety of proxies for socioeconomic rates that are potentially obtainable from archaeological contexts. I also illustrate these issues using data from across the New World. My goal is to show that typical archaeological data are actually surprisingly good, in the big picture, for scaling research.

A Bayesian Approach to the Interpretation of Andean Faunal Assemblages

Zooarchaeology offers a rich source of data for exploring a number of important questions, from domestication and subsistence to ritual and social organization and transformation during the middle Shang period. We are presenting our preliminary results of a refuse pit excavated at Huanbei (late fourteenth century–mid-thirteenth century BCE) in the summer of 2016. Excavation uncovered a variety of ceramic sherds and numerous animal bones, as well as two nearly complete human skeletons. Our results were obtained from a multi-methodological approach, whereby osteological analysis, coupled with statistical analysis of the pottery remains, were employed. We seek to integrate the results derived from these different methods in order to assess what was being created, employed, and deposited within this pit, which will highlight the impact of culturally contingent factors influencing daily practice.

Osborn, Jo (University of Michigan) [222] Preliminary Results from a Multi-methodological Approach on a Refuse Pit from the Middle Shang Period at Huanbei

In the study of refuse pits from Bronze Age China, much effort has been invested in defining chronologies illustrated by ceramic typology, while overlooking the practices surrounding the usage of the pits. Our research is intended to capture and interpret depositional behaviors related to domestic ritual and social organization and transformation during the middle Shang period. Senses of Space: Religious Aesthetics as Heritage among Maya Speaking Christians in Yucatán and a Hindu Diaspora in Amsterdam

Ethnography and ethnoarchaeology have been central to the rich development of research on multisensory experiences of religion across cultural contexts (Meyer 2005; Moors 2005; Chao 2008). This paper will concretize the links between these religious experiences and strategic group making by presenting two cases; a Hindu diaspora in Amsterdam and Maya speaking Christians in Yucatán, Mexico. In Santa Elena, Yucatán, Mayaness is contested through tensions between various Christian denominations and culturally specific Maya conceptions of the relationships between space, materiality and personhood. The ways in which other forms of sensing, specifically in the engagement with precolombian heritage remains, will be shown to contribute to the marginalized position of Mayaness within dominant cultural spaces. Within a Hindu diaspora in the Netherlands, 'correct' sensory experiences of Hindu heritage become central to acts of protest in their campaign against the cultural and neo-colonial appropriation of the spring festival of Holi. We will explore the intersection between the creativity of religious thought (the symbolic world) and the politics of strategic group-making, alongside the implications of this discussion for indigenous and minority heritage management.

This study analyzes the spatial patterns of ceramics from 65 archaeological residential inventories from the center of Sauce and its hinterland to address the appearance of markets and the spatial structure of exchange during the Middle Postclassic period (AD 1200–1350) in south-central Veracruz, Mexico. For Postclassic Mesoamerica, the collapse of the Classic period states is identified as a factor in market development. However, economic
development is rarely the result of a coherent strategy either on the part of managing elites or consumers. Instead, a combination of strategies and overlapping exchange systems provide the context, rather than any one explanation, for how commercial market exchange develops. Analysis of Sauce’s households identified both the exchange mechanisms and their spatial organization. Results support market exchange of most ceramics for households, lending strong support to commoner household prominence in developing local markets. The restrictions of a few ceramics to Sauce and wealthier residences describe political and social inequalities. The analysis also identified socially important residences located away from the center, and ceramic types which had special social significance. In putting social relationships, consumption, and settlements into relational frameworks with archaeologically distinct residues, modeling the generative processes behind socioeconomic changes becomes accessible using familiar data.

Lucayan Connections: Core and Periphery in the Bahama/Turks and Caicos Archipelago

Of the many islands of the Caribbean, the Bahamas and Turks and Caicos—together comprising the Lucayan archipelago—were settled relatively late, seeing seasonal to permanent occupation from ca. AD 600 to 1000. A uniquely Lucayan material culture quickly emerged, from Palmetto ceramics to a distinctive style of wood carving (i.e., duhos/ceremonial seats). While rich in many resources, the Bahamas/TCI are strictly limited in others, notably the absence of hard stone in a purely limestone environment. Imports of lithic materials from the larger islands were important for day-to-day activities and eventually may have come to act as status and prestige markers. This paper introduces project SIBA (Stone Interchanges within the Bahama Archipelago), a new study focusing on Lucayan stone exotics, and how they reflect networks connecting the Lucayan archipelago to the neighboring Greater Antilles (e.g., Hispaniola, Cuba). Travel costs are explored using a preliminary GIS-based seascape model, which seeks to provide an independent baseline for the most probable interisland connections, both within the archipelago and between it and the larger islands. The position taken here places the Lucayan archipelago as the core, with peripheral socioeconomic/political connections to the larger adjacent islands.

Life and Death among the Late Fort Ancient: Injury Recidivism and Perimortem Trauma at Hardin Village, Kentucky

Hardin Village is a Fort Ancient site located less than half a kilometer from the south bank of the Ohio River. It was excavated under the auspices of the Works Progress Administration in the late 1930s. The skeletal remains from the Late Middle and Late Fort Ancient Periods (AD 1450–1675) represent more than 300 individuals, both male and female, aged neonate to 60+ years. Adult individuals presented a range of possible cranial and post-cranial trauma, including blunt force, sharp force, and possible projectile trauma. Several individuals show evidence of repeated blows to the head and other body parts, possibly indicative of episodes of interpersonal violence. In contrast, juveniles with age estimations of less than 18 years show no evidence of violent trauma to the skeleton, suggesting that they were not likely to be targets of interpersonal violence. The results of the skeletal analysis at Hardin Village show repeated episodes of violent trauma that were often nonlethal, but which may have caused severe injury and potential disability among the adult survivors.

Medieval Fish Weirs in Britain and Ireland: Exploring Practice, Power, and Identity among Fishing Communities

Medieval wooden and stone fishweirs are among the most spectacularly preserved evidence for fishing practices among riverine and estuarine communities in Britain and Ireland. Recent archaeological surveys and excavations have traced their types of construction, forms, uses, and biographies across time, and increasingly sophisticated means of dating them has enabled us to identify patterns in their repair over relatively short periods of time (i.e., years and decades). This paper will use recent archaeological evidence to explore how practice, community and identity played out among fishing communities in Britain and Ireland, from the fifth to the fifteenth centuries AD.

ZooaRch: General Audience Release of an R Graphical User Interface for Zooarchaeologists

Zooarchaeologists evaluate fundamental and challenging questions about human nature. Many of these questions are answered through statistical modeling and hypothesis testing. However, statistical software tailored to answer zooarchaeological questions remain unavailable. To alleviate this problem, in 2016, we unveiled “zooaRch,” a statistical software designed with zooarchaeological statistical problems in mind. ZooaRch is a Graphical User Interface (GUI) for Zooarchaeologists who wish to conduct analyses using the R statistical computing language. As such, zooaRch is open source and freely available to users. Here, we present the general audience release of the software. Following further development and pre-release testing, we increased the program’s stability and diversity of statistical tools. The current version of ZooaRch allows users to conduct a suite of common and specialized analyses including univariate statistics, “analyses of bone counts by maximum likelihood” (abcmld), spatial statistics with GIS capabilities, multivariate, geometric morphometrics, and incipient Bayesian analyses. Moreover, zooaRch can display the underlying R-code. Beginning users interested in learning the R programming language will therefore experience an easier transition to the R computing environment. With this release, the zooaRch GUI makes the statistical power of the R language accessible to zooarchaeologists in research and teaching contexts.

[128] A Tale of Two Pueblos: Varying Consumption Practices and Market Dependence within the Margins of the Spanish Colonial Empire in Mexico

Studies of Spanish colonial capitalism often exclude Mesoamerica or relegate it to a peripheral and dependent role in the emerging global economy. Despite prehispanic antecedents for many capitalist practices, such as market-based circulation and market dependence, the economy that emerged in New Spain is often portrayed as a function of the European economy. In contrast, we follow Pezzarossi in considering how colonial shifts in consumption were informed by prehispanic practices and were not strictly the result of top-down forces emanating from the capital. Furthermore, we answer the call of postcolonial theory to decenter and resist flattening Indigenous experiences of capitalism and colonialism by tracing the paths of two neighboring Indigenous communities, Xaltocan and San Bartolomé Salinas—located outside the metropole. Although both participated in the same market networks, their paths diverged by the early seventeenth century congregaciones, and Xaltocan survives today while San Bartolomé Salinas lies vacant. Materials as diverse as pottery, cutlery, and animal bones tell disparate tales of each community’s colonial economic encounter. They also allow us to begin to consider intraregional variation in shifting market engagement across the prehispanic to early Colonial transition, and their possible implications for the varying endurance of these places.

Ozawa, Koji [36] Transnational Considerations at Japanese American Incarceration Camps

In 1942, all people of Japanese descent living along the western coast of the United States were forcibly removed from their homes and imprisoned in 10 incarceration camps. Decades after the incarceration a congressional commission found that racism, wartime hysteria, and a lack of leadership led to this unjust imprisonment. The scholarship surrounding the archaeology of the incarceration centers has grown over the past 20 years, with several ongoing studies conducted by universities and the National Park Service. At the same time research at sites associated with Asian Americans has called for more nuanced interpretations of these diverse populations. Recent exploratory work focusing on gardens at the Gila River Incarceration Camp has highlighted the need for a transnational framework when approaching the material culture of these sites of confinement. Only by considering the global connections of the incarcerated population can we understand the nature and the beginnings of agropastoralism in China. The paper includes a new synthesis of archaeobotanical and zooarchaeological data to understand the nature and the beginnings of agropastoralism as early as the Late Neolithic period (2600–1900 BC). Environmental factors constrained and shaped animal husbandry in the Ordos Region, an area that exhibits a broad range of environmental conditions. However, this data also points to flexibility and diversity in how agropastoralism was originally adopted in this region.

[181] Aging Mandibular Bison Teeth with ArcGIS

This talk presents a new, nondestructive, empirical, and replicable method for aging bison teeth with mandibular tooth photos and ArcGIS digital mapping. Tooth eruption, growth, and attrition can document age-at-death, which informs on hunting strategies, occupation seasonality, environmental conditions, and herd health. Previous dentition studies utilize numerous tooth metrics that commonly require specimen-destructive research methods. Also, occlusal wear age estimates rely on subjective wear patterning classifications and figures. We suggest a new approach that provides age profiles by “mapping” occlusal wear with ESRI’s AcrGIS® software. Planview mandibular tooth photos from the University of Wyoming’s known-age mandible sample, and well-documented prehistoric samples including the Agate Basin, Hawken, Horner, Glenrock, and Vore sites were captured and georeferenced. Next, GIS polygons were digitized for various occlusal surface features. Digitized GIS shape files were then used to generate various occlusal surface feature areas, and multiple statistical methods were employed that explore relationships between quantified occlusal surfaces and specimen ages. Lastly, traditional mandibular tooth figures are presented which demonstrate the extreme occlusal wear detail produced by this tooth mapping method.

[100] Artifacts Talk Back: Technological Analysis of Flakes and Flake Scars

Reading the ancient language of lithic reduction technologies from archaeological assemblages of flakes and flaked-stone tools requires practical knowledge of key physical attributes and their interrelationships. Lithic literacy begins with understanding the basic anatomy of flakes and flake scars formed according to the laws of fracture mechanics. Variability in the expression of this basic anatomy directly reflects characteristics of the lithic material, mechanical actions applied, and technological choices of the person manipulating the stone. Direct analogy through experimental flintknapping and stone tool use provides a basis for understanding the range of technological choices available at each step of often complex processes and the results of the application of these choices relative to key attributes. Practiced flintknappers learn to recognize the distinctive characteristics of different technological systems, including failures and successes, indelibly written into the attributes of flakes and flake scars. While metric approaches cloak lithic analyses in scientific garb, they generally fail to provide meaningful results. Instead, reading the attributes and understanding their structure or grammar is more powerful for comprehending the technological and cultural meaning of lithic artifacts. We propose a framework for combining analyses of flake attributes, types, and assemblages for comprehending the cultural meanings of lithic technologies.
The present paper is part of a doctoral research project. The project develops and reworks a 1930s sociological exploration, conducted as part of the Sociological School of Bucharest. In this paper I will make a broader framing, at a Romanian macro-level, of the funerary practices conducted within the structures and boundaries. Preliminary results indicate that remains of the plantation are not in the immediate vicinity of the sugar mill, warranting further location in Homosassa, Florida. At present, documentation of the plantation boundaries is limited and locations of various associated buildings, including slave quarters, are unknown. To address this issue, a reconnaissance survey is underway in the vicinity of the mill to identify associated plantation structures and boundaries. Preliminary results indicate that remains of the plantation are not in the immediate vicinity of the sugar mill, warranting further survey.

The Dead in a Transylvanian Village

The present paper is part of a doctoral research project. The project develops and reworks a 1930s sociological exploration, conducted as part of the Sociological School of Bucharest. In this paper I will make a broader framing, at a Romanian macro-level, of the funerary practices conducted within the village of Clopotiva, Transylvania. I intend to use both data from the 1930s research, as well as a new exploratory input gained during my fieldwork, which began in 2012. I will tackle handling of the dead body, from the very first interaction, washing with water, until the last, undertaken as part of a secondary burial ritual, within a few years after burial, namely bone cleansing with wine. Between these two acts, I will address the many contexts in which the living interact with the dead, including stabbing the dead before the burial, and body or heart burning, after burial (a practice adopted to appease the undead). In the case of body burning, usually an exhumation is required, because the burning needs to be done far from the village. The evidence for postmortem interaction with the body will also be considered in the context of individual identity, by evaluating different types of burial practices. It is naturally connected to issues such as the relation between language and material culture, transmission, identity, persistence, structure as well as the limits of socially permitted restructuring of practices, and even the possible contingencies which might cause deep change and break the structure and, therefore, Tradition. The objective of this paper is to address these issues within Tupi speaking contexts (i.e., the Tupi-Guarani and other families of this language stock), from the Madeira and Tocantins Rivers, southern Amazonia. The vectors of this discussion are the Polychrome and Tupi-Guarani Traditions, both persistent and geographically broad styles on the precloval Tropical Forest.

Expanding Radiogenic Strontium Baseline Data for Central Mexican Paleomobility Studies

Radiogenic strontium (87Sr/86Sr) isotope values reflect local geology and have long been used in analyses of paleomobility within Mesoamerica. Research has focused on reconstructing individuals’ residential histories by comparing strontium isotope ratios in individuals’ tooth enamel and bone with local baseline values generated from soils, plants, or local fauna. While a great deal of work has been done developing baseline values across the Maya region, work in central Mexico is predominantly focused on the Classic period urban center of Teotihuacán. This study will contribute to paleomobility research in central Mexico by analyzing a combination of modern soil (n = 32), plant (n = 25), and faunal (n = 8) samples to generate an expected “local” range of bioavailable strontium ratios for the Epiclassic (600–900 CE) shrine site Non-Grid 4 in Lake Xaltocan in the northern Basin of Mexico. The shrine was established following the collapse of Teotihuacán, and is associated with a large deposit of human crania showing evidence of decapitation. Characterization of local signatures of strontium isotope values from the shrine indicates whether different sites within the Basin of Mexico can be distinguished isotopically. Additionally, this study serves as the first step in determining whether these sacrificed individuals were of local or nonlocal origin.

Re-Placing the Plantation Landscape at Yulee’s Margarita Plantation, Homosassa, Florida

Yulee Sugar Mill Ruins Historic State Park (C1124B) contains the remnants of a nineteenth-century sugar mill, associated with Margarita plantation located in Homosassa, Florida. At present, documentation of the plantation boundaries is limited and locations of various associated buildings, including slave quarters, are unknown. To address this issue, a reconnaissance survey is underway in the vicinity of the mill to identify associated plantation structures and boundaries. Preliminary results indicate that remains of the plantation are not in the immediate vicinity of the sugar mill, warranting further survey.

The Developing Tale of Sayles Adobe

The Sayles Adobe terrace site (41VV2239) rests within Eagle Nest Canyon 300 m upstream from the Rio Grande confluence. The site name comes from E. B. Sayles’s 1932 sketch map of the canyon which notes an area of “sandy adobe” below Skiles Shelter. ASWT research began at Sayles Adobe this past spring with excavations focused on investigating natural terrace formation and cultural deposits buried within. Using a combination of old and new archaeological techniques, Sayles was quickly found to be a deeply stratified, multicomponent site, sharing similarities with other Lower Pecos terrace such as Arenosa Shelter and Devils Mouth. Numerous compacted-silt flood deposits frame the cultural deposits across the site, demonstrating stratigraphic integrity and in a few cases preserving a unique context for artifacts. A geoarchaeological analysis of the site will be the main focus, based on various sediment analyses—i.e., physical, chemical, magnetic susceptibility, etc. Radiocarbon dating of the cultural zones will lend a hand in the development of the cultural chronology and its relationship to the many sites within ENC. This presentation details the ongoing Sayles Adobe work as part of my master’s thesis research, and presents preliminary interpretations of the natural stratigraphic sequence and observable cultural patterns.

Comparing and Contrasting Community Structure across the Northwest/Southwest

One of the most enduring contributions made by Suzy and Paul Fish was their elucidation of the role played by multi-settlement communities in structuring sociopolitical organization. The community concept, initially elaborated in the Hohokam region, now fulfills a central interpretive role in many regions of Northwest Mexico. In this paper, I compare characteristics of communities across several regions of the Northwest/Southwest to demonstrate qualitatively different organizational precepts. Topographical and environmental parameters play a major role in directing community formation. Social factors, such as spatial juxtaposition to Mesoamerican influence, also substantially impact community character. These community level differences emerge as likely drivers of alternate demographic, political, and ideological trajectories when considered from a pan-regional scale perspective.

Foodway Variability in the Oneota Tradition: A Pilot Study of Cooking Pots

As a tradition, Oneota encompasses a wide geographic area and several groups, each with their own unique developmental histories. It also encompasses multiple population movements and other complex social interactions that took place in the area. Living in a dynamic and shifting setting, different Oneota groups likely negotiated their social landscape in diverse ways. Foodways may have been one way that Oneota peoples either adapted to or set themselves apart from those with which they came in contact. Presented here are the results of a pilot study comparing samples of Oneota ceramic assemblages from the Bold Counselor Phase (AD 1275–1425) Morton Village site in central Illinois and the Brice Prairie (AD 1300–1400) component of the Tremaine site complex in the La Crosse Locality of Wisconsin. Morphological and functional data are used to explore whether cooking patterns and the way ceramics were constructed indicate a uniform pattern of Oneota cooking or a more flexible pattern of foodways.

Ceramic Compositional Analysis from Chiquilistagua, Nicaragua

This paper discusses patterns of production and distribution of pottery recovered from the site of Chiquilistagua through the use of X-ray Powder Diffraction (XRD) and Instrumental Neutron Activation Analysis (INAA) compositional data. Dominant types found in the Chiquilistagua assemblage include Usulutan, Espinoza, Segovia, Chavez Astorga, and Nejapa Roja. Occupational episodes at Chiquilistagua extend across the Temispique and Bagaces ceramic spheres, which have been associated with widespread social and political reorganization. These shifts are reflected in changes in ceramic style and regional distribution patterns. Ceramic samples tested were compared to existing compositional databases and the results of this study continue to illuminate patterns of ceramic production and distribution near Lake Managua.

An Investigation of Genetic Differentiation in Early Domestication of Oryza Sativa Based on InDel Molecular Marker Method

One of the most enduring contributions made by Suzy and Paul Fish was their elucidation of the role played by multi-settlement communities in structuring sociopolitical organization. The community concept, initially elaborated in the Hohokam region, now fulfills a central interpretive role in many regions of Northwest Mexico. In this paper, I compare characteristics of communities across several regions of the Northwest/Southwest to demonstrate qualitatively different organizational precepts. Topographical and environmental parameters play a major role in directing community formation. Social factors, such as spatial juxtaposition to Mesoamerican influence, also substantially impact community character. These community level differences emerge as likely drivers of alternate demographic, political, and ideological trajectories when considered from a pan-regional scale perspective.
The origin of *Oryza sativa* and its genetic differentiation during domestication is a long-lasting problem attracting wide attention of agronomists, archaeologists and geneticists etc. An array of hypotheses have been raised to interpret how wild rice evolved into today’s domestic varieties. However, most studies of rice genetic diversity based on modern samples represent a biased sampling of germplasm from a restricted time period in rice evolution, so that important germplasm for understanding rice evolution has been largely lost. To make up this ignored field of the issue, investigation of archaeological materials is needed. Tianluoshan, a 7,000-year-old site in the lower Yangzi, provided well-preserved water-logged rice remains, allowing a direct study of ancient rice. We employed an accurate and efficient technology of identification of japonica and indica rice, InDel molecular marking method, to analyze the rice husks uncovered from Tianluoshan. The result shows the rice at Tianluoshan site could be a neutral type, not japonica- or indica-prone. This further implies that japonica-indica differentiation of *Oryza sativa* could not appear 7,000 years ago in the lower Yangzi although rice was being domesticated by human there.

Reconsidering the Connections between Ecological Change and Political Change in Colonial California

California is geographically separated from the rest of North America by high mountain ranges and extensive deserts, but paradoxically the region’s Mediterranean climate may have facilitated the imposition of Euroamerican colonial rule in the late eighteenth century. In particular, many scholars suggest that ecological changes accelerated political changes in the missionized portion of California’s coastal strip. There, the rapid spread of invasive plant and animal species had far-reaching effects on regional ecosystems, which in turn undermined local indigenous subsistence economies. These changes are largely thought to signal the collapse of Native Californian polities and to partly explain the decision of indigenous peoples to join the socially restrictive Spanish mission system. Here, I reassess this long-standing interpretation in light of new faunal and botanical data from colonial-era sites as well as emerging approaches to understanding indigenous political and cultural autonomy under colonialism. While there is no doubt that the arrival of Euroamericans on the western coast of North America ushered in dramatic transformations to local ecosystems and indigenous polities, these new data indicate both temporal and spatial variation in the connections between ecological and political change in colonial California.

Archaeological Research in the Recovery of World War II MIA’s on a Pacific Atoll: Tarawa

Archaeological research on 538 MIA’s from World War II has been ongoing on the Pacific atoll of Tarawa over the past two years under the auspices of History Flight, an NGO. Tarawa, one of the bloodiest World War II battles in the Pacific, still has hundreds of MIA’s unaccounted for in one of the most densely populated locations on earth. History Flight, with the collaboration of professionals, para-professionals, military volunteers, DOD and the local community have been successful in locating and recovering over 110 individuals. The team has used a transdisciplinary approach to the research, starting with extensive historical documentation, followed up by extensive archaeological remote sensing, and the use of a cadaver dog. Corroboration of GPR data with cadaver dog alerts and historical information has allowed History Flight to recover over 13,000 human osteological remains, often in direct association and in situ with military artifacts assisting in the field identification of U.S. soldiers versus Japanese. The field detection and archaeological excavation of these “burial” sites has been significantly impeded by the direct impacts to the sites immediately following the cessation of the war, together with impacts of today’s dense population. Procedures and results of this public/private partnership work will be presented.

Pantoja, Luis and Maria Jose Gómez

La muerte entre los Mayas: Variabilidad de las prácticas funerarias en los sitios arqueológicos de la región de Ichkaantijoo

La muerte es un proceso natural a la cual el ser humano le ha otorgado unas cargas culturales tan variables como los grupos sociales mismos: la forma en que será tratada dependerá de aspectos políticos, ideológicos, sociales y simbólicos. Por ende, la variabilidad del tratamiento mortuorio es un reflejo de categorías relacionadas con jerarquía interna que puede estar relacionada con características bioculturales. Durante la investigación del Proyecto Arqueológico Región de Mérida (PARME), en varios sitios de la antigua Ichkaantijoo, se exploraron en grupos habitacionales enterramientos con diferentes características en continente y contenido. Por tanto, nos preguntamos si ¿Existe una variedad en las prácticas funerarias en Ichkaantijoo? de ser así ¿En qué se distinguen? y finalmente ¿Cuáles son los factores que hacen que ésta varíe? A través de la investigación bioarqueológica se analizaron los contextos mortuorios y se identificaron diversos aspectos en los tratamientos de los difuntos que sugirió una interacción social en el norte de Yucatán, México.

Winds of Change: Funerary Practices at the Dawn of Late Bronze Age in Southeast Hungary

The transition from Middle to Late Bronze Age in the Carpathian Basin encompassed a broad range of changes in material culture, settlement, and societal organization. This transition is traditionally seen as a short, war-ridden horizon reflecting the arrival of the Tumulus culture population. Recent research, however, emphasizes the complexity of these transformations, and suggests a longer, less abrupt transition, in which existing Middle Bronze Age populations play a significant role in the formation of Late Bronze Age societies. The study of funerary practices from this period can provide important insight into these changes. Excavations in the early 1960s at Tápé–Széntégláegétő unearthed over 600 Bronze Age burials, thought to be associated with the Tumulus culture. The location of the cemetery at the edge of the preceding Early–Middle Bronze Age Maros culture territory and similarities in funerary custom, however, raises questions about the possible relationship between the Tápé population and the Maros group. The analysis of funerary practices at Tápé highlights both continuities with Middle Bronze Age practices, and the distinctiveness of the new Late Bronze Age
southeast mid-city sector. Salvage excavations in 1998 recovered a small cache in Structure R-183b containing 282 copper bells, two miniature ceramic vessels filled with metal, and production debris including loose casting sprues and failed bells. The structure also contained a tomb that included a metal bell and evidence of apiculture likely associated with lost-wax casting. Further excavations at neighboring structures in 2015 revealed additional metal consumer goods and metallurgical ceramic mold fragments. Metallographic analysis of a small copper bell and wire fragments from the R-183b cache using SEM-EDS reveal lost-wax casting production techniques using technologies also suggested by metallurgical ceramic mold fragments found at the group. The results of portable X-ray fluorescence spectrometry of metal artifacts and metallurgical ceramics from the R-183 group provide insight into the range of copper alloys and technological decisions made by its artisans.

*Relevance to the Registry of Archaeological Sites for Their Protection: Project: Milpa Alta’s Cultural Landscape*  
In the search for alternative ways for the protection of archaeological heritage, especially in Mexico, which has a vast heritage wealth; there is now an urgent need to raise specific protective tangibles in the immediate short term due to different factors that are contributing to their total loss, or the gradual deterioration of the archaeological wealth of our country. The main causes for this: population growth, limited budget, and archaeological looting, as well as many other factors. In this case, it has important relevance to create a good record of all archaeological sites as the basis for the whole research, but also for its future protection. We should emphasis that according to the national regulatory framework that regulates us (a Federal Law for Artistic and Historical monuments and Archaeological Areas), the registry is a tool that allows for legal recognition and essentially the existence of a site in its complexity and temporality. As mentioned, I’m presenting in this paper, the work of archaeological survey that has taken to place in the Cultural Landscape Project in Milpa Alta. As a result, this survey is now marking the importance of good record keeping of these sites, allowing for more comprehensive studies.

**Park, Geuntae (Jeju Archaeology Institute)**

*Neolithic Development on Jeju Island: Adaptation in a Broad Northeast Asian Perspective*  
Jeju Island, locating southwest from the mainland of Korea, documents the earliest Neolithic culture in Korea. The Neolithic period in Jeju can be divided into six phases (Incipient, Initial, Early, Middle, Late, Final). The Gosan-ri type pottery of the Incipient phase has been only identified in Jeju. From the Initial to Final phases, the applique, Youngseon-dong type, Bonggye-ri type, and double-rimmed types of pottery have been found in Jeju, parallel to the Neolithic development along the southern coastal region of Korea. Only the Tasseon chimseonmun, thick, slant line-patterned pottery type of the Middle Neolithic phase, has not been found in Jeju. This study examines Neolithic focuses on the Gosan-ri culture of the Incipient phase, an Early Holocene social formation. These results contribute to a more general understanding of the newly crystalizing Late Bronze Age societies within the Carpathian Basin.

Paris, Elizabeth H. (University of Calgary)

*Metallurgical Production at Mayapán, Yucatán, Mexico: New Discoveries from the R-183 Group*  
The Postclassic period urban center of Mayapán housed numerous household craft production industries, including metallurgical production. The recovery of metal artifacts, production debris, and metallurgical ceramics from contexts throughout the city suggests a number of independent production sites. One of the most significant archaeological contexts associated with metallurgical production is the R-183 group, an elite residential group in the southeast mid-city sector. Salvage excavations in 1998 recovered a small cache in Structure R-183b containing 282 copper bells, two miniaturized ceramic vessels filled with metal, and production debris including loose casting sprues and failed bells. The structure also contained a tomb that included a copper bell and evidence of apiculture likely associated with lost-wax casting. Further excavations at neighboring structures in 2015 revealed additional metal consumer goods and metallurgical ceramic mold fragments. Metallographic analysis of a small copper bell and wire fragments from the R-183b cache using SEM-EDS reveal lost-wax casting production techniques using technologies also suggested by metallurgical ceramic mold fragments found at the group. The results of portable X-ray fluorescence spectrometry of metal artifacts and metallurgical ceramics from the R-183 group provide insight into the range of copper alloys and technological decisions made by its artisans.

*Bipolar Reduction and Lithic Miniaturization: Experimental Results and Archaeological Implications*  
Lithic miniaturization, the systematic production and use of small tools from small cores, was a consequential development in Pleistocene lithic technology. Bipolar reduction is an important but often overlooked and misidentified strategy for lithic miniaturization. This experiment addresses the role of axial bipolar reduction in processes of lithic miniaturization. The experiments answer two questions: what benefits does axial bipolar reduction provide, and can we distinguish axial bipolar reduction from freehand reduction? Our experiments demonstrate the numerous advantages of bipolar reduction in contexts of lithic miniaturization. Bipolar reduction produces more cutting edge per gram and is more economical than freehand reduction. Our cutting edge to mass values exceed even those obtained with pressure blade production on high-quality obsidian. The experimental results show that bipolar reduction produces cutting edge quicker and is more efficient than freehand reduction. We show that bipolar reduction can be distinguished from freehand reduction with a high degree of confidence using the quantitative criteria in these experiments. These observations overturn long-held perceptions about bipolar reduction. We conclude by discussing the role of bipolar reduction in lithic miniaturization and Stone Age economics more broadly.

*Investigating Hopewell Interaction at the Crib Mound Site through Source Analysis of Chert Cache Bifaces*  
The prehistoric cultures of the Middle Woodland Period (200 BC–AD 350) have been a central research focus in North American archaeology since the eighteenth century. One trademark of these culture groups, commonly referred to as “Hopewell,” is the presence of extensive social networks as evidenced by large amounts of exotic materials acquired from great distances. Chert cache discs found in the thousands in burial contexts are reported to have moved along these social networks. Both Wyandotte (St. Genevieve) chert from Indiana and Cobden (Upper St. Louis) chert from Illinois are commonly cited sources for Hopewell cache discs. However, few analytical source studies examine the source of chert to verify the purported long distance movement of the raw material. The study analyzes a sample of Hopewell cache discs found at the Crib Mound Site, Indiana. Hundreds of chert discs were excavated by artifact collectors but can still inform us about exchange relationships with contemporaneous groups from the Illinois Valley or a reliance on more localized deposits.

**Park, Geuntae (Jeju Archaeology Institute)**

*Neolithic Development on Jeju Island: Adaptation in a Broad Northeast Asian Perspective*  
Jeju Island, locating southwest from the mainland of Korea, documents the earliest Neolithic culture in Korea. The Neolithic period in Jeju can be divided into six phases (Incipient, Initial, Early, Middle, Late, Final). The Gosan-ri type pottery of the Incipient phase has been only identified in Jeju. From the Initial to Final phases, the applique, Youngseon-dong type, Bonggye-ri type, and double-rimmed types of pottery have been found in Jeju, parallel to the Neolithic development along the southern coastal region of Korea. Only the Tasseon chimseonmun, thick, slant line-patterned pottery type of the Middle Neolithic phase, has not been found in Jeju. This study examines Neolithic focuses on the Gosan-ri culture of the Incipient phase, an Early Holocene
adaptation to island environments. The Gosan-ri culture shows the Upper Paleolithic lithic technology and Gosan-ri type pottery. One of the critical research issues on the Neolithic Jeju is the why the Incipient Neolithic culture has not been found in mainland Korea and whether this Gosanri type pottery of the Incipient phase can be understood within the Northeast Asian early pottery tradition, including China, Far Eastern Russian Primorye maritime region (Primorsky Krai), and Japan.

Parker, Ashley, Christopher Parker (University of Utah) and Brian Codding (University of Utah) [383] When to Defend? Optimal Territoriality across the Numic Homeland

Research exploring the complex human decisions that lead to territoriality have largely focused on defensibility. Here we explore territoriality using an ecological and evolutionary model from behavioral ecology: the marginal value theorem (MVT). Based on the principal of diminishing returns, the MVT predicts that the utility of a plot of land will decrease with each additional plot, therefore people should defend an area only at a threshold when it becomes energetically beneficial within the local socioecological context. Based on variation in environmental productivity and population density, we suggest these decisions will create an optimal territory size that should be smaller in high productivity areas with denser populations, and larger in low productivity, low population areas, with the former allowing greater opportunities and payoffs for defense. Numic foragers of the Great Basin and surrounding areas provide an illustrative case study to validate the basic ecological model of economic defensibility, and assess predictions about when hunter-gatherers will likely start defending resources. In this paper we explore how environmental productivity, population density, and home range size all play a critical role in determining when a population should defend their territory.

Parker, Christopher (University of Utah), Nicole Herzog (University of Utah), Earl Keefe (University of Utah), James O’Connell (University of Utah) and Kristen Hawkes (University of Utah) [282] The Archaeological Consequences of Human Fire Use: Analyses, Interpretations, and Implications for Understanding the Evolution of Pyrotechnic Behavior

The importance of controlled fire use in human evolutionary history is widely acknowledged, but the timing of initial anthropogenic fire use and control remains contentious. This debate has recently extended to question whether fire-making behavior was maintained and employed by early hominins moving into northern latitudes based on inconsistencies in archaeological fire signatures in the European record. A series of recent publications interpret these inconsistencies as indicating that populations moving out of Africa into colder climes during the Pleistocene did not maintain pyrotechnic behavior, but rather used fire opportunistically. For these analysts, earlier archaeological evidence of anthropogenic fire use does not imply a sustained pattern of fire using behavior. Here, we review the archaeological evidence from European Paleolithic sites interpreted as reflecting opportunistic fire use in light of archaeological and ethnographic evidence of human fire-making and maintenance, and suggest that the inconsistencies in archaeological fire records do not indicate lack of ability to create and maintain fire on the part of early Homo. We argue that the benefits provided by fire control and use are substantial and pervasive enough they would not be abandoned once adopted.

Parker, Daniel [342] Assessing the Strength of Prehistoric Glues

Glues and adhesives have been used since ~200,000 years ago. A significant question about glues and adhesives in prehistoric contexts is exactly what level of holding strength do various blends have. A widely used glue in prehistory is pine pitch; whose ingredients are pine sap, ash, and a binder, such as dried grass. An experiment is presented here to determine how strong variations in concentrations of these ingredients affect holding strength. Six different variations of the glue were used, with modern wood glue as a control. Each glue was tested ten times to measure holding strength by applying the glue to two oak wood blocks and then applying steady force until failure. After all the testing was complete the data was analyzed to see how each sample compared to the control and which concentration of ingredients worked best.

Parker, Evan (Tulane University), George J. Bey (Millsaps College), Tomás Gallareta Negrón (INAH Centro Yucatán) and Betsy Kohut (Millsaps College) [298] Excavation of a Rural Middle Preclassic Maya Village: Investigations at Paso del Macho, Yucatán, Mexico

Paso del Macho is a Middle Preclassic village settlement located in the eastern Puuc region of the Yucatán Peninsula. Excavations of mound architecture, the main plaza, and ball court of the site have established a chronological range beginning in the early Middle Preclassic and ending by the Late Preclassic. The earliest architecture at the settlement includes at least three small raised platforms associated with Ek ceramics, the earliest pottery complex in Northern Yucatán. Following this, the site underwent a major planned renovation, culminating in the construction of eight earth and rubble platform mounds, including a ball court. The excavations included the introduction of exotic trade items such as jade, basalt, and marine shell in addition to the appearance of the Early Nabanche complex of pottery. The manner of the founding and later expansion of Paso del Macho indicates that the introduction of ball courts at rural Middle Preclassic settlements may be associated with the concomitant rise of major monumentai settlements such as Xocnaché, Yaxhóm, Komchen, and Xkóob. Furthermore, the presence of exotic prestige items at a small rural village settlement suggests that the Maya ballgame developed in conjunction with the institution of sociopolitical inequality in the region.

Chair

Parker Pearson, Mike (UCL Institute of Archaeology) [20] Stonehenge: A Late Neolithic Megasite

Stonehenge is part of a larger complex of Late Neolithic (3000–2450 BC) sites and monuments on Salisbury Plain, including a major settlement complex with monumental timber circles at Durrington Walls. Evidence for occupation from this period covers over 8 square miles. In particular, the Durrington Walls settlement covered 42 acres, built in the same period as Stonehenge’s main stage of construction. This settlement was occupied only for decades, or even just a few years, by people with a primarily pastoral subsistence base who brought their livestock from many different parts of Britain, as revealed by isotopic analysis. Faunal evidence indicates seasonal winter feasting at Durrington Walls, suggesting a degree of annual movement to and from this settlement, perhaps inhabited by the builders of Stonehenge. Despite having many of the characteristics of an urban complex, Stonehenge cannot be considered so. Yet it was very much a “consumer” megasite, drawing people, resources and monumental materials (both of stone and timber) from, in some instances, many hundreds of miles away. Just what was considered to be exchanged in the other direction is a major topic of archaeological debate.

Pauketat, Timothy R. (University of Illinois) [393] Bundled Transfers and Water Shrines: The Big-Historical Implications of a Pan-American Phenomenon

Even a cursory outline of the pan-continental history of nondomestic circular architecture impels us to relate similar buildings, some of which are water shrines, in the greater Cahokia region to Mesoamerica and the Southwest. In the central Mississippi valley, standardized steam baths, rotundas, and circular platforms make a dramatic appearance in the late eleventh century CE. Explaining the big-historical patterns, of which this appearance is a part, entails theorizing the bundled transfer of putative religious practices. Thus, this paper draws from both a contemporary relational archaeology and the anthropology of Michael Taussig and Mary Helms. The result involves rejecting yet-common functional categorizations of circular architecture while unpacking how the animacies of buildings are localized. Definitive conclusions are not yet possible, but the implications include rethinking pan-American "connections."

Paynter, Robert (UMass Amherst) [311] Discussant

Pazmiño, Estanislao [220] Spondylus, Mounds, and Pyramids: An Approach to Social Changes in the Northern Andes of Ecuador during the Late Period

During the precolumbian period, the northern Andes hosted an intense cultural interaction that led to the emergence of chiefdoms with diverse forms of political administration, power strategies, and economic integration. For the northern Andes of Ecuador, the archaeological research typically assumes a gradual development of the Cara people during the Late Period between AD 600 and 1525. New archaeological evidence of social and natural events suggests a transitional stage between AD 900 and 1200 that triggered the transformation of late political systems. Evidence of a significant decrease after AD 800 in the acquisition of exotic and sumptuary objects elaborated in gold, copper, and marine shells (such as the sacred spondylus) may have been related with an increase in the construction of mounds and pyramids in the region that took place until the presence of the Inkas. In this paper, I
discuss the evidence from different mound and non-mound sites in a regional context in order to document the development of social complexity in the northern Andes.

Peabody, Elizabeth (University of Central Florida) and Sarah Barber (University of Central Florida) [82] A Contextual and Iconographic Analysis of Precolumbian Stamps from the Lower Rio Verde Valley

Known as estampias, pintaderas, or sellos, ceramic stamps are known from precolumbian sites throughout Mexico although very little research has been done on this group of artifacts. Previously published examples depict a wide range of iconographic themes, including geometric, floral, and faunal designs. This paper presents an analysis of 19 ceramic stamps recovered from excavations in the lower Rio Verde valley. This group of artifacts spans nearly the entire pre-columbian period, from the Late Formative through Late Postclassic periods (circa 300 BC–AD 1522). Given the rarity of these objects, they will be contextualized in reference to examples from various museum collections throughout the world. Focusing on the coastal Oaxaca examples, this paper will determine the frequency of ceramic stamps, patterns in their use, and attempt to determine their function. In contrast with explanations derived from other regions, there is no evidence that stamps were used to decorate pottery in the lower Verde. Instead, we propose that the importance of stamps lay in their capacity to temporarily transform the objects on which they were used. While further data are needed, we suggest that stamps were used for paper marking or temporary body modification.

Peacock, Evan (Mississippi State University) [377] Temper, Temper: Variability in Ceramic Paste Recipes at a Mississippian/Protohistoric Village in Northeastern Mississippi

Mississippian-period pottery in the eastern United States is overwhelmingly described as “shell tempered,” with occasional reference to poorly defined “paste” categories in traditional typologies. Researchers recently have begun to note a high level of variability in the kinds of additional temper added to what macroscopically appears to be shell-tempered wares. An example is provided by the ceramic assemblage from Lyon’s Bluff (22OK520), a mound and village site in northeast Mississippi dating from ca. AD 1200—1650, where analysis via low-power magnification and petrography reveals three to four common temper constituents included with mussel shell. Three different hypotheses potentially explaining this phenomenon are examined: temper variability represents 1) the in-movement of people from different areas; 2) functional characteristics related to vessel production and/or performance; or 3) local-scale signaling associated with the high-visibility production of pots.

Peacock, Taylor (University of Victoria) and Ally Poniedzielnik (University of Victoria) [263] Hebrew Inscription Preservation in a Jewish Cemetery

Inscription preservation and study is an important part of heritage and historical archaeology. Particular to Jewish cemeteries and their communities is the presence of Hebrew inscriptions such as blessings, or the deceased’s Hebrew name. Our project focused specifically on comparing rates of weathering between Hebrew and English, and we hypothesized that Hebrew inscriptions decayed faster than English ones. We estimated that Hebrew inscription would decay faster because of the curvature of the Hebrew alphabet, and the use of small characters, like the yod. Our site was the Congregation Emanu-el Cemetery in Victoria BC, and our sample consisted of 23 monuments of varying sizes, materials and inscription types across the cemetery. The monuments were dated prior to the 1960s, and contained both English and Hebrew. Our primary methodology was comparative observation, relying on photographs as records. Our results suggested that Hebrew inscription decays faster than English inscription. Second, factors that affect this weathering include the size and shape of monuments: larger monuments and granite preserved best. Results from this study also indicated that the placement of Hebrew inscription on a monument and the depth of the inscription carving are significant factors in rates of weathering.

Pebe, Edines (Proyecto Qhapaq Ñan—Ministerio de Cultura del Peru) and Bryan Núñez Aparcana [56] Inca Road Emplacement: The Case of Canturillas–Nieve-Nieve in the Lurin Valley, Huancorhí, Lima, Peru

The Qhapaq Ñan or Great Inca Road was declared World Heritage by UNESCO in June 2014. The section of the road located between Pachacamac Sanctuary and the Inca administrative center of Hatun Xauxa (central highlands of Peru), is one of the most important, and one of the segments considered for the UNESCO declaration. Within this portion, the stretch from Canturillas to Nieve-Nieve is located near to the modern town of Nieve in a desert area, right where the Andes start rising, and dissected by the Lurin River and the streams descending to the central coast of Peru. This study presents a preliminary analysis of the architectural features of the Canturillas–Nieve-Nieve segment, based on a comparison with nearby sections of the road, taking into account the relevance of related sites of Balconcillo de Avilay and Nieve Nieve.

[259] Communal Hunting Facilities as a Record of Human Cooperation

Communal hunting facilities such as drive walls, hunting pits, and other features, are one of archaeologists’ most direct proxies for past human cooperation. At the least, communal hunting facilities are unambiguous evidence for past cooperative effort. They are also informative of the nature of that cooperation, since variation in facility size and configuration should reflect variation in cooperative behavior. In this study, I present a model designed to understand variation in communal hunting facilities. I then test the expectations of that model by presenting a comparative analysis between communal hunting facilities in North America and Eurasia. I conclude by suggesting that communal hunting facilities inform not only the origins of cooperative behavior, but also its evolution alongside larger sociopolitical processes.

[285] Snake Chaps and Shapefiles: Public Lidar as a Tool for Archaeological Exploration in Mid-Atlantic Wetlands

The Great Dismal Swamp of Virginia and North Carolina was home to disenfranchised Native Americans, enslaved canal company laborers and maroons who lived in the wetlands temporarily and long term ca. 1660–1860. In the past decade, the Great Dismal Swamp Landscape Study (GDSLS) has intensively investigated only a few maroon and enslaved labor sites, leaving vast swaths of inhospitable and challenging swampland archaeologically unexplored. Current research seeks to identify new sites in remote areas of the Great Dismal Swamp National Wildlife Refuge. Publicly accessible lidar data, coupled with historic land documents, facilitates study of this difficult to access region by allowing researchers to identify and locate specific topographic features of interest, build terrain models and target specific areas for field survey. This reduces impact on the environment and on the field budget. This poster explains the methodology and initial results of the most recent exploration efforts in the Great Dismal Swamp. Filling in gaps in the map will expand our knowledge of the complex physical and social landscape of the Swamp and support future stewardship of the archaeological resources in the area.

[222] Casma Pottery Production at El Campanario Site, Huarneym Valley, Peru

Pottery production was an important aspect of the social and economic life within Andean societies. In preindustrial societies craft production occurred at the household level and depending upon the social complexity, this production was either independent or sponsored by the elite. Recent archaeological excavation of domestic contexts at the El Campanario site revealed that the area was occupied by the Casma polity during the Middle Horizon (AD 600–1000). This coastal polity occupied the southern region of Peru’s northern coast and their distinctive ceramic style included Casma Molded, Casma Incise, and Casma Serpentine Applique. These styles were also recovered at El Campanario along with evidence of pottery production; moreover, molds, polishing stones, deformed vessels, and unfired clay suggest the presence of a pottery workshop at the site. In addition, the presence of potter’s marks on some of the recovered pottery and the restricted distribution of pottery molds at the site suggests that pottery production did not occurred within each household, instead it is most likely that pottery production at El Campanario was conducted in a specialized and communal workshop.

[275] The Use of Dung in Northern Morocco: Examples from Mountain Communities

This presentation focuses on the various examples collected from northern Morocco during ethnographic fieldwork on the use of dung. Apart from the most known use of dung as fuel, traditional communities in the Moroccan Rif used dung for other purposes such as flooring, tempering, manuring, making containers for storage, etc. This paper will discuss the various uses of this important material and results will be compared to other examples from other Mediterranean areas.
Penfil, Rachael (University of Illinois at Chicago), Patrick Ryan Williams (Field Museum), M. Elizabeth Grávalos (University of Illinois at Chicago) and Lauren Monz (Northwestern University)

This paper presents preliminary analysis and interpretations of a craft production space located within a single residential patio group on the summit of Cerro Baul, located in the Moquegua Valley of Peru on the Wari-Tiwanku frontier. Excavations in a patio group located close to a Tiwanaku temple exposed a dense artifact midden which included obsidian points and debitage, shell and lithic beads, burnt ceramics, and bone. Evidence of subfloor offerings, marked by multiple cuy interments in the western half of one of the rooms, reflect religious ritual in the dedication of the space. The discovery of such a diverse artifact scatter has led us to revise our initial interpretations of the space as an obsidian workshop to a more generalized craft production space with potential ties to ritual components within the Wari Empire.

Preliminary Results from the New Excavation at the Upper Paleolithic Site of Shuidonggou Locality 2, Ningxia (China)

Shuidonggou, a site complex containing multiple Upper Paleolithic localities in Ningxia Province, China, is one of a few archaeological examples in North China that contain artifacts of a blade technology similar to those of the Initial Upper Paleolithic (IUP) in Mongolia and Siberia 30–40 ka. At Locality 2, the occurrence of two blade cores in the lower layers dated to ~34–41 ka; and has led the lithic industry of the locality to be separated into those of the so-called IUP and others of the core-and-flake technology. This is characteristic of the Paleolithic in northern China between 1.6 ma and ~30 ka. However, due to the limited sample of artifacts’ diagnostics of the IUP blade technology and a lack of consistent dates, the timing and technological affinity represented at Locality 2 remains unclear. There are reported preliminary results from a renewed excavation of Locality 2 beginning in 2014. The lithic assemblages of culture layers 1–3 are characterized by the typical core-and-flake technology of the Chinese Paleolithic, although variation between bipolar and free-hand percussion was identified. In addition, numerous ostrich egg shell beads and a single bone pendant were also recovered from the upper layers.

New Archaeological Discoveries of Liao and Jin City Sites in Jilin Province, China

Archaeology at Liao and Jin sites in western Jilin Province has enormously increased our understanding of Liao and Jin period history and social organization. At the Chengsijiazi site, temple remains were excavated and a ceramic architectural element was found with “Ninth year of Da’an” written on it. This site is the Liao city of Changchunzhou and the Jin city of Xintaizhou. At the Tahu city site, structures lining both sides of the north-south site axis were excavated and many ceramics were found. This site was Zhaozhou city of the Jin Dynasty, and used through the Yuan Dynasty. Work at these sites solved long-standing issues in historical geography concerning the regional government system. The spring Nabo site cluster contained a rare, large platform, and is considered the location of the Liao and Jin period migratory or Nabo spring encampment, a significant discovery for understanding the Liao and Jin governmental system. The Liao and Jin temple excavated at the Shuiping site is an important contribution to the study of Buddhism in the northeast. The Yinjiawou site is a Jin Dynasty salt production site belonging to the Zhaozhou salt fields, and is the first salt production site found in the northeast.

Between the Puna and the Valley: An Approximation to Local Communities-Inca State Interactions through Road Network Analysis in Jauja, Central Peru

Research on the Inca occupation in the conquered territories usually addressed the topic from a perspective that has been built on data obtained from state and local sites. The case of Jauja in the central highlands of Peru has not been the exception and much of our current knowledge about the Inca occupation of the region is based on information coming from indigenous settlements and state facilities. This paper proposes an alternative and complementary insight, trying to reach an approach to the interactions between local communities and the Inca state through the analysis of a road network articulated to the Qhapaq Ñan in the area located to the west of the administrative and religious center of Hatun Xauxa, and directly associated to the road that linked that site with Pachacamac in the central Peruvian coast.

Lambayeque Burials in Huaca La Capilla–San Jose de Moro Site

Huaca La Capilla is one of the best preserved architectural mounds in the archaeological site of San Jose de Moro. Its construction corresponds to the Late Moche period, but extends its occupation after its closure. Excavations in the units 55 and 64, located on the northern slope of the mound gives us an approximation to the function that had the structure after the Moche period. This poster presents the results of two field campaigns conducted in 2015 and 2016 where 40 burials of the Lambayeque period were recorded in an total area of 50 m². This case study provides important information regarding how social memory was constructed by social groups in the north coast of Peru.

Information Exchange in the Postclassic Oikoumene: A View from Midcontinental North America

Several years ago Steve Lekson and I proposed a Postclassic Oikoumene stretching from Mesoamerica through the Southwest and into midcontinental North America. A frequent question has been how such a “known world” could have been created in the absence of long-distance trade and transportation systems. In this paper I explore how information was exchanged among the peoples of midcontinental North America in the late
Once scaled and combined into a single file, the project aims to "load" the render of Tektaş Burnu to determine whether the estimates of size are
basis of what we see empirically as a broadly similar iconography of supernatural beings within the Postclassic Oikoumene.

Pereira, Carla (Texas A&M University)
Tektaş Burnu is a Classical Greek shipwreck from the fifth century BCE which sank off the coast of Tektaş Burnu, Turkey. Excavated between 1999 and 2001, this ship was found to carry a cargo of, pine tar, pottery, kitchen tools, and wine in over 200 potentially Erythraen amphorae. The ship itself was consumed by shipworms so the size was determined by the location of the cargo, a pair of marble opthalmoi and lead-filled anchor stocks. This project has taken the findings from this excavation—the remaining amphorae, anchor stocks, and the ship’s metal fastenings—and used them to render a potential model of the ship, and digitally re-create the entire catalog of amphorae and anchor stocks using Rhinoceros 5.0 digital modeling software. Once scaled and combined into a single file, the project aims to "load" the render of Tektaş Burnu to determine whether the estimates of size are accurate, and if there would have been space for a now lost organic cargo. With the assistance of the Rhinoceros add-in Orca 3D, the project further hopes to determine the seaworthiness of such a ship, and what its marine capabilities and hydrostatic qualities might be.

[61] Archaic Fishing in the Eastern Woodlands: An Examination of Social Causes and Environmental Variation
The Eastern Archaic Faunal Working Group brings together researchers and nearly sixty faunal datasets representing twenty-one sites from four major subregions of the Eastern Woodlands. In this paper, we focus on resource availability and the potential causal relationship to cultural choice. The Archaic Period archaeological sites in our study are located in the Mid-South and Ohio River Valley regions, and are well-known for their composition of shell in the form of middens or mounds. In a previous analysis, Walker and Peres (2016) compared the use of aquatic resources between two sites located in the Mid-South region. The results indicated that while people at both sites focused on the exploitation of aquatic resources, there were significant differences in which species were targeted. The current research builds on this by integrating datasets from the Mid-South and Ohio River Valley regions using the data integration tools in tDAR. The aim of this study is to determine the spatial variability in aquatic resource use and correlate these patterns to cultural questions of broad concern: site function, dietary choice, and environmental variability.

[169] Tool Kits, Subsistence, and Land-Use Patterns: The Neanderthal Ecology Revisited across a Dense Cultural Sequence in the Alpine Chain
Studies of the way Neanderthal groups used knapping technologies and organized their economy and land use are sparse in Europe and even scantier in the Alps, so only in some regions can cyclical and seasonal residential movements be inferred from data on the exploitation of ungulates with variable levels of migratory behavior. Two of the most widespread methods used in stone knapping were the Discoidal and Levallois. However, analyses of these lithic artifacts are not yet sufficiently integrated into a corpus of zooarchaeological indicators that outline an ecological profile of Neanderthal mobility. To address this issue, this study presents evidence from Grotta di Fumane in northern Italy, where the use of manufacturing technologies is embedded in a dense Late Mousterian sequence. Given the specific ecologica and contextual setting on the Southern Alps, we assume that Neanderthals exploited knappable rocks balancing transport costs and utility and that hunting activity was shaped by the availability of game and that well-established, cost-effective patterns were used in carcass processing. Compared on a broader scale with other contexts, these foraging practices show striking differences each other and suggest that a common model for Neanderthal subsistence strategy cannot be applied.

[260] Advocating for the Morrow Jones Cabin: Archaeological Investigations at a Historic Homestead
The Pennsylvania Department of Conservation and Natural Resources (DCNR) manages over 2 million acres of state land. Forbes State Forest, located in Fayette County, Pennsylvania, is home to numerous cultural resources, including the Morrow Jones cabin. Given its location on state-owned property, neglect and natural decay are greater threats to this historic house than development, yet DCNR has limited funding and a finite amount of time to devote to such resources. Detailed study of this house and property will result in an occupational history and site analysis. Four research questions are proposed in this archaeological investigation. The primary question concerns age and use life of the house, since DCNR would like their staff and the public to better understand the history and significance of the Morrow Jones cabin and its associated derelict farm. Demographics and domestic activities of the site are also of interest in order to better understand the families occupying this rural area. The physical evolution of the house and the farm's connection, or lack thereof, to local and regional economic markets form the final two questions.
Pérez, Carmen (Doctorado en Estudios Mesoamericanos FFyL-UNAM), Yoko Sugiura (UNAM) and Wesley Stoner (Arkansas University) [215] Producción y consumo de la cerámica Coyotlatelco: El caso del valle de Toluca en el Epipíclasis
La cerámica Coyotlatelco ha jugado un papel importante en el Epipíclasis del Altiplano Central de México. Dicho complejo cerámico se constituye por formas de servicio como ollas, cazuelas, cazetos, platos y vasos, y exhibe características definidas por un alto grado de pulimento y decoración pintada en rojo sobre blanco, cremoso o blanco. Los resultados del análisis NAA y el estilístico, realizados al Coyotlatelco tanto de la cuenca de México como del valle de Toluca señalan que éste no parece provenir en un centro único de producción, sino de varias localidades al interior de dicha región y que se distribuye en gran parte del Altiplano Central mediante intercambios locales y regionales.

Pérez, Jan (University of Puerto Rico, Rio Piedras Campus) and Isabel Rivera-Collazo (University of California San Diego) [69] Using Surface Chemical Markers to Identify Patterns of Human Activity: The Case of Tierras Nuevas, Puerto Rico
Human activities leave chemical traces in the sediments, which can give us clues about the content of the subsoil and the activities that might have occurred in the past. In this study we evaluate the potential of the geochemical evaluation of sediment samples collected from surface survey for the identification of buried patterns of human activity at the site of Tierras Nuevas, an archaeological site in a tropical environment. Based on topographical characteristics, we had identified patterns of mounds and ball courts at the site but very few or no archaeological artifacts were visible. This study sampled the surface along parallel transects and analyzed their phosphate content and their pH levels. The analyses show high correlation between the patterns of geochemical characteristics with the different types of earthen features on the site. This study shows the potential of noninvasive geochemical and georarchaeological testing for the identification of archaeological patterns of human activity, and leaves an open door to continue developing this type of methodology in the Caribbean.

Pérez-Juez, Amalia (Boston University), Kathryn Ness (Boston University), Ricardo Elia (Boston University), Meredith Anderson Langlitz (Archaeological Institute of America) and Ilaria Patania (Boston University) [215] Reconstructing Naval and Shipping Connections through Ceramic Analysis from Islas del Rey, Menorca, Spain
Isla del Rey is a small off-shore islet, located on the Spanish Balearic Island of Menorca. The island is well-known for a British Naval Hospital, constructed over multiple periods of British occupation in the eighteenth century. The hospital was used for 250 years by the British, French, and Spanish, and abandoned in the second half of the twentieth century. In 2013, the Boston University Field School in Archaeology and Heritage Management chartered the island and explored an archaeological site. The material found includes ceramics, the light links of Menorca with other parts of Europe, from the Mediterranean to the Western Atlantic. Pottery from Italy, England, and Spain arrived to Menorca by ship. It was used on site and imitated locally. Because pottery factories often imitated each other, it is difficult to assess the provenience of some pieces, except through additional analyses such as Neutron Activation Analysis (NAA) that allow scholars to pair ceramics with clay source locations. In this poster we will present recent findings at Isla del Rey including a discussion of the pottery, its link to other countries, and the results of the NAA analysis conducted on so-called Ligurian pottery.

Perkins, Leslie and Travis Stanton (University of California Riverside)

The island of Cozumel has long been known to have been a quintessential place in Late Postclassic Maya culture as the home to the shrine of Ix Chel, the lunar goddess of childbirth and fertility. Maya women of this period were expected to make the pilgrimage to the shrine at least once in their lives, which would have transformed the island into one of the most dynamic and multicultural social contexts throughout the late Maya world. Added to the fact that the island is the easternmost part of the Maya area and was known to have one of the most important marketplaces in the Maya region during the Late Postclassic, Cozumel was beyond doubt a unique place that greatly factored into the geopolitics of the time. Occupation on the island, however, dates back at least until the Terminal Preclassic period, suggesting that the importance of the island stretches back into a more distant past. In this paper we discuss our current research at El Ramon and San Gervasio with the idea of understanding the Preclassic and Classic origins of Cozumel as the unique multicultural place it was during the Late Postclassic.

A Geochemical Investigation and Spatial Analysis of the Earliest Living Floors of Housepit 54, Bridge River, British Columbia

Transition to digital form is still rarely linear, even more so when you help others adopt digital solutions for their content. Given the cultural nature of projects we work on, at CoDA, we have adopted a human-centered approach to digital project design, where understanding and translating people's needs come before choosing what technology to use. We engage in deep anthropological inquiry that focuses on humans' interaction with materials and knowledge before deciding on technology, workflow, and data structure. Inspired by the topic of this session, we reflect on how adopting a human-centered approach to digital project design can facilitate adoption of digital solutions. We share some of our user experience stories and what we have learned from them. We hope to inspire the audience toward changing our approach as technologists from being carriers of digital agendas toward more meaningful, impactful, and sustainable cultural digital projects.

Paleoenvironmental Change during the Pleistocene-Holocene Transition at Sloth Hole (B9E121), Northwestern Florida: A Palynological Perspective

This paper presents the preliminary results of a palynological investigation of sediments from Sloth Hole (B9E121), a site in the Auclla River. The Auclla River in northwestern Florida creates a unique preservation environment that has produced rich cultural, faunal and botanical records from the Late Pleistocene to the present. Archaeologists and recreational divers alike have recovered probable Paleoindian-aged bifaces and a possible butchered mastodon fibula from Sloth Hole. In addition, an ivory tool recovered from this site has yielded a Clovis-age date. Recent palynological research at nearby Page-Ladson (B9E591) demonstrated significant variability in both the plant and herbivore communities during the Pleistocene-Holocene transition. Many of the same patterns are reflected in the Sloth Hole sediments, suggesting a regional pattern of plant community change preceding and following megafaunal disappearance in the area. These environmental changes occur during a shift from Paleoindian to Archaic lifeways, when regional tool technologies appear to reflect a move to a more generalized diet, perhaps in part as a response to the disappearance of Late Pleistocene megafauna.

Perry, Jennifer (CSU Channel Islands), Michael Glassow (University of California, Santa Barbara), Terry Joslin (Central Coast Archaeological Research Consultants), Kelly Minas (Channel Islands National Park) and Mark Neal (BeyondMaps)
Santa Barbara Island: Insights into the Prehistory of California’s Channel Islands through Its Smallest Island

As the smallest of California's Channel Islands, isolated and impoverished Santa Barbara Island has received less scholarly attention than its well-known neighbors. Initially described as a "way station" to the other islands, subsequent archaeological expeditions have reinforced the interpretation that the
island was only temporarily occupied in the Middle and Late Holocene. In 2012, an effort to rerecord the 19 known sites was undertaken. Subsequent surveys have increased the number of sites to 55 and radiocarbon samples to 20, dating between ~4100 and 600 cal. BP. Spatial and temporal patterns have emerged from this comparatively more robust dataset, allowing for better contextualization of the few previously excavated sites. Most of the island’s sites are small shell and lithic scatters, although some are larger shell middens with greater faunal and artifact diversity. Their locations and constituents indicate that the island not only served as a stopover during interisland travel, but was also visited to target local resources such as sea mammal rookeries. Our recent research presents a unique opportunity to reevaluate the different roles that this island played in broader settlement and subsistence systems on the Channel Islands in the latter part of the Holocene.

* [390] A Dance with Dragons

What is the relationship between culture and the things that humans create? How do our beliefs affect what we make and how do these creations affect us in turn? This issue is investigated through study of horned water serpent iconography, imagery that is both ethnographically and archaeologically documented as ritually significant in the southwestern United States. This case study focuses on Cottonwood Spring Pueblo, a large aggregated settlement in the Jornada Mogollon culture branch. Salado polychrome pottery is used in the analysis due to its presence at the site, as well as the site’s location on the far edge of Salado polychrome’s geographic distribution. This supports conceptions of Cottonwood Spring as place where different social and ritual practices were a part of its aggregated community. The study uses the principles of behavioral archaeology to examine how objects existed in flows of communication that facilitated community integration and acceptance of religious practice. Communication process modeling provides a way for archaeologists to derive communicative meaning for ritual imagery through the process of logical inference. The analysis explores how materiality and art can influence human behavior in ritual practice and provides methods for obtaining such information from the archaeological record.

* [227] Lidar Data and the Temporal Trends in the Frequency of Hunter-Gatherer Sites in the Northwest Coast of Finland 10,000–2000 cal BP

Investigation of lidar visualizations has become a standard tool in archaeological site detection in Finland, as large part of the country has been lidar scanned. Because archaeologists alone do not have enough resources to thoroughly analyze these big data, part of the work has been crowd sourced. Thanks to active volunteers, not only the number of sites has increased, but we now have new types of sites, and sites in environmental contexts that have previously been ignored in archaeological surveys. Here, we use lidar-derived archaeological data together with data from traditional sources. We track changes in the temporal frequency distribution of hunter-gatherer house pit sites, sites without house pits, and sites with rectangular stone megastructures in northwestern Finland (N = 739). We show boom-and-bust cycles in the frequency of sites between 10,000 and 2000 cal BP. House pit sites and megastructures coincide with the last and the most prominent of the booms peaking at 5800–5700 cal BP. Interestingly, hunter-gatherers do not seem to recover from the subsequent bust, and the number of sites remains low until the end of the study period. We suggest that this is related to the cooling climate and declining productivity of the Baltic Sea.

* [134] The Interior Frontier: Intercultural Exchange in the Formative Period (1000 BC–AD 400) of Quillagua, Antofagasta Region, Northern Chile

Today the modern village of Quillagua, an oasis in the hyperarid Atacama Desert, is of limited regional economic importance. However, there is strong evidence to support the argument that, in the past, the village was a node of ancient routes linking the populations of the Pampa, the Pacific Coast, the River Loa, and the Salar of Atacama. Documents from the eighteenth century suggest that Quillagua was, in fact, an “internal frontier” between populations residing to the north and south of the oasis. Archaeological evidence indicates that this border function may have its origins as early as the Formative Period (1000 BC–AD 400). In this work, we present the results of bioarchaeological, funerary, and isotopic analysis of individuals from distinct spatial/ethnic precincts of Quillagua, as well as settlements and cemeteries in the surrounding regions, in an attempt to characterize the direction, frequency, and intensity of interaction, exchange, and interculturization in the region during the Formative. In essence, we seek to examine how the border function of Quillagua was embodied and internalized by the people who lived and died in its environs.

* [32] Radiocarbon Dating in the Mariana Islands

One of the most enigmatic human dispersals into the Pacific is the colonization of the Mariana Islands. Here the interpretation of radiocarbon (14C) dates from early settlement sites is hotly debated. One interpretation suggests the Marianas were colonized directly from the northern Philippines around ~3500 BP. However, the age of one of the earliest Marianas sites; Bapot-1, has recently been revised down to ~3200–3080 cal BP following research by Petchey et al. (in press) which demonstrated that 14C depleted waters (hardwaters) had been incorporated into the estuarine Anadara antiquata shells, but not into shells belonging to reef dwelling animals. This research has demonstrated the importance of integrating radiocarbon, environmental and zoological information when building island chronologies. This presentation discusses our ongoing research into the marine 14C offsets in this region.

* [171] Development of Craft Specialization during the Pre-Aksumite Period in Eastern Tigrai, Ethiopia: Insights from Modern Hide-Workers

The Pre-Aksumite period in Eastern Tigrai witnessed social and economic changes that have been traditionally attributed to the impacts of external influences, in particular the Sabaeans. Recent studies are exploring internal or indigenous factors influencing the development of economies and early social inequality/complexity in the northern Horn. One such factor may have been the local development of craft specialists to cope with increasing demands for certain goods, such as hides. The export and trading of hides has continued as an important aspect of the modern Ethiopian economy, with possible roots in the early development of the Aksumite state. This paper presents the results of ethnoarchaeological and archaeological studies of
stone scrapers used to processes hides. Through incorporating morphological analysis, low-power use wear, interviews and observations, identifiable trends associated with hide processing are evaluated. Studying the formation of craft specialists within this framework creates one means by which the development of social complexity/inequality can be explored for the Pre-Aksumite through the Early Aksumite periods allowing a focus to be placed on indigenous influences operating within the region.

[287] Archaeology, a Bone to Pick: Pitfalls of a Destructive Science
Archaeology, as a science, has a long history, not all of which has been ideal. Archaeologists in one generation are routinely dismayed with the work of previous generations of archaeologists. Sometimes this less than satisfactory work is due to a lack of knowledge at the time, as we learn more with each new technological advancement, and with each new generation of archaeologists. However, more often than we would like, these flaws in past archaeological work are due to apathy or negligence. In either case, we lose much information. Archaeology, after all, is a destructive process. Once we choose to excavate, it can never be undone. Using excavation examples from the distant past, as well as more recent examples, I argue that archaeology still suffers much from this “dark side.” With these examples in mind, I propose that as archaeologists, we attempt to fill in the gaps where we can, and to take the full responsibility of this destructive science seriously.

[298] Consumption and Construction: Art, Sacra, and the Place of Empire in Postclassic Mexico
In the precolombian era of Mexico, devotional objects served to reinforce existing cultural systems while simultaneously shaping the overarching aesthetic narrative. This presentation will explore the manner by which ixiptla (lit. representation), a type of central Mexican cult effigy, functioned to form the visual rhetoric that is illustrative and formative of conceptions of space, place, and cultural identity in the late Postclassic Period. Within the category of devotional images, ixiptla are unique in that they feature a conceptual continuity with human performers, as a ritual actor can be transformed into a representation. This link functions to essentially turn the performative body into a living, acting object, and furthermore lends the sculptural corpus an agentive function. This presentation will specifically address the broader visual systems in which ixiptla participated as an image type. This presentation concludes that sacred images are, as a class of representation, indices of collective memory and nostalgia through the the mythic narratives inscribed upon the objects themselves and their usage. Within the visual systems employed by the city-states of central Mexico, sacred imagery was merely one of multiple mechanisms designed to pull the periphery to the center and to actively construct specific cultural narratives.

[263] Historic Cultural Perspectives through Cemetery Landscape
The Jewish cemetery in Victoria, BC, is home to approximately 300 interments and is one of the oldest Jewish cemeteries in Canada and the second largest in western Canada. This study explores the Jewish community of Victoria during its earlier period of use from 1914–1918 using four individuals from a variety of economic, social, political, and gender specific backgrounds. The goal of this research was to investigate the biographies of four people buried at Emanu-El cemetery who died during the period of World War I, and to make connections between the individuals and their larger community. Using the grave memorials as a gateway into their lives, we take this public memorial of individuals who have lived and died over a hundred years ago, and extend their stories as much as possible, beyond the dates of birth and death. Research involved exploration of textual materials from a variety of institutions such as University of Victoria, BC, Archives, the Jewish Museum and Archives of BC, as well as from publications, newspapers, census data, military records, ship passenger lists, and online genealogy websites.

[176] The Metlakatla First Nation and Archaeology: An Indigenous Community’s Views in the Course of 50 Years of Archaeological and Related Research in the Prince Rupert Harbour Region
This paper discusses the Metlakatla First Nation’s views and roles in the archaeological and related research that has occurred within their traditional territory over the past 50 years, the core of which is the Prince Rupert Harbour area. Unlike many other First Nations, Metlakatla has long embraced the opportunity to actively participate in the documentation of their ancient history, rather than merely being a subject of research. This view of archaeology has led to mutually beneficial relationships with researchers from academic archaeologists and CRM archaeologists to biological archaeologists and geneticists. All with the long view that the western world has difficulty accepting indigenous oral histories without corroborating evidence from the social sciences and science. More and more we are finding that these tools are confirming what the Metlakatla have known for millennia.

Peuramaki-Brown, Meaghan (Athabasca University) and Linda Howie (HD Analytical Solutions, Inc./Western University)
[236] Precolumbian Ceramics in East-Central Belize: A Petrographic Characterization Study
In 2015–2016, the Stann Creek Regional Archaeology Project (SCRAP) in collaboration with HD Analytical Solutions, initiated a preliminary petrographic characterization study of presumed “local” pottery and daub artifacts, surface collected during settlement survey at the Late to Terminal Classic (ca. 750–1000 CE) Maya site of Alabama, Belize. This initial study, though small, has proved mighty in terms of the new information it has revealed, building on earlier studies of Maya communities in the Stann Creek area by Elizabeth Graham and colleagues. Our data sheds light on geological variability in local raw materials for pottery and building materials; common pottery and daub fabrics; as well as local, mesolocal, regional, and long-distance interactions of the Alabama Maya of east-central Belize. In this presentation, we discuss the results of our study and their impact on the broader S scrap research program at Alabama.

Pezzarossi, Guido (Syracuse University)
Pezzutti, Florencia (Colorado State University), Christopher T. Fisher (Colorado State University), Conrad Albrecht (IBM-Watson), Sharathchandra Pankanti (IBM-Watson) and Francesca Rossi (IBM-Watson)

Here we present preliminary results from a collaborative project between archaeologists and IBM research scientists focused on developing a cost-efficient algorithm for the automated recognition of archaeological features (objects) from lidar data. Our research focuses on challenges of 1) multidisciplinary work integrating expertise from diverse disciplines, 2) identifying complex archaeological features in the context of a dense urban site in a rugged topographic setting, and 3) developing a machine learning algorithm to efficiently identify archaeological features. We will present details of formulation of our approach in addressing the above-mentioned research challenges and provide preliminary results on real archaeological data which we find promising. We believe this improved lidar object feature recognition algorithm will ultimately be a resourceful and cost efficient (both in money and time) tool for future archaeologists conducting archaeological surveys and mapping through the application of lidar.

Pfaffroth, Jake (University of Wisconsin)

Cahokian Colony or Frontier Fusion? Architectural Variability and “Mississippianization” at Aztalan, Wisconsin

The concept of a “frontier zone” in which diverse peoples would have been equally susceptible to each other’s influences offers a dynamic and multiscalar approach to the investigation of “Mississippianization” in Cahokia’s northern hinterland. Aztalan, a site of Mississippian and Late Woodland co-residence in southern Wisconsin (ca. AD 1100–1200), has long been interpreted as a “Mississippian town” or “Cahokian colony.” Mississippian-centric interpretations have led some archaeologists to suggest that Late Woodland peoples were a minority at Aztalan and/or were subjugated by Mississipians. I hypothesize that some aspects of the relations between Mississippian and Late Woodland peoples at Aztalan are reflected in the remnants of domestic architecture at the site. In the U.S. Midwest, Mississippian people typically built fairly uniform, rectangular, wall-trench buildings while structures built by Late Woodland people had various shapes and were constructed using single-set posts. My analysis of architectural variability at Aztalan indicates that few structures were typical Cahokian wall-trench buildings and many were “hybrids” that incorporated traditions from both cultural groups.

Patterns of Weaning and Childhood Diets among Ancestral Huron-Wendat Communities, Determined from Stable Isotopes of Teeth

We report here on the study of ancestral teeth retained after repatriation, with the permission and engagement of the Huron-Wendat Nation. We have documented temporal patterns in reliance on maize, as well as decisions about infant feeding. Significant differences between time periods before and after European incursions suggest concrete ways in which disruptions altered daily lives. Study of horizontal dentine slices from 74 teeth (35 deciduous molars, 39 permanent M1) from five communities, fourteenth to seventeenth centuries, shows initiation of weaning between 8 and 18 months and completion between 2.5 and 3.5 years. Weaned children ingested gender-differentiated diets that were proportionally different from adult diets. Weaning was completed a few weeks earlier in the sixteenth and seventeenth centuries, compared to prior times. This corresponds with the time when maize became a more prominent dietary component for all community members. Both shifts may reflect the impact of geographic and sociopolitical disruptions at that time.

Tutankhamun’s Burial Assemblage: Normative or Atypical Mortuary Practices of the Eighteenth Dynasty of Ancient Egypt?

The burial assemblage found in the tomb of Tutankhamun, a pharaoh of the Eighteenth Dynasty (circa 1330 BCE) of ancient Egypt, is one of the most renowned collection of artifacts to survive from antiquity. But does it fit within the normative mortuary practices of the Eighteenth Dynasty? A closer and more comprehensive examination of the material culture found in the tomb of Tutankhamun indicates that several normative patterns were followed; however, many of the artifacts suggests atypical practices most likely from the despoliation of the burial assemblages of Tutankhamun’s predecessors.

Let's Talk Turkey: Turkey Use and Management at Postclassic Mayapán

The ancient Maya utilized two species of turkeys: the Ocellated Turkey (Meleagris ocellata) native to the Yucatán Peninsula, northern Guatemala, and northern Belize and the Wild Turkey (Meleagris gallopavo) from Central Mexico. The exact timing of Wild Turkey domestication and its introduction to the Maya area is unknown, although evidence as early as the Preclassic exists. The Ocellated Turkey was never fully domesticated but many scholars have proposed the Maya may have managed the species. To understand when the Wild Turkey was introduced to the Maya, whether the Ocellated Turkey was a managed species, and how these two species were treated compared to each other we used a combination of osteometrics, demographic profiles, and stable carbon and nitrogen isotope analysis on turkey remains from the Postclassic site of Mayapán. Previous research here found an abundance of Ocellated Turkeys hypothesized as an example of animal management and an absence of Wild Turkeys. Our results show the presence of both species however isotopic analysis reveals a difference in diet between the two, interpreted here as a difference in animal management strategies. In this paper we discuss these isotopic differences and the implications they have for understanding ancient Maya human and animal relationships.

Forward and "Faug a Balac": An Irish Immigrant Family dugout in Wisconsin

Much of the historical research on Irish immigrants, particularly women and children, focuses on those who moved to urban areas during the time of the Famine. Less has been written about Irish immigration prior to the Famine, particularly to rural areas. The McHugh family immigrated to the United States in 1825, settling in Waupaca County, Wisconsin, circa 1849. The McHugh site (47WP0294) was occupied by this family for over a century. Following her husband’s death in 1856, Mary McHugh was left to run the household. This was further complicated by the involvement of her eldest sons in the U.S. Civil War. The earliest occupation of the site is somewhat obscured by the heavy material culture presence of later generations of McHughs. The absence of material culture from the earliest period, coupled with the archaeological signature of a dugout house structure, provide insight into the lives of pioneer immigrant families in the region, and into the struggles of a female-headed household with many young children. Mid-nineteenth-century Irish immigrants to the frontier may have had more in common with contemporary rural lifeways in Ireland than with their brethren in the urban Irish diaspora.

Neanderthal Short-Term Occupations in Open-Air Sites: An Overview from Eastern Germany

Prehistoric hunter-gatherers frequently relocated in order to avoid foraging in previously depleted areas, and lakes and rivers played important roles in these movements as fixed locations on the landscape where foragers could have access to water and ambush parched animals. The types of human occupations along lakes and rivers could have been various according to the aims of displacements (e.g., logistical, residential) and the activities carried out at the shore (e.g., bivouac, hunting station, base camp). Repeated settlements on the same areas could have generated palimpsests rich of archaeological artifacts that are not always easy to disentangle and interpret. However, the discrimination of the raw materials and the comparison of the lithic assemblages with experimental knapping materials could be indicative of the integrity of the operative chains and the type of artifacts transported off-site. This paper aims to present new data on some Middle Paleolithic open-air sites located in lakeshores and riverbanks in Eastern Germany. The results indicate that the settlements were of short-term occupations and that Neanderthals applied different strategies of production and artifacts exports off-site.

Picin, Andrea (Friedrich Schiller University of Jena)

The Obsidian Trail: A GIS Model for Obsidian Trade Routes in the West Mexican Aztatlán Tradition (AD 900–1350)

The Postclassic Aztatlán Tradition of western Mexico is well-known for its expansive trade networks. Aztatlán merchants traded ceramics, shell, copper, and obsidian across vast distances. Obsidian provides us with a particularly unique opportunity to trace trade networks due to the compositional homogeneity of obsidian sources. Recent studies have identified the source of thousands of obsidian artifacts from numerous Aztatlán centers, allowing for an elaboration on themes such as access to exotic goods and socioeconomic relationships. The aim of this paper is to create a series of models of possible trade routes from seven Aztatlán centers to the most common obsidian sources identified in previous geochemical analyses. These routes have been established through a GIS least cost path using multiple cost surfaces and Tobler’s Hiker Function to estimate path distance accounting for variable walking speeds across differing terrain. Further variables used to estimate possible paths include land cover and various hydrological elements. Ultimately, separate models were created and compared that assume a preference for water and overland travel routes. The resulting models assess the possibility of convergence of trade routes to and from key obsidian sources and various Aztatlán centers and lend themselves to estimating relative import cost.

Late to Terminal Classic Changes in Architecture and Caching Patterns at Structure N10-15 in the N10[3] Palace Group at Lamani, Belize

The Maya site of Lamani in northern Belize exemplifies one of the longer occupation spans in the Maya Lowlands—continuously inhabited from the Preclassic (ca. 1500 BC) through the Spanish and British colonial periods (post-AD 1540). The N10[3] architectural group (Ottawa), located in the Central Precinct of Lamani, has been interpreted as a palace group of significance due to its lengthy occupation span and its location adjacent to two important ceremonial plaza groups. During the Late to Terminal Classic period (AD 624–962 at Lamani), the Ottawa Group underwent a major architectural transformation, which may be an indication of changing functions and strategies on the part of Lamani elites. During the massive remodeling some masonry structures were razed and replaced with wood buildings while others, such as Structure N10-15, continued to be remodeled in masonry. Here the architectural sequence of Structure N10-15 is examined in conjunction with the caching patterns present throughout the different architectural stages. When considered together, the architectural changes at Structure N10-15 and associated changes in cache composition and
placement may signal a shift in emphasis away from exclusive elite-led activities associated with divine kingship toward those of a more inclusive and public nature.

Pigott, Vincent C. (University of Pennsylvania Museum) [271] Putting a “Human Face” on Prehistoric Mining/Metallurgical Communities in the Khao Wong Prachan Valley of Central Thailand
In the context of prehistoric archaeology in Thailand, metallurgy has been accorded significant attention in the literature, ranging from the origins debate to smelting technology as well as the socioeconomic contexts of copper production. An important complementary component of these discussions is seeking an improved understanding of associated human occupations. In the Khao Wong Prachan Valley (KWPV) of central Thailand, a major regional copper production center, the Thailand Archaeometallurgy Project (TAP) has delved deeply in the nature of production processes at the sites of Non Pa Wai and Nil Kham Haeng. Over the past several years, TAP researchers have been making significant inroads into understanding issues including subsistence, bioarchaeology (human, faunal, and botanical), trade and exchange, site chronology, and the effects of copper smelting on human and environmental health. After a brief overview of TAP, this paper addresses several of these issues in the attempt to put a more “human face” on occupation at these two massive prehistoric copper production sites. This will serve as an introduction to a second paper that will present the results of a major new series of AMS dates from the KWPV, and their implications for Thai and Southeast Asian prehistory.

Pikirayi, Innocent, Federica Sulas (University of Pretoria), Tendai Treddah Musindo (Great Zimbabwe University) and Elton Munyaradzi Sagiya (National Museums and Monuments of Zimbabwe) [20] Great Zimbabwe’s Water
In southern Africa, Great Zimbabwe has long been the focus of research, debates and preservation as the remains of what was once the urban center of a vast state system. As new research findings are reframing the development of the Zimbabwe civilization in the region, local environmental settings and natural resources at Great Zimbabwe remain poorly understood. Using approaches in geoarchaeology, this paper presents Great Zimbabwe as a living landscape. New soil sequences from within and around the site reflect a complex history of water and soil management with indications of localized changes, rather than significant transformation over time. By placing Great Zimbabwe in its living landscape, we can access new sources of information for taking stock of the past and its legacies in the present for the benefits of both heritage and people.

Pilaar Birch, Suzanne (University of Georgia), Russell Graham (Pennsylvania State University), Eric Grimm (University of Minnesota), Jessica Blois (University of California, Merced) and Jack Williams (University of Wisconsin, Madison) [227] A New Stable Isotope Data Repository within the Neotoma Paleoecological Database
The Neotoma Database (neotomadb.org) functions as an interdisciplinary, open-access, and community-curated database for paleoecologists. Primary data types include proxies such as pollen, vertebrate remains, diatoms, and plant macrofossils. Because stable isotope data carry essential paleoenvironmental information about hydrology, diet, foodweb, and other signals, the structure of Neotoma has been modified to accommodate isotope data, thus facilitating the integration of these data with other paleo data. To date, the key bottleneck to our understanding of variability across not only spatial but also long-term temporal scales is not lack of data but rather a lack of exchange. Neotoma serves as a hub for storing and accessing diverse types of data that enable the building of “big data” from the long tail of individual sites, and offers an unparalleled opportunity for visualizing the intersection of multiple strands for paleoecological reconstruction from the macroscopic to microscopic and biogeochemical scales. In addition to the launch and initial population of the stable isotope repository, issues that affect all so-called big-data efforts exist as challenges for the future, including establishing best practices and standardization in recording/reporting, monitoring data quality, linking datasets, and increasing accessibility while protecting sensitive information.

Pilless, Peter [84] The Perkinsville Valley: The Fishes Enter the Uncharted Waters of the Upper Verde Valley
In the 1960s, a group of students at Arizona State University organized a multiyear program of archaeological survey and excavations in the Perkinsville Valley, an archaeologically unknown region briefly visited by Jesse Walter Fewkes in 1906. Starting with a wide-ranging reconnaissance, a survey identified 21 sites, indicating a long-term occupation throughout the entire cultural sequence of the Verde Valley, from the Early Archaic through the terminal AD 1300–1400 periods. A number of sites were excavated, identifying multicultural occupations by people of the Hohokam, Prescott, and Southern Sinagua traditions. This work was documented in a series of student papers but only a few publications, but the provided a tantalizing glimpse of the importance of the Upper Verde Valley to the prehistory of central Arizona. This paper will summarize the results of Arizona State University’s early work in the valley, and the significant contributions that Paul and Suzanne Fish have made to clarify the murky waters of Verde Valley prehistory.

Middle Horizon “Local” and “Exotic” Styles in Castillo de Huarmey and Pachacamac: Menzel’s Ideas Revised

Recent excavations at Castillo de Huarmey and Pachacamac leave no doubt that the earliest archaeological contexts associated with Middle Horizon in both sites are related to the second half of that period and coincide with the collapse of two main regional political systems on the Peruvian coast: Moche and Lima, respectively. Both systems, consolidated and politically transformed, have overcome adverse climate conditions of the sixth and seventh centuries AD. In the case of Castillo de Huarmey and Pachacamac, the ceramics of different styles and from various epochs (according to Dorothy Menzel’s terminology) are found within the same stratigraphic contexts. Our analyses show that styles, with “local” and “exotic” characteristics, both were locally produced. Style and technique diversity would be conceived as the result of the presence of workshops with craftsmen of native and foreign origins that could even be involved in the same artifact production. A complex political network capable of moving long-distance specialists and craftsmen, similar mutatis mutandis to the Inca Empire, had to be made to change the descriptions above possible.

El Registro de los Monumentos Arqueológicos como una Forma de Protección

El registro de los monumentos arqueológicos, muebles e inmuebles, que de acuerdo con la legislación mexicana vigente, son patrimonio de la nación, implica, amén de un ejercicio académico, un instrumento legal de protección, en tanto que significa el reconocimiento de la existencia física de dichos bienes patrimoniales, a través de su inscripción en un Registro Público. Esta tarea, iniciada hace más de setenta y cinco años, está encomendada al Instituto Nacional de Antropología e Historia (INAH), a través del Registro Público de Monumentos y Zonas Arqueológicos, Históricos y Paleontológicos. En esta ponencia se busca destacar el marco jurídico en el que está inmersa esta tarea, la génesis del registro de los bienes arqueológicos, vinculada al propio desarrollo de nuestro instituto y, de manera preponderante, su importancia no sólo como herramienta de protección de esta forma de patrimonio, sino también como “piedra de toque” para el desarrollo de investigaciones. Finalmente, nos interesa hacer una reflexión sobre los retos que encara esta tarea de frente al siglo que corre y al contexto académico, social y económico en el que se circunscribe.

Pink, Jeremias (Oregon State University), Ronald K. Fauselit (Pierce College) and Carlos Rojas Ortiz (Universidad Veracruzana)

Domestic Production and Use of Mold-Made Whistles and Figurines in Late Classic Oaxaca, Mexico

Mold-made ceramic figurines and whistles are a common component of Late Classic assemblages in the Valley of Oaxaca, Mexico, yet little is known about their ceremonial significance or context of use. Our excavation of an elite residential complex at the site of Dainzú-Macuilxóchitl yielded nearly 5,000 fragments of these ritual objects, the majority from midden deposits associated with an open stone platform that likely served as a ceremonial space for the residents. A small ceramic kiln located adjacent to this platform and recovery of 30 figurine molds from the same deposits provide solid evidence that many of these objects were produced on-site by members of this household. These findings suggest that figurine production and use were an important part of elite domestic ritual and that these activities were not exclusive to ceremonies held in the civic-ceremonial core of the site. This is consistent with broader patterns of political and social reorganization during the Late Classic, which were manifest in part through a shift in ceremonial focus from public, communal ritual to more private activities emphasizing the importance of individual lineages of elites.

Hunter-Gatherer Home Ranges in Arid Environments: Exploring Some of the Differences and Similarities

Deserts have traditionally been considered marginal environments, because survival depends on several factors. Some researchers have pointed to the importance of water for hunter-gatherers living in these environments, as well as the increased knowledge of the environment they lived in, and its resources, as well as the awareness and knowledge of neighbors on whom to call in lean times or with whom to interact and exchange partners and the knowledge of resources. Here we present two cases from two South American cold deserts—Patagonia and Puna, located at distances greater than 150 km from the coast and where evidence analyzed corresponds to the “effective human occupation” of the space, i.e., a moment when all desirable spaces were occupied, with the presence of neighbors. Aside from the difference in latitude, altitude varies between both deserts: Patagonia lies at lower elevations than the Puna. Within an ecological framework, we use raw material and plant provenance to evaluate home ranges, as well as the use of distant resources, including those of marine origin, to discuss interactions with groups located in other ecological regions. Reasons for similarities and differences found are analyzed and discussed.

Reevaluating the Case for America’s First Cities: Evidence from the Norte Chico Region of Peru

The Late Archaic Period (3000–1800 BC) was a time of dramatic cultural transformations in the Central Andes. At the beginning of the third millennium BC, at least 30 large, sedentary agricultural settlements with monumental architecture appeared between the Huaura and Fortaleza river valleys in a region known locally as the “Norte Chico” (“Little North”). Given the quantity, size, and complexity of monumental architecture at these sites, as well as the unique settlement patterns, some have argued that the Norte Chico region was home to America’s first cities. Despite over 20 years of research in the area, many basic questions remain concerning demographics, the built environment, and sociopolitical organization. This paper presents recent evidence from the Late Archaic sites of Huarcancha and Caballente. The precious development of the Norte Chico region during the Late Archaic Period challenges our current understanding of the development of social complexity, and these new data will inform models of settlement growth by providing insight from a unique cultural history not normally considered in discussions of urbanism.

[104] A Comparison of Miniature Pottery Vessels from the Reserve and Mimbres Branches of the Mogollon of Southwestern New Mexico

This study will compare the attributes of Miniature Pottery Vessels in the Mimbres and Reserve Branches of the Mogollon Cultural Area. I will focus on their types, forms, decorative elements, traces of use, and depositional context. The vessels will be no more than 10 cm (4″) or less in any dimension. This long-term comparison compares the similarities and differences of the vessel’s characteristics in the two regions in the years between AD 450 and 1450. This study may yield important data about interactions over time between the two important regions. I hypothesize that the social structure and regional interaction changed during over time. Further, this study may also show if and how populations moved, especially in the post-AD 1150 period. Did this late period with changes in environment and cultural reorganization, that included new religious movements, change or enhance the uses of these vessels?

[159] Modern Floods, Historic Fires, and Unstable Urban Landscapes in Charleston, South Carolina

The city of Charleston, South Carolina is situated on a peninsula in a naturally marshy environment threaded with tidal creeks. Since European settlers first began to develop the city in the late seventeenth century, these wet, low-lying areas were drained and filled in to accommodate expansion of the southern metropolis and combat disease. The result is a landscape, both in shape and relief, that has changed dramatically from one generation to the next. Fires, the threat of war, hurricanes, and slave rebellions all contributed to the making and remaking of this urban environment. Captured both in a carefully researched map constructed by Alfred Halsey in the 1950s and represented by a digital Geographic Information System (GIS) generated by the author, this paper argues for a landscape in constant flux that profoundly affects each generation’s relationship to the city around them. In light of recent construction projects on the peninsula destroying below-ground heritage despite robust protections for the built landscape on the surface, this raises important questions regarding archaeological interpretation of these complex urban sites and how those interpretations could be and are represented to the public.

[191] The Effects of Different Defleshing Practices on δ13C and δ15N of Modern Faunal Bulk Bone Collagen

Stable isotope values obtained from modern faunal skeletal material often provide important comparative data in zooarchaeological investigations of past food-web dynamics and human-animal interactions. Unlike archaeological material, modern faunal material requires additional time-consuming preparatory work prior to analysis (i.e., defleshing). Cooking and the application of proteolytic enzyme are quick and effective methods, but it is unclear if these techniques alter original bone collagen isotopic composition. This study explored the impact of four different defleshing methods on the δ13C and δ15N of modern mammalian bulk bone collagen. Mandibles from Castor canadensis carcasses (n = 4) were divided into four, and each subsample was subjected to a different defleshing treatment (manual defleshing; soaking in room temperature water; boiling; soaking in water-Protease solution). Three individuals demonstrated negligible (within the range of measurement error) δ13C and δ15N variation (±0.1‰, 1SD) among subsamples subjected to different defleshing methods. One individual demonstrated small, but significant variation in subsample δ13C (±0.2‰) and δ15N (±1.1‰) among defleshing methods. This variability is probably linked to method efficacy and remnant soft tissues contaminating the collagen sample. Overall, this work is a promising initial step toward reducing preparatory time of modern faunal material intended for stable isotopic analysis.

Households and Hopewellian Interaction in the American Southeast

The Middle Woodland period in the American Southeast was marked by a fluorescence of interaction, evidenced most prominently by Hopewellian exchange of exotic, symbolically-charged artifacts of stone, bone, shell, and minerals. The focus on exotic artifacts and their mortuary contexts has created a myopia toward exchange among elites, be they conceived as chiefs or religious specialists. However, recent work suggests that the exchange of exotics may have been secondary to more common exchange among households, including both utilitarian and craft goods, over both short and long distances. Household exchange may thus have provided the context for elite exchange, rather than the other way around.

Pobin, Briana (NMNH, Smithsonian Institution) [305] Early Stone Age Hominin Habitat Preferences: Predictions from a Modern Taphonomic and Ecological Study in Kenya

Two key resources that would have conditioned hominin behavior and habitat preferences in the Early Stone Age of Africa are food and water. This talk presents an examination of spatial relationships of these resources from a modern taphonomic and ecological study of large mammal carcasses at Ol Pejeta Conservancy, Kenya. The locations of fresh carnivore kills and older bone scatters that still retained within-bone nutrients (marrow and brains) are examined to determine whether these dietary resources are clustered or randomly distributed across the landscape, which habitat types they are most often found within, and how closely associated they are with fresh water. Based on these results, I will offer some ideas regarding hominin habitat preferences during the Early Stone Age—a time of increasing evidence for procurement of food resources from large mammal carcasses.

Poh, Yi Jia Gabriela (Poh Yi Jia Gabriela) [33] A Preliminary Discussion on the Migration of Early Xianbei and Their Subsistence Adaptations

The Xianbei tribe, prior to establishing their political regime, embarked on a journey of migration from the now-Northeast China to the “Central Plain”; and archaeologically, we observe their burials en route. Past studies focused on identifying the Xianbei from other tribes, but in the era of ethnic fusion, the in-congruence of burial goods with ethnic identity poses a range of complexities. This paper shifts focus to look at the Xianbei from an economic perspective to depict the social development that was previously underestimated. Unlike its politically-inclined development in later pre-regime stages, early Xianbei present a case of their adaptation to the external environment. Referencing related studies that have been done for Neolithic China, this paper utilizes primarily quantitative methods to analyze the burial goods of Xianbei tombs—production tools, ornaments, birch bark containers among...
others—and seeks to outline this economic shift in subsistence structure. A further comparison between tombs of three different sub-tribes—the Tuoba Xianbei, Tanshihui Xianbei and Eastern Xianbei also reveal varying degrees of adaptability among them. Unlike Tanshihui Xianbei’s unsustainable military exploits or Eastern Xianbei’s inactive migration efforts, this paper argues that Tuoba Xianbei’s eventual political success is linked to economic foundations laid via a steady, adaptive migration process.

Benefits of Time Travel: The McMaster Ancient DNA Centre

Our laboratory focuses on the preservation and degradation of organic signatures in archaeological remains. We devise and use state-of-the art genetic techniques to pull DNA sequences from tooth and bone remains to address questions of ancestry, origins, extinctions, and evolution. Currently the lab is focusing on the evolution of infectious disease, namely plague, using full genomic evidence garnered from victims of past pandemics. I will speak about the center, the overarching questions we are trying to address and the training graduate students can expect to receive during their MA and/or PhD work.

Faunal Remains from Recent Excavations at Shishan Marsh 1 (SM1), a Lower Paleolithic Open-Air Site in the Azraq Wetlands, Jordan

Excavations from 2013–2015 at the open-air site of Shishan Marsh 1 (SM1) located along the former wetlands shoreline in the Azraq Basin of eastern Jordan have yielded substantial Middle Pleistocene lithic assemblages in association with faunal remains. Skeletal preservation is poor, favoring the representation of megafaunal species and more robust elements. Multiple megafaunal taxa have been identified, including Gazella sp. (antelope), Bos cf. primigenius (wild cattle), Camelus sp. (wild camel), Equus spp. (two species of equid), cf. Stephanorhinus hemitoechus (steppe rhinoceros), Elephas sp. (extinct elephant), cf. Panthera leo (lion), and an additional large carnivore. The largely steppe-dwelling taxa were drawn to the relatively lush oasis environment, where they may have become the prey of the carnivores represented and the extant hominin groups exploiting these and other wetland resources. Blood residues from multiple taxa (horse, rhinoceros, bovine, camel, and duck) have been recovered from lithics displaying use wear, providing direct evidence of exploitation of the represented faunal species plus waterfowl by hominins.

Public Opinion and Archaeological Heritage: An Initial Perspective from Egypt

A recent survey of Egyptian public opinion on archaeological heritage issues focused on four main areas: level of public interest and participation in archaeology, the role of antiquities and monuments in contemporary society, perceived reasons behind the spread of the illicit antiquities trade, awareness of problems and issues that endanger Egyptian antiquities and monuments. Data collected from a sample of 908 residents across nine governorates in Egypt are used to examine trends and patterns in these areas. Respondents’ education, age, and gender examined as factors affecting opinion.

Late Pleistocene Archaeology in Argentina 47 Years Later

In the 1970s Ruth Gruhn and Alan Bryan spent several weeks in Argentina as part of a one-year trip around South America. In those years, Ruth and Alan started to challenge the Clovis-First Model for the peopling of the America, and their visit to South America was instrumental in consolidating their ideas as well as stimulating the research of Late Pleistocene archaeological sites. Subsequent travels to the region, especially the one made by Alan in 1980, contributed to generating the hypothesis that there were people in the Southern Cone before Clovis and promoted the investigation of local ideas as well. In this paper I summarize the recent advances in the study of these early archaeological sites (ca. 14 to 12 cal kyr BP) and focus on the sites of the Pampas region.

Pollack, David (Kentucky Archaeological Survey) and A. Gwynn Henderson (Kentucky Archaeological Survey)

Fort Ancient (AD 1350–1450) Domestic Rituals of the Middle Ohio Valley

In many parts of the world, the construction and maintenance of a domestic dwelling is often accompanied by rituals intended to bless the house, appease the ancestors, or please the spirit world. Within the Fort Ancient (AD 1000–1750) area of the middle Ohio River Valley, as evidenced at Fox Farm, a large Fort Ancient village in north-central Kentucky, such rituals may take the form of objects (pipes, shell or bone pendants, marginella shell beads, drilled deer toe bones [cup and pin game], projectile points, discoidsals, and ceramics) placed in the holes dug for exterior structural wall posts or interior roof support posts, and concentrations of animal bones (deer jaw mandibles or bear tibia) placed along the edge of a house basin. Other rituals are represented by sacred pole-pits that contain portions of ceramic vessels, animal bones, and plant remains deposited after the pole was removed but before the pit was sealed. In this paper, we examine the contextual association of these materials within houses at Fox Farm that were occupied during and after the Fort Ancient Transformation (AD 1375–1425) for how they may inform our understanding of Fort Ancient ritual life.

[320] Charting Long-Term Social Stability in the Tres Zapotes Region: Theory, Method, and Settlement Patterns
In 2014 we initiated the Recorrido Regional Arqueológico de Tres Zapotes (RRATZ) to implement the NSF-funded project, “Long-term Social Stability in the Tres Zapotes Region.” The goal of this project was to better understand the resilience of a tropical lowland polity through a millennium of political, economic, and environmental challenges, to document the preconditions that gave rise to this Olmec and Epi-Olmec polity, and to document the transformations that occurred in the wake of its decline in an area of some 400 km² that encompasses montane, piedmont, alluvial, wetland, and aeolian environments. In this paper we offer a theoretical and methodological overview of the project, grounded in political-economic and landscape perspectives and combining traditional pedestrian survey with advanced remote sensing technologies, including lidar. Further, we present initial assessments of changing settlement patterns within the Tres Zapotes hinterland.

[104] Archaeological Adhesives in the American Southwest
The ancient cultures of the American Southwest used various plant and insect exudates as adhesives in a range of artifacts, including mosaic plaques, arrows, wooden tools, and in pottery as a repair and sealant. The conservation department at the Arizona State Museum surveyed the adhesives used in the Pottery and Archaeological Perishable Collections, analyzing over 100 objects that included every major cultural group in the Southwest sourced to 35 different archaeological sites. Identification was made with Fourier transform infrared spectroscopy (FTIR). The study revealed that pine resin and insect lac were the primary adhesives. Insect lac, a polyester exudate from insects (Tachardiella spp.) endemic to the desert lowlands, was the predominant adhesive used by the Hohokam. Both pine resin and insect lac were found in artifacts from the Mogollon and the Ancestral Pueblo. Most notable is the extensive use of insect lac by the Mogollon, as most of the artifacts analyzed were excavated from areas dominated by pine. Host plants for lac insects do not occur above ~5000 ft., which indicates trade of this material into the Mogollon Rim and Colorado Plateau. The results also potentially indicate preference for lac in certain applications, especially as a hafting material.

Pope, Carly
[370] The Monagrillo Ceramic Complex of Panama in Subsistence and Social Contexts
The Monagrillo ceramic complex has been identified at myriad archaeological sites around Parita Bay, Panama. These vary widely in geography from coastal, to inland, to riverine places. In these different environments, there is disparate and varied evidence of agriculture, indications of hierarchical social structures, and relationships with the creation of pottery at Panamanian sites. I theorize that maritime resources as opposed to cultivation formed the basis of these sedentary or semi-sedentary groups, which made and used Monagrillo pottery to meet specific social needs. Some have posited that ceramics were initially created to store or cook staple grains, but the evidence from Panama indicates that agriculture was either not practiced or not relied on at the time pottery first appears in the archaeological record. Instead, maritime resources likely formed the foundation of these economies, as evinced by their geographic positions and the abundance of shell and fish bones excavated in the strata containing this incipient pottery. Without an agricultural impetus to create pottery, another catalyst for its invention must have existed. The scale and decoration of these sherds indicate that this catalyst was likely social: the expression of group or individual identity, status in a hierarchical society, or ideology.

Pope, Melody
[264] Exploring the Ineffable Aspects of Stone Tools
Use-wear analysis provides precise functional attributes for materials and provides yet another source of data for archaeologists to use in classifying objects. People who used objects in the past knew them in other ways including what they did, when and how they were used, and by whom. In my presentation I propose that by combining use-wear, technological, and spatial evidence it is possible to approach more closely the complex correspondences that exist between materials and people. Insights gained in doing so raise questions as to the ineffable nature of materials, the archaeological practice of classifying things, and the complex relations that exist between people and things like sickle blades for harvesting plants, drills for making beads, and points for tipping arrows and lances.

ZooMS and results compared to ascertain FTIR as a screening technique. This method was tested on assemblages from two Northwestern Italian sites: Riparo Bombrini and Arma Veirana. Both sites document the Middle-Upper Paleolithic transition with overlapping dates from distinct environmental components of the mineral fraction, in powdered bone fragments, as well as indicators of burning and fossilization. The bones were then analyzed by faunal analysis from newly excavated mound midden assemblages dating from AD 1400–1560. Around AD 1450, the settlement pattern in the region shifted and certain ritual practices were emphasized as others fell out of favor, suggesting there was a change in social organization. This paper demonstrates that there was a greater range of mound-top food consumption activities occurring during this time than previously documented. This newly observed pattern of food consumption in a ritual context at a large ceremonial center has implications for the communal nature of social organization in prehistoric Southeastern societies.

Portillo, Marta (Department of Archaeology, University of Reading) [275] 
*Human-Animal Interactions in Early Sedentary Societies in the Near East and Northern Africa: The MICROARCHAEODUNG Project*

The MICROARCHAEODUNG project aims to develop, standardize and integrate much-needed holistic interdisciplinary sampling protocols and analytical strategies for multi-proxy studies of livestock dung as an important archaeological material that is routinely overlooked or missed using conventional excavation procedures. MICROARCHAEODUNG integrates state-of-the-art analytical techniques in geoarchaeology, bioarchaeology and biochemistry to enable a robust identification and interpretation of ancient dung remains, their content and context. The project aims to develop these methods firstly in examination of dung in experimental and ethnographical research to provide comparative analytical data-set on the characteristics, preservation and context of modern dung materials, dung-products and depositional contexts. To explore the potential contribution of dung studies for tracing human-animal interactions and the developments of early farming, a selection of archaeological contexts are included from a transect through the Near East, one of the key heartlands in which plants and animals that were later domesticated occur naturally, and from still under-investigated regions of North Africa, a potentially critical area with implications for surrounding regions including the Mediterranean and the Sahara. These case studies span the critical periods of transformation from ca. 10,000 cal BC to the last centuries BC to delineate human-animal interactions through time.

*Andean Population Dynamics Revealed by Genome-Wide Data from the High Elevation Cuncaicha Rockshelter*

Present-day Andean human populations harbor a relatively high genetic diversity but a minimal population structure and differentiation among them. Moreover, mitochondrial DNA (mtDNA) and Y chromosome studies on precontact human remains suggest that both modern and ancient Andean populations derive from a single ancestral origin. However, nuclear ancient DNA (aDNA) data from the Andes in particular and South America in general are still too scarce to fully address questions on genetic continuity through time. The employment of enrichment techniques in the aDNA field now provides the opportunity of targeting over a million autosomal variants and increases the resolution on past population dynamics. Here we analyze mtDNA and genome-wide data of five human burials from the Cuncaicha rockshelter spanning between 9,000 and 4,000 years ago. Cuncaicha is an archaeological site at 4,480 m above sea level in the southern Peruvian highlands, which exhibits human occupation from the Late Pleistocene onward. Tracking genomic changes at the same site over a temporal transect will provide insights on the demographic processes shaping Andean populations across the Holocene.

*New On-Site Method to Evaluate the Quantity and Quality of Collagen in Archaeological Faunal Assemblages Using a Portable FTIR and ZooMS*

Faunal remains play an important role in helping reconstruct Paleolithic hunter-gatherer subsistence and mobility strategies. However, differential bone preservation is an issue in southern European prehistoric sites, which often makes morphological identification impossible. Zooarchaeology by Mass Spectrometry (ZooMS) is a new, low-cost method that will improve NISP statistical significance in a replicable way by using diagnostic peptides of the dominant collagen protein as a fingerprint of animal (including hominin) species. It is also a powerful tool to assess collagen preservation for radiocarbon dating. We present a test of a method for evaluating collagen preservation in the field prior to ZooMS analysis. Using a portable Fourier Transform Infrared Spectrometer (FTIR) equipped with an attenuated total reflectance accessory, we evaluated the relative abundance of collagen and various components of the mineral fraction, in powdered bone fragments, as well as indicators of burning and fossilization. The bones were then analyzed by ZooMS and results compared to ascertain FTIR as a screening technique. This method was tested on assemblages from two Northwestern Italian sites: Riparo Bombrini and Arma Veirana. Both sites document the Middle-Upper Paleolithic transition with overlapping dates from distinct environmental contexts (coastal and mountainous hinterland) differing greatly in collagen preservation.

Feasting and the Ritual Mode of Production in the Mesa Verde Region of the American Southwest

In the Southwest, feasting is understood as one of the primary mechanisms whereby small-scale agriculturalists of the past increased the social, demographic, and political scale of their societies. This study examines both artifact assemblages and communal architecture from a number of prehistoric sites in the Mesa Verde area. Consistent increases in the number and elaborateness of decorated serving bowls and the size of communal spaces suggest an increase in the frequency, intensity, and scale of ceremonial feasting from AD 600 to 1300. This trend tracks many of the expectations of Spielmann’s Ritual Mode of Production model, wherein ceremonial feasting creates the demand that underwrites and sustains economic intensification in small-scale societies.

Paleodiet in the Atacama Desert (Arica, Chile) and Andean Highlands (Ayacucho Basin, Peru) Using Stable Isotope Analyses of Dental Calculus

Long-considered a nuisance, dental calculus has recently enjoyed attention as a potentially useful alternative biomaterial for a variety of anthropological applications, including stable isotope analysis as a technique to study paleodiet. Carbon and nitrogen stable isotopes of dental calculus have been measured for populations near Arica, Chile in the Atacama Desert (Archaic-Late Intermediate period), and post-Wari (Late Intermediate Period) populations from the Ayacucho Basin, Peru in the Andean Highlands. The Arica analyses are characterized by very heavy δ15N compositions, from +17.5 to +31.1‰. These values can be explained, in part, by a diet with significant components of isotopically heavy marine resources and plants with δ15N shifted toward heavy values due to the hyper-aridity of the Atacama Desert. The heaviest δ15N values suggest the use of locally derived, isotopically heavy guano as a fertilizer during crop cultivation. The Ayacucho analyses show δ13C values ranging up to −12.3‰, consistent with the use of C4 plants as a major component of diet. δ15N values range up to +18.8‰, and as the site location likely precludes the use of marine resources, the heaviest values suggest the possibility of aridity-driven isotope enrichment and/or the use of camelid dung as a fertilizer during crop cultivation.

Pozi, Jacqueline (University of Wisconsin-Milwaukee)

Cultivating Methods for New Conclusions: An Analysis of Oneota Copper Artifacts of the Lake Koshkonong Region in Southeastern Wisconsin

Despite almost two centuries of North American prehistoric copper research, intensive archaeological investigations focusing specifically on Oneota copper are less abundant. Building upon previous studies, this project documented and analyzed over 500 Oneota copper artifacts in an effort to assess the production, utilization, and ideological and social significance of this copper materials. The artifacts of this study were recovered from four Oneota sites adjacent to Lake Koshkonong in Jefferson County, Wisconsin, dating to AD 1100 to 1400: Crabapple Point (47Je93), Schmeling (47Je833), Koshkonong Creek Village (47Je379), and Crescent Bay Hunt Club (47Je904). Methods for analyzing North American prehistoric copper artifacts are presented as well as the results of investigations in object form, damage, and general depositional context. For example, manufacturing marks and use worn observed on these objects provide arguments for multiple manufacturing traditions in the area and call into question previous assumptions about their technical utility. Additionally, the distribution of these artifacts and the iconographic symbols present among the collections suggest larger
ideo logical and social significance of copper within Oneota groups. Overall, this research provides possible standardized methods for future prehistoric copper studies and hopes to inspire additional Oneota copper research.

[358] When Archaeology Meets History: Documenting the Conquest and Transition Period at Pachacamac, Peru  
Traditional accounts of the conquest of Peru are well-known and universally accepted: in 1535, Francisco Pizarro—who had arrived two years earlier—decided to create a new capital in the neighboring Rimac river valley, which would one day become the current city of Lima. In order to achieve this, Pizarro forcibly displaced all the contemporary inhabitants of Pachacamac, leaving this major Inka pilgrimage site completely abandoned. However, new finds recovered during the 2016 excavations at Pachacamac are raising questions about this traditional view. Several pages of Spanish text written on parchment pages, dating to the sixteenth century AD, have been discovered. The pages were found in caches in building B4, and had been deliberately torn up. It clearly indicates a hitherto unrecognized continuity of occupation and building construction at Pachacamac in the early sixteenth century. A horseshoe along with horse and donkey bones were also unearthed in the same building. In this paper we discuss the original occupation and use of B4, as well as its transformation in early Colonial times.

[220] Form Is Emptiness, Emptiness Is Form: Reimagining the Pyramids at Cochasquí, Ecuador  
The archaeological site of Cochasquí, located north of Quito in the Ecuadorian highlands, has long been defined by its massive quadrangular pyramids with extended entry ramps. When Max Uhle arrived on site in 1932 he focused his excavations on the largest of the 15 known pyramids. Uhle’s work laid the foundations for the interpretations and the chronology of the site, which are still applied today. Archaeologist Udo Oberem conducted the most extensive excavations on site between 1964 and 1965, dating the occupation of the site from AD 950 to 1500. Oberem’s publications over his work have been considered the authoritative source on the composition of the pyramids at Cochasquí. Until recently, no excavations or reinterpretations of the site had taken place since the time of Oberem. In 2016, the Proyecto Arqueológico Cochasquí-Mojanda was created to place the archaeological site within a regional context and reexamine the deep-rooted conceptions of the site. While the pyramids are often thought of as being constructed in a uniform architectural style, recent analysis has indicated evidence of differing forms, construction techniques, and cultural associations which may hint at the intended function of the site’s most dominating and well-known structures.

[38] Effective Population Size and the Effects of Demography on Cultural Diversity and Technological Complexity  
The “demographic hypothesis” provides a recent example of how models can play an important role in driving new and interesting archaeological research. Influential models by Shennan and Henrich inspired the notion that, holding all else constant, members of larger populations ought to display more diverse and more complex tool kits than those in smaller populations. Empirical tests of this idea against the material culture of recent small-scale societies have yielded mixed results, raising valid concerns about the efficacy of the demographic hypothesis for explaining changes in technological complexity during the Paleolithic. Here I address whether the mixed results reflect deficiencies with the formal models or with the expectations archaeologists derived in order to apply them to ethnographic data. I use simulation to show that Shennan’s and Henrich’s models highlight different demographic effects, each of which applies to a different set of conditions. The concept of effective population size is central to understanding this distinction. In light of my findings, I argue that one way to increase the power of empirical tests of the demographic hypothesis is to hew them more closely to the conditions of the formal models that inspired the demographic hypothesis in the first place.

[50] Housepit 54 at Bridge River: Seventeen Anthropogenic Floors in Time and Space  
The Bridge River Archaeological Project initiated excavations of Housepit 54 in 2012 with the goal of developing an understanding of household history during the period of ca. 1,000–1,500 years ago. Excavations at Housepit 54 have revealed a remarkable sequence of 17 anthropogenic floors, 16 of which predate 1,000 years ago and reflect periods of rapid growth and stability. The earliest three floors derive from small (estimated 4–6 m diameter) oval structures followed by a seven-floor sequence representing an approximately 6 by 10 m rectangular house form. The final six-floor sequence consists of a much larger (approximately 13 m in diameter) oval structure. Within the floor sequence is evidence for consistency in domestic activities but also some significant variation. Two floors appear to have been engaged in large-scale cooking events as might be associated with community feasting. The final floor sequence provides some evidence for change in social relationships that may have included some degree of wealth-based inequality. This poster introduces the ancient floors of Housepit 54, placing them in their temporal and spatial context.

Strontium, oxygen, and carbon isotopes are measured in human tooth enamel from 66 burials in the Late Classic (ca. AD 600–750) Núñez Chinchilla residential group at. Approximately 50% of the individuals are identified as nonlocal based on strontium and oxygen isotope ratios. They came from a surrounding region including new data from Central America, and with the Maya area in general. More than 150 individuals from Copan have now been more individuals coming from the east later in time. These results are compared with other data from Copan, with baseline measurements from the introduces the project and its archaeological range: issues central to our understanding of how Scandinavia came to be what it is today, and the concerns the very origins of the Viking phenomenon, and our focus is thus on the critical period 750–850 CE and the decades either side. This paper in December 2015, the Swedish Research Council made an unprecedented investment in archaeology with a 10-year, multimillion dollar grant to the Viking Phenomenon. In December 2015, the Swedish Research Council made an unprecedented investment in archaeology with a 10-year, multimillion dollar grant to establish a center of excellence in Viking Studies at Uppsala University. Much of the recent research into the Vikings and their time (c. 750–1050 CE) has focused on the complex processes of state formation and Christian conversion that eventually gave rise to the modern Scandinavian nations. Far less attention has been devoted to the very beginnings of this trajectory: who really were the Viking raiders in a specific sense, why did they do what they do, what kind of societies produced them, and why did they start to expand so violently at precisely this time? The answers to these questions concern the very origins of the Viking phenomenon, and our focus is thus on the critical period 750–850 CE and the decades either side. This paper introduces the project and its archaeological range: issues central to our understanding of how Scandinavia came to be what it is today, and the sometimes problematic ways in which this knowledge of the Viking-Age past is received in contemporary society.

Price, Max (Harvard University)

Animal Husbandry at Late Chalcolithic Tell Surezha (Iraqi Kurdistan)
The Late Chalcolithic (fourth millennium BC) in northern Mesopotamia was a period defined by an increase in social complexity and inequality. The Oriental Institute of the University of Chicago’s excavations at the site of Tell Surezha on the Erbil Plain in Iraqi Kurdistan have brought to light new information regarding the settlement of the region during this crucial period. This region is not well understood, especially when compared to adjacent regions, such as SE Anatolia and the Jezireh. Moreover, there is virtually no prehistoric faunal data from sites on the Erbil Plain. In this paper, I present new data from Tell Surezha collected during the 2013 and 2016 excavation seasons. I focus on the management of animals during the transition to complex society in the early–mid-fourth millennium BC.

Assessing Hunter-Gatherer Mobility in Australia’s Western Desert Using Historic Aerial Imagery from the 1950s
Access to water, food, and other resources is a critical factor structuring hunter-gatherer mobility, but few landscape-level studies have examined how resource availability influences where foragers go and how long they remain at one place before moving on. Using a newly available set of aerial images from the Western Desert of Australia taken in 1953, we utilize a simple ideal-free distribution model to reconstruct forager mobility by the fire footprints they leave behind. We examine three predictors of forager mobility and population density as measured by the density and dispersion of recent fires: 1) water availability, 2) habitat diversity (access to two or more high-ranking ecological habitats), and 3) serial diversity (higher prior use by human hunters). If foragers are attracted to high quality patches, there are substantial implications for understanding the spatially heterogeneous nature of forager-landscape interactions as mediated through fire. This, in turn, has broad implications for understanding and interpreting land use and population movements from initial colonization of the continent to the present.

Price, Neil (University of Uppsala)
The Viking Phenomenon
In December 2015, the Swedish Research Council made an unprecedented investment in archaeology with a 10-year, multimillion dollar grant to establish a center of excellence in Viking Studies at Uppsala University. Much of the recent research into the Vikings and their time (c. 750–1050 CE) has focused on the complex processes of state formation and Christian conversion that eventually gave rise to the modern Scandinavian nations. Far less attention has been devoted to the very beginnings of this trajectory: who really were the Viking raiders in a specific sense, why did they do what they do, what kind of societies produced them, and why did they start to expand so violently at precisely this time? The answers to these questions concern the very origins of the Viking phenomenon, and our focus is thus on the critical period 750–850 CE and the decades either side. This paper introduces the project and its archaeological range: issues central to our understanding of how Scandinavia came to be what it is today, and the sometimes problematic ways in which this knowledge of the Viking-Age past is received in contemporary society.

New Isotope Data from Classic Maya Copan
Strontium, oxygen, and carbon isotopes are measured in human tooth enamel from 66 burials in the Late Classic (ca. AD 600–750) Núñez Chinchilla residential group at. Approximately 50% of the individuals are identified as nonlocal based on strontium and oxygen isotope ratios. They came from a variety of places in the Maya area. Comparison with an Early Classic burial group suggests substantial changes took place in the origins of migrants with more individuals coming from the east later in time. These results are compared with other data from Copan, with baseline measurements from the surrounding region including new data from Central America, and with the Maya area in general. More than 150 individuals from Copan have now been isotopically measured and these data provide a detailed picture of human movement at Copan and in the Maya region more generally.

White Bones in Black Caves: Cave Burials and Social Memory
Caves have always been part of contemporary, living landscapes: as such, they have acted not only as natural, cultural, social, economic, and ritual places, but also as political locales. One of the most recent, and contested, examples of this phenomenon in Slovenia is the use of karstic shafts as sites of post-war executions between May 1945 and January 1946, in the aftermath of the Second World War. Such sites of mass executions are used as a starting point of this paper in exploring the tensions between cave burials and social memory. More specifically, particular caves are examined in relation to local knowledge, identity, storytelling and the tensions between public remembering and forgetting. The findings of the historical and ethnographic research are then used to reflect on selected examples of historic and prehistoric cave burials, their relation to place-power, local identity, and social memory, with the aim to demonstrate the need to rethink many of traditional archaeological interpretations.

[319] *The Beaver of Children and the Poor: The Social Dimension of Fur-Bearing Mammal Exploitation in Central British Columbia*

The intensive Historic Period exploitation of beaver and other fur-bearing mammals, especially those that are small bodied, has typically been seen as a fur trade phenomenon that can be explained in terms of optimizing returns of both material capital and prestige represented by European goods through the use of more efficient technologies introduced by Europeans. If this were strictly the case, we might expect to find a greater representation of the remains of beaver and small fur-bearers in Historic Period Indigenous archaeological sites than we do in Prehistoric contexts, but such comparisons are rarely undertaken. An analysis of faunal assemblages from contexts spanning the last millennium on the Nechako Plateau of central British Columbia is presented here and demonstrates that beaver and other fur-bearers were a ubiquitous part of people’s prey choices. I argue that, in the long term, the place of these animals in the diet and culture of the area is better explained in terms of their potential social values than as strictly a matter of economic optimization.

[300] *Dietary Ethnogenesis? An Examination of Dietary Patterns at the Santa Clara Valley Medical Center Potter’s Field, California*

Previous research into nineteenth-century dietary variation within the United States has found significant variation based on social class, ancestry, and region. However, research to date has not systematically examined the specific social, cultural, and economic factors that contribute to dietary variation found throughout the United States during the nineteenth century. This study examines stable isotopes of carbon, nitrogen, and oxygen to examine the relationship between ethnic preferences, regional specialization, and socioeconomic status and diet among individuals interred at the Santa Clara Valley Medical Center potter’s field (1870–circa 1935). The results demonstrate that local agricultural industry and low socioeconomic status play more important roles in explaining dietary patterns than ancestry or ethnic differences at the Santa Clara Valley Medical Center. Despite cultural preferences in food preparation, the ingredients regularly consumed are often isotopically similar. This factor likely explains some of the variation observed in diet across the nineteenth-century United States. Stable isotope analysis provides a useful tool for exploring the relationship between the development of agricultural industries and dietary patterns, and provides an avenue to research how socioeconomic status related to food choices in the nineteenth-century United States.

[270] *Mapping the Mines: Simulating Transit Routes between Mining Centers in the Colonial Andes with GIS*

Least cost path has been the method most commonly employed by archaeologists in attempts to determine routes from one site to another. This is due to the relative ease of use of this particular tool, as well as the parsimonious logic of this approach. The tool is also particularly useful where material remains of roads are no longer visible. However, the use of network analysis provides a more realistic possible route by taking into account known possible paths. Network analysis provides an alternative mode of simulating routes as it utilizes previously defined paths as the basis for its analysis. This method of route reconstruction is used less frequently, in large part in the face of insufficient data on probable paths. However, in many cases, data on ancient routes is available to archaeologists in the form of survey or technical reports. This study aims to compare the relative effectiveness of least cost path analysis and network analysis in extrapolating the most plausible route between Huanacavelica and Potosí in the seventeenth century, using available data on the Qhapaq Ñan.

[11] *Maya Child Sacrifice via Cranial Punctures*

Our knowledge of Maya human sacrifice is drawn from iconographic representations and contact period Spanish sources. Unfortunately, the corpus related to child sacrifice is extremely limited. In 1971 David M. Pendergast described the burial of a child from Eduardo Quiroz Cave with traumatic perimortem holes in the parietals. Later, Brady reported on a second child with similar wounds. Both Pendergast and Brady interpreted the evidence as reflecting child sacrifice. The recovery of thousands of human bones and bone fragments from Midnight Terror Cave in 2010 yielded evidence of similar perimortem trauma in the cranial of at least one individual. This poster compares the contexts of the punctured skulls found in the human remains in...
Eduardo Quiroz Cave, Naj Tunich, and Midnight Terror Cave to suggest this as a heretofore unrecognized method of Maya sacrifice, at least for children.

Prüfer, Keith M. (University of New Mexico) [162] The Development and Resilience of Complex Polity in the Southern Maya Lowlands: A Decade of Research at Uxbenká, Toledo, Belize
The original goals of Uxbenká Archaeological Project were to understand the geopolitical history of the polity in the context of wider regional developments during the Classic Period. Long suspected to be the earliest complex polity in southern Belize had intrigued archaeologists for decades based on its prominent locations between the Petén and the Caribbean Sea as well as its long history of descendant communities farming lands around the archaeological ruins. From 2008–2015 the Human Social Dynamics project greatly expanded our understanding the ecological context of human occupations in the region. These studies included detailed landscape histories of occupations throughout the Holocene, the development of extremely high-resolution climate proxies from nearby caves, and expanded archaeological research into the sociopolitical development and decline of the polity and its associated settlement system. Parallel to these studies, ethnographic and human-ecological research in the local community detailed linkages between past and present and developed integrated education programs in cultural and environmental heritage for children and adults.

Pryor, Alexander (University of Southampton), Alistair Pike (University of Southampton), Jiri Svoboda (Masaryk University and Czech Academy of Sciences.), Alexander Dudin (National Archaeological Museum in Kostenki, GBUK VO,) and Clive Gamble (University of Southampton) [223] Reconstructing Paleolithic Prey Migration Using Oxygen and Laser Ablation Strontium Isotope Measurements in Tooth Enamel
This presentation reports isotopic data collected for an investigation of food storage behaviors at the European Gravettian sites of Dolní Věstonice-Pavlov (Czech Republic) and Late Glacial site of Kostenki 11 (Russian Federation) dated between 30,000 and 20,000 years ago. Our methods use strontium isotope (high-resolution measurements by laser ablation) and oxygen isotope analysis to investigate seasonal mobility of the main prey species: woolly mammoth, reindeer, horse, fox and wolf. The isotopic data reveal when animals were seasonally present near to the sites, when they were seasonally absent, and how predictable the animals were year-to-year with their movements. Data measured for woolly mammoth are particularly interesting as their teeth grow continuously throughout life and record up to ten years continuous mobility/climatic data per tooth. Results for each site show a clear pattern of habitual migration in mammoth and reindeer, while horses lived in single territories the whole year round. Additionally, in choosing where to locate their basecamps, humans do not appear to have targeted the migratory routes themselves but instead focused on the seasonal territories where fauna reliably spent several months each year. The talk will conclude by discussing the potential significance for Paleolithic food storage behaviors at 30,000 years ago.

Pryor, John [366] We Travel Together: A New Archaeology that Blends Western Science with Native American Perspectives and Values
After 45 years of doing archaeology in both an academic and CRM context, I have come to the conclusion that archaeology as I have been practicing it simply no longer works for me. For the last 15 years my archaeology has been with and for Native Americans, and this collaboration has led me to many wonderful insights and has enriched the archaeology I have come to practice. This new approach is not a rejection of Western science but the blending of the best that we both have to offer. This new approach must be an equal partnership based on respect from both sides. To create this new archaeology will perhaps be a long journey, but one we must travel together—Native Americans and archaeologists.

Przadka-Giersz, Patrycja (University of Warsaw) [316] Ladies of Castillo de Huarmey: Women’s Wealth and Power during the Wari Empire
In recent decades, Andean archaeology has shown an increasing interest in studying women and the roles they played in ancient society. The spectacular discovery of the imperial mausoleum at Castillo de Huarmey represents the first undisturbed burial context of 58 noblewomen accompanied with six human sacrifices, two tomb guardians, and hundreds of precious artifacts, and provides groundbreaking data on female status in Wari Empire. The amount and the richness of the luxury and prestige items, which comprise over 1,300 objects of the most various kinds, provide important data regarding the identity of high-status women and their social and economic role in the Andean world in the past. Supplementary ethnohistorical sources of the wills of indigenous elite women of the early colonial period claim that both female attire and personal grave goods imitated the symbolic image of the queens and princesses of antiquity, who had a very similar role to that of the noble ladies buried in the mausoleum of Castillo de Huarmey.

Psomiouennou, Aikaterini (University of Illinois at Chicago, Anthropology Department) [294] The “Visible” Dead: Mortuary Patterns and Ceremonial Activities in the Dawn of the Bronze Age in Southern Greece
Following anthropological theory regarding the dynamic relationship between the living and the dead, this paper will explore the role of mortuary and ceremonial places as important venues for human activities related to broader social phenomena and cultural changes. By the mid-third millennium BCE southern Greece had witnessed the emergence of social stratification evident both in the settlement and mortuary archaeological record. Little is known, however, regarding the preceding period and the processes that led to this inequality. Based on case studies from the end of the Neolithic and the beginning of the Bronze Age (mid-fifth—end of fourth millennium BCE) in southern Greece, this paper provides a preliminary study of mortuary analysis and radiocarbon dating of human burials. The end of the Neolithic period is characterized by a proliferation of burial remains, a variety of ceremonial activities, and the creation of the first extramural, organized cemeteries. Further investigation on this mortuary dataset could provide valuable insight on the emerging complexity evident in the later period.

Puckett, Neil (Texas A&M CSFA), Kelly Graf (Texas A&M CSFA) and Angela Gore (Texas A&M CSFA) [332] The Spatial Statistics of Owl Ridge: Identifying Activities and Camp Use
The Owl Ridge site, located in central Alaska's Nenana Valley, is an excellent example of a stratified, three-component campsite. The three components span the late Pleistocene/early Holocene boundary with component 1 dating to 13,110–12,730 cal BP, component 2 dating to 12,580–11,310 cal BP, and component 3 dating to 11,400–10,710 cal BP. The presence of discretely dated and stratified components provides an ideal opportunity to identify local changes in land use, in the distribution of camp activity areas, and in the nature of camp activities over time. Statistical analyses including nearest neighbor, K-means clustering, and kernel density estimation were performed using ArcGIS. Tests were performed on each site component as well as within-component artifact types using both two- and three-dimensional views. The results demonstrate that there are distinct, statistically significant spatial arrangements of general artifact clusters and artifact clusters by type within each component. The spatial arrangement of artifact clusters differs by component illustrating site use change over time. When combined with previous spatial analyses focused on artifact raw material type, the spatial analysis at Owl Ridge reveals that humans were using the landscape and the site area in appreciably different ways during each period of occupation.

Ancient Metal Routs in the Tarascan Señorío: Mining, Smelting, Smiting

At the Tarascan Señorío, all the metal work aspects were controlled by the uacúsecha (most important clan) leaders, from their central cities of Pátzcuaro, Ihuatzio and specially Tzintzuntzan by the Pátzcuaro Lake in central Michoacán. In this paper we present the different aspects of the metal work, and the control that the uacúsecha nobles imposed, expressed in the architecture and their most relevant adornments like metal earplugs and lip-plugs, from the mining sites in the Tierra Caliente, where are their most important mines, sites for smelting near by the mines, to another ones far away in key parts of the most relevant routes, sites far away from the mines for primary smelting and other ones where specialized artisans create unique metal items, consumed by uacúsecha nobility and all the caciques of the Tarascan territory.

Archaeobotanical Analysis from the Cane River Site (31Yc91)

In this paper, we present the results of archaeobotanical analysis from the Cane River Site in Yancey County, NC. Thirty-three samples were collected during the 2013–2014 field season from features associated with different spatial contexts such as household architecture and palisades. Our results show that corn, beans, and squash are ubiquitous in the assemblage, indicating that Cane River has unexpectedly high amounts of domesticates given its higher elevation and lack of lowland floodplains. In addition to the evidence for agricultural practices, wild plant foods such as mast seeds and acorns demonstrate that a broad variety of mountain resources were exploited. We will compare the thriving cultivation of domesticates and collection of a wide variety of wild plant resources at Cane River to other Mississippian botanical assemblages from adjacent South Appalachian sites to determine how it fits into a broader pattern of Mississippian food practices in the region.

Cahokia’s Mound 34 and the Moorehead Moment

Cahokia’s Mound 34 was an essential component of the dramatic reorganization of the eastern portion of Cahokia’s site core at the turn of the thirteenth century. Since the 1990s the Mound 34 Project has included examination of a copper workshop, the exploration of a complex mound construction history, and extended study of Mound 34’s special role in the production and exchange of Southeastern Ceremonial Complex art. The construction of this mound and a series of other low platforms adjacent to the sunken Ramey Plaza permits the development of a novel ritualized public space in east Cahokia, as the occupants created and re-created an artificially leveled field and the second largest plaza of Cahokia’s history. Our ongoing excavations have recently confirmed the southern margins of a large trench excavated into the mound in the 1950s, along the way confirming additional sub-mound structures connected to the Late Stirling/Early Moorehead (circa AD 1200) pre-mound surface adjacent to the developing Ramey Plaza, and portions of the architecture of a moundtop structure likely built early in the Moorehead phase.
Pursey, Lance (University of Birmingham)

Recent insights into how urbanism and permanent settlements can function and be integrated into mobile societies has helped to overturn the notion that human societies ‘progress’ from mobile forms of production through irrigated agriculture to urbanism. Indeed the Liao Empire (907–1125 CE) of Northeast Asia shows how these three modalities can coexist and be interdependent. City and kiln sites, standing architecture and tombs are distributed extensively through the former Liao territory, and yet in a society that encompassed sedentary and mobile populations the cultural salience of being “urban” remains unexplored or presumed to be homologous to those of Tang (619–907) or Northern Song society (960–1125). This paper uses textual geographical data found in published epigraphical and biographical sources from the Liao period, combined with the spatial and archaeological context of Liao epigraphy to map the movements of Liao elites over the landscape, as well as political relationships within networks of the Liao administrative geography, with an aim to elucidate what it meant to be ‘urban’ in the Liao.

[325] An Interactive Scenario of Agricultural Intensification and Environmental Evolution: A Case Study at Sanyangzhuang Site

Over the last 10,000 years, agriculture has gradually been intensified, and become the globally dominant way of subsistence. However, the relationships between agricultural intensification and environmental evolution are not fully clarified. Deeper understanding of the issue may be gained through research at Sanyangzhuang, a rural settlement site in present Henan Province in central China. Many agriculture features, such as ridge-and-furrow fields, have been recovered in three strata. Additionally, a complete history of the Yellow River floods has been recorded in the stratum around Sanyangzhuang site. All these features enable our further exploration of interactions between agricultural intensification and environmental evolution. By use of data from Sanyangzhuang site, this paper first examines two dynamic environmental factors as the potential driving force of agricultural intensification: the East Asia Monsoon determined paleoclimate and the alluvial process of the Yellow River. Then it explores the impact of agricultural intensification on the environment and landscape from a geoarchaeological perspective. By integrating these two lines of evidence, the interactive process of the agricultural intensification and the environment in the Central Plain, China from the late Neolithic to the early Iron Age is revealed.

Qu, Tongli (School of Archaeology and Museology, Peking University)

[78] Subsistence in the Late Pleistocene of China: A View from Laonainaimiao Site

The paper presents the taphonomic and zooarchaeological analyses of the fauna from the Laonainaimiao site of Late Pleistocene in the central plain area of China. The taphonomy observation shows that the bones were accumulated by human activity. The taxa of the fossil assemblage is composed mainly of Equidae and Bos primigenius, followed by gazelle, deer, wild boar, rhinoceros, etc. Most carcasses of Equidae and Bos were likely to be transported to the site as a whole. The carcasses were intensively exploited for marrow and grease, probably due to the lack of fat during the harsh season. A prime-age dominated profile of the Equidae and Bos indicates the capability of hunting and the potential cooperative behavior. Laonainaimiao site adds important insight into the subsistence and culture in the middle Upper Pleistocene in China.

[117] Multiple Evidences for Variations in Subsistence Strategy of Prehistoric Humans from the Guanzhong Area in Shaanxi Province, China

Influenced by the continual infiltration of surrounding cultures and the extension of agriculture originating in various independent centers, the multi-cultures and diversified economy had been formed in the Guanzhong area, Shaanxi, in the process of the prehistoric culture evolution. In this paper, the comprehensive analyses of stable isotopes (carbon and nitrogen) of humans and animals and the plant and faunal remains from the different periods and sites in the Guanzhong area will be employed to examine the evolving regularity and the influential factors of subsistence strategy of prehistoric humans. It will present compelling evidence to study the key topics on the agricultural origin and development, agricultural extension and dissemination, and the influence of cultural communication on agricultural development and agriculture responses to climate changes in the Holocene, north China.

[196] Burning Questions about Preservation: An Investigation of Cremated Bone Crystallinity in a Bronze Age Cemetery
The elemental and isotopic analysis of human skeletal remains has greatly added to our understanding of diet, mobility, and social variability in prehistoric societies. For studies of this nature, it is critical to evaluate the preservation of the skeletal material prior to analysis to make sure that taphonomic processes have not affected the original chemical signatures. Calcined bone (usually produced from cremation burial practices) is generally avoided for chemical analysis due to heat induced chemical changes (e.g., isotope fractionation) and the porous structural properties of bone (as compared to tooth enamel). Recent work indicates that calcined bone may in fact retain “in vivo” chemical signatures for radiogenic isotopes due to increases in crystallinity that makes it more resistant to postdepositional diagenesis than unburned bone and teeth. In this study, Fourier Transform Infrared Spectroscopy (FTIR) is used to evaluate the crystallinity of cremated bone from a series of burials from the Békés 103 site, a Bronze Age cemetery from Eastern Hungary. This technique is used to investigate the crystalline and chemical structure of calcined and non-calcined bones within the cemetery. Our study will be used to determine which specimens could potentially be analyzed for strontium isotope composition in future work.

Status and Identity at the Margins of Empire: Foodways in Pre-Inka and Inka Cuzco

Diet and cuisine are key practices in the daily negotiation of status and identity, particularly when studied at the household level. In the Maras region of rural Cuzco, the developing Inka state and a rival polity known ethnographically as the Ayarmaka maintained autonomous economic, social, and political practices. While other groups in the Cuzco region exchanged goods and shared some cultural practices with the Inka, the Ayarmakas did not. In the fifteenth century, the Ayarmaka suddenly abandoned the principal settlements in their homeland, and Inka rulers developed the Maras area into royal estate lands in the generations that followed, settling foreign retainer laborers there instead. Recent excavations at the largest sites in Maras during the pre-Inka and Inka periods provide a diachronic view of household economies at the margins of the growing Inka empire. Faunal analysis at both sites yields intrasite and intersite comparisons of social status and ethnic identity. We find greater distinctions among pre-Inka Maras contexts, and fewer in the Inka resettlement of retainers, based on the examination of taxa, species richness, cameldid age-at-death and meat yields, and meat preparation techniques. This study reconstructs the local interactions of rival and subject populations in the imperial Andes.

Long Distance Provenances of Jewelry (Variscite and Turquoise) along Atlantic Europe during the Neolithic (Fifth–Third Millennium) Based on PIXE Analysis

The exceptional quality of the green lithic adornments (jade axes, beads) deposited in the large grave mounds from Brittany, France, constitute the most impressive funerary architecture of the Neolithic period in Western Europe. The highest density of callais jewelry occurs in the Carnac region with over 800 green beards and pendants found in 33 Neolithic sites. A research program based on the chemical analysis of archaeological artifacts and geological samples from European deposits using the PIXE technique (particle induced X-ray emission) was conducted in order to determine their provenance. A chemometric model has been established from the acquired geochemical database. It allowed to conclude that 1) most artifacts were made of variscite, very few of turquoise; 2) all archaeological materials originated from the Iberian Peninsula; 3) from the half of fifth millennium until about 4000 BC, variscite was extracted from sources located in SW Spain (Encinasola, Huelva); 4) a procurement change occurred early in the fourth millennium, most variscite originating from NW Spain (Palazuelo, Zamora); 5) none of the Neolithic objects from Brittany were made of variscite from the well-known Mediterranean deposit (Gavà, Barcelona); and 6), during the Neolithic period, long-distance exchange of variscite-turquoise mostly developed along the Atlantic coast.

Toward a Deep History of Southern Appalachian Copper Mining: New Agendas and Approaches

Copper was an important raw material throughout the prehistory of the Eastern Woodlands of North America. The role of southern Appalachian copper in social, economic, political, and ideological systems across the Eastern Woodlands has received little attention from anthropological archaeologists, particularly compared with copper from more famous procurement zones in the Great Lakes region. In this paper, we present the first steps of a new collaborative research project designed to understand the deep history of southern Appalachian copper extraction, production, and exchange. Building on a synthesis of geological information and historical records of copper mining in the southern Appalachians, this paper presents the context and background that informs research agendas and analytical approaches to the study of the origins and development of copper mining in the region. We argue that a holistic research approach that considers copper extraction at multiple temporal, spatial, and social scales is necessary to characterize how copper procurement was organized and changed throughout prehistory and to better understand the roles of copper in the lives of communities within and beyond the southern Appalachians.

Toward a Further Understanding of Samoan Star Mounds: Considering the Intersection of Ecology, Politics, and Ritual in Ancient Samoa

Star mounds, named for their star-like shape, have been an enigmatic feature class in the Samoan Archipelago. Researchers have posited several potential functions for these monumental architectural features, including grave and territorial markers, but their primary function appears to have been as surfaces for pigeon catching. But, excavations of these features have been few and data limited. Here, we review old as well as recent data on star
mounds relating to their physical attributes (size, shape, and materials), distribution, and chronology to identify patterns of similarity and variability. In so doing, we provide a more robust understanding of their relationship to the landscape and their role in ancient Samoan society, notably politics and ritual. We argue that when placed within a ritualized context, the “sport” of pigeon catching provided an avenue for the demonstration of mana and prestige. In Polynesia, such demonstrations were important for legitimizing and substantiating status, both individual and group (the higher the rank of the individual, the larger the group represented). Star mounds thereby served as arenas for status competition, potentially taking the place of warfare. The distribution and form of star mounds is the outcome of ecological reasoning, ritual logic, and political maneuvering.

[276] When Provenience Is Lost: Achievements and Challenges in Conserving the Historical St. John’s, Belize Skeletal Collection

Funding in small developing countries like Belize for archaeological research and post excavation curation remains one of our greatest challenges to preserving our tangible cultural heritage. The state of curation of human remains and artifact collections at St. John’s College in Belize City is a perfect example of what can go wrong when there is not established a properly funded and managed curation program both at the national level or the institutional level. This paper highlights the rediscovery of a historically significant group of human remains (n = 70+) in the biological collection of Friar Deickman that was forgotten in an attic after his death in 2003. We outline the process and accomplishments in improving the curation conditions of these individuals while uncovering their context and importance to Belize’s history in the eighteenth–twentieth centuries. Preliminary analysis reveals life-histories of slavery and indentured servitude of individuals of African, Maya, European, and possible mixed African and European descent. We emphasize the importance of ethical responsibility to properly curate human remains once excavated, the challenges researchers face once poor curation results in lost provenience, and suggestions for scientific analysis in recovering the information lost as a result of poor excavation and/or curation methods.

“Big Data” requires consistency in the structure and description of data from different sources, so that patterns in the same attributes can be identified across datasets. Unfortunately, archaeological datasets are notoriously inconsistent in both structure and terminology. Various attempts have recently been made to resolve this problem and enhance interoperability. One strategy that has worked well for the aggregation of spatially situated data involves spatial gazetteers expressed as Linked Data; these allow heterogeneous data sources to align place information through the use of unique place identifiers maintained by a shared external reference. Temporal information, however, remains a problem, as archaeological chronology is often expressed in terms of interpretive periodizations rather than absolute dates. The PeriodO project seeks to translate natural-language period terms into machine-readable coordinates in time and space. The project’s first phase created a Linked Data gazetteer of period definitions, each including specific spatio-temporal boundaries explicitly stated by an authoritative source. Here we report on the second phase of the project, involving the implementation of PeriodO identifiers in large datasets. These identifiers make it possible not only to align period terms across datasets, but also to compare absolute dates with conventional period boundaries on a larger scale than ever before.

[167] Micro-Regions and Materiality: Artifact Analysis at Panchmata, India

Regional, landscape, and spatial analyses in South Asia are often conducted at large scales in order to encompass all potential sites that share a common material culture, polity, or economic system. As these analyses often overlap with culture history designations and simultaneously span multiple geographic and environmental conditions, they can obscure material diversity and human-environment relations. This paper carefully considers scale of analysis and argues that micro-regions, small areas that comprise just a few sites in the same environmental context, are the perfect size for studying material culture in South Asia. Sites within a micro-region lie within walking distance in the same ecological niche, and often draw from the same resources. Micro-regional analysis acknowledges that much social activity happens “off-site,” in the fields, rivers, and woods that lie between designated archaeological sites. That is, inhabitants of micro-regions created communities that crossed site boundaries, participated in overlapping economic networks, and shared common histories. Utilizing a micro-regional framework also allows researchers to consider social formations apart from national narratives. This paper provides a micro-regional analysis of the site of Panchmata, in the Mewar Plain of northwest India with the goal of providing an alternative narrative about Indian pasts.

[300] Return to the West End Site: Zooarchaeological Results from a Tongva Village on Catalina Island

Native American subsistence practices on the California Channel Islands are characterized by a variety of rich marine sea foods ranging from shellfish to dolphin. Fluctuation in these maritime diets throughout the Holocene has been posited to represent social and ecological phenomena in the ancient past. This poster presents recent zooarchaeological results, as well as the first radiocarbon assays, of a faunal collection that was excavated from the West End Site on Santa Catalina Island in 1972. The site has previously been characterized as a craft specialization site focused on small soapstone objects that were traded in the region. This study builds on past scholarship and expands our understanding of Island Tongva (Gabrielino) activities at this site through an analysis of the animals they incorporated into their lives.

[226] From Los Tapiales to Cuncaicha: Terminal Pleistocene Humans in America’s High-Elevation Western Mountains

Among Ruth Gruhm’s remarkable archaeological accomplishments has been the investigation of the first truly high-elevation Paleoindian sites discovered in the Americas. The open-air camps of Los Tapiales and La Piedra del Coyote in the Guatemalan highlands, located respectively at 3,150 and 3,300 m above sea level, contained fluted Fishtail projectile points and rich, diverse tool and flake assemblages. Importantly, both sites were securely dated to ~12,500 cal BP, indicating early use of high-alpine meadow habitats beyond the limit where low-oxygen conditions affect human physiology. Provenance analysis of Los Tapiales obsidian indicated acquisition from sources 50–75 km distant to the east and the west, suggesting long-distance mobility or exchange between diverse ecological zones. Since Gruhm’s seminal publications on these Guatemalan highland sites, many early sites from America’s western mountains have come to light, from the Rockies, to the Central American Sierras, to the South American Andes.
Among these, Cuncaicha in the high Andes of southern Peru has provided especially high-resolution data that enrich our understanding of early highland forager adaptations. There are more similarities than differences among these early sites in the western hemisphere’s highlands, a pattern that calls for greater archaeological attention to mountain landscapes and international collaboration.

Reverse Engineering Dart Point Design Requirements Using Whole Points from a Middle Woodland Site in Mississippi
Reverse engineering involves using products of a technology, in the absence of documentation, to determine design parameters. A set of 46 whole hafted biface points from 22OK746 in Oktibbeha County, Mississippi, which contained a Middle Woodland occupation, were studied. They were determined to be projectile points based on shared size, shape, and hafting traits with bifaces from the site that displayed impact fractures. The whole points were analyzed using parameters derived theoretically, experimentally, and empirically by other researchers to characterize dart points: shoulder width, dart/arrow index, weight, tip angle, length-thickness ratio, raw material, and cross-sectional area. The dart/arrow index showed all 46 points to be dart tips; that only half of them were identified as dart points using shoulder width was attributed to blade reworking that affected the entire blade length. Tip angle and cross-sectional area did not explain discord of these whole points, as they were within design parameters for all points. Four points were low weight. Forty-five of the 46 points were thick relative to their length, indicating that reworking had made them unusable as dart points. There is likely to be variability over time and space as to which of these parameters are most operable.

Rafferty, Sean (University at Albany, SUNY) [229]
Recent Research in Residue Analysis in Old World and New World Contexts
Analysis of organic residues continues to be a productive method of extracting information from prehistoric material culture. This paper presents current results of several ongoing research projects, involving several teams of researchers. Two projects present recent research into the origins of tobacco smoking through the analysis of tobacco pipes, including a sample of pipes associated with the Southeastern Late Archaic Poverty Point culture, and a second sample of pipes associated with Early Woodland cultures in Eastern North America. Shifting gears to the Old World, a third project addresses the use of secondary agricultural products in Neolithic Ukrainian sites. All three projects are multi-institutional endeavors, involving researchers from numerous universities, labs, and nations. In conclusion, we present possible directions for future research.

Raffield, Ben (Simon Fraser University) [15]
Bands of Brothers: The Sociopolitical and Military Organization of Viking Armies during the Ninth Century
During the mid- to late ninth century, historical sources attest to large Viking raiding-fleets and “armies” operating in northwestern Europe. These itinerant groups were not only seeking plunder but also land to settle, and some managed to establish colonies and enclaves with varying long-term success. The size and impact of these groups came under scrutiny during the latter half of the twentieth century, when some scholars sought to downplay the influence of warfare as a catalyst of social and political change during the Viking Age. However, in recent years, others have begun to seriously reconsider and challenge these perspectives. It is now widely accepted, for example, that Viking “armies” could be very large indeed, and that they were powerful military and political entities in their own right. Focusing primarily on the Great Army, which was active in England during the period 865–878, this paper explores the structure and objectives of these groups through the consideration of archaeological material and contemporaneous annals. I argue that the Great Army is better considered as a mobile society or polity rather than an armed force, a distinction that has many implications for our understanding of this and other such Viking groups operating during the period.

A Large Shell Midden Complex on the Outer Central Coast of British Columbia
Site EjTa-4 located on Calvert Island is a large midden complex capped with dozens of culturally modified cedar trees, and it has revealed older cultural material in the intertidal zones. Over the last five years the Hakai Institute has supported excavations of the large, undisturbed shell midden through the University of Northern British Columbia’s archaeology field school. The midden rises to 10 m above the shoreline and radiocarbon dates indicate relatively continuous use of the site for 7,500 years and possibly much longer. Like the site of Namu, which is not far away, this is one of many persistent places on the seascapes that is still intact and visible due to the relatively stable sea level history in this region. These sites are repositories for ecological and cultural data that reflect fluctuations in resource availability and use over several millennia. But they are also important places on the social landscape, purpose-built landforms that are significant historic and cultural markers. This large midden in particular has a high density of faunal material as fill, and the volume of shellfish suggests that clam gardens were in use in this area perhaps by the middle Holocene.

Railey, Jim (SWCA—Albuquerque) [142]
Bell-Shaped Pits in the American Southwest
Bell-shaped storage pits are a global phenomenon, and most (but not all) of these features were used for grain storage. Native Southwesterners’ use of bell-shaped pits began well back in preceramic times. Both highly mobile hunter-gatherers and less mobile farmers dug and used them, and in a very general sense storage pit sizes track variation in settlement-subsistence patterns. Specifically, mobile hunter-gatherers dispersed small caches throughout their foraging ranges. This was a sort of divided-risk strategy in the face of odds that some stored food would not be revisited and recovered. Less mobile farmers, on the other hand, invested more heavily in fewer and larger storage pits, which they were prepared to defend. Part and parcel with these differences is variation in subsistence emphases on back-loaded versus front-loaded food resources.

Ramireddy, Pranavi (Hampshire College), Julia Giblin (Quinnipiac University), Jaime Ullinger (Quinnipiac University) and Laszlo Paja (University of Szeged) [196] An Evaluation of Preservation, Sex, and Age Using Cremains Weight and Volume from a Bronze Age Cemetery in Hungary

In well-preserved osteoarchaeological samples, numerous anthropological methods are employed to determine age at death, biological sex, diet, and pathologies. However, with cremated human bone (cremains), determining demographic information is complicated by fragmentation and postdepositional damage. A simple way to assess variability in demographics, taphonomy, and burial treatment in cremains is to measure total bone weight and volume, which can then be examined in light of sex, age-at-death, and preservation. In this study, we present results from the analysis of cremains weight and volume from the Békés 103 cemetery. Békés 103 is a Bronze Age cemetery and settlement in Eastern Hungary; 68 burials have been excavated, a majority of which are cremations interred in urns. As predicted, well-preserved burials have higher cremains weights and volumes (with a notable exception), and young subadults (0–6 years) had lower weights than adults. Interestingly, females had variation in weight and volume, while the few confirmed males clustered together and did not necessarily have a higher weight or volume. This technique has potential for identifying anomalous individuals with respect to taphonomy, sex, and age.

Ramirez Rizo, Isaac David (Dirección de Registro Público de Monumentos y Zonas Arqueológicos e Históricos) [328] La importancia de Registro Público para la investigación arqueológica en México: Un análisis geoespacial de los registros de piezas en custodia de personas físicas y morales

Los trabajos que realiza a diario la Dirección de Registro Público en el área de Bienes Muebles, generan información fundamental para conocer la dinámica actual que tienen las colecciones arqueológicas en el territorio nacional. A partir de la identificación vestigios disporsos por los Estados de la República Mexicana y tras la creación de la ley de 1972 del Instituto Nacional de Antropología e Historia, se dispuso realizar el registro de bienes; uno de sus objetivos fue regular y conocer la existencia de las piezas que tiene en custodia las personas físicas y morales. Durante los años que se inició con esta labor, se requirió visualizar la existencia de cambios sobre la cantidad de registros que se realizan anualmente en el país. La propuesta para observar dicho cambio, fue la realización de un mapa con parámetros geo-estadísticos para analizar la distribución de las colecciones que se han realizado en toda la nación. Con lo anterior, se tiene la finalidad de abrir campos para la investigación sobre el tema del coleccionismo en México, por medio de una plataforma georreferenciada de las colecciones reguladas por la Dirección de Registro Público de Monumentos y Zonas Arqueológicos e Históricos.

Ramirez-Urrea de Swartz, Susana (Universidad de Guadalajara) [288] Flying on the West: The Butterfly Imagery in the Aztecatn Iconography: Meaning and Worldview.

The Aztatlán Tradition is a widespread cultural and economic system in west and northwest Mexico from AD 850 to 1300. The Aztatlán iconography is remarkable, not only because it is rich in the variety of images and icons related to the codices, but also because it reflects a concept related to the medio de una plataforma georreferenciada de las colecciones reguladas por la Dirección de Registro Público de Monumentos y Zonas Arqueológicos e Históricos.

Ramos, Elizabeth [69] Applied Zoorarchaeology, Food Practices, Conservation Biology Programs, and Contemporary Cultural Traditions in the Caribbean Region of Colombia

At present, human population groups in the Colombian Caribbean, in common with people from most regions of the world, face problems associated with the sustainability of resources that results to a large extent from the indiscriminate use of plant and animal species for food among other uses. The
phenomenon not only impacts plant and animal species but rebounds, too, on human beings. Although governmental and nongovernmental bodies have made some efforts to implement preventive programs designed to protect both the endangered species and human population groups, the hoped-for results have not been achieved. On the one hand, this paper discusses the Caribbean region of Colombia, the contribution of anthropological and in particular archaeological research to reconstructing the history of food practices associated to the use of animal’s species since prehispanic times, many of which are now under threat. On the other hand, it discusses the contribution that the results obtained in the frame of this particular research program can make to conservation biology programs in the region.

[95] A Growing Investment in “Place”: Exploring Late Pleistocene Perceptions of “Nature” in the Southern Levant

The concept of “place” is given structure and meaning by human experience and can be viewed in several forms, including art, monuments and architecture. However, the by-products and material remains associated with hunter-gatherer place-making, including food and material production as well as processing waste, are also important expressions of human experience and the construction of “place.” These material remains provide critical archaeological insight into how people in the past organized their world and perhaps, how they perceived their relationship with material production as well as processing waste, are also important expressions of human experience and the construction of “place.” These material remains provide critical archaeological insight into how people in the past organized their world and perhaps, how they perceived their relationship with nature. This paper uses microbotanical evidence from dwelling structures, foodways, and broader landscape impacts at Kharaneh IV and Ayn Qasiyya. Excavations of building collapse document the destruction at Kharaneh Iskander and large quantities of carbonized food stores that were recovered from EBIII levels support this event. Thousands of barley grains (Hordeum vulgare) and lentils (Lens culinaris), as well as significant quantities of emmer wheat (Triticum dicoccum), common pea (Pisum sativum) and chick peas (Cicer arietinum) attest to the agricultural nature of the region and the vital role of storage in early complex societies. This poster documents the archaeobotanical assemblage from Kharaneh Iskander in order to gain a better understanding of the implications of the destruction of food resources and the role of the agricultural economy at the end of the EBIII period.

Ramsey, Monica (University of Toronto)
[101] Organization of Late Classic Maya Polities in Rosario Valley, Mexico

This presentation focuses on intra and inter polity organization of the Late Classic (AD 600–900) Maya polities in the Rosario Valley, Mexico. Past approaches have generally used civic-ceremonial architecture to investigate settlement hierarchy, here however, the focus is turned to interaction. This approach explores how the strength of interactions between settlements can be used to explore political hierarchy. To measure the strength of interactions, a formula borrowed from the law of gravity is applied to calculate the degree of possible interaction based on the population of settlements and the distances between them. Following this, these webs of interaction are used to distinguish the core, peripheral and marginal areas of each polity, as well as the potential interactions between different polities. The results from this interaction based analysis differ from those based on the civic-ceremonial architecture. This suggests that bureaucratic administration based on civic-ceremonial centers may not have been the case in the Rosario Valley. The results also imply that one important function of civic-ceremonial architecture could relate to enhancing interaction within the region.

Coastal Alaska played an important role in U.S. defenses for the Pacific Theater during World War II. Many resources on Kodiak Island have been listed on the National Register of Historic Places. These include the Kodiak Naval Operations Base, Fort Greely, and Fort Abercrombie, which are listed together as a National Historic Landmark. Two other installations within the military command structure on Kodiak Island include Fort Tidball and Fort J.H. Smith. These two installations and the batteries under their command were part of the larger command network in the Pacific Theater and should be considered and documented as important components of a complex World War II landscape on Kodiak Island. This poster will address components of the two military installations and the challenges of incorporating large landscapes and historic districts into Section 106 compliance activities.

The practice of the Chinigchinich religion at sites such as Lemon Tank on San Clemente Island suggests continuity in Tongva ritual practice into the Mission Period in Alta California (AD 1769–1834) radically changed the lives of indigenous people such as the Tongva. The strict discipline of the Franciscans’ enculturation program in the missions contrasted with the relative autonomy of Tongva people on San Clemente Island. Evidence of ritual practices observed by the Spanish missionaries, such as the construction of kivas and the use of sacred objects, indicate a continuation of traditional beliefs and practices despite colonial influences. The discovery of landscape changes in the area of Lemon Tank, with artifacts dating from the period of Spanish occupation, suggests that the Tongva people maintained their cultural practices even under the pressures of colonialism.

The Snyder Site Complex consists of stratified, multicomponent prehistoric localities at Carpentersville, New Jersey, situated on a series of terraces adjacent to the Delaware River. The Paleoindian components of the complex stand out because of the extensive landscapes involved, the number of fluted bifaces and diagnostic tool types that can be associated with occupations, and the fact that it is revisited throughout the Paleoindian period. Research that has been completed at the complex has placed it in the context of Paleoindian studies in the Delaware Valley. Factors that may have influenced the repeated use of complex landscapes are considered including: the ecology and resource potential of the environmental setting; proximity to sources of chert and jasper toolstone; its location as a potential gathering place, a location that is compatible to the territories of a number of Paleoindian bands, where exchanges of information, trade, and socializing could take place; and its positioning along what may be a travel route linking the Delaware Valley and Middle Atlantic Region with Paleoindian peoples in the area of the greater Northeast. Site complexes like Snyder, spread over large areas, emphasize the importance of a landscape perspective and intra/intersite spatial patterning when identifying and interpreting archaeological deposits.

Recent soil coring and reexamination of mound height changes through time have revealed an extremely high historic sedimentation rate of 5.2 cm per year in the North Plaza, resulting in deep burial (around 4 m) of the Mississippian landscape. Modernly, the North Plaza is noticeably lower than other plazas surrounding Monks Mounds; however, the North Plaza would have been a dramatic topographic feature during Mississippian occupation. The discovery of landscape 6 m lower than the rest of Cahokia questions previous assumptions regarding the North Plaza’s function as a mound and plaza group.

Preliminary results from a Late Archaic Site in Canaan, Connecticut
Robbins Swamp is a large freshwater swamp located within the Housatonic River drainage in Litchfield County, Connecticut. Archaeological sites within its environs and along nearby rivers date from the Paleoindian period through the Woodland period, indicating the wetland and nearby rivers and streams were an important resource for Native Americans for over 12,000 years. With the exception of George Nicholas’s extensive work for his dissertation, which identified 500 additional sites, few professional excavations have been conducted in the area. A railroad project initiated by the Connecticut Department of Transportation resulted in a data recovery of archaeological site 21-85 in Canaan prior to the construction of an access road, as required under state and federal law. This paper presents the preliminary results of our recent excavations of a Late Archaic encampment, located just south of the swamp, on the Hollenbeck River, a tributary of the Housatonic River.

Site complexes like Snyder, spread over large areas, emphasize the importance of a landscape perspective and intra/intersite spatial patterning when identifying and interpreting archaeological deposits.

Chinigchinich Ritual Practice among the Tongva: Exploring Patterns of Colonial Consumption and Revitalization
The Mission Period in Alta California (AD 1769–1834) radically changed the lives of indigenous people such as the Tongva. The strict discipline of the Franciscans’ enculturation program in the missions contrasted with the relative autonomy of Tongva people on San Clemente Island. Evidence of ritual practice of the Chinigchinich religion at sites such as Lemon Tank on San Clemente Island suggests continuity in Tongva ritual practice into the Mission Period. At the same time, Spanish missionaries and colonists introduced new material culture that the Tongva selectively incorporated or excluded in their traditions. Therefore patterns of consumption of native and foreign material culture may reveal new layers of meaning in persistent ritual practices. The abundance of shell beads and relative dearth of glass beads at Lemon Tank suggests that San Clemente Islanders may have shunned Spanish material culture in their ritual practices. If Tongva people were actively avoiding incorporating colonial material culture (such as glass beads) in their ritual practices, then the Chinigchinich religion could have been part of a nativist revitalization movement in which people tried to expunge colonial influence.

13,000 Years of Obsidian Prospecting in Eastern Beringia: A Status Report on Obsidian Source Studies in Alaska and Yukon
The archaeological record of Eastern Beringia plays an important role in understanding global human dispersals and settlement, and is a proving ground for testing ideas about high latitude hunter-gatherer land use, technology, and socioeconomic interaction. Obsidian provenance studies provide an excellent means to address these issues. Since 2006 we have compiled, organized, and generated new obsidian geochemical analyses for more than 11,000 artifacts from 1,200 sites across Alaska and Yukon Territory using portable X-ray fluorescence (pXRF) and laser ablation inductively coupled plasma mass spectroscopy (LA-ICP-MS). More than 60 geochemically distinct obsidian groups have been defined, and the major geological sources of obsidian have been pinpointed. A well-developed framework for successful provenance analysis is now available. Here we describe the major obsidian sources for the region and recommend a standardized terminology for source locations and geochemical groups. We share key insights about prehistoric raw material procurement and distribution gained from this exceptionally large and geographically expansive dataset, including 1) a surprisingly rapid pace of landscape learning and identification of obsidian sources upon initial human colonization in each subregion, and 2) the tremendous influence raw material package size exerts on the distribution extent of obsidian from a particular source.
Rautman, Alison (Michigan State University)

Rural and Feasting in the Field: The Role of Theoretically Informed Practice in Creating Resilience within the Archaeological Field Crew
Katherine Spielmann has contributed to the scholarly literature on ritual and feasting, the archaeology of sustainable and resilient societies, and long-term economic and social changes in archaeological record of the Salinas region in central New Mexico. Less well-known, however, are her long-term contributions to the performance dimensions of these models. In fact, her theoretically informed archaeological practices, implemented in the context of the undergraduate field school, illustrate the importance of ritual and also feasting in fostering productive and resilient working relationships among crew members in the small-scale, short-lived social world of archaeological field work.

Ravesloot, John (EcoPlan Associates, Inc.)

Full-Coverage Regional Surveys: Insights Gained about Hohokam, Akimel O’odham (Pima), and Pee Posh (Maricopa) Landscape Use
Full-coverge regional archaeological surveys conducted throughout the world in diverse environmental contexts have demonstrated the advantages of this methodology for addressing a broad range of anthropological issues. The Northern Tucson Basin Survey (1980–1987) directed by Suzanne and Paul Fish represents the first application of this methodology to documented prehistoric Hohokam settlement and land use. Contiguous survey blocks centered on three Classic Period platform mounds and their associated settlement complexes, located primarily in a non-riverine context, covered more than 470 km². The survey data acquired have contributed significantly to our understanding of the organization of Hohokam communities. Based on the success of the Fishes research project, a full-coverge approach was implemented by the Gila River Indian Community’s Pima Maricopa Irrigation Project (1994–2004) to survey 140,000 acres (567 km²) of the reservation. This paper discusses some of the insights gained from the Gila River full-coverge survey regarding Hohokam and historic Pima-Maricopa use of a riverine environment. The survey enabled examination of topics such as settlement response to changing geomorphic landscapes, the organization of Hohokam communities and irrigation systems, understanding the use of nonresidential spaces between villages, and protohistoric and postcontact Akimel O’odham (Pima) and Pee Posh (Maricopa) settlement dynamics.

Refining Architectural Classifications of Preclassic Monumentality at Early Xunantunich, Belize
The site of Early Xunantunich in Belize provides us with a rare opportunity to conduct large scale investigations of Preclassic architecture due to its lack of Classic Period overburden. Since 2008, ongoing excavations at the site have yielded a wealth of information regarding Preclassic activities in the area. However, recent investigations of a monumental flat-topped platform at the site have illuminated issues with the ways in which we describe and classify these early structures. In this paper, we argue that the current typologies used to describe Preclassic monumental architecture are insufficient and obscure our ability to make meaningful formal comparisons. In particular, we argue that the blanket terms used to describe Preclassic platforms must be honed and refined in order to reflect important distinctions in both the form and function of these structures. Such distinctions would facilitate a deeper understanding of early monumental forms, enabling us to rethink the symbolic meanings being conveyed through early civic and ceremonial centers. Finally, by distinguishing between these varying forms, we can begin to explore the processes of accumulation and architectural repurposing that led to the expansion or abandonment of these structures during the Classic Period.

Ray, Erin (University of New Mexico) and Holley Moyes (University of California, Merced)

The Archaeologists Role in Looting: Commodity Fetishism and the Tragedy of the Commons
In Marxist philosophy, commodity fetishism imbibes an object with a value not inherent to the object itself. This paper explores the ways in which archaeologists have contributed to the fetishizing of archaeological material which in turn promotes the looting of archaeological sites. By nature of our profession, old objects hold more value than modern objects or even replicas. Contextual information about these objects is arguably just as, if not more, important than the object itself. In many communities where archaeologists work, we transfer the perceived value of old objects to members of the community. But the value of the contextual information is not transmitted. We suspect that our selective transmission may lead to a tragedy of the commons in which individuals outside of the profession consume or loot a shared resource—the archaeological record. We will take a critical look at how we as archaeologists influence looting and suggest possible solutions at a community level.

Spatial and Temporal Variation of Prehistoric Cultural Elaboration in the Yazoo Basin of Mississippi
The Yazoo Basin of Mississippi is a rich and varied landscape that has been inhabited by humans for millennia. Sediment cores and tree-ring dates have documented that populations living in the basin had to contend with massive flooding events as well as substantial environmental change over the course of the Holocene. Populations contended with these changes by shifting settlement patterns, altering in subsistence strategies, engaging in intergroup competition, as well as varying investments in cultural elaboration. The freshwater mussel shell ring phenomenon that emerged during the Archaic and Woodland periods, for example, may reflect a combination of these factors. This paper explores the degree to which spatial and temporal patterns of refuse deposition can be explained as cultural responses to environmental instability during the Archaic through Mississippian periods.

Unraveling a Neanderthal Palimpsest from a Zooarchaeological and Lithic Perspective: Abingo de la Quebrada Level IV (Valencia, Spain)
Excavations at Abridge de la Quebrada (Chelva, Valencia) have revealed nine archaeological levels belonging to Neanderthal occupations. Level IV, characterized by a high density of lithic (>18,000) and bone (>100,000) remains, has been dated with AMS between 43,930±750 BP (Beta-244002) and >50.8 ka BP (OxA-24855). Human presence in the shelter has been favored by its location, giving rise to a kind of natural trap where hunting animals would be feasible. The immediate environment is varied (abrupt and plain zones), allowing the presence of a wide range of prey. The high density of lithic and bone elements and the large number of combustion structural remains with small variations in spatial distribution reflect a typical structure of palimpsest with frequent, repeated and seasonal occupations with intense on-site processing. The characteristics of the sample (seasonality, exploitation intensity, taphonomic data, lithic refits and raw materials) support that idea and tell us about short-term occupations; the absence of modification by carnivores facilitates the study of the Neanderthal behavior. With this study we have obtained more information on the subsistence and behavior of Neanderthal groups, which can be compared to other regional contexts in the central area of the Mediterranean Iberian.

Reamer, Justin (University of Pennsylvania- Department of Anthropology)  
[52] Reconsidering the Monuments of the Precontact Peoples of the Northeastern United States  
In the literature on monumentality there is little to no discussion of precontact Native American monuments in the northeastern United States. However, this does not mean the region was completely devoid of monumental architecture before the arrival of European, but monuments are not a common topic of archaeological research in the northeast. In this paper, I will discuss two structures—shell mounds, and stone and brush heaps—and argue that they should be discussed as monuments and further studied by archaeologists trying to understand the precolonial societies of the northeastern United States. I will first discuss the documentation of shell mounds and stone and brush heaps in ethnohistoric and survey records, such as those of Cyrus Thomas. I then will argue for why these structures should be included in archaeological discussions of monumentality. While I recognize the problems that keep archaeologists from studying these structures, I argue that this neglects an important aspect of the archaeological record. Lastly, I make an argument for how archaeologists of the northeastern United States can further our study of these structures to gain a fuller picture of the region’s archaeology.

Reaux, Derek (University of Nevada, Reno), Geoffrey Smith (University of Nevada, Reno), Ken Adams (Desert Research Institute), Nicole George (University of Nevada, Reno) and Sophia Jamaldin (University of Nevada, Reno)  
[140] Preliminary Results from the Paleoindian Record of Guano Valley, Oregon  
Guano Valley is located between Warner and Catlow valleys. Relative to the surrounding valleys, it has received little attention from professional archaeologists over the years despite early visits by Luther Cressman. During the 2016 field season, the Great Basin Paleoindian Research Unit (University of Nevada, Reno) began a long-term research project in Guano Valley focused on searching for Paleoindian sites in the area. Although our work is in its infancy, we have already uncovered a very rich record of Terminal Pleistocene/Early Holocene (TP/EH) occupation associated with a delta system that likely brought fresh water into the basin while those sites were occupied. Because TP/EH lakes in Guano Valley were stable for long periods due to the presence of a low sill above which they could not rise at the northern end of the basin, the valley likely supported a long-term productive marsh system that attracted early groups to the area.

[173] Cautious vs. Interesting: Cultural Interpretation of Absorbed Organic Pottery Residues  
Absorbed organic pottery analysis is a technically easy but interpretively difficult branch of archaeometry. Given the complex interaction between organic chemistry, pot use, pyrolytic effects, depositional effects, and modern contamination, it is often difficult to balance interpretations between appropriately cautious and culturally and anthropologically useful information. This issue is illustrated through the analysis and interpretation of a suite of absorbed organic pottery residues extracted from pottery excavated from the Louisiana Gulf coast. Compounds in these sherds result from a complex mixture of events, including archaeological usage, the Deepwater Horizon oil spill, post-spill use of dispersants, and normal depositional issues. How do we untangle these interlocking cultural events to produce a meaningful interpretation?

[85] Assessing Differential Fragmentation of Mammal Bone: A New Proxy  
Relative bone density has been utilized as a proxy for differences in survivability among mammal bones during pre- and postdepositional fragmentation/destruction processes. Since bone remodels during an animal’s lifetime to resist directional forces and cancellous bone forms patterns of trabeculae oriented in directions to compensate for forces exerted on the bone, I think that estimates of density of a bone are an inadequate proxy for survivability. In an attempt to develop a new proxy for survivability I have subjected bones from sheep to force using a drop tower. The height of the drop was varied to generate between 7.5 and 15 Joules. A piezoelectric sensor measured the amount of force, in Newtons, required to fracture an element. A graph of force, overtime, describes the fracture of each element. The force required to fracture each element is compared to the bone density estimates for sheep. Also, patterns of fracture were recorded. Secondary and tertiary drops were conducted to further fragment the elements. In a future study the fracture patterns obtained will be compared to the fractures observed in archaeological faunas from Egypt.

[80] **Nighttime Food of the Ancient Maya**

Societies, present and past, consume particular foods at certain times of the day, and these foods often symbolize quotidian practices. Even in American culture, certain foods are taboo at certain times and in certain contexts, such as dessert after breakfast or the increasing concern of healthy eating with respect to bedtime snacking. Food functions as a social vehicle beyond its nutritional value, and mealtimes or food events serve as occasions to reinforce culturally appropriate behaviors. Furthermore, chronobiology posits that the circadian rhythm influences metabolism and food consumption patterns. We have previously shown that food is a marker of social distinction for the ancient Maya through paleodietary reconstructions, production technologies, bioarchaeological analyses, and glyptic readings. Whether for energy replenishment or ritual purposes, we expand on previous work to begin understanding the sustenance of the Maya diet and how nighttime eating was distinguished from consumption at other times of the day. Drawing on a larger theoretical perspective, consumption practices are set in the context of agents and recursive structures that established enduring practices of routinized and ritualized nighttime food consumption and how that may have aided social structures of inclusion and exclusion, and reinforced social connections and possibly dominance hierarchies.

[373] **The Late Bonito Phase at Aztec North and West Ruins: Interpreting the Ceramic Data**

Pottery from Earl Morris’s excavations in Late Bonito phase contexts at Aztec West Ruin and recent surface collections at Aztec North Ruin are examined to shed further light on Chacoan period developments at these two great houses. Morris’s early twentieth-century excavations focused specifically on West Ruin, but the North and East Ruins filled out the triad of great houses comprising a substantial complex within the modern boundary of Aztec Ruins National Monument. Several researchers have suggested that North Ruin was the first great house constructed at Aztec, representing a local interpretation of a Chacoan great house. In contrast, West Ruin was built several decades later by Chacoan engineers and specialists who were intent on building in the meticulous and grand style of Chaco Canyon and establishing a new great house complex in the Animas River valley. In this paper, I look at the Late Bonito phase occupations of both Aztec North and West great houses, examine the local and Chacoan ceramic traits, and evaluate the extent of Chaco’s reach via the pottery assemblages.

[224] **Shell Middens and Sea Level Rise: Learning from the Past and Preparing for the Future**

Shell middens, like other forms of coastal cultural heritage, are heavily threatened by sea level rise, climate change, and human land use. These sites, however, store information about these same challenges in the past. We present results from recent research near the mouth of the Rhode River, a small sub-estuary of Chesapeake Bay in eastern North America. We chose an area we knew well, having worked on the 31 previously recorded shell middens, to test the importance of more specialized techniques aimed at rapidly assessing and mitigating loss of shell middens. We employed a three-step process—modeling to understand the distribution of threats, targeted survey to locate sites, and radiocarbon dating to understand the timing of settlement. We relocated eight sites believed to be lost to sea level rise and identified 16 new sites using specialized survey techniques, including survey by kayak during extreme winter low tides. Through extensive radiocarbon dating, we were able to refine our previous conclusions about settlement in this region, including the elimination of an apparent settlement gap between the Late Woodland and Historic periods. Our results suggest that similar survey techniques may be a valuable addition to research strategies along submerging coastlines around the world.

[182] **Entangled Ideologies on the Pacific Coast: The Teotihuacán-Style Maya Censers from the Department of Escuintla, Guatemala**

Teotihuacán-style censers from the Pacific Coast of Guatemala are seminal markers of “international” interaction and ideology during the Early Classic Period (250–550 CE). But the paucity of archaeological data for this artifact class and the lack of recent in-depth analysis of their iconographic narratives leave unexplored a potential body of material concerning interaction, identity, and ideological shifts in this gateway region of southern Mesoamerica. Data from archaeological investigations, iconographic studies, and nuclear chemistry are brought to bear on a group of more than 15 censers from the region to address the function and meaning of these ritual objects and their potential for investigating the sociopolitical and ideological motivations steering the region’s Early Classic communities.

[302] **A New Method for the Identification of Temper in Pottery**

This poster presents new research on a novel technique to analyse temper in archaeological ceramics. The outcome of the study was to assess whether petrographic analysis of temper grains can be automated through the combination of mineral mapping and remote sensing. Ten pottery samples were analyzed by automated mineral mapping. The output of analysis is an image of mineral distribution, based on 15 micron spot analyses, with a quantification of total abundancies of minerals in the sample. The addition of remote sensing technique allows the processing of the image combining analysis points to grains, which then allows the quantification, as well as the analysis of structural and spatial distribution of temper grains in the sample. Here, I will highlight some challenges encountered throughout the experiment and will propose future directions of this research.
Rees, Mark (University of Louisiana at Lafayette), Samuel Huey (University of Iowa Office of the State Archaeologist), and Scott Sorset (Bureau of Ocean Energy Management)

**Assessment of the Effects of an Oil Spill on the Disaster Archaeology of Louisiana’s Gulf Coast**

In April of 2010, the Macondo well blowout and Deepwater Horizon drilling rig explosion led to the discharge of an estimated 4.9 million barrels of crude oil from Mississippi Canyon Block 252 (MC 252) in the north-central Gulf of Mexico. Within three months the Macondo blowout became the largest marine oil spill in history, impacting more than 1,000 miles of shoreline. Disaster response and cleanup were followed by studies of subsequent impacts on coastal and marine ecology, natural resources, health, and lifeways of people affected by the spill. The long-term effects on cultural resources are only now beginning to be understood. Eight archaeological sites on the Gulf Coast of Louisiana were assessed for the effects of hydrocarbon contamination from the Macondo oil spill as part of a cooperative agreement between the Bureau of Ocean Energy Management and the University of Louisiana at Lafayette. Hydrocarbons found in sediment samples and ceramic sherds have been sourced to MC 252. In addition to the effects on archaeometric techniques and site formation processes, we consider the implications for future archaeological investigations, cultural resource management planning, and disaster archaeology on Louisiana’s Gulf Coast.

**Pottery Production at Cowboy Wash Pueblo: A Central Village on the Ute Piedmont Frontier**

Cowboy Wash Pueblo (SM7740), south of Sleeping Ute Mountain in the Northern San Juan Region, is the largest and latest pueblo in the Cowboy Wash Community. In collaboration with the Ute Mountain Ute Tribe, Potter and colleagues (2013) recorded a large rubble area (~1000 m²), 13 pit structures, a potential D-shaped structure, and a surprisingly sparse surface assemblage (n = 206). They also noted that the east edge of the pueblo is endangered by arroyo cutting. Due to this and because it was unclear if the surface pottery was representative of its occupation, the CU-Boulder field school (2016), under the direction of Potter and Ortman, conducted test excavations in an exposed room, kiva, and 13 midden units. This poster presents the results of an analysis of pottery from these excavations. Included in these contexts was an unfired corrugated vessel and raw materials used in its production on the floor of the kiva. Results reveal a short-occupation period during the AD 1225–1280 interval, patterning in the distributions of vessel form and design, and information about pottery production, acquisition, and the aggregation process when the village was established.

Reese-Taylor, Kathryn

**Creating the Center: Interaction in the Central Karstic Uplands during the Preclassic**

From roughly 800 BCE, evidence supports the development of a widespread regional interaction sphere centered in the Central Karstic Uplands. This paper discusses specific data regarding the origins of this network and the subsequent integration of the Central Karstic Uplands as an economic force in the Maya lowlands. Scholars have long recognized the strong affiliations among the major cities that comprise this network during the Preclassic. Recently artifacts recovered from sites point to extensive trade with distant regions. Further architectural layout and city planning suggest major ties to other areas in the Maya lowlands, such as the Northern Yucatán and the Chetumal Bay area. No doubt, the strategic location of the Central Karstic Uplands with regard to transportation and the development of an extensive road system in the Preclassic contributed to its development as a major commercial hub for cross peninsular exchange and beyond. Finally, we suggest that the control of trade by centers in the Central Karstic Uplands was a major factor in the precocious urbanization of the region.

**Behavioral Inferences from Early Stone Age Sites: A View from the Koobi Fora Formation**

The Early Stone Age record is a spatially continuous palimpsest representing thousands of years of artifact discard. The record thus reflects a long-term pattern of hominin movement at a landscape scale. Despite this, most recent research continues to employ interpretive perspectives suited for finer temporal grains and relies on targeted excavation of dense concentrations of artifacts. Here ‘sites’ are investigated as discrete functionally organized places and analytically interpreted based on differences in gross artifact density and the frequencies of different typo-technological forms. Such a perspective ignores the spatial extent, formational complexity and temporal depth of this record. What is needed instead is a better understanding of the behavioral processes that contribute to the formation of the record at broader scales. Here we investigate the regional structure of the archaeological record through the lens of movement. We apply assemblage-scale measures to quantify movement of stone across the Okote Member in the Koobi Fora Formation. Results demonstrate that hominin movement patterns structure the archaeological record at large spatial scales. We suggest that a movement-ecology framework is better suited for understanding the Early Pleistocene record than activities facies or cultural-historical models. This research is supported by NSF-IRES(OISE-1358178 and 1358200).

Reid, Andrew (University College London) [76] Longevity and Authority in a Mobile World the Megasites of the Ugandan Grasslands
Much of the recent past of Great Lakes Africa is characterized by short-lived settlements and mobile societies that produced ephemeral occupation sites. In part because of this, attention has long been drawn to sites like Bigo and Ntusui which seem to offer much more substantive archaeological remains. Yet, notwithstanding the longevity of the latter and the extent of both, this is clearly not a simple occupation site featuring a large population. Rather it is much more effective to understand sites like Ntusui as focal points in the landscape, which accrue and develop status and significance, both politically and religiously, and hence encourage repeated settlement. Therefore, such sites need to be understood as active locations which provided a perpetual focus for the mobile and transient world around. This emphasis then helps to understand the nature of the site at Bigo, encompassing a vast area, but with a very small population. Both Ntusui and Bigo remind us that there are other very different settlement trajectories than those conventionally encountered in the classic centers of urban archaeology.

Reid, David (University of Illinois at Chicago), Patrick Ryan Williams (Chicago Field Museum) and Donna Nash (UNC-Greensboro) [170] The Role of Infrastructure in Wari State-Making in Southern Peru
In southern Peru, the transition from the Early Intermediate to the Middle Horizon during the seventh century AD was marked by the expansion of Wari state colonists and influence from the Ayacucho heartland. Andeanists have long postulated the role of climate change and drought during this initial state expansion, while issues of chronology complicate this issue. Here, we reevaluate the radiocarbon data from the early Wari colonies of Cerros Baúl and Mejía in the upper Moquegua Valley in comparison to recent investigations of Middle Horizon roads and waystations that connected Peru’s southern coastal valleys. We investigate how systems of infrastructure (i.e., irrigation canals, agricultural terraces, and road networks) integrated local Early Intermediate social groups within the processes of Wari state-making on the southern frontier. Furthermore, we argue that these systems of infrastructure are crucially important when considering processes of cultural resilience during periods of environmental and social stress.

Reid, Kenneth (Idaho State Historical Society) and Franklin Foit, Jr. (Washington State University) [226] The Western Stemmed Tradition and the Glacier Peak Eruptions: A Precautionary Tale
Recent reviews of the radiocarbon record for Western Stemmed components on the Columbia Plateau suggest a post-Clovis age for this tradition. Controversies over the timing question are intensified by highly selective frames of references for mapping regional patterns of site distribution. Some sites are highlighted, other relevant sites ignored, and still others find their way into the debate through uncritical confirmation bias. This paper focuses on the latter confusion, examining the use of Glacier Peak tephra to establish terminus post quem Clovis or pre-Clovis ages for Western Stemmed components at the Spalding site on the lower Clearwater River, and Pilcher Creek in the Blue Mountains. The tephra identifications at both sites rest on personal communications from the same analyst/laboratory, but without supporting glass chemistry data. Subsequent reanalysis of the Spalding tephra identified it as redeposited Mazama. Potential misidentification of its nominal counterpart at Pilcher Creek encourages a second look there as well. If it is Glacier Peak rather than Mazama, the thickness of the deposit and its downslope position are consistent with a secondary rather than primary deposit. To date there is no convincing evidence of contemporaneity between the Western Stemmed tradition and primary Glacier Peak B/G eruptions.

Reilfschneider, Meredith (Stanford University) [348] Scale in Health-Related Research: Situating Topographies of Health Care
The social production of scale in archaeology has figured prominently in research that aims to develop understandings of local, regional, national, and global processes by tackling various scalar modalities. Oftentimes, “the global” is posited as the causal and ultimate force, relegating “the local” to the status of a case study. Within social science research more broadly, conceptualizations of scale have increasingly undergone complex formulations in order to address political processes of connectivity. In this paper, I argue for discarding binary, hierarchically organized global/local approaches in lieu of focusing on specific sites of action and social production. This paper addresses the social politics of medicine in the context of enslavement in the former Danish West Indies. Understandings of health and health care practices in the Danish colonies were not the local instantiation or reterritorialization of global attitudes, but were sites of intimate relations between bodies, objects, and orders. This research seeks to historicize present boundaries of normality in health discourse by reframing health as a dynamic and complex process. By refocusing on specific sites of social life, researchers gain theoretical and methodological purchase on how ideas are formed, how actions are produced, and how relations are generated and maintained.

Reilly, Frank (Texas State University) and Sean McClure (Texas State University) [80] The Liminal Space between Night and Day in the Mesoamerican Formative Period
Iconographic investigations have revealed how the spread of the symbolism associated with NIGHT and DAY and the liminal space that separates the two were the major focus for the layout of sacred space or ritual precincts throughout the Mesoamerican Formative Period. Night was perceived as the home of much of the spiritual power which the ancient Mesoamericans perceived as inherent within the cosmological structure of the cosmos. In order to control the public and supernatural interface of this religious understanding, the division between day and night became the most significant ritual focus for the mobile and transient world around. This emphasis then helps to understand the nature of the site at Bigo, encompassing a vast area, but with a very small population. Both Ntusui and Bigo remind us that there are other very different settlement trajectories than those conventionally encountered in the classic centers of urban archaeology.

Reilly, Sophie (McMaster University) [232] Plants in Ancient Pots: A Comparative Study of Paleoethnobotanical Results from Unwashed and Washed Ceramics
Paleoethnobotanists study human-plant interactions in the past, including the role of plants in ancient foodways. Microbotanical remains (phytoliths and starch grains) enable the identification of many plants because their morphology can be diagnostic to the family, genus, and species. Microbotanical samples can be extracted from specific artifacts, such as ceramics, enabling a better understanding of their use. Paleoethnobotanists can thus discern associations between certain vessel types and plant remains, and begin to understand the presentation and consumption of ancient meals. Unwashed artifacts are ideal in such studies, as they increase the likelihood of recovering microbotanical residues and mitigate the risk of contamination. However,
not all archaeological projects keep samples of unwashed artifacts for future research. This poster presents comparative results from unwashed, washed, and charred ceramic sherds from the Late Formative (200 BC–AD 400) sites of Kala Uyuni and Challapata in the Lake Titicaca basin of Bolivia. I compare the utility of microbotanical results obtained from each of these kinds of sherds and consider whether carrying out analysis on washed or charred sherds is a viable alternative when it is impossible to access unwashed sherds.

Reiner, Rudy [334] A Squamish Nation/Coast Salish Sense of Time
The foundation of understanding time and the past lays in the realm of constructing cultural historical chronologies through the use of radiocarbon dating and the determination of temporally sensitive artifacts. Along the shores of the Salish Sea of the southern Northwest Coast of North America the long established cultural historical sequence has been questioned and critiqued for its utility in modern day archaeological frameworks. Yet, the foundation of many regional interpretations regarding changes in lithic technology, subsistence and cultural complexity still rely on an entrenched sense of time from a western scientific perspective. While useful, regional researchers need to broaden the understanding of the past. This paper presents an Indigenous view of the past through the lens of Squamish Nation oral history, archaeology and the paleoenvironmental record. It offers an alternative sense of time that is culturally meaningful and pushes regional research to consider this perspective as a means of decolonizing the past, present, and future for Indigenous communities.

Reindel, Markus [156] see Fecher, Franziska

Reindel, Markus (German Archaeological Institute, Bonn, Germany), Franziska Fecher (German Archaeological Institute, Bonn, Germany) and Peter Fux (Museum Rietberg Zürich, Switzerland) [326] New Investigations on the Northeast Coast of Honduras
As part of the Central American Isthmus, Honduras adopted a special role in prehispanic America. Together with Nicaragua, the territory of modern Honduras functioned as a bridge between the culture areas of Mesoamerica and the Intermediate Area. In spite of that unique situation, archaeological investigations in Honduras have been focusing on the western, Mesoamerican part, especially on the Maya city of Copan. In contrast, cultural developments in the east remain largely unknown. With the goal to enlarge the data base about the settlement history and cultural developments of that zone, archaeological excavations were realized for the first time in Guadalupe, near Trujillo, on the northeast coast of Honduras. The first excavation campaign revealed an extended settlement with a central platform, dating in the upper layers to the late Postclassic Period (Cocal). The unexpected abundance of artifacts (ceramics, obsidian, shell, greenstone, etc.) will allow to refine the existing artifact typologies and chronologies. These first results permit preliminary ideas about the characteristics of archaeological sites in that region and about their relations within an interregional exchange network.

Reinhardt, Karl (University of Nebraska–Lincoln), Luz Ramirez de Bryson (University of Nebraska–Lincoln), Nicole Searcey (University of Nebraska Medical Center), Isabel Teixeira-Santos (University of Nebraska–Lincoln) and Calogero M. Santoro (Instituto de Alta Investigación, Universidad de Ta) [143] Human Coprolite Diet Reconstruction Confirms Wetland Resource Use in the Coast of the Atacama Desert, 6580 cal. yr BP
It has been proposed that Chinchorro coastal people along the Atacama Desert in northern Chile had marginal access to plant food, a position refuted by recent scholars. The older perspective comes from bone chemistry analyses which showed a nearly exclusive reliance on marine animal resources. Newer analyses of mummy gut contents shows a substantial reliance on wetland plant resources, especially sedge rhizomes and seeds. Therefore, existing analyses present very different ideas of Chinchorro diet. We undertook the analysis of 16 coprolites from two Chinchorro sites. The analysis of pollen from these sites demonstrates two further uses of different plant communities beyond sedge wetlands. At one site, polleniferous cattail flower heads were eaten. The second site shows an exploitation of desert scrublands where mesquite, acacia and goosefoot were available. These data expand our knowledge of Chinchorro use of wetland and dryland plant communities.

Reinhart, Eduard [22] see Fletcher, Beatrice

Reinhart, Katrinka (Stanford University) [72] Daily Life and Ritual at Yanshi Shangcheng: Subterranean Deposition and the Puzzle of Blended Deposits
At the early Bronze Age city of Yanshi Shangcheng (Henan, China), an important aspect of the lifeways of residents was the practice of depositing various sorts of materials underground. Pottery, human and animal bodies, implements, ornaments, and other materials were deposited in pits, wells, ditches, and graves. These “depositional practices” resulted in a bounty for future archaeologists. However, deposition has been undertheorized in Chinese archaeology. Depositional features are often uncritically assigned to categories such as “ash pit” or “sacrificial pit” (ordinary versus special deposits). In this paper, I investigated deposition in two areas of the Yanshi Shangcheng site, a walled elite area and an artisan residential/work area. In this presentation, I will illustrate that some depositional features defy neat identifications, problematizing categorization that assumes a universal definition of “refuse” and that separates ritual and daily life into two distinct spheres of practice. I will question whether a mundane/ritual dichotomy is appropriate for understanding early Bronze Age life in northern China. I also considered archaeological methods (excavation, recording, reporting, and analysis) if to enable a more critical approach to daily life and ritual in the early Bronze Age of northern China.

Reinhold, Sabine (Eurasia-Department DAI) [221] Late Bronze Age in the North Caucasus: Shaping a New Culture for a New Millennium
After more than one millennium of mobile pastoral lifeways, the mid-second millennium BC witnessed the reappearance of village-based life in an area stretching from the Black Sea, across Caucasia to Anatolia and North Western Iran. Its manifestation is the emergence of stone-built dwellings clustered in small or middle-sized settlements. Concurrently, the transformation of the third millennium BC mobile pastoralism into combined mountain agriculture allowed retaining a pastoral economy in spite of a stationary lifeway for another 600 or 700 years. A German-Russian cooperation project investigated more than 280 sites in the Northern Caucasus (Russia) that reflect the formation of the new settlement system using an integrated spectrum of
multidisciplinary research methods. As a result, we can today draw a first picture on the formation and the transformation of the Late Bronze Age in the Northern Caucasus, a period before nearly unknown due to fact that sites in the lowlands are missing. This epoch sees a new mountain based culture that incorporates local groups as well as shifting populations from the steppe region. This overview will present the first draft of the chronological, economic and social developments that shaped this new cultural phenomenon in the second millennium BC.

Reitze, William (University of Arizona) [304] Building on an Archaeological Record: Preliminary Results of the Three-Year Petrified Forest Boundary Expansion Survey

In 2004 Congress authorized Petrified Forest National Park to more than double in size, in part to protect unique cultural resources. This poster introduces the preliminary results of three seasons of pedestrian survey in these new lands. So far this research has recorded archaeological resources dating across the spectrum of the human habitation of North America, beginning with Paleoindian lithics and extending through the historic period. Sites ranging from lithic landscapes covering hundreds of acres to masonry structures with dozens of rooms are spread across the grassland landscapes of Petrified Forest. Mapping in semi-stabilized dunes has focused on large Basketmaker village sites and detailed ceramic analysis has documented phenomenal diversity of ceramic types and sources. Large-scale, systematic pedestrian survey has been conducted across a variety of landscapes to better understand how prehistoric people used the variation in environments and resources across the park through time. In addition to the boundary expansion work, this past season park archaeologists worked in the pre-2004 core of the park to better contextualize previous research with the archaeology in the expansion lands. To date, this program has also provided 20 college student interns with in-depth field training and independent research opportunities.

Rendu, William (CNRS—NYU), Morgan Roussel (Leiden University), Sylvain Renou (Université Bordeaux), Marie Cecile Soulier (CNRS-Université Toulouse Jean Jaures) and Marie Soressi (Leiden University) [169] Les Cottés Sequence: A New Lens for Investigating the Cultural Changes Occurring during the Middle to the Upper Paleolithic Transition

During the transition from the Middle to the Upper Paleolithic in Europe, the replacement of Neanderthal populations by Anatomically Modern Human ones is concomitant of major cultural transformations. Progressively, human population incorporated new raw materials in their personal gear cumulating into an explosion of the cultural material diversity. Les Cottés in France preserves a detailed sequence with levels attributed to the late Mousterian, Chatelperronian, ProtoAurignacian and Early Aurignacian. Through combined zooarchaeological and lithic technology approaches we investigate how the need for new raw material extracted from mammals’ body impacted the lithic tools production. Our results underline a strong interaction between needs and technological production. They also suggest that the changes we observed are related to major changes through time in how and for what for the site was used. Thus it is not only the technology that was impacted by the development of these new needs, but also the logistic organization of the society itself.

Rengifo, Carlos [170] see Uceda, Santiago

Rennaker, Patrick W. (Portland State University) and Virginia L. Butler (Portland State University) [228] How Were Pacific Cod at Tse-whit-zen Affected by Climate Change?

In 2011, U.S. federal agencies listed Pacific cod (Gadus macrocephalus) in the Salish Sea as a species of concern. Fishery managers typically use historical data from the past ~ 50 years to create baselines to manage reduced fisheries, which does not take into account long term environmental change or how human populations have affected the ecosystem in the past. Archaeological data extends these baselines much further back in time. The Tse-whit-zen faunal project provides a ~ 2,200-year history of indigenous fisheries for one part of the Salish Sea and thus presents a unique opportunity to address questions relevant to current management. Measurements of the quadrate, premaxilla and abdominal vertebrae were used to reconstruct body sizes and taxonomy. Abundance provides a crude estimate of changing fish abundance, that were compared to predictions from changing sea surface temperature linked to the Medieval Climatic Anomaly and the Little Ice Age or overfishing. Minor fluctuations in size over time were seen, but these are not linked to known climate trends. Cod abundance decreases during the Medieval Climatic Anomaly and increases after the Little Ice Age, which is consistent with predicted response. Impacts from exploitation pressure are not evident.

Renteria, Rebecca (University of Arizona Tree-Ring Lab) and Ronald Towner (University of Arizona Tree-Ring Lab) [188] Homesteading in Cebolla Canyon, New Mexico: Ethnicity Studies in Using Dendrochronology, Historical Documents, and Oral Histories

Cebolla Canyon, in the El Malpais National Conservation Area, New Mexico, was homesteaded extensively in the late eighteenth and early nineteenth centuries by Hispanic and Euro-American families. The local environment provided grazing resources for sheep and cows, and the ability to homestead in this area allowed families to pursue seasonal or year-round occupation. The regional histories of these migrants differ, but the exploitation possibilities of land and timber provided people with the promise of land ownership and sustainability with respect to their necessities and desires; these are strongly based on sociopolitical factors of the time. Focus here is on Hispanic and Euro-American homesteading sites, comparatively. Using dendrochronology we can provide target dates for felling events, and in combination with archaeological remains we can grasp the duration of occupation for homesteading sites. We can also identify methods in which ethnicity can be delineated in the historical archaeology record. Further insight is provided by historical
documents, such as census records and homesteading patents that can give us an idea of how people institutionally- or self-identified as an ethnic group. Further, we can see how migrant groups were perceived by others by incorporating the use of oral histories.

The Chonos Archipelago: From Hunting-Gathering to Industrial Productivity in the Western Patagonian Channels (43°50’–46°50’ S), Chile

The Chonos archipelago is a series of islands and fjords in the northernmost part of western Patagonia, South America. It has been disconnected from continental landforms since glacial retreat, thus it is an ideal area for assessing the human use of maritime habitats. We analyze the spatial and temporal distribution of the archaeological record focusing on the emergence of human intense signatures in the last part of the late Holocene. The archaeological record (87 sites) includes open-air and within cave shell-middens, collective burials inside rockshelters, fishing pens, and historical camps. The radiocarbon record (90 dates) is discontinuous since the first evidence at 6300 cal BP until a recurrent occupation at 2000 cal BP, being particularly strong during the last millennium. Historical records from the Chonos peoples disappeared by the XVIII century and the archipelago became the territory for extractive activities (whalers, industrial shellfish processing, wood extraction) leaving traces in the shoreline. Today, the archipelago is used intensively, but productive activities (pisciculture) occupy marine surfaces, thus diminishing the production of materials on the coast. Assessing the continuous record of fully maritime societies should prove useful for understanding broader pictures including the variability in human signatures during the Anthropocene. FONDECYT #1130151.

Reynen, Wendy [374] New Insights into the Dynamics of Human Behavior during the Last Glacial Maximum and Terminal Pleistocene in the Pilbara, Northwest Australia

The emerging picture from the Australian archaeological record shows a varied pattern of human responses to the environmental and climatic fluctuations that characterized the Last Glacial Maximum (LGM) and the terminal Pleistocene in arid Australia. Archaeological data suggests a decline in site use and reorganization of human landscape use in correlation to broad shifts in climate and environment. The nature of these changes is complex and requires unpacking on a high-resolution scale as it is likely that localized environmental fluctuations strongly influenced mobility and occupation patterns. However, only 11 Australian arid zone sites have unequivocal evidence for LGM occupation and few sites have detailed published analyses of cultural material to understand the nature of Aboriginal occupation at this time. A case study from arid northwest Australia provides a fresh insight into the human-environment relationship and human behavior during the Pleistocene. Material assemblages from several recently excavated rockshelters are analyzed to provide a high-resolution narrative of Aboriginal rockshelter use and occupation during the LGM and post-LGM Pleistocene period.

Hominin Land Use of and Movement in the Koobi Fora Formation (Kenya)

The occurrence of large densities of lithic and fossil material in Early Pleistocene contexts have been the focus of much interest. Several hypotheses modeling hominid foraging strategies have been generated to explain their formation. Assemblage formation is often hypothesized to be the result of particular land use strategies that relate to the movement and discard of stone artifacts. These hypotheses are difficult to test because they rely on ethnographic models of human movement, yet they are applied to assemblages that reflect millennia of time averaged behaviors. Assemblage level measures such as the volume ratio, cortex ratio, and flake to core ratios are useful tools for quantifying the movement of different components of lithic assemblages largely because they require a time averaged signal to describe patterns of movement in hominin behavior. To quantitatively test these hypotheses, we generate theoretically grounded expectations for these assemblage level measures in the context of various foraging strategies. We apply these measures across a series of Early Pleistocene archaeological localities in the Okote Member (1.6–1.39 Ma) of the Koobi Fora Formation to test these hypotheses against this archaeological record. This research was supported by the NSF Internment Research Experience for Students (OISE-1358178 and 1358200).

The Promontory Caves Macrofossil Record

The dry deposits in Promontory Caves #1 and #2, northern Utah, contain abundant well-preserved plant materials related to the late prehistoric occupations there. Much of the plant macrofossil record in both caves, especially Cave #1, represents the manufacture of textiles, in particular the production of bulrush matting. Plant remains attributable to dietary use constitute a small part of the overall assemblage, consistent with the negligible evidence of plant food processing such as milling equipment. Here I consider the place of plant utilization in the Promontory Caves occupations, and potential indications of cultural connections with proto-Apachean populations and with local Great Basin societies such as the Fremont.

Linguistic Relationships between the Apachean Subgroup and Northern Athapaskan

Linguistic evidence has long played an important role in determining the relationship of Apachean peoples to Northern Athapaskans (Sapir 1936). While Apachean membership within the larger Athapaskan family is firmly established, the more precise determination of their linguistic affiliation to Northern
Athapaskan linguistic groups has proved more difficult (Rice 2012). The reasons for this difficulty arose chiefly from the lack of available data and the limitations in the power of analytic methods employed. Recent scholarship has led to improved availability and quality of lexical source materials for Athapaskan. Lexical comparison, the cornerstone of historical linguistic research, can now be carried out on more wide-ranging and disparate data. Methodologically, comparative linguistics has developed to a stage where reliable methods for the investigation of historical linguistic relationships have become established, especially in the fields of dialectometry (Nerbonne et al. 2011) and phylogenetic linguistics (Greenhill and Gray 2009). In this paper, we apply these quantitative methods to lexical data compiled in the Pan-Athapaskan Comparative Lexicon, a database containing over 20,000 words from the terminological domains of anatomy, kinship, fauna/food/animals, flora, landscape, and gaming, among others. We compare the results of our analyses with existing hypotheses concerning the closest linguistic relatives of the Apacheans.

[326] The 2016 Season at El Rayo, Nicaragua: Civic-Ceremonial Structures, Tombs, and Feasting from the Bagaces to Sapoa Transition Expanding on prior field seasons, the 2016 field school at El Rayo, with the support of the Institute for Field Research, continued the exploration of the unique Bagaces to Sapoa transition period site, located on the Asease Peninsula, Lake Nicaragua. This season focused on the excavation of four loci, continuing to explore previous questions regarding cultural activities in Pacific Nicaragua. Loci 2 and 4, which had been studied in previous field seasons were expanded, while new Loci 6 and 7 were opened. Highlighting this season’s findings were the continuation of Locus 4 large civic-ceremonial structure, located near to a structure at Locus 6 and Locus 7. Locus 7 also features an intriguing double burial, which was unfortunately looted in antiquity. Finally, the deep excavations at Locus 2 revealed multicomponent domestic trash deposits from the Sapoa period, superseding the deep layer of Bagaces period cultural material. Preliminary vessel form analysis of the Bagaces ceramics, in relation with the faunal assemblage, indicated probable short term consumption such as feasting activities. With each new field season, El Rayo continues to reveal more unexpected and unique site characteristics, displaying valuable data relating to Pacific Nicaraguan ceremonial and domestic activities.

[392] Beyond Polychrome and Greenstone: FTIR and SEM-XEDS Analysis of Fine-Grained Remains from Two Ancient Maya Royal Tombs at El Perú-Waka’ Ample evidence suggests Classic period Maya royal tombs were intentional arrangements of symbolically-charged objects and offerings. Because of this, critical examination of the entire array of a tomb's contents is vital. Analysis of polychrome vessels, greenstone jewels, and human remains are certainly essential. Relative to these more well-preserved or spectacular components of a mortuary assemblage, small-scale or fine-grained remains have historically tended to be understudied or overlooked, yet provide important clues about other integral elements of elaborate burial tableaux. This paper presents results of FTIR and SEM-XEDS analysis of a variety of pigment, residue, and matrix samples from royal Burials 24 and 39 at El Perú-Waka’, Petén, Guatemala. Specifically, results of these analyses permit fuller appreciation of the gamut of objects, materials, and substances utilized or incorporated in the interment of Maya elites. More broadly, the data enhance contemporary comprehension of the potential range of uses for specific materials and substances, both organic and inorganic, by ancient Maya people.

Richards, Julian (University of Wisconsin–Milwaukee), Robert C. Mainfort Jr. and Seth A. Schneider
[341] Comparative Compositional Analysis of Parkin Phase Red-slipped Pottery and Red Ochre Deposits Using pXRF and Petrography Portable X-ray fluorescence (pXRF) was used in conjunction with petrographic analysis of ceramic thin sections to characterize a sample of red-slipped potsherds from selected late Mississippian sites in northeast Arkansas. Data from this analysis is compared to a similar characterization of two separate hematite rich deposits from the same region. Results are used to evaluate the potential of this type of analysis to distinguish ochre sources from one another and to identify deposits that were used as constituents of ceramic slips.

Richards, Julian (University of York Archaeology Data Service)
[227] Size Isn't Everything: Are Our Data Good Enough to Be Big? Archaeological data may not yet meet the criteria for Big Data, but the growth of archaeological cyber-infrastructures is providing the foundations for “big data” research. Using digital repositories such as the ADS in the UK and IDAR in the USA, we have access to millions of records, from multiple resources. Data and text mining tools allow us to extract information from published and unpublished fieldwork reports, while the ability to create Linked Open Data or to integrate metadata via portals such as ARIADNE in Europe and DINAA in North America should allow us to break free from individual data silos. Nonetheless, the idea that “big data” somehow carries an aura of truth, objectivity, and accuracy through size alone has been identified as a myth. This presentation will underline the importance of adequate metadata, and data standards, in allowing us to integrate disparate data resources and to employ “big data” methodologies. It will consider the strategies adopted by recent projects that have sought to combine massive datasets to provide archaeological synthesis, and review their success.

Richards, Katie (Washington State University)
[368] Evaluating and Reevaluating the Importance of Cacao, Nicotine, and Macrobotanicals at Alkali Ridge Site 13, an Early Pueblo I Site in Southeast Utah Alkali Ridge Site 13 is one of the largest and earliest Pueblo I sites ever found in the American Southwest. Located in southeast Utah, the site was originally excavated by J. O. Brew in the early 1930s. Brew’s final site report includes brief descriptions of most major artifact types found at the site, but largely ignores the abundant botanical remains discovered there. Even though little research has been conducted on the macrobotanical remains, recent residue studies on pottery have shown surprising evidence for cacao at this early site. Recent excavations and re-excavations at Site 13 in 2012 and 2013 have provided new and better controlled datasets from which to study plant use. While maize was by far the most dominate botanical material recovered from the site, other charred remains as well as residues from a variety of ceramic types have helped us gain a broader understanding of what plant materials were and were not commonly used at this important Pueblo I site.

[341] Challenges to the Wisconsin Burial Sites Preservation Statute (WisStats 157.70)
The 1987 Wisconsin Burial Site Preservation Statute (WisStats 157.70) serves as the basis for the protection of all burial sites in the state of Wisconsin and assures that all human burial sites be accorded equal treatment under the law regardless of age or affiliation. Recently, challenges to the law have taken the form of an introduced bill (LBR 2890—eventually withdrawn), and the convening of a Wisconsin Legislative Study Committee of the Preservation of Burial Sites. This committee is charged with reviewing the present law in the context of landowner rights and includes land developers, real estate lawyers and legislators. This poster summarizes suggested changes to the law, and presents the results of three burial site excavations in Milwaukee County, Wisconsin, as case studies of the law in practice. The burial sites presented are the Old Catholic Cemetery (47 MI-0254), the Milwaukee County Poor Farm Cemetery-Froedtert Tract (47 MI-0527), and the Second Ward or Gruenhagen Cemetery (47 MI-0523).

Thinking Socially: Digital Archaeology beyond Technological Fetishism

As research momentum gathers alongside the adoption of digital technologies into everyday life, the terms “virtual reality,” “online,” and “cyberspace,” increasingly fail to recognize the degree to which the adoption of digital technologies, and the material objects through which the digital is accessed, have been domesticated and made normal. The entanglement of social communication networks in the variety of digital environments provided by archaeological organizations is often seen as peripheral to digital archaeology, which is absorbed in technical applications and data analysis, or simple, ephemeral communications, in the case of social media. The social contexts, platforms, and technologies involved in digital archaeology have, on the whole, been under-explored and under-critiqued, and have, as Huggett argues, “left archaeologists open to accusations of technological fetishism” (Huggett 2015:87). This paper will attempt to address these concerns by reasserting the relevance of sociological theory to the contemporary human condition, and anticipate future social and technological trajectories, which may impact our practice.

A Course on “Digital Heritage Tools”: A Reflexive, Engaging, and Ever-Changing Pedagogical Experience

Digital Heritage . . . ? A definition could be “the valuing, protection, documentation, and understanding of humanity’s shared heritage through the application of digital tools, media, and digitally-enabled spaces.” The take-away—Digital Heritage is a big concept. As scholars and educators making use of digital tools and methods, we face challenges of big data, rapidly changing technology, proprietary vs. open source, and the list goes on. Yet, increasing use of technology necessitates that we teach the digital. For three years, I have taught a course on “Digital Heritage Tools”—a course that serves not only anthropology but also English, history, and other disciplines. Given the broad definition of heritage and the diverse student audience, course development has been challenging, eye-opening, and energizing. This paper describes a morphing course on digital heritage—speaking to successes and ongoing challenges, particularly focusing on balancing teaching critical analysis alongside technological skills. Course topics include design and usability, web technologies, preservation and access, analysis and visualization (e.g., GIS, 3D modeling), and relevance of digital technologies in heritage interpretation, education, tourism, and outreach. Students carry out individual or collaborative semester projects to gain hands-on experience with not only technology, but importantly, digital storytelling to reflexively engage with heritage.

The Function of Candeleros and the Enigmatic Relationship between Teotihuacán and Honduras

The ceramic vessel known as Candeleros, which is commonly associated with Teotihuacán, is problematic for several reasons. Candeleros are generally small ovoid vessels with one or more chambers, often associated with domestic use and believed to be a type of incense burner. However, residue analysis that has been conducted to date does not always find materials associated with burning. Candeleros are most often associated with Teotihuacán, but are also found in Northern Honduras at sites such as Copan. Why Candeleros are commonly found in these two geographically distant areas and at a much lower concentration in between these two sites is unclear. This project uses residue analysis from a sample of Candeleros from Teotihuacán to shed light on the function of Candeleros as well as discussing the possible relationship between Teotihuacán and Northern Honduras.

The Tamtoc Scroll Style: Assessing the Relationship between the Huasteca and Classic Veracruz

What were the Huastec region’s interregional relations during the precolombian period? This is one of the pressing questions about the Huasteca that archaeologists, linguists, and art historians have tried to tackle since the nineteenth century. Scholars have identified cultural relations with the southeastern United States, central Veracruz, central Mexico, west Mexico, and the Maya region. Yet, the archaeological data supporting these identifications are sparse because few scientific long-term excavations have been carried out in the Huasteca. Recent excavations at the site of Tamtoc, one of the major and most extensively excavated sites in southern San Luis Potosí, however, have shed new light on this question. Monumental sculptures in particular have yielded stylistic and iconographic details, such as interlaced scroll designs, that indicate links to central Veracruz during the Classic period. This paper establishes that Tamtoc sculptures present a local variant of the Classic Veracruz style as defined by Tatiana Prokouriakoff (1953, 1954), while also maintaining a distinctively Huastec identity. This analysis of the sculptural evidence from Tamtoc sheds new light on the relationship between the Huasteca and Classic Veracruz and redresses the frequent omission of the Huastec region in discussions about cultural interactions along the Gulf Coast.

On We Sweep with Thrashing Oar: Interaction Networks in Aegean Prehistory

Prior to the introduction of sailing technology during the third millennium BCE, communication and movement throughout the Aegean Basin was greatly shaped by the region’s mixed landscape of open sea, island clusters, and mountainous interiors. Modeling the physical landscape and accounting for travel rates and physical restrictions to travel over both land and sea, I examine the nature of movement across the Aegean during the Neolithic and Early Bronze Age (6500–2000 BCE). Based on these variables, I use techniques and approaches from GIS and network analysis to model how social interaction between the various subregions (e.g., the Cyclades, Thessaly, Crete) took place and changed over time. I relate these models back to the
archaeological trajectory of the region and explore how patterns of large-scale interaction may have influenced changes in demographies and social organization at the regional and local levels.

Riede, Felix (Dept. of Archaeology, Aarhus University) and Russel Blong (Macquarie University) [77] Can Archaeology Provide an Evidence Base for Realistic Disaster Scenarios That Contribute to Reducing Vulnerability? Extreme climatic events and natural disasters often have a recurrence periodicity beyond that of ethnographic, sociological and, at times, even historical investigation. In a deep historical perspective focused on geo-cultural heritage, however, human communities have been affected by numerous kinds of natural disasters that may provide useful data for scenario-based risk reduction management vis-à-vis future calamities. Using selected past volcanic eruptions as examples and merging Lee Clarke’s sociological argument for "possibilistic thinking" and David Staley’s notion of "historical thinking" with a concern for contemporary and future resilience, this papers suggests that such comparative, cross-cultural “paleosocial” information on the constellations of vulnerability and resilience pertinent to deep-time disasters can be employed usefully in Realistic Disaster Scenarios (RDSs).

Riel-Fitzsimmons, Belinda, Tomasin Playford (Saskatchewan Archaeological Society) and Karin Steuber (Saskatchewan Archaeological Society) [122] The SAS ArchaeoCaravan-Museums Program: Archaeology and the Public in Saskatchewan The ArchaeoCaravan-Museum Program brings archaeology and history alive in the province of Saskatchewan. The Saskatchewan Archaeological Society spent the past five years visiting community museums with our mobile activity center to educate and inform the public about our rich and diverse archaeological heritage. In total, we visited 107 museums (in 11 museum networks), 102 communities, and reached over 10,000 people of all ages. At the same time, we were able to view museum collections that may not be well-known in the archaeological community. In 2013, we were chosen as a finalist in the Governor General’s History Award for Community Programming. This award is part of a series administered by Canada’s History Society that celebrates the best achievements in Canadian heritage and history. This presentation will discuss the successes and challenges of this award-winning program, how it developed and evolved over the past five years and where we go from here.

Riel-Salvatore, Julien (Université de Montréal), Fabio Negrino (Università di Genova), Marco Peresani (Università di Ferrara), Martina Parise (Università di Genova) and Jamie Hodgkins (University of Colorado Denver) [389] Characterizing Ephemeral Paleolithic Occupations at Arma Veirana (Liguria, Italy) This paper presents a description of recently studied assemblages from Middle and Upper Paleolithic levels at the site of Arma Veirana, a large cave located in the mountainous hinterland of Liguria. While one Mousterian level shows an intense occupation, all other levels indicate rather short-lived, low intensity occupations. Beyond technological and typological analyses of these assemblages undertaken to characterize them, we also report preliminary data on raw material procurement patterns from these levels. While the Mousterian suggests predominantly local acquisition, the Upper Paleolithic is comprised mainly of exotic lithotypes. Beyond these results that largely agreed with received wisdom about the technology and mobility strategies of the two periods, we also discuss the presence of a distinctive reddish radiolarite in some of the assemblages from both periods. This material has historically been considered exotic, raising a number of questions about how local and exotic materials contributed to the tool kits of foragers during their comparatively ephemeral occupations of the site. Lastly, we tackle the question of what these results mean for our understanding of Ligurian prehistory more broadly, since it has almost exclusively focused on coastal as opposed to inland sites.

Rieth, Timothy (IARII) and Derek Hamilton (University of Glasgow, SUERC Radiocarbon Dating La) [180] Quantifying the Number of 14C Determinations Required to Improve Dating Accuracy for Lapita Deposits The use of radiocarbon dating to calculate the dates of Lapita deposits remains largely a single-step, ad hoc procedure. The accuracy of dating results can be greatly improved through Bayesian modeling. However, this depends on the number and stratigraphic distribution of radiocarbon determinations and the shape of the calibration curve. Beyond these issues, we used Oxcal 4.2 to simulate, through the process of back-calibration, radiocarbon determinations that we could expect to receive as measurements on a series of samples of “known”, Lapita dates in Remote Oceania. We then ran a series of Bayesian models in which the number of radiocarbon determinations was incrementally increased, stratigraphy altered, and temporal parameters varied. Because the radiocarbon determinations are based on “known” calendar dates we were able to evaluate when a particular Bayesian model provided results that were accurate and precise and at what point the addition of further age determinations did not affect the results. Our analyses demonstrate that dating of Lapita deposits must be approached as an iterative process, requiring a sampling strategy that allows for an assessment of redundancy in results that is indicative of a high degree of accuracy in the calibrated dates.

Riggs, Charles and Blythe Morrison (Northern Arizona University) [122] Holes in Student Education: Policy and Adequate Field Training in Contemporary Archaeology Despite the importance of Cultural Resource Management (CRM) in contemporary archaeology, the task of teaching students proper field techniques still largely falls on academic institutions in the form of summer archaeological field schools. Although CRM derives from numerous federal laws and policies, the same laws have made the conduct of field school increasingly difficult as federal, state and tribal land managers impose restrictions on the scope of excavations on lands that were once critical to academic field training operations. These changes have forced many academic programs to either limit their curriculum or have caused field schools to increasingly rely upon private land for field training purposes, often opening an entirely new Pandora’s box of ethical concerns. We suggest that training within this limiting environment cannot adequately prepare students for the complex field situations they will encounter as they embark on careers in Cultural Resource Management.

Riggs, Erin (SUNY Binghamton) [198] Materializing Nationhood: The Many Roles of Built Landscape Management Policy in Post-Partition India and Pakistan This paper discusses built landscape management policies put in place during the aftermath of the 1947 Partition of India and Pakistan. It is argued that the management of out-migrant associated buildings (both monumental and residential) was influenced by three divergent goals of nationhood: 1) modernization, 2) secularism, and 3) cultural cohesion. These goals pointed toward conflicting actions. Providing shelter to millions of incoming refugees required the hasty allocation of dwelling spaces. Establishing a shared sense identity required repackaging built heritage as something commensurate with emergent understandings of national histories. Finally, upholding ideals of modernism and scientific objectivity required protecting architecturally

When Is a Pithouse a Pithome? Reconstructing a Fremont Household underneath the Book Cliffs of Utah
Perched along the northern edge of the Colorado Plateau, the Tavaputs Plateau is best known among archaeologists for its interior canyons, including the incredible rock art in Nine Mile Canyon and the well-preserved Fremont communities located in Range Creek Canyon. Despite the greater water resources and arable land along the Book Cliffs escarpment of the plateau, it has received little professional attention. This research program focuses on a small segment along the Grassy Trail Creek, a formerly perennial stream with several village and single structure sites well-known to local collectors. This drainage serves as a gateway to both Nine Mile Canyon and Range Creek Canyon. Initial studies suggest that this drainage may be best considered as a dispersed community, although the lack of temporal data precludes any rigorous statements about occupational overlap between sites. Recent excavations at a site called the Martinez Pithouse have revealed a burnt and collapsed structure with an intact floor and associated assemblage. This excavation provides the first dates for the Fremont occupation of this drainage as well as an opportunity to examine the household structure of the people who called this place their home.

When Smuggling Sailors Met the First Angelinos: Material Messages from Forgotten Santa Catalina Island, California
These episodes reveal that the sea-otter hunters, intent on smuggling, also used the island to careen and repair their ships, conceivably resulting in material exchanges. The ways in which the Pimu Tongva mixed the old with the new reveal how a coastal Californian group continued to craft their own identity in a rapidly changing world.

When Is a Pithouse a Pithome? Reconstructing a Fremont Household underneath the Book Cliffs of Utah

Micromorphological Analysis of Thin Sections from Bear Creek (45KI839), Redmond, King County, Washington
Micromorphology samples were collected during data recovery at the Bear Creek Site (45KI839) in Redmond, Washington in order to supplement the site's formation history. Micromorphological analysis of these samples has shed light on the taphonomic and sedimentary depositional processes at work prior to, during, and after Late Pleistocene-Holocene transition (LPH) occupation of 45KI839. This poster presents the micromorphology research design, sampling and analysis methodology, and results of analysis. The formation history of 45KI839 is marked by diastems. Several soil surfaces that represent periods of stability were identified in thin section, including a buried surface at the base of artifact-bearing Stratum V. In general, the buried surfaces show that the shifts to and from the depositional environment of human occupation were more gradual than the field observations suggested. The buried surfaces are separated by accumulations of sediment that represent periods of change. Although these sedimentary deposits are dominated by evidence for gradual accumulation, the 45KI839 stratigraphic profile also shows evidence for punctuated, event-driven deposition and erosion. In addition to site formation history information, petrographic analysis has also informed on internal site structure. The thin sections show vertical and horizontal variability within Stratum V and among Stratum V contacts throughout the site.

Lidar-Aided Ground Survey in the Puuc Hills, Yucatán, Mexico
A 2013 NASA lidar mission passed over the eastern extreme of the region being investigated by the Bolonchen Regional Archaeological Project (BRAP), in the process partially imaging the secondary site of Acambalam II/III. A substantial portion of the site was ground-checked during the summer of 2016. This paper discusses post-collection lidar processing and the possibilities for feature detection and landscape use revealed by ground truthing. The data also provide interesting demographic information on a broader scale for comparison with our 11 km² 100% pedestrian survey carried out by Gallareta.

Celebration and the Mining Way of Life in Magistral del Oro Durango
In this paper I present the historic and archaeological records, of social gatherings that formed an integral part of the mining way of life and the material culture that represents it. The study is focused on the town of Magistral del Oro, Durango in northern Mexico. This region was forged by mining activity in colonial times. Though the village today has been largely abandoned, traces of both labor and domestic areas still remain. Furthermore, photographs...
and interviews with people who worked the mine and lived in the village shed light on important festivities that have become a part of northern Mexican culture. I combine this information, with a study of architecture and spatial configuration, in order to reveal the significance of social gatherings for the miners of the past.

*Conceptual and Technical Connectivity in Indigenous South American Rock Art Traditions*

Archaeologists have long sought to explain the distribution of rock art traditions across Amazonia and circum-Amazonia with reference to stylistic variability in the iconography, often as a proxy for exploring shared concepts of symbolic representation, mediated through local cultural norms. Where it has been possible, cross-referencing this kind of data with the ethnographic and archaeological records has engendered valuable new interpretations of indigenous symbolic repertoires in a variety of settings. As more systematic research takes place, comparative syntheses of rock art have begun to emerge that hint at the true scope of a variety of traditions, providing tantalizing evidence of the extent that rock art is bound up in the exchange of other categories of culture, both material and ideational, across time and space. Building upon these trajectories, this paper will outline some new suggestions for how rock art, and perhaps indigenous iconography more generally, may be formally investigated along the axes of technical and iconographic variability. Methodological and conceptual challenges are identified in order to suggest the steps which may be taken to mitigate them. In doing so, the ultimate goal will be to connect disparate datasets by adapting cross-disciplinary methods to the study of indigenous art.

*Satunsat Revisited: Comprehensive Digital Documentation of an Architectural Cave at Oskintok, Yucatán*

Satunsat, or the Labyrinth, at Oskintok is one of the most unique structures in the Maya lowlands. Inside this otherwise unremarkable terraced building platform are interconnected vaulted passageways that span three levels. In addition to functioning as an observatory, Satunsat has also been interpreted as a symbolic cave, and was in fact referred to as a cave by the residents of Maxcanu during the nineteenth century. The phenomenon of architectural caves is well documented and lies along the continuum of subterranean or semi-subterranean spaces, which includes artificial caves. Recent 3D documentation enables researchers to better examine the complex morphology of the structure while revealing more naturalized tunnel forms and the relationship between carved bedrock and masonry. Results suggest that the cave-like nature of the passageways in Satunsat is not incidental, but rather reflects the interplay between domains more common to Maya notions of sacred space.

*Peripatetic Kingship, Pilgrimage and Pastoralism: Reevaluating the Politics of Movement in the Ancient Near East*

Pilgrimage is a popular phenomenon, one which involves people traveling to and gathering at specific places during specific times, usually as part of a shared religious tradition. In the Ancient Near East, religious travel existed alongside other forms of mobility with important political and social consequences, like peripatetic kingship—in which there is no one fixed court—a characteristic of the Urartian (ca. 800–600 BC), Achaemenid (ca. 550–330 BC), and Seleucid (ca. 300–100 BC) empires, or the widespread practice of pastoral nomadism. This paper will focus on the relationships between these three forms of mobility, with special attention to the complex relationships of how human and nonhuman actors that each sort of mobility permitted. Religious pilgrimage flourished in areas that had long histories of mobile pastoralism and drew upon many of its practices. At the same time, peripatetic courts congregated in places charged with affect. In some cases, these could be cultic centers like Musasir in Urartu, places of ancient political importance like Babylon in the Persian Empire, or new capitals like Seleucia in the Seleucid Empire. Juxtaposing these practices will allow us to view pilgrimage in a new light.

*The Highland Maya Conquests of the Northern Transversal Strip from the Early Postclassic through the Twenty-First Century*

Salinas de los Nueve Cerros was a massive city in west-central Guatemala that was built around the only non-coastal salt source in the Maya lowlands. In spite of this lowland location, highlanders were drawn to it for its agricultural potential and the rich concentration of salt. In this paper, we will look at the three major colonization attempts of the salt works and the surrounding region by Maya highlanders—the Early Postclassic, the conquest period, and the late twentieth century. After the city was abandoned in the Early Postclassic, the salt source was actively exploited by highland groups. Around 1600, the Gulf Coast Akalaha’ Maya pushed them out; the conversion of the Maya of Verapaz appears to have been part of a larger strategy to take it back. The region was largely devoid of permanent residents after a Spanish incursion in the 1690s, leaving it to be exploited by Q’eqchi’ and other highland Maya families. During the Guatemalan civil war, many of these families started to move into the region full-time, and today it is one of the principal centers of highland Maya culture in spite of its lowland location.

*Celtic Crosses and Quetzal Masks: On the (Re)production of the Archaeological Record*

In an era of globalization and mass production, archaeological objects and images are not immune to being transformed into commodities and sold for profit. This (re)production of the past can profoundly influence the ways that consumers understand the history of particular times and places—often erasing the experiences of marginality and resilience that archaeologists work so hard to recover. This paper examines two distinct cases in which historical images (and periods) are being transformed into objects for consumption: the proliferation of Victorian-era Irish concept pubs, and the production of “ancient” Maya masks for the tourist trade in the Yucatán. These examples show how the archaeological record is increasingly implicated in the negotiation of identity and memory within a global market culture that values the past as a spectacle.

Second Line Resources? Evaluating the Relationship between Human Demography and Aquatic Resource Use during the Eastern Archaic

As part of its investigations the Eastern Archaic Faunal Working Group (EAFWG) has been examining multiple explanatory models for Archaic variability and change in aquatic resource use. One traditional model argues that the intensified use of aquatic animals can be attributed to population growth and aggregation. In order to test this model, the EAFWG has been exploring possible methods for reconstructing Archaic population demographics. Until recently, broad-scale Archaic population reconstruction has proven difficult to pursue, due in part to relatively few Archaic period sites and a lack of traditional population markers preserved within these sites. However, the development of networked digital repositories has made Archaic population reconstruction possible on a regional level. For this investigation, information on Archaic sites was accessed for seven states located in the Eastern Woodlands region using site file data curated in the Digital Index of North American Archaeology (DINAA). Using site distributions and temporally diagnostic artifact data as proxies for population combined with site topographic setting the EAFWG was able to estimate population growth and aggregation over time throughout the Archaic period. These estimates can now be correlated with data on the use of aquatic resources from the EAFWG collection of faunal databases.

Mineros del Alto Cielo: Social Space and Materiality during the Capitalist Expansion in the North of Chile (Ollagüe, Twentieth Century)

In Chile, the process of modernization, expressed by the expansion of capitalism and industrialization, had many economic and social impacts. Based on sulphur mining camps located in Ollagüe, a commune of the Antofagasta region, we show the importance of modern materiality associated with the development of mining industries in northern Chile during the twentieth century. We consider that the modernization process, the industrial ruins and the materiality of the recent past, have generated memory spaces which are intertwined with local indigenous communities contemporary preoccupations. The peculiarities of Latin America’s modernization and capitalist expansion can be understood through the uniqueness of local practices and the material remains to which they are associated. Essential to the recognition of such processes, notions of temporality allow us to approach this materiality in terms of continuity and ruptures. Heritage policies and archaeological practice, through their material remains, gives us new insights about local memories and identities. This archaeological approach gives presence to this temporal fragmentation, generating a local and global political commitment toward the recent past, its material culture and industrial sites.

Assessing Stable Isotope Data from Archaeological White-Tailed Deer Remains as a Paleoenvironmental Proxy at the Site of La Joyanca, Northwestern Petén, Yucatán Peninsula

The sociopolitical reorganization of the Maya that took place during the Terminal Classic (AD 850–1050) has been interpreted as being correlated to regional environmental change, specifically drought. However, few climate reconstructions come from the southern Maya lowlands where the decline occurred during this period. While most paleoenvironmental reconstructions lack a local, site-related signature and instead reflect regional trends, stable isotope analyses of herbivore faunal remains have proven to be a useful tool to providing local insight into ancient environments. Our research is the first to examine the potential of white-tailed deer (Odocoileus virginianus) teeth for recording seasonal changes in precipitation and vegetation at the southern site of La Joyanca, northeastern Petéén, Petén, Yucatán Peninsula.

Puerto Rican Cultural Heritage under Threat by Climate Change

As a tropical, oceanic island in the northeastern Caribbean Sea, Puerto Rico is feeling the effects of climate change. Rising sea level, increased storminess, and unpredictable sudden weather events combine with heavy coastal occupation and little or no coherent development planning, to increase social vulnerability to coastal change. The burden of economic problems that the Island is suffering from also increases the complexities of working toward resiliency. Within this context, coastal heritage and local and traditional knowledge are not priorities for the government and only have been superficially considered within climate change conversations. This presentation summarizes the work that has been conducted in Puerto Rico to assess coastal heritage under threat by climate change and the actions under way to improve the prospects of documentation, recording and preservation of the mostly unknown coastal history of this island.

The Origins and Development of Arsenic Bronze Technologies on the North Coast of Peru: Preliminary Results from Archaeometric and Experimental Investigations

This paper highlights the preliminary results of an ongoing study that aims to further characterize the origins and subsequent development of arsenic bronze technologies on the north coast of Peru. While the production of arsenic bronze on the north coast has been studied in detail over the last several decades, the spatial and temporal origins for the use/production of these alloys—and how they spread throughout the region during the Middle Horizon (600–1000 CE)—are not yet well understood. The study aims to address these questions through the synthesis of isotope and geochemical data obtained from metallurgical materials/by-products from multiple Middle Horizon archaeological sites across the north coast, with a particular emphasis on diachronic and spatial analysis of the data so that a narrative of the use/production of arsenic bronze on the north coast of Peru can be written. Still in its early phases, the paper thus highlights the results of current archaeometric and experimental investigations of arsenic bronze use/production. Additionally, the Late Moche site of Huaca Colorada (600–900 CE; Jequetepeque Valley), and the Middle Sicán (900–1100 CE) site of Huaca Loro (La Leche Valley), are used as analytical case studies.

Osteobiography: A Conceptual Framework

Osteobiography provides a rich conceptual basis for understanding the past, but its conceptual basis has never been systematically outlined. It both stands in conceptual opposition to a traditional statistical approach to bioarchaeology modelled upon clinical studies in biomedicine, and is interdependent with it. As such, its position mirrors those of clinical case histories as opposed to statistical studies, participant-observation ethnography as opposed to quantitative sociology, and microhistory and biography as opposed to quantitative history. Such comparisons provide a framework for
exploring the strengths and weaknesses of osteobiography. It is not merely a tool for engagingly illustrating the “typical” life history as established statistically. Rather, it allows us to understand issues which population studies cannot explore. These include both analytical directions (exploring the complexity of deeply layered data, understanding the role of contingency in human lives, integrating osteological and cultural evidence) and philosophical directions (the interaction of material and conceptual factors in the creation of human bodies, embodiment, the experience of time).

[179] The Daily Experience of Space in Teotihuacán
This paper will explore the daily experience of space in one of ancient Mesoamerica’s quintessential urban environments, Teotihuacán. We often understand places like Teotihuacán through a consideration of its monumental structures and their relationship to the natural landscape, and emphasize the impact of specific burial events on social memory. Classic examples like the Street of the Dead’s geomantic procession in the heart of the city plan, or the Ciudadela’s stage-set quality, seemingly designed for large-scale gatherings of people witnessing rituals performed by the city’s rulers, help define one of its most urban qualities—the synchronization of behavior and movement. The scale of such activities suggests they were reserved for special occasions. But how were these varieties of Teotihuacán’s spatial synchronization present on a regular, less singular basis? How did quotidian rituals of waking up and going about everyday life reflect or resist the dominant spatial practices of the city center? Informed by a binary understanding of its ceremonial spaces as carefully calibrated alternations between accessible and inaccessible; visible and invisible; inside and outside; above and below, I will argue that Teotihuacán’s numerous apartment compounds provided the small-scale experience that the city as a whole amplified and transformed.

[367] Fremont Worked Bone Gaming Pieces: Their Life History Using Data from Wolf Village
We examine the life history of Fremont worked bone gaming pieces. Fremont gaming pieces have long been interpreted as instruments of gambling due to their similarity to items used historically in Native American gambling practices. During our research we analyzed all of the worked bone gaming pieces from Wolf Village and compared our results with ethnographic accounts of Native American gaming pieces. Our research focuses on two aspects of the Fremont gaming piece life histories which have been mostly overlooked: production and disposal. By focusing on the neglected portions of the life histories we can develop a more holistic understanding of the use of Fremont gaming pieces. We also consider the role that gaming pieces had in trade, specifically trade at Wolf Village. The results of our research indicate that the Fremont had well-developed ritual practices which may have included divination and imitative magic.

[394] Local Archaeology Societies in the United Kingdom
Local archaeology societies in the UK are unique. They are a product of the British political and legal system combined with cultural attitudes to the past and the development of the archaeological profession. They are a melting pot of inexperienced beginners, expert volunteers, professional archaeologists, and everybody in between. As a unique form of public and community archaeology, they allow volunteers to have a significant positive impact for and on both archaeology and society. This includes archaeological practice as well as material culture and landscape. This presentation will illustrate doctoral research that has documented the activities undertaken by local archaeological societies. It will consider the context for local archaeology societies, the motivation that drives their members, and the impact that they have. Finally, it will suggest a model for best practice to ensure that the potential for these societies is capitalized upon to most benefit all involved.

[126] Around the Lower Pecos in 1,095 Days: A Baseline Rock Art Documentation Project
The Lower Pecos Canyonlands of southwest Texas and northern Mexico houses some of the most complex and compositionally intricate prehistoric rock art in the world. Presently, there are over 300 archaeological sites reported to include rock art in Val Verde County Texas, with a vast majority not being revisited since they received their site designation 30 to 50 years ago. In January 2017, Shumla Archaeological Research and Education Center launched the Baseline Rock Art Documentation Project: a three-year project designed to gather an extensive dataset from all known sites and from previously unreported rock art sites discovered through canyon surveys. Data such as accurate site locations, high resolution panoramic images, 3D models created by Structure from Motion, and context photography will be collected in the field. New, amended, updated, and revised TexSite and Shumla Rock Art Site Forms will also be completed and submitted to our SHPO designated repository. This vast and multifaceted dataset will open areas for future research including rock art distribution and directionality patterns, motif attribute studies, landscape archaeology, and conservation assessments. It will also digitally preserve into perpetuity the full rock art assemblage for an entire archaeological region.

[273] Laser Removal of Graffiti from Pictographs at Hueco Tanks State Park and Historic Site, El Paso County, Texas: A Five-Year Review
In 2009, a three-phase project was initiated at Hueco Tanks State Park and Historic Site to remove graffiti that was painted over Native American pictographs, using portable lasers. The first phase of this project tested the ability of a laser to remove graffiti from an area of rock that did not contain pictographs; this test showed that a laser could be used to remove layers of graffiti from the igneous formations at the site. In 2010, samples of graffiti paint that was not directly on the pictographs to be treated were taken and subjected to multiple laboratory tests to identify their composition. Noninvasive techniques, including X-ray fluorescence (XRF), Raman Spectroscopy, and Fourier Transform Infrared Spectroscopy (FTIR), were used in the field to identify the composition of the pictographs themselves. These tests were also used to help identify the mineral content of the underlying rock. The resulting information was beneficial in calibrating, and testing, the lasers to distinguish rock imagery from graffiti. In 2011, lasers were used for the first time at Hueco Tanks to successfully remove graffiti from pictographs. As of 2016, after five years of monitoring, there was no evidence of negative impact resulting from this laser treatment.

[126] The Tale of Rattlesnake Canyon: Ongoing Documentation of an Endangered Rock Art Site
The Rattlesnake Canyon mural represents one of the most well-preserved and compositionally intricate rock art murals in the Lower Pecos Canyons, and perhaps the world. Deposited gravels from a major flood episode in June 2014, however, raised the canyon floor approximately 10 feet, enabling future floods to destroy the fragile panel. This presentation provides an update on emergency documentation efforts currently underway at Rattlesnake Canyon. Documentation and analyses of this mural includes 3D modeling and other advanced photographic techniques engaging color management, digital field microscopy to examine paint layer stratigraphy, production of graphic databases for the 271 figures comprising the mural, elemental analyses of the pigments using pXRF, and the collection of detailed attribute data for each of the figures. This level of detailed documentation is not only preserving the site for future generations, it is also revealing a highly sophisticated graphic expression produced by foragers approximately 3,000 years ago.

Robertshaw, Peter (CSU San Bernardino)  
[136] Decline, Collapse, and Regeneration of the State in Sixteenth-Century Bunyoro (Uganda): A Diachronic Archaeological Perspective on Ritual and the Negotiation of Creative Power  
Historical research by David Schoenbrun has identified the arrival of a new ruling dynasty in the sixteenth century as a pivotal moment when instrumental power was decoupled from creative power in Bunyoro. Unlike previous rulers in Bunyoro, the new Bito kings were not healers and spirit-mediums. New state rituals developed both in new places and at preexisting shrines, as is evident from historical and ethnographic sources. Archaeological investigations at known shrines and other sites, all of which were probably locales of ritual performance, situate these events of the sixteenth century within a longer-term (and AMS-dated) perspective that explores the complex interplay of ritual, healing, and drought in the development and decline of complex polities in the region. A major challenge, however, is the identification of ritual in this archaeological record, which is attempted here by invoking ideas of conceptual metaphors that link the materiality of the archaeology to belief systems. Future research should perhaps focus on the more recent past, specifically historic capital sites and regalia.

[378] New Insights into the Quileute Whalers of Washington State from Ecology and Archaeology  
The Quileute people of Washington State are an ocean going people dependent on marine resources. They are skilled fishers and hunters, and like their neighbors to the north, the Makah and the Nuu-chah-nulth, they have a history of exploiting the once abundant marine resources in both coastal and offshore waters. While much is known about the whaling activities of the Makah and the Nuu-chah-nulth, little is known about the whaling activities of the Quileute, especially 20–40 miles offshore. We used a combination of archaeological, ethnographical and ecological sources to determine which species were hunted, which species would have been available, and where Quileute hunters would have had to travel to find them. Gray whales would have been the most abundant and were regularly harvested by the Quileute in the 1800s. Humpback whales were harvested in the same manner as gray whales. Both species occurred close to shore, but also as much as 20 miles offshore. Astonishingly the Quileute successfully caught nine documented fin whales in 1888—a species found along the shelf-break some 30–40 miles offshore. The evidence of where Quileute whalers were hunting indicates that they were exceptional seamen, navigators, and whalers.

[81] The Paleoindian-Archaic Transition in the Western United States: A Bayesian Approach  
Summed probability distributions of large radiocarbon datasets provide a powerful method for investigating prehistoric population change at multi-centennial and millennial scales of analysis. However, summed probability distributions cannot account for statistical scatter and uncertainties accompanying individual calibrated radiocarbon dates, which means that they are ineffective for answering questions related to cultural persistence and change on shorter centennial scales. For these shorter time scales we turn to Bayesian statistical analysis for its ability to develop probabilistic models that explicitly incorporate statistical uncertainties in the analysis and enable robust estimates for the start, end, and transition dates of prehistoric cultures. We propose a working relationship between summed probability approaches and Bayesian modeling by using the latter approach to test hypotheses developed by the former approach, using a comprehensive radiocarbon database for the Paleoindian and Archaic periods in the Western United States.

[218] Interaction in the Late Classic Kaqchikel Area and Adjacent Pacific Coast: Least Cost Routes  
Least cost analysis of prehistoric nodes of interaction in the Kaqchikel Guatemalan highlands and Pacific Coast indicates the locations of viable travel routes. Several classes of data, such as sculpture, obsidian and ceramics, indicate that there was communication and economic exchange in the Kaqchikel Maya area in the central highlands and Cotzumalguapan Piedmont during the Late Classic Period (AD 600–830). Today people walk between neighboring towns on foot paths and roads designed for cars that span ravines and flat land. This practice indicates that walking these routes is a viable means of communication for an agricultural people today and have been documented for other areas, such as Chinauta. Using the distribution of San Martin Jilotepeque obsidian and Cotzumalguapan style sculptures as a guide to areas of interaction, trade and communication, this paper will explore efficient means of foot travel determined by least cost routes throughout the highlands and piedmont in the Late Classic period.

[174] Integrating Archaeobotany to Provide Insight into Domestic and Public Ritual in Southern Brazil  
Archaeobotanical results are integrated with archaeological and paleoecological data for the southern proto-Jê of the southern Brazilian highlands. Results from a domestic structure displays a pattern of architectural termination and renewal that not only uncovers an ancient ritual practice, but also
reveals practices of plant management when considered alongside paleoecological data. Within the wider context, the data support a change in the performance of ritual practices revolving around fire from the domestic to the public landscape. The data show the value of archaeobotanical research and its integration into the wider research design, as well as the importance of developing methodologies that are appropriate to ask questions about the specific culture being studied.

Robles Cortés, Erika Lucero (Proyecto Templo Mayor) [225] Crocodiles in the Offerings of the Great Temple: Use and Symbolism

The numerous animals placed in the offerings of the Templo Mayor were brought in through tributes, trade, or spoils of war from every corner of the Aztec Empire—from tropical jungles to deserts. Indeed, the largest part of the fauna included in the collection at the Templo Mayor is identified as foreign. Crocodiles are among the exotic animals on display. This presentation explains the process of how these crocodiles were acquired, from their selection, to their hunt or capture, and, later, their transportation to Tenochtitlan. If crocodiles arrived alive, they were probably sheltered in “Moctezuma’s Zoo.” When deposited in the offerings, some of these crocodiles were buried entirely, while others were turned into leather or ornaments. The location, orientation, and relation of the crocodiles with other animals and objects from the offerings were carefully planned. Some deposits were consummated in conjunction with the building’s consecration, others were situated in the occasion of a funerary ritual, and some others were placed as messages to the Gods.

Robrahn Gonzalez, Erika (UNICAMP) [360] Collective Intelligence in Cultural Environment: Predictive Models, Preservation, and Valorization of Cultural Identity in a Brazilian Context

The current days are becoming more and more demanding for researches on social sciences, considering the great changes happening globally on the last decades, changes that seem to be happening always on a faster pace than before. Many international institutions, including UNESCO, have been promoting discussions intended to bring new ideas on the role of Humanities on the current society, this from the standpoint of a global perspective. This challenge is also about the integration of knowledge, considering both the scientific one and the knowledge traditional communities that lived or are living on the sites built studied. On this scenario, the knowledge of past communities that were obtained through archaeological research, reveal different experiences or alternatives on how to handle the environment. Adding all of these experiences along the past and present, creating a process that will result in the current Cultural Environment. On this paper the conceptual synthesis on the subject and its applicability on research projects in Brazil is presented, three main topics are analyzed:

• Archaeology and Preservation on the perspective of global challenges;
• Predictive models on Archaeology;
• Cultural Identities and Collective Intelligence.

Rocha, Bruna (UCL–UFOPA) and Vinicius Oliveira (UFOPA) [327] Connectivity beyond the Floodplains: The Case of the Upper Tapajós

The first millennium AD saw an increase in population density throughout much of Amazonia; this is testified by an increase in the number and size of coeval archaeological sites, many of which include anthropogenic dark earths, widely considered as proxies for intensive and continuous human habitation and alteration of the environment. The Terra Preta do Mangabal and Sawre Muybu sites were village settlements occupied from c. AD 700 and c. AD 900 respectively, located along the rapids of the upper Tapajós River. In spite of this geographical barrier, ceramics and lithics excavated from these sites suggest connections to faraway areas, reaching as far north as the Caribbean and south to the Brazilian shield. These materials simultaneously materialize local technological practices, processes of transmission, innovation and appropriation. As such they are well suited for an
It is now generally accepted that humans are the primary drivers of environmental change; virtually no ecosystem has escaped our influence. With European contact in the sixteenth century, Native American cultural diversity in the Appalachian Summit, the upper Catawba River Valley, and northeastern Tennessee at the point of early but so also did groups from areas in northeastern Georgia and northwestern South Carolina, and the Pisgah phase is also important in understanding changes in deep time. Ancient DNA (aDNA) analysis combines the precision of genetic analysis with the time depth of archaeology, and thus it can explore of approaches related to the concepts of communities and constellations of practice. Following an exposition of the sites and their materials, a comparison with the wider region will be presented. This will enable an evaluation of the interpretative potential of “communities and constellations of practice” and related concepts to provide us with tools to study past historical processes and social boundaries on local and regional scales.

Roche Recinos, Alejandra (Brown University) and Mallory E. Matsumoto (Brown University) [369]  
Economic Production at Piedras Negras, Guatemala: Production and Exchange in an Elite Architectural Complex

In recent years significant headway has been made to understand New World marketing systems. In contrast with the highly complex and easily identifiable market systems of the Mexican Highlands, ancient Maya systems of production and distribution have traditionally been assumed to have operated at the level of the household, and thus have been overlooked. However, recent work in the Maya area has shown the likely presence of production beyond the household at possible market areas. In this paper, we examine evidence from the 2016 field season at Piedras Negras, Guatemala for trade and production of jade, obsidian, and chert in the southern sector. We rely on a combination of lithic analysis, ethnographic data, and recent research on pre columbian markets to better understand economic dynamics at this major Maya site.

Beyond Ceramic Provenience: Interdisciplinary Research into Social Practices at LIRAC

Dr. Kostalena Michelaki founded the laboratory for Interdisciplinary Research of Archaeological Ceramics (LIRAC) in 2006, thanks to funding by the Canadian Foundation for Innovation. She established this facility to examine the relationships between technology, society and the environment, through the archaeometric analysis of technological choices made by people in the production and use of ceramics. Scholars working in LIRAC, and in associated McMaster research centers such as the Brockhouse Institute for Materials Research and the McMaster Institute for Applied Radiation Sciences, have analyzed materials from North and South America, the Near East, and the Mediterranean. In this talk we explore three research projects—the Neolithic and Bronze Ages in Calabria, Italy, Late Woodland Ontario, and Formative Period in the Lake Titicaca Basin, Bolivia—to highlight the successes of LIRAC, and reflect on some of the challenges associated with analytical approaches in what might be called a social geoarchaeology. What unites these regionally diverse case studies is their application of geochemical and mineralogical methods to both explore questions of provenance but also underlying social practices. Our paper demonstrates the shared view that embedded within ceramic objects is a record of human decisions that constituted a range of social practices.

Rodning, Christopher (Tulane University) and David Moore (Warren Wilson College) [160]  
South Appalachian Mississippian in the Appalachian Summit: The Pisgah and Qualla Phases in Western North Carolina

Archaeologists have generally characterized the Pisgah phase in western North Carolina as the manifestation of Mississippian culture in the Appalachian Summit province, dating from AD 1000 to 1450, and the precursor to the Qualla phase, which dates from the 1400s through 1800s and is associated with historic Cherokee towns. The Appalachian Summit encompasses rugged topography, sprawling mountain ranges, and some of the tallest peaks east of the Mississippi River, and it is an area with some of the highest amounts of annual precipitation in eastern North America. This paper summarizes the chronology and characteristics of the Pisgah phase in the Appalachian Summit, its relationships to the Qualla and Burke phases in western North Carolina, and environmental conditions and climatic changes that shaped the development of the South Appalachian Mississippian cultural landscape. The people associated with Pisgah sites did contribute to the development of historic Cherokee culture in the Appalachian Summit, but so also did groups from areas in northeastern Georgia and northwestern South Carolina, and the Pisgah phase is also important in understanding Native American cultural diversity in the Appalachian Summit, the upper Catawba River Valley, and northeastern Tennessee at the point of early European contact in the sixteenth century.

Rodrigues, Antonia (Simon Fraser University) and Chelsey Geralda Armstrong (Simon Fraser University) [77]  
Ancient DNA and Historical Ecology: An Innovative Approach to Environmental Conservation

It is now generally accepted that humans are the primary drivers of environmental change; virtually no ecosystem has escaped our influence. With increasing awareness of the impact of humanity on the biosphere, researchers have begun to focus on understanding, protecting and perpetuating biological diversity at all scales and levels of biological organization. One of the best ways to understand current and future anthropogenic impacts on biodiversity is by studying their effects in the past. Archaeological sites can be a great resource, containing evidence of environmental and cultural changes in deep time. Ancient DNA (aDNA) analysis combines the precision of genetic analysis with the time depth of archaeology, and thus it can provide unique insights when studying historical ecology. This presentation will provide a broad overview of aDNA analysis and use case studies to highlight the potential contributions this field can make to historical ecology. Finally, the use (or lack of use) of aDNA data in historical ecology will be explored, ending with recommendations on how to facilitate meaningful collaborations between the fields.

Rock Art Conservation in the Gila River Indian Community, Arizona

The Gila River Indian Community is dedicated to preserving its heritage, and consequently has developed a rock art conservation program in order to care for, restore, and protect petroglyphs within community lands. The proximity of the large Phoenix metropolitan area increases the risk of trespass and vandalism within the GRIC. In recent years, damage at archaeological sites has included defacement and graffiti, and the theft of rock art boulders. Current restoration work has experimented with and utilized numerous techniques and products for cleaning paints and engine exhaust from rock art; these will be discussed in this presentation. We will consider the efficacy of the various graffiti removal products, including “elephant-snot” and “shadow max.” The work done by the Community’s Cultural Resource Management Program has resulted in an efficient and evolving plan for restoration
and conservation. Preservation efforts include community outreach and education as well as emplacement of barriers and increased law enforcement patrols. The combined efforts have resulted in numerous sites being cleaned and restored and an increase in awareness of the significance of rock art in communities on and off the GRIC.

Rodríguez, Miroslava

El Cerro Magoni o Nonoalcatépetl en el registro histórico

El presente ensayo utiliza documentos del registro histórico para investigar la reasignación de significados al Cerro Magoni por diferentes grupos desde el siglo XVI hasta su presente definición como parte del Ejido de la comunidad Huerto Nantzha mediante el marco conceptual de la territorialidad. Ésta consiste en la apropiación y dominación de un espacio mientras que el territorio es distinguible y defendida por su dueño y defendida. El poseedor será quien dote de significados específicos al entorno natural que habita y posee: su ecuméneo. Una manera de legitimación de la propiedad es el ‘título de propiedad,’ que puede consistir en documentos elaborados de acuerdo a tradiciones pictográficas prehispánicas, los escritos introducidos por la llegada de los españoles, u otros. Los documentos a menudo contienen información literal, pero esconden un trasfondo ideológico, cosmogónico, y social que reclama y respalda la legitimación del propio contenido. El presente trabajo considera el Cerro Magoni en su condición de tierra patrimonial de los antecesores de Pedro Moctezuma para permitir comenzar con el rastro de la reasignación de significados a un mismo espacio a través del tiempo.

From the Green Belt: an Appraisal on the Circulation of Western Iberian Variscite

The Western half of the Iberian Peninsula plays a significant role for understanding the production and circulation of “green stone objects” (mainly variscite adornments, but also some jadeite ax heads) during the Neolithic and Copper Age of Western Europe. This importance lies in the presence in the area of two out of the three prehistoric variscite mines in Europe. Through an extensive review of the variscite adornments found in the archaeological contexts of Western Iberia, we will try to offer a comprehensive view of the spatial and chronological distribution of these objects and also to provide some hints that may help to increase our understanding of the significance that the “green stones” would have had for the prehistoric communities of the study area.

Roe, Peter G. (University of Delaware)

Bayamanaco and the Cayman: The Mythic Origin of Manioc Cultivation, Amazonia-Antilles

Recent trace analysis of Greater Antillean culinary implements finds a paucity of evidence for manioc until late times. This is anomalous since it was believed that manioc accompanied the first truly horticultural and ceramic-producing groups, the Saladoids, from the Orinoco lowlands of South America through the Lesser Antilles to Puerto Rico at 800–500 BC. Such late occurrence also contradicts the fact that manioc is a lowland cultigen, spanning northern tropical South America. Actual tubers from and early sites along the Peruvian coast at 3000 BC suggest even earlier lowland dates, early enough for the Saladoids to have taken it with them. Utilizing “cultural archaeology,” pioneered by Irving Rouse and Donald Lathrap, this paper address this anomaly, comparing the Bayamancao myth from Hispaniola, recorded by Fray Ramón Pané (1498), to the Caymanic origin of manioc instantiated @900 BC on the Tello Obelisk at the ancient Andean ceremonial center of Chavín de Huántar, Peru, as well as in ethnographic Pan-African mythology. Thus the “mythic charter” for this crucial horticultural pattern is equally old and spans the Amazonia-Antilles culture areas. This implies that preservational bias may account for the lack of early manioc residues on artifacts from the Antilles and northern South America.

Political Process, Polity Formation, and the Role of Urban Centers in Inner Asia

By 200 BCE the eastern steppe regions of Inner Asia saw the development of expansive and complex political systems usually referred to as empires. The origins of these polities and the processes of consolidation can be described within the concept of a political community, reflecting the actions of competing groups in expansive social network. For Inner Asia, community was linked to issues of mobility, dispersed control hierarchies, and the economics of multi-resource pastoralism. Together, these patterns offer an alternative vision of the origin and operation of early complex polities. Archaeologically, the pastoralist way of using the built environment provides a window into the dynamics of political processes that operated within a particular polity, but also within multiple polities across long stretches of time. Based on a sample of 77 sites within 13 steppe polities distinctive patterns of political processes altered and incorporated community and place in the building of fortified settlements, palaces, military posts, and other constructions. The evidence suggests that these polities operated as spatial networks that relied more on mobility than the direct interactions seen in urban centers in sedentary societies. Urban centers tended to be the byproduct of polity formation, rather than the source.

Rogers, Thatcher and Elizabeth Peterson (Simon Fraser University)

From Medio to Missionization: A Comparison of Lithic Technology in the Casas Grandes Valley into the Protohistoric Period

After the early Medio period, populations subsisting in the Casas Grandes region, northwest Mexico experienced internal and external pressures that led to drastic reorganization of their socioeconomic system. This is reflected by significant changes in their lithic tool kit, where differences in raw material use and tool morphology accrued through time. Presented here are the results of our lithic study comparing multiple excavated Medio and the only excavated protohistoric site located throughout the Casas Grandes regional core. Comparing the organization of lithic technology of early/late Medio large-medium size sites to late Medio small sites in Casas Grandes, as well as studying changes in lithic types into the protohistoric period, provides one means by which to explore how people respond to drastic cultural changes through time.

Engendering Ballajá: A 1910 Case Study from San Juan, Puerto Rico

In the northwest corner of the capital city of San Juan, Puerto Rico, formal urban blocks were proposed and constructed in the nineteenth century in an area known as Ballajá. As part of a larger investigation, documentary research was carried out, and quantitative and qualitative data was analyzed to study the presence of women using the 1910 census. German to that investigation, were specific variables such as professions, trades, race, nationality, age and civil status, therefore providing specifics to characterize them. This presentation explores the viability of using the census information to describe domestic units within the ward. By incorporating a 1921 plan of the ward to this study, it will be possible to create various layers that show the distribution of women based on race, profession/trade, and civil status. Also relevant, will be information about women that were recorded as head of the household, and those who rented out rooms, as well as those who lived with other families, not necessarily related. The analysis of historic sources can be connected to the archaeological collection excavated in five blocks, and provide a better understanding of the people who lived in particular spaces, and the objects employed by them.

Cahokia: City at the Center of the Mississippian Cosmos

Cahokia stands as the flagship city of the ancient Mississippian world. One of the enduring mysteries concerning Cahokia has been how to account for its skewed orientation and unique layout of its mounds and plazas. What accounts for the site’s orientation east of north; and why are the mounds situated where they are? In this presentation I use recently obtained lidar imagery together with archaeoastronomic analyses to explore the idea that Cahokia was built according to a grand master plan. This master plan employed a standard unit of length and specific geometric shapes oriented to important celestial events. In this design, the structure of the cosmos was represented. There was more, however. As I will show, the layout of Cahokia was perhaps intended to facilitate the movement of spirit entities as well as human souls between cosmic realms. Cahokia functioned as an axis mundi—connecting This World to the Upperworld and Lowerworld. Among the spirit entities that may have moved along the Cahokian axis mundi were the mythic founders of the great city, arguably represented in proxy form by the so-called Mound 72 “beaded burial.”

New AMS dating sequences for the Chumash Ventureno Early Period: Revisiting the Question of Antiquity of Ventureno Chumash Inland Occupation

The dating of sites within the Ventureno Chumash interior region has been robust for Late Period, but less well represented for the Early and Middle periods. We present here a suite of dates that document a well-established “complex of sites” that all date to the Early to Middle period located adjacent to the Santa Monica Mountains and proximal to the Late Period ritual site of CA-VEN-632.

La práctica del desollamiento humano entre los mexicas

El desollamiento humano es una de las características más notorias asociadas a Xipe Tótec, una de las deidades más enigmáticas del panteón mexica. Durante largo tiempo los investigadores han aceptado sin reservas lo que las fuentes señalan con respecto a esta práctica ritual. Sin embargo, en fechas recientes han surgido varias preguntas en relación a esta práctica. Por ejemplo, ¿Es posible establecer un lugar de origen, temporalidad y evolución de esta práctica en Mesoamérica?, ¿Cómo se realizaba tal procedimiento? Es decir ¿Existió un procedimiento estandarizado para efectuar dicha operación?, por señalar solo unas cuantas. En este trabajo se pretende explorar, como antecedente, los casos que se tienen reportados en la literatura especializada donde se tengan indicios de la existencia de la práctica ritual del desollamiento en la época prehispánica. Interesantes de ellos varios aspectos: su temporalidad, su localización geográfica, la cultura que la practicó. El objetivo final es abordar lo más desconocido de este ritual: la forma en que se realizó en el preclásico tardío; es decir, la técnica empleada para desollar a los individuos y los probables instrumentos utilizados por los mexicas, ello a partir de las huellas de corte observadas en los huesos.

Molecular Disease Characterization in a Precolumbian Indigenous Population of Punta Candelero, Puerto Rico.

Skeletal remains belonging to a Late Saladoid population from Punta Candelero site (AD 640–1200), southeast Puerto Rico were used for the detection of Pathogens. Previous studies have established the presence of trace genetic indicators of molecular disease in skeletal remains, such as syphilis and tuberculosis, with associated history or pathology. In this study, we are investigating the presence of various pathogens associated with precolumbian Indigenous populations of Puerto Rico. Paleopathology and preservation were a significant factor in sample selection. Characterization of the pathogen component of the ancient DNA was initially directed toward the detection of oral infections consistent with paleopathology and Neglected Tropical Diseases (NTDs) hypothesized to be widespread among the population. NTDs are a group of bacterial, viral and parasitic diseases, caused by known pathogens often with an unknown phylogenetic origin. Using sensitive ancient DNA amplification and sequencing techniques we have assayed this population to determine a pathogen Index for each individual and the population overall. We present preliminary results in compliment to existing archaeological information on the disease dynamics of this indigenous population to generate a comprehensive picture of the islands’ complex precolombian past.

Romero, Ashuni (Escuela Nacional de Antropología e Historia) and Ramón Santacruz (Instituto Nacional de Antropología e Historia) [353]
Quimicho: A Classic Site in Northeast Tlaxcala, Mexico.
Through an archaeological salvage project, the Quimicho archaeological site was explored for the first time. During the prehispanic period there was a system of circulation of natural, human, and ideological resources, which different groups in different moments took advantage of. For this system to work, different routes of distribution of wealth were established, generating a cultural exchange between diverse ethnic groups. The Quimicho archaeological site, situated in the Northeast region of the modern Mexican state of Tlaxcala, is part of the Teotihuacán corridor, a route that was controlled during the Classic period by the site of Teotihuacán, as proposed by García Cook in 1981. The archaeological exploration of Quimicho provides a model of archaeological indicators (such as ceramics and architecture) that can be reproduced at other sites along this corridor and can help to explain the cultural relationship between different ethnic groups and the large urban center of Teotihuacán.

Romero, Danielle (NV SHPO, NVFCP), Barbara Roth (UNLV) and Darrell Creel (University of Texas, Austin) [303] Chasing Tlaloc and Dragonflies in the Mimbres Valley: An Analysis of Ceramic Distribution and Style
Anthropomorphic and zoomorphic figures were common design elements on Classic Mimbres ceramics. However, certain forms and motifs were more widely used than others. During the 2016 field season at the Elk Ridge Ruin, a bowl with a Tlaloc figure was recovered from a burned ramada area, and a sherd with a partial dragonfly was found in one of the pueblo rooms. When both of these figures were included on rock art panels, they were infrequent on ceramics. This paper examines the presence of dragonflies and Tlaloc figures on ceramics through time and space within the Mimbres Valley. Site reports and Mimbres ceramic databases were consulted to gather an inventory of ceramic vessels and sherds where either of these images occurred. This allowed for a visual analysis of styles and a means of gathering geographic data to map the sites in which these artifacts were recovered. Distribution patterns coupled with stylistic similarities and differences may help resolve the question regarding why these particular figures were used.

Ronsairo, Karleen (George Washington University) [369] Figurines, Households, and Social Identities at La Blanca during the Middle Preclassic Period (900–600 BCE)
La Blanca was one of two major regional centers during the Conchas phase (900–600 BCE) of the Middle Preclassic period in the Soconusco region of Pacific Guatemala. Household differentiation and social stratification at Preclassic sites in this region can be explored by analyzing the distribution of ceramic figurines across elite and commoner households at La Blanca. Through an analysis of typological distributions of figurines from La Blanca, I provide insight into the production and consumption of figurines and how figurines may have been used in practices of identity formation and social negotiation. Moreover, I consider standardization and variation in figurine attributes in order to further investigate figurine production and consumption as ways for their makers and users to distinguish themselves from others and to maintain household identity and status. Through my analysis of the La Blanca figurines, it is my goal to provide further insight into emerging centralized political systems in Preclassic Mesoamerica. By taking a microlevel approach to analyzing household differentiation and social identities at La Blanca, the results of this figurine study will inform us of the different ways people responded to increasing social and political inequality during the development of social complexity in ancient Mesoamerica.

Roos, Christopher (Southern Methodist University), Julie Field (Ohio State University) and John Dudgeon (Idaho State University) [123] Geographic Variability in the Onset and Intensification of Swidden Cultivation on Viti Levu, Fiji
At some point between initial colonization and first contact with Europeans, Fijian economies transformed from being dependent upon marine foraging to dependence upon intensive agriculture. The timing and spatial pattern of this transition has beguiled archaeologists because the archaeology of Post-Lapita, “Mid Sequence” archaeology has been so scantily preserved and recovered. We employed geoarchaeological coring of terrestrial soil and sedimentary sequences along a transect from near the coast to more than 40 km inland to reconstruct the timing and geographic context of the transition to agriculture. We used radiocarbon dated charcoal concentrations and stable carbon isotope ratios to reconstruct natural fires, initial slash-and-burn cultivation, and swidden intensification from 5–6 m cores near known “Mid Sequence” archaeological sites. Our results suggest that local decisions to initiate or intensify swidden cultivation were complex and dependent upon local and regional climate, environment, and social contexts.

Rosado Ramirez, Roberto (Northwestern University), Heather McKillop (Louisiana State University) and E. Cory Sills (University of Texas at Tyler) [281] Analysis of Marine Sediment of Ancient Maya Salt Works in Paynes Creek National Park, Southern Belize
In this paper we present the results of archaeological research at two Classic period Maya salt works currently submerged in a shallow salt-water lagoon in Paynes Creek National Park, Southern Belize. These two contexts are part of the more than 100 locations so far identified in the area where salt was produced by boiling brine over fires near wooden structures. Through the study of marine sediment recovered at excavations from sites 24 and 35, we were able to document environmental and anthropogenic changes over time. This research included loss-on ignition of 32 sediment samples, along with macroscopic and microscopic descriptions of marine sediment. The results of these marine sediment analyses, in conjunction with data on their spatial distribution and their relation with cultural remains, provide insights on the timing and rate of sea level rise at these submerged salt works. These results advance our understanding of the abandonment of such salt production facilities in Southern Belize at the end of the Classic period.

Roscoe, Paul (University of Maine)  
**[324] The Perplexing Complexity of Some New Guinea Communities**  
At contact, a number of New Guinea communities boasted considerable ‘horizontal’ complexity—very large populations (up to 2,500 people) and ceremonial arenas that engaged even more. Many also constructed monumental architectures of organic material and staggering size. These communities included complex fisher-foragers and Big-man horticulturalists, organizations that are commonly identified as only minimally hierarchical. Certainly, their hierarchical institutions were insufficiently developed to account for the scale of their ‘horizontal’ complexity. After briefly surveying this complexity, this paper analyzes why these communities became so complex and the mechanisms that allowed them to manage their complexity.

**[366] Pima County Cultural Resources Management on County Conservation Lands: Predicting Archaeological Sensitivity Zones and Refining Spatial Models**  
Geographic Information Systems (GIS) modeling is vital to improve and focus cultural resources management strategies on the approximately 100,000 acres of conservation lands acquired by Pima County since 1997. These lands are dedicated for cultural and biological resource conservation and are the result of lands identified in the Pima County Sonoran Desert Conservation Plan (SDCP). The SDCP includes a static model depicting archaeological sensitivity that combines all archaeological site types and time periods together into low, moderate and high archaeological sensitivity zones throughout the County. The SDCP has been used for informing land conservation management decisions including infrastructure placement and ranching operations for mitigating threats to cultural resources by encroaching development. In order to account for the broader spectrum of potential impact agents on cultural resources, including erosion, ecotourism, vandalism, recreational use, and grazing, a newly designed GIS database using dynamic and contemporary data sources will allow us to refine the SDCP model. This poster presents an analysis of cultural resources from two sample conservation land areas in which archaeological sensitivity and threat assessments are modeled and field tested by sample survey to enable informed and efficient land management strategies to better conserve cultural resources.

**[389] Short-Term Neanderthal Occupations and Carnivores in the Northeast Iberian Peninsula**  
Short-term human occupations can be developed in very distinct places and be related to very diverse functions. The low number of items left by the human groups in these sites usually generates discrete assemblages, which often adds difficulties to the subsequent archaeological interpretations. In the European Middle Paleolithic, are common short-term human occupations in caves and rockshelters frequented by carnivores as well (bears, hyenas, large felds, canids and other small carnivores) as hibernation places, dens or refuges. From an archaeological perspective, the resulting assemblages are a mixture of anthropogenic and carnivore items (palimpsests) in which the intensity of human occupation(s) is usually measured by the quantity of recovered lithic artifacts, hearts or modified bones. However, the detailed study of these sites can be significantly informative to understand some basic questions about the development of the human communities in a landscape, their movements across the territory, the diversity of activities that they were able to do and, the relationships established between them and other biological entities (mainly carnivores). This work aims to present the results on four sites with these characteristics located in the northeast Iberian Peninsula: Llenes and Tritons Caves (Lleida) and Toll and Teixoneres Caves (Barcelona).

Rosen, Arlene (University of Texas at Austin), Jennifer Farquhar (University of Pittsburgh), Joan Schneider (California State Parks) and Tserendagva Yadmaa (Mongolian Academy of Sciences)  
**[27] Holocene Vegetation Cycles, Land Use, and Human Adaptations to Desertification in the Gobi Desert of Mongolia**  
Since the retreat of the Pleistocene some 11,700 years ago, the landscape and vegetation of the Mongolian Gobi Desert has been profoundly changing, punctuated by the appearance of lakes, wetlands, and finally aridification. Vegetation communities have responded to these changes according to temperature shifts and northward to southward movements of the edges of East Asian monsoon systems. Human groups have lived, foraged, and traveled through the landscape of the Gobi for millennia, adapting their technologies and systems of plant and animal use with the dramatic changes of flora and fauna, and likely contributed to the character of the vegetation communities in the region today. Yet little is known about the availability of plants and plant use from the early Holocene through to the end of the Middle Holocene, and the impact of human populations on these fragile natural environments. Research at the Ikh Nart Nature Reserve, Dornogobi Province, Mongolia, has yielded geoarchaeological and archaeological phytolith data which shows changing landscape and vegetation patterns associated with extensive use of small spring-fed drainages. Human land use shifted from foragers who exploited wetland plants to hunter-pastoral communities, whose use of wild plant resources changed with increasing desertification.

**[230] Trade and Sacrifice: Osteometry, Skeletal Part Representation, and Paleopathology of Camelid Assemblages in the Central Andes**  
Chavín de Húantar is a complex ritual site widely recognized for its connections to other regional centers. While much of this regional interaction is understood based on common ceramic styles and designs as well as the presence of nonlocal material, much less is known of the actual mode of transportation. Llama caravans most certainly played a key role in the movement of goods across space during Chavín times. Were llamas for caravans...
raised in the proximities of Chavín? Were caravan llamas a prestigious item? Were caravan llamas consumed in different ways than other llamas or other camelid species? In this poster, I use osteometric analysis, paleopathology analysis, and skeletal part representation analysis to explore these issues. Preliminary analysis at Chavín indicates the presence, in some sectors of the site, of some unusually large sacrificed llamas with pathologies consistent with those of burden animals. In contrast, other sectors of the site include the presence of regular size llamas and alpacas with no pathologies in daily food residue contexts. The results have implications for better understanding economic and social aspects of ancient human behavior at this important site.

Rosenswig, Robert (University at Albany) [182] Formative-Period Izapa Kingdom and Its Neighbors

Mesoamerica is one of the cradles of civilization where the first kingdoms and states emerged during the latter part of the first millennium BCE. Recent lidar mapping and pedestrian survey documents the extent and internal political structure of the Izapa kingdom from its emergence at 700 BCE through its collapse after 100 BCE. At its peak, a four-tiered political hierarchy maintained internal cohesion and the distribution of large centers around the kingdom’s perimeter established external sovereignty. The largest of a network of early kingdoms on the Pacific coast of southern Mesoamerica, the Izapa polity provides insight to the origins of urban life and hierarchical political relations.

Rosenthal, David (Smithsonian Institution, National Museum of Natural History) and Kerry Button (Smithsonian Institution, National Museum of Natura) [2] Disaster Struck: Smithsonian Museum Support Center Earthquake Response and Recovery

On August 23, 2011, an earthquake centered in Louisa County, Virginia, affected the nation’s capital in Washington, D.C. Measured at a magnitude of 5.8, this was the strongest quake in the area since 1944, reaching as many as 12 states and felt as far away as Canada. The quake caused damage to a number of national landmarks including the Washington Monument, the National Cathedral, and several Smithsonian buildings. The Smithsonian Institution’s Museum Support Center (MSC) in Suitland, MD, home to over 43% of the Smithsonian’s 155 million objects and specimens, was severely impacted. This presentation will discuss the immediate response period at the MSC, longer term recovery efforts, and lessons learned to help mitigate future impacts, with particular attention paid to the collections housed and cared for by the Department of Anthropology.

Ross, June (University of New England) [210] Narrative or Analysis: Identifying Scenes in the Rock Art of the Kimberley and Central Desert, Australia

Analysis of the composition of figurative motifs within rock art panels holds the potential to provide information on the relationships intended by the artist(s) between humans, between humans and animals, or between animals depicted. Two contrasting rock art assemblages from Australia illustrate this potential; the paintings from the remote Kimberley in the tropical northwest, and the diverse geometric assemblage from the arid heart of central Australia. Ethnographic data provides explanations for the most recent painted scenes in both areas, with each assemblage depicting the activities of Ancestral Beings in the creation period, known as the Tjukurrpa in the desert or the Laili in the Kimberley. However, it is the formal analysis of earlier assemblages that enables us to identify scenes and formulate relationships between the motifs depicted. Social, ceremonial, economic and gender roles can be identified in panels depicting the elegant, Kimberley anthropomorphic figures known as Gwions. Relationships between the geometric motifs within panels in the desert present a greater challenge but analysis indicates that these are likely to have been created as an active part of ritual practices.

Rossen, Jack (University of Hawai‘i at Hilo), Mahealani Pai (Kamehameha Schools) and Keonelehua Kalawe (Kamehameha Schools) [43] The Social Organization and Engineering of Agriculture at Maluaka in the South Kona Field System, Hawai‘i Island

Two field seasons of excavation have been completed at Maluaka above Keauhou on Hawai‘i Island. The project is a collaboration between Kamehameha Schools, which administers the site as an educational facility, and the University of Hawai‘i at Hilo. We wish to describe the collaboration between academics, Hawaiians and the lineal descendant community interested in cultural practice and revitalization, as well as the integration of Hawaiian knowledge and archaeological science. The site has been plane table and alidade mapped over several years. The 2016 work focused on platform and mound areas located at high promontories of the site. Excavations revealed fire pits excavated into pahoehoe lava and underground ventilated drainage canals. These activity areas, including high artifact density middens as deep as 1 m, may have been supervisor stations (konohiki) stations for directing work crews and observing the landscape and its alignments. Presented are preliminary observations on the social organization, artifacts and engineering of the site plus some directions for future research.

Rossi, Franco (Boston University) [39] The Obsidian Order at Copan: A Discussion of Science, Education, and Institutions in Late Classic Statecraft

This paper investigates an order of ranked specialists marked by title Taaj (“obsidian”), as they occur at Late Classic Copan. This “obsidian order” was first identified on a mural at the site of Xultun, Guatemala, where archaeological evidence revealed that its members held expertise in indigenous Maya sciences, ritual practice and codex book production. Since then, the Taaj have been identified at several Classic Maya centers besides Xultun—with the texts of Copan providing the most detailed account of one Taaj in particular who lived during the reign of the sixteenth Copan king, Yax Pasaj Chan Yopaat; as well as mentioning another Taaj alongside the earlier, ill-fated ruler “18 Rabbit” (Waxaklajun Ubaah K’awil). This paper constitutes a focused inquiry into the relationship between these Taaj, their rulers, and the courts of which they were a part, presenting associated archaeological evidence and considering related epigraphic data in the process. Through such analyses of the Taaj at Copan, I hope to shed light on a previously unknown aspect of Maya courtly life and pedagogy that is relevant to our models of sovereignty, ritual performance and knowledge transmission in the Classic Maya world.

Rossi, Francesca (McGill University)

[25] Not Sourcing: Prospecting for Khitan/Liao Ceramic Production Locales through the Geochemical and Mineralogical Characterization of Khitan/Liao Ceramic Assemblages

Often the use of geochemical and mineralogical techniques to characterize archaeological ceramics is performed with the underlying idea that the goal of the enterprise will be the sourcing of the ceramics to their production locales. However, in many situations this goal may not be achievable due to such factors as a lack of variability in regional geologies or a lack of information on the scale, type and location of ceramic production. This paper looks at one such case from the Chifeng Region, Inner Mongolia, where the sourcing of Khitan/Liao (907–1125 CE) earthenware ceramic assemblages is not possible due to a lack of basic information on ceramic production. Instead ceramic mineralogical and geochemical data, attained by portable X-ray fluorescence spectrometry and optical petrography, is used to narrow down the possible locations of Khitan/Liao ceramic production sites. This approach reverses the goal of characterization away from assigning a ceramic to a production locale and instead uses mineralogical and geochemical data to prospect for possible production locales as well as to provide some comment on the variety and scale of ceramic production within the Chifeng region.

Rotem, Yael (Penn Museum, University of Pennsylvania)

The EBA Southern Levant experienced a dramatic pathway to complexity, creating a small-scale urban society. The transition from EBI to EBII periods was characterized by urbanization processes, in which sweeping changes in social structure, political landscape, and economic networks occurred. While the majority of research centered on the nature of the fully urban society in the region, there is no consensus for the specific mechanics and causes of the emergence of these early towns, and the reasons for the demise of the complex village society that preceded them. None of the existing explanatory models capture the regional variabilility and cultural diversity that differentiated this period in the southern Levant, nor were they able to identify the different paths that led to the development of urban system in this region, within the existing chronological framework. The study presented here seeks to tackle this gap, and focus on the critical period leading up to life in these urban centers in a specific geographic region: the Central Jordan Valley. I will argue that in absence of leveling mechanisms to maintain egalitarianism, EBI village society slowly transformed into a large, densely settled and non-egalitarian village system, setting the stage for urbanism in the EBII.

Roth, Barbara (UNLV)

Changes in household organization were a major catalyst for social change in the Mimbres River Valley of southwestern New Mexico across the transition from pithouses to pueblos. This paper summarizes recent work at a large Pithouse period village, the Harris Site, and the Elk Ridge site, a large Classic period (AD 1000–1150) pueblo that is illuminating the relationship between households, community integration, and social change. Work at the Harris Site has documented the important role that corporate kin groups played in intra- and inter-village social dynamics. These social groups made up the “core households” (defined by Shafer 2003) that were the initial land-holding occupants of many of the larger Classic period pueblos. Data from Elk Ridge is further illustrating the different trajectories that households took as pueblos expanded during the Classic period. I explore the reasons for the fundamental changes in household organization that occurred during the Pithouse period, the implications that these have for understanding the initial development of pueblos, and the reasons for the variability in households that are seen at different Classic period pueblos across the Mimbres region and through time.

[139] The Politics of Death: An Anthropological Excavation of Political Ascension through the Strategic Manipulation of Postmortem Bodies as Objects to be Used, Misused, and Abused—and the Historic Ghost We’ve Inherited, Materially and Immaterially

Three kinds of postmortem manipulations occur for three distinct reasons. They are connected by the need for authoritative power and the desire to be seen as strong. Selfish notions of self-preservation are manifested through governmental bodies in the name of freedom and evolution. The three kinds of postmortem configuration can be categorized like this: A) political ascension; B) national or geographic control and domination; C) reactive exclamations, usually performed by the powerless and the oppressed. I will excavate the historic realities of similar political occurrences and their strategic engineering of death and the bodies of the dead. The examples are 1) the death of Caesar, AD 44; 2) the deaths of Zulfikar Ali Bhutto, 1979, and Shanawaz Bhutto, 1985; 3) the deaths of Che Guevara, 1967; Maurice Bishop, 1983; Bin Laden, 2011; 4) the deaths of 9/11 victims at ground zero, 2001; and 5) the deaths of military service officers: Black Hawk Down, 1993, and Iranian hostage crisis, 1980, and the Russian pilots in Syria, 2015. Focus will be placed on the deaths themselves, the manipulated funeral arrangements by the State apparatus, the demagogic eulogies, and the political aftermath—the postmortem body is a symbol to be used, misused, and abused.

Prehistoric Mining in the High Mountains of Northern Colorado

Rupturing and buckling of fissures along the present valley of the Colorado River in Middle Park, Colorado, during the Miocene resulted in thick deposits of tuff and flow basalt which resulted in the Troublesome Formation. The Troublesome Formation primary consists of weakly consolidated siltstone, minor interbedded sandstone and conglomerate, and locally unconsolidated sand and gravels, and chaledonies. As the result of the chaledony filtering through the tuffaceous linear deposits of jasper immediately beneath the tuff were formed. The Granby Site (5GA151) is a prehistoric mining site, whose knowledge of the area has been passed down for at least 11,000 years, from Goshen to Ute. The location of the mining site on the toe of a basalt flow that has been tilted by tectonic forces brought three deposits of jasper to the surface enabling the material to be mined. A recent project on the Granby Site enabled the site to be studied and to identify numerous purposely shaped “tabs” of jasper. These tabs enabled easy transport of the mined material away from this high altitude mine. The jasper material was traded up and down the Colorado River valley and became a major source of toolstone for over a millennia.

“Rerighting” History—c̓əsnaʔəm: The City before the City

c̓əsnaʔəm is an ancient Musqueam village and cemetery located in what has become contemporary Vancouver. Over the past 125 years, archaeologists, collectors, and treasure hunters have mined c̓əsnaʔəm for artifacts and ancestral remains for their collections. The land has also been given various names since colonialism, including Great Fraser Midden, Eburne Midden, DhRs-1, and Marpole Midden. Today, intersecting railway lines, roads, and bridges to Vancouver Airport obscure the heart of Musqueam’s traditional territory, yet c̓əsnaʔəm’s importance to the Musqueam community remains undiminished. In 2012 c̓əsnaʔəm became the subject of public controversy and debate when burials were exposed during construction. This led to a 200+ day community vigil at the site and eventual purchase of the property by Musqueam. Intense public debates took place about the rights of private property holders versus the rights of Indigenous communities and the very nature of public space. Who defines heritage? Who decides what is preserved? Whose heritage is celebrated? c̓əsnaʔəm: the city before the city is a series of three museum exhibitions pointing to the city and histories of development with a new lens. In this talk we discuss the role of community voice and public archaeology in this exhibitions.

Rowseff, Keri and Matthew Collins (University of York)

Simple Nondestructive Extraction of Biomolecules from Human Skeletal Remains

Opportunities for the nondestructive study of archaeological human skeletal remains (HSR) can often be limited by museum regulations that only permit nondestructive analyses. This restriction, coupled with the fairly common practice in England of quick reburial (due mainly to a lack of storage space), can result in a wealth of information being lost. It is therefore important that bioarchaeologists work to establish successful nondestructive methods for the biomolecular analysis of archaeological remains. This paper reports the development of a nondestructive technique for the extraction of collagen from HSR, which has been tested against traditional collagen extraction techniques, in order to establish its relative effectiveness. This technique has subsequently been applied to over 200 post-medieval samples from London, England, where access for sampling and destructive analysis would otherwise have been refused. The eventual aim is to use the collagen extracted from these individuals to study human health and dietary deficiencies in England during the late eighteenth century.

Ancient DNA Analysis of Fish Remains from Charlie Lake Cave (HbRF-39), British Columbia, Canada

Excavations of Charlie Lake Cave (HbRF-39) in northeastern British Columbia, Canada, have recovered well-preserved faunal remains from stratified deposits that span the Late Pleistocene and Holocene. These remains represent a variety of taxa, including amphibians, birds, fish, mammals, and reptiles. A previous morphological analysis of the fish remains from the site (n = 1,235) identified the majority of the fish remains as sucker (Catostomus sp.) (n = 669). Due to bone fragmentation and other challenges associated with morphology-based species identification, only a small number (n = 20) of the remains were identified to the species-level. To facilitate the identification of more of these fish remains to the species-level, we used ancient DNA analysis to assign species-level identification to a sample of fish remains from Charlie Lake Cave. These data will aid in investigating temporal changes in the species composition of the assemblage of fish remains from the site. In addition, we sought to use ancient DNA analysis to document temporal changes in the population structure of the fish species represented at the site. By documenting these kinds of temporal changes, this research can shed light on the dynamics of the complex relationships between fish, people, and the environment over the longue durée.

Rozwadowski, Andrzej (Institute of Eastern Studies, Adam Mickiewicz University)

Embodied in Contemporaneity: Negotiating Identity through Rock Art in Contemporary Siberia and Central Asia

Along with the collapse of the Soviet Union, Indigenous people in Siberia and Central Asia began to pay more attention to their past, which since then has been vigorously explored as a source of cultural identity. Particularly interesting aspect of this process concern contemporary use of prehistoric rock art. In the presentation I will refer to different contexts of such uses, which imply negotiating of the identity. Basing on the examples, I will show that rock art in Siberia and Central Asia is a real part of contemporary culture, that it actively influences everyday life and is used politically, socially and artistically. I will pay a particular attention to contemporary art, a very new phenomenon, where artists consciously adapt rock art imagery to manifest their link with ancestral past. All of the issues explored in the paper will demonstrate that prehistoric rock art in Central Asia and Siberia is embodied in contemporaneity.

[90] Do Good Fences Make Good Neighbors? Pilot Osterøy Field Project (PILOST) and Redefining Boundaries in Southwestern Norway

PILOST is an archaeological survey of southwestern parts of the Island of Osterøy, Norway, focusing on the changes in landscape enclosure (ideologies?) practices as well as settlement and burial patterns from the Neolithic through the Historic Periods in southwestern Norway. This project examines a unique form of human landscape manipulation through time, taking different forms than those observed elsewhere in Scandinavia. The first field season of PILOST (summer 2016) initiated extensive field survey, with subsequent seasons in planning stages for summer 2017 and beyond. GPS units were utilized to both track survey progress and create GIS maps of the surveyed areas. This continuing project further informs wider archaeological understandings and discussions regarding not only land use and ownership through time, but the interpretation of and attachment of fishing-farming communities to the archaeological landscape. The dataset includes over 145 distinct landscape features, consisting primarily of walls, fences, and other boundary markers. These features were identified based on their potential utility to document and inform a discussion of the evolving nature of boundaries, in/outfield usage, and land ownership within fishing-farming communities throughout prehistory, and the modern era.

[165] Symbolic Behavior at the End of the Paleolithic: A View from Cantabrian Region Rock Art

In the field of graphic activity, the recent Magdalenian (14,500–11,500 BP) is characterized by a homogenizing process along a vast territory in southwestern Europe. It also represents the most splendid rock art period and, at its end, figurative graphic activity suddenly disappears from Europe for millennia. A representative assemblage of recent Cantabrian Magdalenian rock art sites has been studied. The results of this research led to the discovery of several unpublished figures and reinterpretations of an even larger number of graphic units. Most importantly, they form a body of data large enough to produce statistically significant information. This can be used to define guidelines about the symbolic behavior of the populations that inhabited the Cantabrian region during that period. This communication summarizes the main results and presents a brief discussion about the implications of these data in the social and cultural context of Late Pleistocene populations in southwestern Europe. The conclusions reveal the existence of rich graphic activity that reflects complex societies with large exchange and social networks, including cultural elements within a common realm of ideas that covered many hundreds and even thousands of kilometers at the end of the Pleistocene.

[82] Diet and Migration in Coastal Oaxaca: Identifying Effects of Political and Social Collapse through the Utilization of Stable Isotope Analysis

This study reports on diet and mobility among people living in the lower Rio Verde Valley, Oaxaca, Mexico, during the Late Classic (AD 500–800) and Early Postclassic (AD 800–1200) periods, specifically focusing on how political and social collapse affected subsistence practices, diet, and human migration. Archaeological evidence suggests that Rio Viejo, the region’s largest urban center before AD 800, experienced multiple periods of political fragmentation and instability during its long history, specifically during the Early Classic (AD 250–500) and Early Postclassic periods, making it an ideal place to test these relationships. Stable carbon, nitrogen, and oxygen isotopic analyses of human bone and tooth samples were used to reconstruct diet and migration history. Samples were extracted from the skeletal remains of twelve Late Classic and eleven Early Postclassic individuals. Stable carbon and nitrogen isotopes provided insight into maize consumption. In addition, nitrogen values indicated the exploitation of aquatic resources. Stable oxygen isotopes determined whether individuals were locals, travelers, or foreigners. Results demonstrate collapse following the Classic period led to a dietary shift that included a wider variety of resources, specifically aquatic. Human mobility also increased during this time and suggest movement within the valley and along the coast.

Runnels, Curtis (Boston University)
[180] Pleistocene Occupation of the Greek Islands: The Perspective from Crete

Pleistolithic stone tools have been identified on a number of Greek islands recently. These include the oceanic island of Crete, where lithic artifacts on the southern coast at Plakias occur in association with raised marine beaches and paleosols in karstic depressions dated to > 130 ky, and on the northern coast at Mochlos Bay associated with as-yet undated Pleistocene alluvial fans. Other islands, including Aiyios Efstratios, Alonissos, Gavdos, Kephalonia, Lesvos, Melos, and Naxos, have also produced documented Paleolithic materials, although excavations have taken place only on Lesvos at the site of Rodafnida (Lower and possibly Middle Paleolithic) and Stelida on Naxos (possibly Lower and Middle to Upper Paleolithic). Although Lesvos was inhabited the Cantabrian region during that period. This communication summarizes the main results and presents a brief discussion about the implications of these data in the social and cultural context of Late Pleistocene populations in southwestern Europe. The conclusions reveal the existence of rich graphic activity that reflects complex societies with large exchange and social networks, including cultural elements within a common realm of ideas that covered many hundreds and even thousands of kilometers at the end of the Pleistocene.

Rusch, Bruce (NH SCRAP; University of Exeter)
[16] Settlement Organization of Paleoindian Caribou Hunters: Inferences from the Other Side of the Valley–The Potter Site, Randolph, New Hampshire

In the Northeast and especially New Hampshire, Paleoamerican small lithic sites or scatters represents one of the most common site types. Even though represented by small lithic scatters some of these sites also contain evidence of short-term habitation, food preparation and tool production activities. Twenty km to the east, opposite the Israel River Complex, is situated a site with an area of 2.5 acres, 11 excavation units (1 m × 1 m or greater), and
approximately 15,900 lithic artifacts, known as the Potter site (27-CO-60). This portrayal suggests similarities between the Potter, Whipple and Bull Brook regional sites manifest in terms of the significant number of “hotspots” or loci, rarity of its large size, earliest fluted point styles, low number of lithic material sources, rich artifact assemblages, site positioning overlooking a remnant of a glacial pond, and a chokepoint topography. As characterized by earlier researchers, was Potter a large single occupation marshaling or hunting aggregation; or alternatively, a seasonal social aggregation site type, or something altogether different?

A Queer Reframing of Gendered Archaeological Theory  
Archaeologists must move beyond outdated paradigms of biological sex as an objective and cross-culturally applicable category, even when presented distinctly from gender. These paradigms prevent recognition of gender’s full variation, and exclude those outside of Western gender ideology from participation in research. To move toward a more inclusive gender archaeology, I propose that culturally-specific definitions of gender replace these epistemologies to prioritize emic viewpoints. I critically analyze the strengths and shortcomings of theoretical perspectives on gender that previously attempted to decolonize ethnocentric sex and gender conceptions. To further develop these theories, I recommend identifying and distinguishing gender assigned culturally and gender assigned archaeologically, with the goals of respecting cultural and individual agency as well as being cross-culturally relevant. To achieve this, I propose two complementary modes of gender categorization. This ontological reconceptualization maintains a standard of classification and incorporates culturally specific models of gender when available. Multiple cross-cultural case studies, including reanalysis of the Vix grave, substantiate this method and show applicability in practical contexts. Decoupling gender assigned at birth and gender assigned after death creates a powerful tool which, in its implementation, serves to establish scientific thought as a culturally specific method itself.

Organic Analysis of Smoking Pipe Fragments and Residue Scrapings  
Chemical analysis of organic residues from archaeological artifacts is shedding new light on past human activities. Here we report on the residue analysis of smoking pipe fragments and residues scraped from pipe sherds. Our goals were twofold: 1) to ascertain whether nicotine was present in the residues, thereby providing a positive indication for tobacco use; and 2) to identify the presence of other biomarkers that would allow us to establish which other plants were smoked, furthering our understanding of the natural resources exploited for religious activities. Our samples included residue scrapings from Woodland and Mississippian period pipe sherds collected at the Glass Site (9TF145) in Telfair County, Georgia. We also analyzed pipe fragments from the Feltus Mound Site (22JE500) in Jefferson County, Mississippi, considered to be from the Late Woodland period. Our methods included methanol:chloroform solvent extractions using ultrasonication to isolate the organic compounds in the residues. Our analysis utilized both gas chromatography–mass spectrometry (GC-MS) and gas chromatography flame ionization detecting (GC-FID). The results demonstrate the presence of nicotine in many of these artifacts, along with other compounds that could signal the existence of a complex smoking tradition among indigenous populations of the southeastern United States.

[166]  
Globalization in the Bronze Age? In Search of a Metaphor of Connectivity in the Central Mediterranean  
The world in which native Sicilians and Sardinians exist in the second half of the second millennium BC is an increasingly connected one. As we move beyond static, binary, and often unidirectional frameworks for assessing social and material change (e.g., “acculturation”), beyond the entrenched categories of “Mycenaeans” or “Cypriotes” vs. “natives,” there is an opportunity to explore new analytical avenues to describe or explain the sociocultural shifts that occur on these two islands. In this presentation I will propose that certain aspects of modern globalization studies—recently applied to debates concerning Romanization, Hellenization, or Iron Age Orientalization—may also work as an acceptable metaphor for the cross-cultural consumption of goods and ideas that we encounter as the Bronze Age winds to a close. Even without the hyper-connectivity or an existing single cultural framework that later periods can claim, examining modern globalization “in action” can inform us about material changes and social reconstructions at the beginning of the Mediterranean connectivity story.

All the Gods of the World: Modern Maya Agricultural and Rain Ritual in Yucatán, Mexico  
The modern residents of Yucatán, Mexico blend traditional Maya beliefs in a pantheon of ancient gods and other supernatural forces with more recent Catholic traditions flowing from centuries of Spanish colonial influence. This paper compares and contrasts modern rituals from the Yucatec Maya village of Telchalquiquio, Yucatán. Each rite was associated with a local cenote, limestone sinkholes that along with caves serve as access to the Maya underworld and homes to the gods themselves. My research suggests considerable cultural continuity with the ancient residents of the Postclassic Maya center of Mayapán where cenotes were regularly paired with important ritual architecture and sometimes contain human remains and other indications of participation in research. To move toward a more inclusive gender archaeology, I propose that culturally-specific definitions of gender replace these paradigms prevent recognition of gender’s full variation, and exclude those outside of Western gender ideology from participating in research. To move toward a more inclusive gender archaeology, I propose that culturally-specific definitions of gender replace these epistemologies to prioritize emic viewpoints. I critically analyze the strengths and shortcomings of theoretical perspectives on gender that previously attempted to decolonize ethnocentric sex and gender conceptions. To further develop these theories, I recommend identifying and distinguishing gender assigned culturally and gender assigned archaeologically, with the goals of respecting cultural and individual agency as well as being cross-culturally relevant. To achieve this, I propose two complementary modes of gender categorization. This ontological reconceptualization maintains a standard of classification and incorporates culturally specific models of gender when available. Multiple cross-cultural case studies, including reanalysis of the Vix grave, substantiate this method and show applicability in practical contexts. Decoupling gender assigned at birth and gender assigned after death creates a powerful tool which, in its implementation, serves to establish scientific thought as a culturally specific method itself.

Russell, Glenn (County of Santa Barbara) and Christopher Attarian (Baker College of Owosso)  
[382]  
Between 1989 and 2000, the Chicama Valley Archaeological Project, led by Glenn S. Russell, Banks Leonard, and Christopher Attarian, conducted archaeological survey and excavations in the lower Chicama Valley. This presentation will focus on a broad summary of settlement pattern change with reference to key excavation data that informs interpretation of the survey data. A focus will be how sociopolitical complexity developed in the context of control of irrigation systems. Approximately 25% of the lower valley was surveyed, resulting in the recording of over 200 archaeological sites and features. Key settlement pattern changes discussed include the emergence of defensive settlement in the Late Intermediate Period, the shift to the site of Mocollope as a primary valley floor monumental site by Gallinazo through Moche occupation, and the emergence of a major polity in the lower valley during the pre-Chimu period as evidenced by a cluster of several of the largest Huacas constructed in the valley.

[95]  
Wild Meets Domestic at Neolithic Çatalhöyük, Turkey  
One of the classic ways the nature/culture dichotomy manifests itself in human interactions with the environment is through the categories of wild and domestic. Some have argued that this distinction is not helpful, and certainly the boundaries are complicated, but it seems most useful to start by asking whether it was meaningful to particular people in the past. Here I will explore whether wild and domestic were relevant concepts to the inhabitants of Çatalhöyük (Central Anatolia), and to some extent in the Neolithic Near East more generally, in their relations with animals. I will argue that this was in

The Presence and Potential Representation of Turquoise at the Mimbres Site of Galaz

Turquoise, both the mineral and the color, are inexorably linked to contemporary ideas of the indigenous Southwest. Without doubt, the importance of turquoise extends back into prehispanic times, although we know relatively little about its cultural significance. The mineral turquoise may also have been represented in a more abstract way; J. J. Brody and Stephen Plog have suggested that Chacoan contemporaries of the Mimbres tradition may have used hachured elements on pottery to represent the color turquoise. In this paper, we examine the distribution of both hachured pottery and actual turquoise from nearly 1,000 Mimbres burial assemblages to understand whether this conceptual association extended to Mimbres ceramics. We also analyze the distribution of turquoise artifacts and hachured pottery from mortuary assemblages to determine whether they were preferentially associated with a particular social group or class. Our findings, which intersect with Puebloan ethnographic data, contribute to the study of Mimbres inequality, identity, and exchange, as well as the situation of Mimbres society within a larger social landscape.

Rust, William (Athena Review) [76]

Evidence for Complex Society at Middle Preclassic La Venta Settlements

In the past, abundant ceremonial evidence found at La Venta and other Gulf Coast Olmec sites has spawned widely ranging views on the emergence of complex society in Mesoamerica. Evidence of dense local riverine settlement was gained from my survey at La Venta and surrounding sites in 1986–1987, revealing household sites both on La Venta and surrounding villages on abandoned river courses. The chronological sequence has been guided by over 50 radiocarbon dates recovered from a series of domestic features which range from ca. 3050–350 cal BC. Findings of house floors, refuse pits, caches, and workshops as well as burials and offerings revealed specific distributions of pottery, figurines, and both ceremonial and utilitarian lichis. Several basic trends in long-term settlement evidence show an in situ emergence of complex society around La Venta. By the Late La Venta 2 subphase (ca. 650–350 cal BC), a local three-tier settlement hierarchy had evolved, with some riverine sites with small central mounds, fine paste pottery, figurines, and jade. Other village sites, however, lacked central mounds, had few figurines, and little fine paste pottery or carved jade. During the same time frame, when local riverine settlement peaked, maize use at all sites was accelerated.

Rutecki, Dawn (Grand Valley State University) [197]

Entangled Complexity: Spiro, Religion, and Food

Understanding past peoples—those living in different places, spaces and times—requires archaeologists to reorient how we see and experience the world. We have the ability to move beyond recording the physical traces of past lives to get to the central goal of our discipline—understanding how people lived, participated in and tied themselves to communities, and connected to larger systems. Instead of forming stagnant images of the past, we need to remember the dynamism of choices made and changed in an individual’s and a community’s continual process of becoming. Through analysis of subsistence data, evidence of religious practices, and ethnohistoric accounts, this paper discusses the lives of people in the Spiro community, Oklahoma, circa AD 1000–1450. It explores the relationships between food and religion to situate how North American archaeological theoretical frameworks can renegotiate their place in the past. I argue that through applying a critical lens, we can usefully expand how we conceptualize social complexity and develop a more nuanced understanding of how these entangled social relationships remain fluid, living connections.

Ruuaska, Alex (Northern Michigan University) [175]

Memory and Materiality in Rock Art and Ghost Dance Performances

In this paper, I examine the materiality of memory practices as expressed in rock art associated with the Ghost Dance in the Great Basin, Colorado Plateau, and Eastern California. Building on Jeff Malpas’s (2010) claim that “place is perhaps the key term for interdisciplinary research in the arts, humanities, and social sciences in the 21st C.” (Creswell 2015:1), and Susan Kuchler’s perspective of “landscape as memory” in which embodied experiences “govern the mnemonic transmission of land-based relationships” (Bender 1995:86), my paper explores embodied ontological, epistemological, and discursive relationships between and among people, places, and the land.

Archaeobotanical Chenopodium Seeds from across Central Asia

Plants in the Chenopodium genus have attracted human interest around the globe for millennia; they have been used for grain and vegetable food as well as being a key forage plant for herd animals. Historically, several wild species have been economically significant across Eurasia, notably in Central Asia, and the genus has been domesticated in various parts of the world, including East Asia. Wild Chenopodium seeds are the dominant category of archaeobotanical remains found in the vast majority of archaeological sites across Central Asia. Scholars working in Central Asia continue to discuss the possible economic significance of these remains and what use they are for understanding paleoecology and anthropogenic landscape change as well as human and herb animal diet. In this talk we will present a summary of this Chenopodium data and discuss the ongoing debates in Central Asia.

Ryan, Ethan, Pei-Lin Yu (Boise State University) and Matthew Schmader (City of Albuquerque) [50]

Household Hearth-Centered Activity Areas and Cache Pit Patterning at the Bridge River Site
Archaeological investigations at Housepit 54 within the Bridge River site have, to date, exposed seventeen discreet floors primarily dating to ca. 1500–1000 cal. BP. In this poster we draw data from three of the site’s floors, Ilk, III, and Illm, where the most recent investigations have yielded an interesting pattern of hearth and cache pit features. Questions will be addressed specifically toward formation processes as well as the potential relationships between the patterning of hearth-centered activity areas and nearby cache pits by examining variability in artifacts, faunal remains, and other features. Using the same methodological and theoretical approach for each floor, we examine feature form and function, lithic tool production and maintenance, animal and plant processing, taphonomic processes, and potentially, ritualistic practices to reconstruct the means by which the items in each activity area came to be co-associated. From these studies, we draw conclusions regarding the roles of these spaces on the house floor. We then seek to address potential relationships between activity areas by application of re-fitting analysis and examination of inter-assemblage variability. Results of this research permit us to develop a range of implications regarding household occupational history and sociality.

Ryan, Susan (Crow Canyon Archaeological Center)

Architectural Communities of Practice: Identifying Kiva Production Groups in the Northern Southwest

Researchers in a number of fields have recognized the vital importance of the built environment not only as material culture, but as symbolic expressions of the larger cultural framework through which social relations are produced and reproduced. Over the last half-century, studies have demonstrated how architectural characteristics—such as building size, shape, and the presence of various architectural materials, features, and furnishings—have a demonstrated influence on human behavior and interaction and are material manifestations of worldview ideologies. One of the most important functions of the various elements within a structure is the encoded messages that convey group identity and provide clues into ancient social organization. This paper will analyze ancestral Pueblo vernacular architecture from the Pueblo II (AD 900–1150) and Pueblo III (AD 1150–1300) periods in the northern Southwest in order to shed light on communities of practice and their social, temporal, and spatial production techniques. This research examines public and residential kivas—or round rooms used for communal and domestic activities, respectively—to address how architecture emphasized the ways in which structures were actively mediated by production groups, and how their architectural signatures reflect identity during periods of population aggregation and dispersal.

Ryan, Thomas (City University of New York Graduate Center)

Using Multidimensional Analysis for the Presentation of Zooarchaeological Data

Management and dissemination of data has long been a challenge for archaeologists, and this challenge has increased in recent years with demands from various funding agencies for data management plans. Additionally, querying the complex datasets generated often results in iterative rounds of SQL code creation as each answer raises further questions. Online analytical processing (OLAP), a tool for multidimensional analysis used by many private companies for reporting, management, and forecasting, as well as by government agencies, such as the Department of Labor, to track the effectiveness of their programs, provides a possible solution to the difficulties in data management and querying in archaeology. Defining data in terms of dimensions and measures, OLAP allows rapid and complex querying without a developer anticipating the specific questions a researcher may ask. I will demonstrate the effectiveness of this tool for analyzing data using zooarchaeological data from the North Atlantic region. Using OLAP to present such data also can serve as an aid in outreach efforts to policy makers and researchers in related fields. The ability to integrate disparate datasets and create complex queries in an ad hoc fashion will also be shown.

Late Shang Cooking and Cooking Technology from Yinxu, China

A great deal of effort has been dedicated to developing detailed ceramic chronologies at the late Shang capital of Yinxu (ca. 1200–1045 BCE) in China, but there has been comparatively less focus on the specific, actual uses of ceramic vessels and the roles that they played in the day-to-day life of Shang citizens. Local cooking practices and cooking technology in particular, both of which are key aspects in household dynamics and cultural identity, hold the potential to reveal important information about the daily lives of Shang residents as well as regional variability during the Shang period. This paper explores Shang cooking technology by conducting microstructural comparisons of li cooking vessels from three different Shang sites, highlighting the impact of local resources on ceramic technology despite stylistic similarities. This paper also discusses cooking-related finds excavated in May 2016 from a refuse pit at Dasikongcun, a residential locus of Yinxu, and presents use-wear analyses for li cooking vessels found at the site that may indicate particular cooking practices. This paper highlights the need for further investigation of cooking vessels at differing Shang sites as a method of exploring both daily life and regional variability during this period.

Sadongei, Alyce

Engaging Tribal Relations and Tribal Collections

The use of museum collections by tribal researchers began as a result of cultural and political efforts. The combined movement of cultural resurgence and political expression culminated in the passage of NAGPRA which provided entrance for a variety of tribal researchers and practitioners to engage with cultural objects and archival information. Since the passage of NAGPRA, tribal researchers have primarily been focused on the eligible categories of museum collections for repatriation. However, museum collections have increasingly been used to re-enforce cultural identity by validating tribal memory of emergence, replication of cultural items and revitalizing Native languages. Thus museum collections as a source of cultural information have gained in importance for tribal communities. Access and use of museum collections by tribal researchers requires navigation and negotiation of western museum standards for collections management. This presentation will discuss how tribal researchers are using museum collections to further community goals of cultural maintenance and survival while offering a glimpse of how tribal nations respond to standard museum collections care. By understanding the subtle complexities that tribal researchers face when engaging with museum collections non-tribal museum curators and other professionals will increase their ability to facilitate mutually beneficial collection based research visits.
Særheim, Inge
[282] Words for Domestic Animals Used as Metaphors in Coastal Naming
Place-names are important sources to understand and reimagine past conceptions of the landscape. Toponyms map animal lives on to the landscape. In some cases, however, words for animals—wild as well as domestic—are used as metaphors. In some names denoting sunken rocks along the Norwegian coast, e.g., Sugga (‘sow’), Oksa (‘bull’), Hesten (‘horse’), Porthunden (‘watchdog’), the words either refer to the shape or sound of the locations, or to some special circumstances, e.g., dangerous rocks in the sailing route. The names serve as warning to boatsmen. Words for animals were earlier taboos among Norwegian fishermen (who were also farmers). At sea they would instead use other words and names (noa) for the animals and the locations. Special behavior was linked to some locations, e.g., to sting a pig or roar like a bull. The grammatical form indicates that some names date back to medieval times. Similar names of Old Norse origin are found in Viking settlements in the North Atlantic area. This paper discusses how words for domestic animals are used as metaphors in coastal naming, and how this type of naming reveals special traditions and conceptions among fishermen and sailors.

Safi, Kristin (University of Tennessee Knoxville)
[59] A Costly Signaling Model for Chacoan Great House Construction
Peer polity interaction has been suggested as a primary driver of interaction among communities with Chaco-style great houses. Unfortunately, the peer polity model lacks underlying theory and therefore using it to empirically examine the relationships between great house groups is difficult. We propose instead that costly signaling theory is a better framework for evaluating the construction of these monumental structures, the ritual or group level activities associated with their use, and patterns of interaction among great house communities. This presentation details where the model fits well with existing great house community datasets and where we are lacking crucial data lines necessary to develop more robust empirical tests for costly signaling as applied to the Chacoan Southwest, and to archaeological phenomena more broadly.

Sagebiel, Kerry and Helen Haines (Trent University)
Maya archaeologists commonly discover “smash-and-trash” deposits, collections consisting of large quantities of broken sherds, lithics, faunal materials, and other remains, in varying contexts on Maya sites. Interpretations of these deposits vary from simple trash or midden deposits, to remains of feasting, to termination and other rituals. These interpretations are often strongly influenced by the theoretical and analytical approaches taken by the excavators. At Ka’Kabish, Belize, a series of problematical “smash-and-trash” deposits, consisting primarily of sherds and reconstructible vessels, were encountered in Plaza D South. This paper will explore how the application of different analytical and theoretical approaches to these deposits can influence how they are interpreted, and attempt to provide insights into which approaches are most reasonable for analyzing and explaining these kinds of deposits.

Sailors, Damion
[380] Mapping Island “Moka”: Assessing the Spatial Patterns of Customary Fishing Weirs in the Fiji Island Group
Customary Fijian fishing weirs, known locally as “moka,” are an archaeological feature type that can be readily identified due to their large size, uniform shape, and conspicuous location on the tidal flats and shorelines of both high and low islands. Recent advances in remote sensing technology have allowed for an improved survey of Fijian fishing weirs adding to the existing inventory and informing upon early settlement patterns in the Fiji Island group. While “moka” do not play a major part in the local economy today, they likely served a significant role in early Fijian subsistence and knowledge of this customary practice is valuable to current socioenvironmental studies. This paper will discuss the preliminary results of an archaeological investigation that utilized satellite imagery and kite aerial photography, along with pedestrian survey, to map 683 customary fishing weirs on 79 Fijian islands. The spatial configurations and physical characteristics of these fishing weirs have been documented and are being explored statistically at the regional and island scale as part of a doctoral thesis in order to better understand Pacific Island settlement patterns as they might apply to cultural adaptation, social complexity, and human evolution in an island-coastal setting.

Saintenoy, Thibaut (CIHDE-CONICYT [Chile], ARCHAM-CNRS [France]) and Mauricio Uribe
Located on the edge of the Atacama Desert at the foot of the Carangas Altiplano, the Belén Valley witnessed substantial construction of imperial infrastructures during the late prehispanic period. The Inca occupation was mainly related to agriculture, metallurgy and a sanctuary. The Belén Valley contains, in fact, the most important water resources in the upper basin of Azapa, copper and tin mines and an important mountain summit, which formed both economic and symbolic resources of special interest for the Empire’s political economy and religious purposes. In addition to explaining the characteristics of the Inca occupation at Belen based on the results of recent archaeological research, this presentation will develop a multi-scalar perspective to identify the specificities of the territorial situation of Belén, following a comparison with the Inca occupation of the surrounding areas: the Carangas Altiplano, the coastal valleys of Arica, and the Tacna sierra.

[211] Evolution of Feasting among Jomon Societies Based on Wooden Artifacts
Cross-culturally, wooden items such as bowls, ladles and spoons play an important role as ritual offerings to deities and ancestors. Thus, they are keys to understanding feasting and ritual activities, and can provide archaeological signatures of these activities. This paper explores evolution of feasting among Jomon societies focused on the analysis of wooden artifacts. The analysis is based on three sources of information: 1) temporal and spatial distribution; 2) stylistic analysis; and 3) archaeological contexts. For the analysis, a database was created, based upon such attributes as archaeological context, wooden vessel form, and presence/absence of decoration, which were obtained from published sources. This database provides invaluable information to assess the number, type, and context of wooden artifacts throughout the Japanese archipelago. Although the most of wooden artifacts represent secondary deposition, items found in housepits, burials, storage pits, and elsewhere suggest temporal and spatial variability of feasting among Jomon societies.

[155] The Reevaluating Diachronic Trends of Corrugated Ware and Rim Eversion of Jars in the Virgin Branch Ancestral Pueblo Ceramics Using Optically Stimulated Luminescence (OSL) Dating

Although the ceramic chronology in the Virgin Branch Ancestral Puebloan area requires more well-dated ceramic assemblage, there are some generally accepted diachronic trends based on surface treatment and form. Corrugated ware, for example, is believed to date around AD 1050. Rim eversion of jar is also often used as time indicator; sharply everted rim is considered to be associated to later time period, and little or no everted rim is associated to earlier time period. This information may be useful for assessing the general site chronology, especially at the first stage of the survey. However, many more well date ceramic assemblages without ambiguous assumption are necessary to confirm these diachronic trends. The use of radiocarbon dating, however, is not the ideal option in the Mt. Trumbull area, as many sites in this area were occupied by multiple generations and few radiocarbon dates have been generated. This is in the ambiguity of applying radiocarbon dating of organic remains to determine the age of associated ceramics. Thus, in this study, I apply optically stimulated luminescence (OSL) dating, which dates ceramics directly, to corrugated ware and rim sherds from Mt. Trumbull to reevaluate these proposed diachronic trends of the region’s ceramics.

Salazar, Julian (Universidad Nacional de Cordoba—CEH Segreti—CONICET)

Long term evolutionary narratives on South Andean precolombian history have stressed lineal processes of complexity intensification, defined by big changes on subsistence strategies, from small and egalitarian hunter-gatherer groups to complex multicommunitarian chiefdoms. These changes were thought to influence or even determine the structure of household and consequently daily life of people. Nevertheless recent household archaeology studies have demonstrated that the reproduction of quotidian practices within specific material settings were creative scenarios where the whole society was created, reproduced or challenged. In this contribution I present new researches on early village settlements from the eastern slopes of the South Andes addressing the material dynamics of houses and the constitution of collectives which allowed the formation of early villages. Rather than being determined by mandatory structural or subsistence forces, society was continually created and reproduced within the material mesh of daily life and household relationships. On the other hand, these performative creations were not multiple free willing actions but defined by the long history of other precedent material meshes. This dialectic dynamics shaped early villages at multiple scales.

Early Formative Public Architecture and Corporate Identity in the Mixteca Alta, Oaxaca

Public spaces appeared early in Mesoamerica, often linked to emerging communal identity and/or sociopolitical complexity. Their construction, and subsequent maintenance and renovations, reflect the collective effort of different social actors and corporate entities. In Mesoamerica, public space first appears during the Early Formative period (1500–900 BCE), a time of emerging sociopolitical complexity at sites such as San Lorenzo, San Jose Mogote, and Paso de la Amada. The arrangement and orientations between platforms and plazas or open space lay the foundations for later innovations in public and ceremonial space throughout this cultural region. In addition to the construction of space, the placement of different deposits and offerings, both contemporaneous with the public space as well as later to its use, reveal important dimensions in understanding both the development of larger ritual and religious concerns as well as the emergence of local elites. Recent excavations at the site of Etlatongo, in the Mixteca Alta of Oaxaca, have confirmed the presence of public space during the later portion of the Early Formative. We both compare and contrast what has been documented about this public space with contemporaneous examples across Mesoamerica, recognizing variations in layout, style, contextual and construction history of these spaces.

“What’s in that hole?” Engaging Subterranean Spaces in the Three Rivers Area of the Southern Maya Lowlands

The importance of subterranean space has been well established through studies of Maya sacred landscape. The Maya word “che’en” is used for any natural feature that penetrates the earth such as caves, cenotes, rockshelters, chultuns, sinkholes, springs, and crevices, all spaces where the sacred nature of animate Earth are expressed. In the Three Rivers area of the southern Maya lowlands, non-cave Maya archaeologists appear to be at a loss on how to engage landscapes where sacred landmarks take more subtle forms. This presentation will bring to light the variety of subterranean space in the Three Rivers area, and their importance in understanding the surface archaeology around them.

*Colonialism and Tupi Persistence on the South Shore of São Paulo State, Brazil*  
During the last few decades, many studies deconstructed the traditional colonial narratives about the Americas. They rethought the history with a less Eurocentric point of view, emphasizing the dynamic cultural values established among European, Indigenous peoples and Africans, contributing together to combine new and old social practices in colonial situations. This work aims an alternative narrative about Brazilian Indigenous peoples, which uses a Tupi settlement located in Peruíbe on the South shore of the State of São Paulo, Brazil as a background. These are ruins of a Franciscan settlement (seventeenth century) and several older/more recent vestiges (fifteenth–nineteenth centuries). They indicate the historical persistence of Tupi people along centuries, which contrasts with the narrative centered on the extinction of this group. Thus, archaeological evidences play an important role on the reinterpretation of the colonial history and also identifies short-term events within the habitus concept. This work uses ceramics and other evidence for the construction of a more inclusive history of Tupi people. The results have indicated indicating the permanence of these peoples since precolonial times up to the nineteenth century, wherein they negotiated cultural practices as creative players in a constant process of self-determination in a long term history.

**Material Technology as an Indicator of Past Species Size**  
Archaeological materials can provide data useful for modern conservation and resource management efforts. Zooarchaeological materials have been used to provide information about past species distributions as well as their characteristics. I am interested in using the material technology of prehistoric resource harvesting to provide information about species in the past. This poster will discuss my research using traditional halibut fishing technology to provide information about the fish being caught. Northwest Coast halibut hooks were crafted to target certain size fish. My research involves morphometric analysis of halibut hooks to determine the size of fish they were targeted to land. This data is needed because there is ambiguity in the archaeology of the region about the importance of halibut in past subsistence systems. Ethnographic material points to the importance of this species as a major food source for many different groups. However, archaeological research has not been able to provide evidence of this level of utilization. Furthermore, since the beginning of modern commercial fisheries, halibut size has been declining. Data about the characteristics of halibut prior to industrial fishing can be useful for species management efforts.

*Most beautiful favorite reindeer*: Life Histories of Reindeer Offered at Sámi Offering Sites in Northern Fennoscandia  
Animal offerings made at various sacred sites were an integral part of the ethnic religion of the Indigenous Sámi people of northern parts of present-day Norway, Sweden, Finland, and Russia from ca. AD 800 onward. The offering tradition was intertwined with subsistence patterns and human-animal relationships, as in the Sámi worldview, offerings were a means to communicate with gods and guardian spirits of animals to negotiate things such as success in hunting or reindeer husbandry. In this paper, I will focus on the life histories of the reindeer individuals selected for offering as they unfold by looking at age, sex, and size of the individuals, the stable isotope composition of their teeth and bones, and the offering site context where their bones were deposited. I will especially concentrate on two individuals offered at the Paddusas offering site in Northern Sweden in ca. AD 1170–1280 and AD 1445–1635, respectively. I will discuss how the lives of these reindeer were tangled with those of humans and other animals against a backdrop of changing social and economic environment, colonial contact between the Sámi and Scandinavian state powers, and reindeer domestication.

[238]  
*Assessing Prehistoric Herding Strategies through Stable Isotope Analysis: A Case Study from the Dry Puna of Argentina*  
The relationship between human groups and animal populations in the past can be studied through stable isotope analysis of zoarchaeological remains. More specifically, the isotopic analysis of domestic animals' tissues can help us to investigate herd composition, diet and mobility strategies employed by herders in the past. However, before these methods can be applied to resolve such questions, variation in isotopic composition and its causes must be addressed and explored by a modern reference dataset. For this purpose, we conducted a study of the variation in δ13C and δ15N values measured on bone collagen from modern herds of domesticated South American camelds (Lama glama) of the Dry Puna of Argentina. At the same time, we compared those results with the δ13C and δ15N values measured on bone collagen from domesticated South American camelds (Lama glama) recovered at different archaeological sites from the same area dated to the Late Holocene. Our results showed that the δ13C and δ15N values of
prehistoric herds displayed a similar pattern to those values measured on modern herds, indicating the complementary use of different altitudinal ranges by the herders that occupied the area during the Late Holocene as occurs in the present.

**Zooarchaeological Investigation of Late Pleistocene Subsistence Adaptations in Iran**

Economic decisions of Late Pleistocene foragers bore heavily on the nature, timing, and intensity of the adoption of agriculture in different parts of Eurasia. Decades of intensive research in the Levant and Anatolia have made significant contributions to our understanding of Late Pleistocene economic strategies in the western parts of the Near East. A recent surge of interest by Iranian researchers and internationally collaborative teams in Paleolithic archaeology of Iran has renewed attention on the more eastern parts of Near East. This has significant implications for Late Pleistocene research in other parts of the region, and warrants an in-depth examination of the current state of knowledge in Iran. Here, we synthesize the existing faunal record from Late Upper Paleolithic and Epipaleolithic deposits and sites from environmentally diverse habitats—Northern, Central, and Southern Zagros Mountains, Caspian littoral, and the Iranian Plateau. The faunal record is a sensitive indicator of the effect of climatic and ecological factors on subsistence adaptations. We combine our observations with other archaeological lines of evidence to provide a more holistic reconstruction of forager economic strategies during the pivotal time period between the Last Glacial Maximum and the beginning of the Neolithic period.

**Time, Place, and Community: Visualizing the Living Cherokee Landscape**

First Landscapes is a digital conservation project with two major goals: to protect and preserve First Nation/Native American heritage in culturally situated manner, and to make information accessible and usable in ways determined by stakeholders. This project organizes and presents results of several seasons of archaeological fieldwork as well as historical documents, maps, ethnographic records, and imagery by and about Cherokee people curated in several institutions across the United States. Recent and ongoing archaeological work at the historic Cherokee Towns of Cowee (31MA44) and Nvnvni (31SW3) included discovery of abundant evidence of architectural remains through remote sensing (ground-penetrating radar, magnetometry, resistivity) and excavations. 3D models present each kind of imagery as a flyover and fly-through experience. The First Landscapes web interface and mobile app give the ability to traverse the Cherokee landscape replete with Cherokee names, stories, images, and information through exhibits organized by territorial divisions that are historically documented and that Cherokees implement today. Within these exhibits are areas and locations that range from well preserved or well-known to nearly destroyed. QGIS, mbira, and other open-source programs offer opportunities for new ways of visualizing spatial data that benefit both archaeological professionals and the public.

**Examining the Religious Dynamics of the Columbian Exchange: Islands of Belief and Conversion**

The major moments of cultural exchange in global accounts of encounter have happened across the oceans and therefore island communities have often been first to experience contact and shape the nature of this encounter. This is certainly the case in the Caribbean where the island Taíno were the first to encounter Europeans in the New World. The archaeology of Mona Island provides insights into both the origins of indigenous Taíno identities and religious communities, and the processes of religious creolization in colonial worlds. Recent research has revealed a well preserved indigenous subterranean landscape on Mona Island in the Caribbean. Archaeological and speleological survey in over 60 of the islands 200+ caves, and an exploratory dating program of cave floor deposits, artifacts, and pigments, delineate a distinct horizon of late pre columbian and early colonial cave use spanning approximately 170 years, and continuing into the sixteenth century after the Spanish invasion. This paper will explore the role of subterranean archipelagic interactions and ensuing processes of co-conversion and which shaped religious life in the Americas.

**New Information on Marine Hunter-Gatherers of the Southernmost End of South America: Technological and Zooarchaeological Study of Site Bahía Mejillones 45, Chile**

In this poster we present the results of research at Bahía Mejillones 45, located at the northern coast of Navarino island, at 55° parallel south, Chile. We describe and illustrate the results of an extended archaeological excavation, including stratigraphic and radiocarbon information (6850 cal BP) concerning the Middle Holocene assemblage. Bone technological elements are characteristic of early marine hunter-gatherer groups of the region, considering multi-dentilcate harpoons, detachable harpoon points with one barb and cruciform base, chisels made on pinniped ulna, cruciform base stemmed wedges on whale bone and ornament artifacts. The archaeological deposit has a short formation timeline of less than 100 radiocarbon years, providing the assemblage with a high-resolution chronological frame and excellent context integration for specialized fauna and artifact analysis.
Mensabak Lake, en el Lacandon Rainforest, está rodeado por cuevas que fueron usadas como destinos de peregrinación y para rituales diferentes en el Protohistorico. El papel de las mujeres mayas en los rituales y ceremonias ha sido delimitado a través de la fertilidad y estereotipos dependiendo no solo en los documentos históricos, sino en la investigación arqueológica. Esta presentación discute el papel de las mujeres mayas en una red de peregrinación multirregional, en un marco cultural de Territorio Astractivo.

Tizatl y tizatlalli: El uso de diatomea fósil en el engobe blanco de la cerámica Coyotlatelco en Santa Cruz Atizapán

La utilización de restos de diatomea fósil referida en las fuentes históricas como tizatl o tizatlalli, sin duda, fue una práctica cultural de larga historia en las poblaciones del valle de Toluca. Existe evidencia que nos sugiere la continuidad de una larga tradición cromática desde, por lo menos, hace aproximadamente 3500 años. Esta ponencia se centra fundamentalmente en torno al uso de engobe blanco en los materiales cerámicos Coyotlatelco, procedentes de varios sitios localizados en el valle de Toluca, y en especial el sitio arqueológico de Santa Cruz Atizapán. Mediante la aplicación de microscopía electrónica de barrido (SEM) y espectrometría por dispersión de energías de rayos X (EDX), se han analizado los engobes blancos de fragmentos cerámicos, cuya cronología corresponde al Epiclásico (650 dC-900 dC), concretamente al tipo cerámico rojo sobre blanco. Los resultados de dichos análisis permiten aproximarnos a la larga tradición del uso de colorantes blancos procedentes de roca sedimentaria silícea de origen orgánico. En el caso de los materiales analizados, provenientes del valle de Toluca, se reconoce que la aplicación de diatomita, ampliamente disponible en la región lacustre como pigmento, tiene una tradición muy arraigada desde, por lo menos, el periodo Formativo.

Sanchez, Gabriel (Department of Anthropology, University of California Berkeley)

Cetacean Hunting on the Northern Oregon Coast: Evidence from the Par-Tee Site (35CLT20)

Indigenous whale hunting on the Pacific Northwest Coast is predominately associated with whaling cultures north of Oregon in northern Washington and British Columbia’s Vancouver Island. Ethnographic and ethno-historical records from the northern Oregon Coast suggests whaling occurred locally, at least opportunistically. To date the only physical evidence of local whaling is a humpback whale (Megaptera novaeangliae) phalanx with an embedded elk (Cervus elaphus) bone harpoon point. A calibrated date for the embedded harpoon places the whale-hunting event between ~ cal AD 430 and 550. These dates suggest that whale hunting took place on the Oregon Coast more than a millennium before historic contact. This paper synthesizes recent research on Oregon Coast whaling including ethnographic and ethno-historical data, artifact analysis, and blood residue analysis to investigate whale hunting during prehistoric times along the northern Oregon Coast.

Sanchez Miranda, Guadalupe (Instituto de Geología-UNAM/INAH)

Between Seri, Cahita, and Tepima: Paleoethnobotanical Research on the Central Coast of Sonora, Mexico

El Fin del Mundo is a multicomponent Clovis site located in north-central Sonora, Mexico. Here we present some preliminary result of the plant use as food and implements at several sites. Agave fibers and spines were used as needled and ropes; mesquite seeds, cacti (e.g., saguaro, barrel cactus, and pitahaya) and weeds are very well represented and appear to be an important foodstuff, corn and beans are also present and probably represent a commodity that was exchanged between the farmers and the Seri bands of the coast.

Sanchez-Morales, Ismael (School of Anthropology—University of Arizona)

The Clovis Lithic Technology at El Fin del Mundo: Early Paleoindian Mobility and Land Use Patterns in North-Central Sonora, Mexico

Clovis populations are thought to have been wide ranging, highly mobile foragers, as reflected in stone tool raw material procurement patterns and technologies. At El Fin del Mundo, a multicomponent Clovis site located in north-central Sonora, Mexico, non-cryptocrystalline stone raw materials dominate the Clovis point assemblages, and extensive sources of igneous rocks were intensively exploited by Clovis flintknappers, which has been interpreted as evidence of less mobile, place oriented groups. At El Fin del Mundo, a multicomponent Clovis site located in north-central Sonora, Mexico, local sources of rhyolite were largely exploited, and more than half of the Clovis stone tools were made on locally available raw materials. However, the analysis of the overall lithic technological organization at the site indicates that the stone tool assemblage is consistent with the idea of Clovis groups as wide ranging and highly mobile. Furthermore, the Clovis component from El Fin del Mundo is comparable to those from the San Pedro River Valley, which have been interpreted as resulting from highly mobile strategies.

Sanchez-Morales, Lara (Department of Anthropology, University of Texas–Austin)

The Impacts of Cattle Introduction in Puerto Rican Landscapes during the Colonial Period

In this presentation I examine the environmental impacts that cattle introduction had in Puerto Rico by combining geoarchaeological and ethnohistorical methods. During the sixteenth century hides became one of the most profitable commodities to be produced in the Caribbean. For the bigger islands of the Antilles, it has been reported that these early populations proliferated, leading to underground economies based upon their exploitation. Through the analysis of historical accounts and the provisional analysis of sedimentation rates associated to grazing in various sites in the island from the sixteenth century onward, I will explore how the presence of cattle played a role in transforming Puerto Rican environments. This study is part of a broader effort to elucidate the long history of human occupation and its impacts on the landscapes of Puerto Rico.

[143] Early Fishing on the Atacama Desert Coast of Southern Peru
The coastal Atacama Desert in southern Peru has some of the oldest and best documented fishing sites in western South America, including Terminal Pleistocene through Early Holocene components at Quebrada Jaguay and Quebrada Tacahuay and Early to Middle Holocene components at the Ring Site and Quebrada de los Burros. These sites have offered insight into the antiquity and variability of the early fishing tradition, the antiquity and features of coast-highland interaction, and coastal settlement patterns. Focusing in particular on data from Quebrada Jaguay and the Ring Site, I summarize current understanding of early maritime adaptations in the northern Atacama Desert. I conclude by identifying unresolved questions and potential approaches to solving them, such as: use of terrestrial resources by fishing groups in light of differential preservation of floral and faunal remains; did objects move between coast and highlands via trade or group mobility; and what is missing from the archaeological record—especially in the water and resource rich coastal valleys where no early sites have been recovered—and what that may mean for understanding early population dynamics.

[324] Socializing Novel Landscapes: Reconsidering “Colonization” through Indigenous Philosophies
Archaeologists have long been interested in studying how landmasses became “colonized.” Using biological analogies, archaeologists often describe colonization as a process by which ecological niches become filled by human populations that evolve to best fit into their new environs. This paper suggests an alternative informed by Indigenous philosophies that describe a world filled with animate and powerful beings emplaced throughout the landscape. Forging relations with these beings is a critical goal for many Native American communities and are typically formed through points of revelation at which communication across worlds is made possible. Informed by these worldviews, the occupation of a novel landscape would require the creation of social networks between newly arrived humans and the powers living there. To explore the applicability of Indigenous frameworks to archaeological research, this paper looks at how the American Southeastern coastline was occupied shortly after its formation during the Late Archaic period. This occupation is quite distinctive in that it largely consists of highly structured deposits of shell arranged in circles or open arcs that surround broad plazas. I posit that these constructions are means by which communication between human and nonhuman worlds were formed.

[225] Conservation of Sawfish Rostra in the Great Temple of Tenochtitlan
Throughout the explorations of the Templo Mayor Project, numerous offerings have been surveyed, most of them standing out for the large number of animal remains recovered including a great deal of sawfish, characterized by an anterior long and flat snout that has teeth on both sides. Their skeleton and snouts are chemically composed by hydroxyapatite and collagen in different crystalline arrangements. This causes the stabilization and conservation processes to be a challenge for the archaeological conservators. After almost five hundred years of burial, the object’s chemical structure
and mechanical properties have been severely altered and the material has become highly fragile. Given the valuable information these findings shed to light, their preservation is necessary. For almost forty years, the conservators at Templo Mayor have applied different restoration treatments in order to preserve these rostra. Nowadays, the interdisciplinary work between conservators, archaeologists, and biologists has resulted in a better understanding of the role of this fish in prehispanic world, as well as of their alteration and deterioration processes and the evaluation of the methods and materials used for their preservation. In this paper we discuss the different methods used to preserve these materials as well as their benefits and disadvantages.

[134] An Isotopic Evaluation of the Classic Andean Mobility Models in Northern Chile during the Late Intermediate Period (AD 900–1450)
Research on the Late Intermediate Period (AD 900–1450) in northern Chile has been strongly influenced by two mobility models: John Murra’s classic vertical archipelago model and the more recent gyrotary mobility model. The use and application of these two models, however, is problematic since there is insufficient supporting archaeological evidence. The use of stable isotope analysis allows a direct approach for studying diet and mobility patterns, in contrast to material culture. The aim of this work is to evaluate the presence of colonies and specialized highland pastoralist groups in the lowlands of northern Chile through the application of δ13C, δ15N, δ18O and B7Sr/86Sr to various human tissues, including tooth enamel, bone collagen, bone apatite, and hair-keratin. The results show strong local traditions in terms of diet and mobility associated with the Pica Tarapacá and Atacama cultures. However, a small number of isotopic outliers suggest a nonlocal origin for some individuals in both groups. Based on the isotopic evidence, it is suggested that there is no evidence to support either the ‘colony’ or the gyrotary mobility model. Mobility patterns were, instead, diverse and flexible including female and male individuals that moved at different moments during their lives (infancy and adulthood).

[236] Exploring Ceramic Variability at Tlatilco, Mexico
Tlatilco is an Early Formative society located in the Basin of Mexico dating from c. 1250–600 BCE. The site which was discovered by Mexican archaeologist, Miguel Covarrubias in the 1930s has undergone several phases of archaeological seasons often with very little material published. Many of the cultural objects uncovered were dispersed into museum collections in North America, used primarily as illustrative material. My research involves gathering iconographic and archaeological data from major collections all over the United States, as a supplement to understand the variation within the material expression of this ancient culture. Through comparative techniques, as well as utilizing advanced laboratory analysis, I am investigating the diversity of the community of Tlatilco and its neighbors. The analysis of the many objects is contributing to a better understanding of the identity, ideology, and the political roles concerning Tlatilco’s efforts to participate as one of the Early Formative communities within Mesoamerica.

[143] Unearthing the Deep Roots of the Long-Term Human History and Environmental Interaction in the Atacama Desert
New archaeological evidence demonstrates that by 12,800 years ago, bands of hunter-gatherers effectively occupied the hyperarid basins of the Atacama Desert. The selection of the habitats they exploited and the location of their activity areas were constrained by specific environmental circumstances that coincide with positive moisture anomalies that provided abundant resources. The distributions and properties of which were likely managed by these people to create complex landscapes using specialized adaptive strategies. Considering that by at least 14,500 years ago, humans inhabited the southern tip of South America (i.e., Monte Verde), and that favorable environmental conditions existed in the Atacama Desert between 17,000 and 14,000 years ago, we discuss the idea that human occupations in the Atacama Desert were likely preceded by an even earlier phase of exploration. This means the first migratory South American groups traversed and eventually colonized the Atacama Desert perhaps as early as 15,000 years ago under environmental conditions that would have been extremely favorable to human dispersion.

[395] Santa María de la Antigua del Darién: The Aftermath of Colonial Settlement
What kind of relationships were created between the indigenous people of the western region of the Gulf of Urabá (Colombia) and the Spaniards in the early years of the conquest? What happened in Santa María de la Antigua del Darién (1510–1524), the first European city founded on the American mainland, in the course of its short history, and immediately after its abandonment? We have a number of clues that can be drawn from contemporary historical sources (Oviedo), sources immediately following the demise of Santa María (the reports of the travels of Julian Gutiérrez) and archaeological investigations now in progress in the area of the city. This paper will offer new reflections on these questions, on the basis of archaeological data obtained during the 2014–2016 excavations directed by the author. These findings include ritual burials dated to the phase of the city’s abandonment; “contact” pottery from the Basurero Norte area; and, the “F Excavation”, a possible house inhabited by indigenous servants (naborias).

Sarjeant, Carmen [271] Comparative Techniques to Uncover Networks of Ceramic Technology in Southern Vietnam

The analysis of ceramics in Southeast Asia has evolved from typologies and broad comparative discussions of vessel forms and surface treatments. Like other material culture, studies on ceramics from mainland Southeast Asian prehistoric sites that employ archaeometric techniques have escalated in recent years. The appearance of fine, incised and impressed ceramics in southern Vietnam dating to the Neolithic period (4500–3000 BP) is closely associated with sedentary settlements, cereal agriculture, and domesticated pigs and dogs. In southern Vietnam, new data about Neolithic settlements were obtained during the excavations at An Son and Rach Nui in 2009 and 2012. This paper presents systematic comparative methods, including a correspondence statistical analysis, for analyzing ceramic vessels from Neolithic sites in southern Vietnam to identify potential paths of communication for ceramic technology in the past, particularly along river courses. This is an ongoing project, and as sites are excavated or re-excavated, ceramic data can be included in the comparative study. As a result, modeling ceramic technology in southern Vietnam and beyond to other areas of mainland Southeast Asia can reveal migration pathways and interactions between different groups.

Sasaki, Yuka (Paleo Labo Co., Ltd.) [211] Feasting from the Early to Middle Jomon Period Deduced from Seed Impressions on Pottery

Seed impressions of cultigens have been recovered from pottery of the early to middle Jomon periods in the central highland of Honshu and the western Kantō district of Japan. These include such cultivars as Perilla frutescens introduced from China and Azuki bean (Vigna angularis) and Soy bean (Glycine max) domesticated in Japan. They often occur in large numbers and are also found even in clay figurines (Dogu). I found that the seeds exist not only on pottery surfaces, but also within pottery clay from X-ray CT observation. Image analyses of pottery revealed that even those impressions on pottery surfaces were not applied on the surfaces after shaping, but included in the clay while mixing. Seeds included in large numbers derive only from the above three cultigens, Cornus, and Zanthoxylum that people used commonly. However, inclusion of these seeds occur irrespective of pottery types. Thus, inclusion of the seeds of these five plants in the pottery was intentional, and these seeds had a special or ritual importance in the people's lives such as wishes or acknowledgements for rich crop. Restricted occurrence of pottery with many seed impressions in large settlement sites seems to reflect hope for continuous use of plant resources.

Sato, Takao (Keio University, Department of Archaeology and Ethnology), Andrzej Weber (Department of Anthropology, the University of Albe), Taichi Hattori (Graduate School of Letters, Keio University), Tomonari Takahashi (Graduate School of Letters, Keio University) and Hirofumi Kato (Center for Ainu and Indigenous studies, Hokkaido U) [396] Animal Utilization and Animal Rituals of the Okhotsk Culture: with Special Reference to Their Period and Regional Differences

In the animal utilization and animal rituals of the Okhotsk culture, chronological and regional differences can be observed. Significant differences can be seen between the northern and eastern regions of Hokkaido in terms of the volume of archaeological artifacts recovered relating to both domestic animals (dogs, pigs) and wild animals. In northern Hokkaido, there are conspicuous differences in the use of a variety of fishes and types of sea urchins between the early period (Towada) and the middle period (Kokumon). In addition, in eastern Hokkaido, there appears to have been a rapid increase in the incidence of beliefs and rituals relating to deer during the late Okhotsk culture (Tenpumon Period). In this paper, we review this variation based on the findings of recent excavations, and we discuss the social and economic changes affecting the people of the Okhotsk culture in response to changes in climate and shoreline conditions, as well as the success or failures of neighboring peoples.

Tochak-McGrath Discovery: Three Precontact Individuals from the Upper Kuskokwim River, Alaska

Three precontact individuals inadvertently discovered in the village McGrath, Alaska provide a novel understanding of human history of the Upper Kuskokwim River region of Eastern Beringia. Collaboration between the McGrath Village Council, MTNT, Inc. and Tanana Chiefs Conference enabled a community research endeavor that has yielded a radiocarbon age estimate of c. 600–700 cal BP, isotopic dietary reconstruction suggesting a strong reliance on anadromous salmon, rare dental traits including a two-rooted lower canine and a fourth molar, and a population relationship similar to modern Alaska Natives through mtDNA (A2a and A2 root) and yDNA (Q). The three individuals are intergenerational (c. 30, 20, 2–3 years of age) and shared a similar high marine diet. Additional faunal remains at the multicomponent site include dog (C. lupus familiaris), bear (Ursus sp.), beaver (Castor sp.) and burbot (Coregonus sp.). Situated in the alluvial floodplain or the Kuskokwim River, the context suggests the Tochak family dunked together and were buried rapidly by natural sedimentation processes. The results of interdisciplinary research on the Tochak McGrath site provide rare insights into the precontact lifeways of Alaska Natives in the upper reach of the Kuskokwim River basin.

Site Map Validation and Quantifying Linkages between Multispectral and Lidar Remote Sensing for Settlement Pattern Mapping

Fifteen years of field survey and image processing of commercial satellite optical data have contributed to robust site maps of San Bartolo and Xultun, among other PROSABA sites in northeastern Petén. The recent acquisition of lidar-derived DSM and DTM data through PACUNAM has made new types of analyses possible, including the validation and enhancement of the site maps. We present recent mapping discoveries in the PROSABA region and research into the validation and extrapolation of settlement pattern signatures through vegetation canopy responses in northern Guatemala.

Entre dos épocas: Laguna de los Cerros y la transición del Preclásico Temprano al Preclásico Medio

Laguna de los Cerros enclavado dentro de la región Olmeca, ha figurado al lado de tres grandes centros: San Lorenzo, La Venta y Tres Zapotes, aunque su posición en la jerarquía regional durante el Preclásico nunca se equipará a ninguno de ellos. San Lorenzo y La Venta se han considerado como las grandes capitales del sur de la costa del Golfo, representativas del Preclásico temprano y medio respectivamente. En este sentido, Laguna de los Cerros tuvo una ocupación continua e importante durante estos períodos de tiempo, resistiendo los cambios en las dinámicas regionales. Nuestras observaciones oscilan sobre la transición entre estos dos períodos y el cambio en la rectoría regional a través del papel desempeñado por Laguna de los Cerros, nuestro argumento se apoya en el análisis sobre los monumentos registrados en este asentamiento, ya que presentan particularidades estilísticas e iconográficas. Además, en el presente escrito, discutiremos los trabajos previos de corte regional realizados en esta zona, estos testifican la continuación del asentamiento incluso hasta un periodo muy posterior, el Clásico tardío. ¿Laguna de los Cerros puede representar la clave en el entendimiento de las manifestaciones culturales que tuvieron lugar en el relevo de San Lorenzo por La Venta?

Late Precoloniindia Circular Villages in the Brazilian State of Acre

The archaeology of Acre has been widely drawing the attention of the scientific community due to the discovery of an ancient civilization building geometric earthworks labeled “geoglyphs.” In the course of field surveys realized at the geoglyph sites other types of archaeological sites were documented as well, including sites consisting of small artificial earthen mounds arranged in a circular form. At first, the mound sites were also classified as geoglyphs, but through the recent fieldwork it became clear that they represented a distinct type of archaeological site, with features, contents, and functions differing noticeably from the geoglyphs. Initial surveys conducted at sites featuring circles of approximately 1.5 m high mounds around a central open space with a diameter of roughly 100 m, indicated a feasible residential use of the mounds for the late precolonial period. Ethnographic circular villages are known in central Brazil and in southern Amazonia, and are associated with the G6 and Arawak ethno-linguistic groups. In these regions, as well as in central Amazonia, archaeological sites comprising vestiges of circular plaza settlements have been recorded, but until now they were not acknowledged in southwestern Amazonia.

Prehistoric Thule Whaling Societies in the Canadian Arctic: Ritual, Symbolism, and Ideology

Prehistoric Thule Inuit in the Canadian Arctic were preeminent whalers, focusing on the bowhead whale, the largest prey species hunted by any prehistoric or historic hunter-gatherer society. The ethnographic literature provides a rich source of information dealing not only with the importance of bowheads in the diet of early historic bowhead-hunting Inuit societies, but also how social structure, ritual, symbolism and ideology were all centered on complex Thule-bowhead relationships. This rich data source has for the most part been virtually ignored by Canadian Arctic archaeologists, who often cite the “active hunting vs. stranding” problem and/or the related problem of dealing with bowhead remains (bones) as primarily architectural as opposed to diet-related (as will be discussed, these are both non-issues). In this paper, the distribution of archaeological bowhead whale remains associated with dwellings, ceremonial features, burials, flensing beaches, etc., when considered through the lens of not just only diet, but also ritual, symbolism and ideology, offers a much richer understanding and appreciation of Thule-bowhead relationships.

[203]  
The Origins of Pastoralism in Eastern Africa: New Human Dental Evidence from Mid-Holocene Pillar Sites in the Turkana Basin

Herding spread into Eastern Africa ~5000 BP, but mechanisms of spread are still debated (migration, diffusion, or a mix). If herders migrated from desiccating areas of the Sahara, Sahel, or Ethiopian Rift, they would have passed through the Turkana Basin, where the earliest livestock coincides chronologically with the construction of megalithic “pillar sites.” Recent excavations at three pillar sites revealed extensive human burials, plus caprine remains and zoomorphic artifacts suggesting these people were pastoralists. Their dental remains can therefore shed light on the biological affinity of
Eastern Africa’s earliest herdiers and the likelihood of different mechanisms of spread. To test the migration hypothesis, 37 nonmetric permanent tooth dental traits from this new sample (n = 25 dentitions) were compared with Holocene LSA (n = 40), early herder (n = 53), and Pastoral Neolithic (PN) (n = 91) skeletons from Kenya and Tanzania. Mean measure of divergence analyses reveal no significant phenetic differences between any of the sample groups, although greater distance is observed between the pillar sites and LSA. Therefore, if early herding involved in-migration, there was substantial gene flow between indigenous foragers and incoming herdiers. Continuity between the pillar sites and PN suggest these interactions strongly influenced subsequent development of herding-intensive cultures in the south-central Rift Valley.

Evaluating the Effects of Time Averaged Deposits on Archaeological Chronologies

Establishing intra-and intersite chronologies for the dwellings and workshops at Monticello’s Mulberry Row has been a focus of study for decades. While broad temporal outlines are clear, we argue here that further progress depends on gaining better analytical control of a key issue: time averaging of archaeological assemblages. In this poster, we present our iterative process to develop methods to estimate variation in time averaging between these assemblages at different levels of aggregation. We highlight how the results can advance our understanding of Mulberry Row’s complex formation processes by accounting for postdepositional disturbances and different archaeological practices. Ultimately, controlling for variation in time averaging is key to obtaining more accurate estimates of synchronic variation and change over time in assemblage content among different sites. Future intersite analysis will use this as a foundation to explore a plethora of research topics, including evaluating artifact assemblages from concurrent structures and comparing Mulberry Row sites to contemporaneous field quarter sites.

Diet in Coastal Arequipa, Peru, at the Dawn of the Wari Empire

Excavations at Uraca, a cemetery in the Majes Valley, Arequipa, Peru, uncovered incomplete human skeletons (MNI = 157) and associated grave goods dating to the Early Intermediate Period and the early Middle Horizon. Interpersonal violence was omnipresent at Uraca: 67 of 100 adults suffered cranial wounds (7 were insults received around the time of death), and 20 individuals were violently decapitated and/or defleshed after death. AMS dates show the individuals buried at Uraca lived from approximately AD 300–650. The terminal portion of this date range corresponds with severe flooding and drought events, as well as the spread of Wari imperial influence throughout southern Peru. To understand whether this violent period is associated with dietary change, we compare childhood and adulthood diets from Uraca individuals to those from contemporaneous neighboring sites, such as Beringa. We compare stable carbon isotope ratios from dental enamel samples at Uraca, which show C4 plant consumption during childhood.

Archaeological Patrimony, Spirituality, and the Construction of a New Indigenous Class in Highland Bolivia

The ancient citadel and urban center of Tiwanaku (c. AD 300–1100) in Bolivia’s highland plateau is a notable archaeological site that has been deployed in nation-building discourses by both Bolivia’s white minority and its indigenous majority since the inception of this small Andean republic. With the approaching bicentennial of the country’s independence from Spain, Tiwanaku has become the symbolic center from which a new generation of upwardly mobile indigenous business and political leaders are invoking this culture’s iconography and features to embrace a new take on Andean cosmopolitanism. These religious beliefs are loosely put together from contemporary Andean religious practices, invented traditions, and archaeological publications, and represent the bricks and mortar for this new indigenous class. The disciples of this new faith are quick to critique the sanitized and romantic visions of Tiwanaku’s past that endeavored to mediate cultural and racial disparities. However, since this spirituality is inextricably linked to the indigenous nationalism of Evo Morales’s administration, it remains to be seen whether this new iteration of Andean religion will provide a platform for a new indigeneity, or whether it will fade into oblivion with the Bolivian people’s disenchantment with Morales near the end of his tenure.

World Prehistories and the Development of a Global Archaeological Narrative

The origins of prehistoric archaeology as a discipline lie in the New Learning of the sixteenth and seventeenth centuries and derive from a number of sources: antiquarian researches in northwest Europe; European exploration and the encounter with non-European peoples; and speculative accounts of human origins and development. It was only in the nineteenth century that these strands first began to be woven together to create a global narrative of human prehistory. Such a narrative raises a number of problematic issues: regional balance, thematic emphasis, and cross-cultural perspectives. As
early as 1896 Franz Boas criticized the ‘comparative method of anthropology,’ and some post-processualists of the 1980s and 1990s entirely rejected the validity and utility of cross-cultural analysis. Prehistoric archaeology, however, offers the unique advantage of viewing the development of human societies over the long-term and in global perspective. In the current age of globalization such a perspective should be more relevant than ever before. This paper reviewed the development of global narratives of human prehistory over the past 150 years and explore the theoretical and practical challenges that they present.

[164] The Contribution of Northwestern Argentina to the Metallurgical Andean Tradition

The most developed metallurgy of precolombian America originated and evolved in the Andes, reaching great levels of technical sophistication. However, as a few interesting cases of the first moments of experimentation with metals come from Perú, with them comes the popular idea that any technical advance took place in the Peruvian Andes. Because complex societies later emerged in what is now Central Andes, there is a tendency to think that all technological innovations did as well. This could be the cause of the low visibility of metallurgical evidence from Northwestern Argentina. Moreover, early proofs of copper metallurgy in the Central Andean region are scant. By contrast, some crucial evidences are emerging in the meridional region of the Andes. Several archaeological finds point to the Southern Andes as an innovative area that made important contributions to the metallurgical traditions of the broader region. Based on the finding of an anthropomorphic copper mask in a funerary context dated to 3,000 years before present, we argue that the Cajón and nearby valleys have been an important focus of copper metallurgy supporting a very early tradition of metalworking in Northwestern Argentina, thus suggesting more than one center for the origin of this technology.

Schaafmsa, Polly (Research Associate, MIACl/OA)  
[28] Pueblo Regalia and the Cosmos: Past and Present

Images of the human form can be analyzed for what they reveal about social roles, hierarchy, and other identities, as well as culturally determined perceptions about humanity’s relationships to the natural environment and supernatural realm. It is proposed that the portrayal of the multitudinous human subjects related to religious ideology and practice in Rio Grande Tradition and Navajo rock art focuses on the interconnectedness of all things, deflacting meaning away from human beings as prime subjects as seen in Western religious art. Rather, informed by ethnographic data, the Native American abstracted, costumed forms along with conflated human/animal subjects, define humanistics’ intimate link to the cosmos, and their added attributes evoke the supernatural strengths of other living beings, along with animated entities such as rain clouds and the sun. These images themselves are perceived as active agents, attracting the pictured forces, sanctifying place, and facilitating communication with resident spirits. What is pictured on stone extends to the performative dimensions of ethnographic contexts, thereby blurring the boundaries between the ceremonial participants, the representations, and the animistic cosmos.

[143] Dressing the Child: An Analysis of Camisas at Chiribaya Alta

Children learn and communicate their social identities through dress. Thus, examinations of ancient clothing can reveal the process of socialization in past societies. The presence of child and adult sized camisas in the graves of Chiribaya children suggest that these items communicate more than a child’s living identities. Here, we analyze camisas at Chiribaya Alta to examine the process of socialization and the role of death as a potential rite of passage. The site of Chiribaya Alta, an elite Late Intermediate Period site located ~10 km from the ocean along the Osmore River of southern Peru, provides an ideal location for this study because its nine cemeteries represent a large sample of Chiribaya tombs (n = 307), many of which contain preserved camisas. Chiribaya camisas are buried with individuals of all ages and sexes. These garments consist of single web warp-faced structure, are either trapezoidal or rectangular in shape, and are often decorated with lateral stripes and embroidered finishes. Through comparisons between the camisas buried with children to those with adults, we will address the process of socialization in Chiribaya society and whether or not children are acquiring adult identities in death through a funerary rite of passage.

[301] Shifting Social Networks and Identity along the Southeastern Edge of the Cibola World

The work reported here represents the initial results of recent NSF supported field research near Mariana and Cebolleta mesas in west-central New Mexico. These investigations targeted previously known Pueblo II and Pueblo III communities on both public and private lands for detailed mapping and in-field artifact analysis. While the ware-level diversity of ceramic assemblages in the region has long been known, our work employed new methods of analysis of corrugated vessel forming techniques, architectural styles, and lithic source materials and production techniques. Preliminary results suggest variability in regional social ties are present even within individual communities and as represented by different material classes. The results of these analyses contribute to a larger project utilizing targeted fieldwork and reexamination of museum collections along with interdisciplinary analytical frameworks to investigate shifting identity and demography across the southeastern Cibola region during the Chaco through Pueblo IV periods.

[233] Sacrifice Reconsidered: Interpreting Stress from Archaeological Hair at Huaca de los Sacrificios

The Inka Empire (AD 1450–1532) practiced flexible forms of statecraft that affected their periphery populations across the cordillera. Lived experiences of different Inka subjects differed in varied ways, which therefore requires nuanced bioarchaeological approaches. This study aims to interpret psychosocial stress through assays of cortisol in archaeological hair from sacrificed individuals (n = 19) recovered in the Huaca de los Sacrificios at the Chotuna-Chornancap Archaeological complex. This site is located in the Lambayeque region on the north coast of Peru and was used as a ritual and ceremonial complex by both the Inka and earlier Chimu states; the remains analyzed here are associated with the Inka period. Utilizing enzyme-linked immunosorbent assay (ELISA) to obtain both overall and segmented cortisol levels, this study examines spikes in cortisol and analyzes these data along with existing data from this study sample. These archaeological cortisol levels are also compared to published cortisol data from living participants, in order to better reconstruct and infer overall stress levels in this cohort. Preliminary results suggest elevated cortisol levels in a number of sacrificed individuals may indicate high levels of psychosocial stress. This analysis also considers other potential confounders as this cohort includes young adult females and subadults.
Scheffer, Bryan (Florida State University)  
**Cosmogenesis in the Mixtec Codices: Visual Narratives of Place, Emergence, and Movement**

In the Postclassic Mixtec codices, the integral and integrative themes of place, emergence, and movement converge. Neglected in much of the scholarly literature on the sacred books of the Mixtec, the visual representation of supernatural and historical figures’ emergence and movement from place to place is an integral component of the codical narratives. Emergence and movement are tethered to and integrative with Mixtec portrayals of place, of various kingdoms through a standardized glyphic sign called a ‘toponym.’ The significance of emergence and movement or travel underscores Mixtec conceptions of space and directionality, of certain human actions that mirror specific supernatural, generative actions. Such emergence and movement, as visualized in the codices, are tied to primordial cosmogenesis and to the origins of Mixtec ethnogeography. In this presentation I will connect visual narratives from the Mixtec codices with archaeological and anthropological lines of inquiry in order to demonstrate how the Mixtec conceptualized, and therefore visualized, their autochthonous identity in the Mixteca, the region of myriad Postclassic kingdoms. I will also examine and question why place, emergence, and movement were aspects of cultural and historical significance for Mesoamericans in general and for the Mixtec gods and human rulers in particular.

Scharf, Elizabeth (University of North Dakota)  
**Dangerously Close to Big Data: The Intriguing Possibilities of Statistical Time Series Analysis in Archaeology and Paleoenecology**

Increasingly, archaeologists are producing larger databases and asking questions about processes that play out at larger scales. To better understand the working of long-term and regional-scale relationships, archaeologists are seeking to compare proxy variables measuring phenomena such as population, climate, and the environment. In this presentation, statistical time series in the time and frequency domains is used on sample datasets to illustrate the benefits of this approach in archaeology and paleoenecology. For such applications, statistical time series analysis promises to reveal interactions, lead-lag relationships and statistically partition variability in ways that other approaches (such as visual inspection, regression, and correlations) cannot, providing insights into possible causal relationships and revealing subtle interactions that are otherwise hard to assess.

Scharlotta, Ian (Aix-Marseille University)  
**Investigating Temporal Shifts in diet and behavior at Shamanka II, Cis-Baikal, Siberia**

Using a high-resolution chronological framework developed for Early Neolithic Cis-Baikal, Siberia, grave goods and stable isotope data are analyzed for specific relationships between functional items, prestige goods, and diet. Evidence suggests increasing importance of fishing during two separate phases of cemetery use at Shamanka II. Dietary changes and interlinked social structures may have contributed to differentiation in the cemetery. Fishing specialists are identifiable in grave assemblages. Individual fishers did not employ methods consistent with intensification. Their role in providing important food resources did not translate to apparent prestige or wealth in certain grave goods at Shamanka II. Bulk data have indicated the presence of a mixed population in terms of origins and diet, the need for caution prior to their use in support of clear behavioral inferences, and further refinement of the methodological approaches. Dentine micro-sampling provides direct examination of three primary data goals, 1) weaning patterns; 2) mobility between three primary types of watersheds; and 3) the possibility and nature of stored resources used to ameliorate the returns of seasonal subsistence activities. The ramifications of these three data goals support different subsistence approaches and sociopolitical organizational structures within middle Holocene Cis-Baikal hunter-gatherers.

**Constructing Stories from Archaeological Evidence and Documentary Sources**

The archaeological collections crisis we have been facing for the last couple of decades has forced many of us to rethink how to conduct research without adding to the problem. Although the idea that you need to excavate in order to do “archaeology” still permeates the opinions in academia, we have been seeing more research projects that revisit archaeological collections. Therefore, how can we make archaeology students aware of other research possibilities? The archaeological excavations conducted in five urban blocks of Ballajá, a nineteenth-century area located on the northwest part of San Juan, Puerto Rico, yielded a large collection of urban material culture. Twenty-four years after the completion of the excavations the majority of
the collection still has not been analyzed, and there is limited access to researchers. As part of a larger project, I started developing smaller investigations with undergraduate archaeology students in an effort to rethink, and reinterpret this archaeological collection. In this paper, I will present the advantages of using the data from censuses and newspapers which can be included in writing stories about people, places and objects.

Chair

Schieber de Lavarreda, Christa (National Archaeological Park Takalik Abaj) and Miguel Orrego (National Archaeological Park Takalik Abaj)

Where Is Tak'alik Ab'aj within the Fabric of Preclassic Interrelations?

Three decades of research at Tak'alik Ab'aj have repeatedly confirmed that this ancient site at the southwestern piedmont of Guatemala was an important link of the transcultural trade-network along the Pacific littoral of Mesoamerica. This presumes strong and functional interactions among the stronghold-players of this hanseatic system operating during a given timespan by means of a common shared concept proposed as “market of rituality,” permeated in each case according their own local nature in their cultural and economic realm. This is examined anew under the framework of the current discussion of chronological revision.

Archaeology Fairs: Measuring Informal Learning

Archaeology Fairs are held across the United States in honor of Archaeology month and the International Day of Archaeology. Students and families are exposed to many facets of archaeology, tools of the trade, the difference between archaeology and paleontology, and what to do when they find artifacts. Often this learning takes place in an informal setting, a museum or university campus. So what are students actually learning at these Archaeology Fairs and how can we measure their understanding? Project Archaeology, a national archaeology education program, hosts an annual Junior Archaeology Day at the Museum of the Rockies in Bozeman, Montana. Project Archaeology staff measured student’s understanding of archaeological concepts at the 2015 and 2016 fairs. This paper discusses the results of this research, the difficulties of hosting an archaeology fair in a paleontology museum, best practices for measuring informal learning, and improving fair activities based on research results.

Monks Mound: Retrospective Thoughts and Prospective Potentials

Monks Mound stands as the pinnacle of platform mound building at Cahokia and in North America. Built very rapidly near the end of the eleventh century AD, it was the largest single public works project undertaken in North America until the nineteenth century. At first glance, the mound appears as an immutable fixture on the landscape yet a closer examination shows that the mound has several severe structural deficiencies that may eventually lead to collapse. Archaeologists and site managers have long studied the mound to understand its internal structure and potential long-term solutions to the structural problems. Researchers have developed multiple theories about how and when the mound was built. The most recent work reveals that these problems are inherent in the materials and techniques used in construction. While the builders were intimately familiar with their materials, because of the scale of the construction, Monks Mound may be more susceptible to erosion and slumping than smaller earthen mounds. Recent work demonstrates that mound builders of Monks Mounds and other Mississippian sites successfully coped with and repaired problems during construction. More large-scale geoarchaeological studies are needed to both understand the mound and maintain it for future generations.

Surface Archaeology as Site Assessment: The Haynie Site and the Northern Chaco Outliers Project

Crow Canyon Archaeological Center is beginning a multiyear project at the Haynie site, a Chaco outlier in the central Mesa Verde region of southwest Colorado. In 2016, the goal was to assess the spatial and temporal characteristics of Haynie through in-field analyses of pottery and chipped-stone artifacts from the surface. This was done via systematic dog-leash collection units placed across the site, as well as judgmental analysis of artifacts in disturbed contexts. Through analyses of artifacts from dog-leash units over the entire 5-acre site property, we discuss temporal and spatial patterning reflected by observed pottery and lithic raw material distributions. Although surface architecture reflects the Pueblo II period (AD 900–1150) component at Haynie, the surface-based artifact analyses demonstrate much greater time depth, with pottery types suggesting continuous use from the Basketmaker III period (AD 500–750) through the Pueblo III period (AD 1150–1300). This project will help guide test excavations which will begin in 2017.

Landscape Reconstruction at the Black Sea Coast

Landslapes are subject to ongoing geological transformation which change, hide or even destroy for their part anthropogenic remains. The reconstruction of historic landscapes as well as the causes of their changes is subject of geoarchaeology. As a noteworthy example for a reconstruction of the historical landscape of a whole region is demonstrated by an interdisciplinary and international project on the South Russian Taman peninsula in the North Pontus. The new insights that were made by geoarchaeology to the phases of the geomorphological formations of today’s Taman Peninsula during the Holocene allow now to interpret the archaeological sites as well as together with historians and classical philologists the ancient topography in another way. Modern landscape reconstructions on the one hand and the ancient written sources on the other hand, and their relation to the known archaeological sites cannot in many cases be brought convincingly in harmony. Hence, numerous drilling cores were taken in several years at well-chosen places. The results of these cores were determined chronologically according to their radiocarbon dating. Unexpectedly appeared that the Taman Peninsula was in ancient times an archipelago and therefore was beside the still existing Strait of Kerč a second waterway further in the east.

Recreating the Timing and Patterns of First Peopling with the Bayesian Approach

The timing and patterns of first peopling offer exciting opportunities to understand the legacies of colonization. In particular, islands are defined territories where colonization processes can be tracked through a rigorous synthesis of empirical data and a systematic application of Bayesian statistics. Iceland provides one of the world’s premier case studies for human interactions of pristine ecosystems because its colonization in the ninth century occurred relatively late in history. Furthermore a suite of tephrochronological and radiocarbon data helps define this process in Iceland. This study systematically reassesses 500 radiocarbon dates from the settlement period that have been a matter of fierce contention. Bayesian statistical modeling is used to evaluate the reliability of the data using calibration methods; material classes; life span; isotopes; archaeological contexts and associated tephra layers of 300 settlement and 25 burial sites. The data summarized here for the first time allows a countrywide comparison and a classification of these settlement sites into pre-Landnám (AD pre-877), Landnám (AD 877–939) and post-Landnám (AD 939–1104). It demonstrates that it will be possible to reconstruct the tempo and development of the colonization process in decadal resolution by more systematically utilizing the dating potential of tephrochronology and radiocarbon dates with Bayesian approaches.

The Kwajalein MIA Project

Kwajalein Atoll, Republic of the Marshall Islands, is located in the western Pacific, ~2,100 miles southwest of Hawai‘i and is home to U.S. Army Garrison Kwajalein Atoll. During World War II, it was the site of Operation Flintlock and major bombing operations in the Pacific Theater. The Kwajalein MIA Project (KMP) is a public archaeology project dedicated to identifying aircraft and wreckage in the atoll lagoon that are linked to missing U.S. servicemen from World War II. The project is comprised of an all-volunteer team that includes veterans, active-duty military, and civilians that specialize in boat operations, diving, archaeology, fundraising, and historical research. The KMP has located 3 of 8 American aircraft that were lost in the lagoon and are currently facilitating efforts with the Defense POW/MIA Accounting Agency to recover the associated servicemen. This project exhibits how a public archaeology project can help provide closure to MIA-families who have waited decades to hear of their loved ones’ fates but also how it can function as a source of pride and healing for team members who have more recently served our country and for those who have been affected by the invisible impacts of war that are not exclusive to those in uniform.

Daily Practices and the Creation of Cultural Landscapes in Amazonia

Short-term, small-scale interactions between humans and the environment may result in profound transformations of that environment over time. Recent archaeological research in Amazonia has revealed the extent that daily practices, such as refuse disposal or cultivation, have modified the soil in the vicinity of ancient and modern settlements. The fertile anthropic soil known as terra preta, formed mainly through the discard of refuse around habitation areas, is an example of how quotidian actions by humans and other organisms together created these landscapes. These activities have resulted in a widespread pattern where similar features are found in ancient settlements across the broad Amazon region. The landscapes have been documented in several widely spaced areas and in differing environmental and cultural contexts, including large sites along major rivers as well as smaller sites in interfluvial areas. Daily activities resulted in patterns of modified soils and geomorphology that reflect the organization and use of space in settlements. Once these features are formed, they may serve as landesque capital that is repeatedly used by succeeding generations or occupations.

Schmidt, Peter (University of Florida)

Sacred and Magnificent, Degraded Landscapes: Crater Rims as Sacred Places and Transformed Spaces in Western Uganda

One of the most vexing problems in the archaeology of eastern Africa is the absence of burial evidence from deep antiquity. This issue is now moot with the documentation of multiple burials on the narrow rims of steep volcanic calderas in far western Uganda. Dating to the early first millennium CE, these cemeteries contain well-preserved individuals who lived in a forested environment they modified by fire while subsisting on a mixed diet of fish, game, and agriculturally produced grains. Previously characterized as hunter, fishers, and gatherers, these pioneer forest dwellers were more varied than previously believed. They buried their dead with large funerary urns on the western sides of spectacular calderas where the first rays of the rising sun strike—suggesting beliefs linked to celestial cycles. Responsible for pulses of forest clearance over the last millennium BCE and first millennium CE, they were replaced by major but short-lived agriculturally based population in the mid-second millennium CE that utilized large scale forest clearance and agriculture on the crater slopes.

Excavating the Intertidal at Hup’kisakuu7a, a Summary and Artifact Analysis

The Barkley Sound region of Vancouver Island has a rich archaeological record that is important to the Nuu-chah-nulth people. Due to changing sea levels, places that were once exposed are now underwater, meaning that the earliest possible occupations cannot be excavated. We excavated in the intertidal at Hup’kisakuu7a because of the possibility of finding evidence of human occupation between 5500–7000 cal years BP when sea levels were just a few meters below modern. From the excavations conducted we found fire-cracked rock (FCR) and possible artifacts which point to humans being present at this time. However, due to the lack of dateable samples and uncertainty of artifacts it is not something that can be confidently concluded. Further work is required to be done in the intertidal at Hup’kisakuu7a, especially because the artifacts found at Hup’kisakuu7a are so promising.

**The Ritual of Return: Mounded Landscapes in Colonial California**

In the United States, prehistoric and historical archaeology subfields are characterized by distinct intellectual histories, methods, and theoretical frameworks that continue to guide where archaeologists apply their craft. For California prehistorians, deeply layered shell mounds long represented ideal sites for chronology building. Until recently, shell mounds were also unlikely places for historical archaeologists to investigate interactions between Native Americans and colonial institutions. Building on a recent study comparing shell isotope data to colonial mission records, this paper explores Native American mobility and the possibility of persistent visits to San Francisco Bay shell mounds during the Mission Period (1776–1830s) and afterward. Focus here is on the ritual of return, or Native people’s trips to and reuse of aged mounds, for assessing the resiliency of people and mounded landscapes.

**Influence of Animal Proxy Choice on Use of Carbon, Nitrogen, and Oxygen Stable Isotope Ratios for Determining Past Environmental Variables**

The stable isotope ratios of carbon, nitrogen, and oxygen (δ13C, δ15N, and δ18O values) in animal tissues show promise as environmental indicators. We evaluated the use of chimpanzee hair and leporid (jackrabbit and cottontail) bones. Chimpanzee hair δ13C values correlate negatively with mean annual precipitation (MAP) as expected based on isotope variation in C3 plants, whereas δ15N values do not because of diet selectivity. Leporid bone δ13C values do not correlate with MAP because of leporid feeding on C4 plants, but both δ13C and δ15N values correlate significantly with temperature. The lack of significant temperature variation across chimpanzee sites negates testing for temperature-related variation in chimpanzees. Leporid bones also show significant covariation of δ18O and MAP as expected for a nondrinking species. Our results suggest that mammalian δ13C values should be useful general indicators of MAP in C3-feeding animals and of temperature in C4-feeding animals. δ15N values need to be evaluated on a taxon-specific basis. Each animal proxy must be considered in the context of its feeding and drinking ecology in order to interpret the isotope data properly. All three isotopes have potential for use with museum specimens in studies of climate change and for reconstruction of paleohabitats.

**A Natural and Unnatural History of Faunal Change in Southwestern New Mexico since AD 500**

An important intersection between archaeology and the study of natural history lies in understanding the long-term processes of human-environment interaction that affected local biotas in the past and have shaped contemporary landscapes. This study integrates information from archaeological faunal assemblages and historic and modern data from the major watersheds of southwestern New Mexico—specifically, the upper Gila-San Francisco and Mimbres drainages—to examine changes in the status and distributions of animals and their environments over the past 1,500 years of human occupation. Using this approach we seek to clarify the roles the presence and activities of prehispanic farmers, the subsequent effects of Europeans and their livestock, and concurrent climatic factors have played in this region’s contemporary faunas and landscapes. Contributing a clearer understanding of changes to local faunas and their environments over long periods of time can assist contemporary restoration efforts by providing more realistic benchmarks for evaluating prior states of land health.

---

**Effects of Sample Pretreatment and Contamination on Bivalve Shell and Carrara Marble δ18O and δ13C Signatures**

Stable isotope signatures of bivalve shells serve as important proxies of past environmental conditions. However, such data can be biased as a consequence of physical and chemical pretreatment and contamination during sampling. To systematically assess these issues, homogenized aragonitic shell powder, as well as Carrara marble powder (calcite) were exposed to ultrasound, a set of different staining solutions and cleaning agents that are typically employed in bivalve sclerochronology. Furthermore, these materials were artificially contaminated with peristrucrum, Alcian Blue and cured adhesives. Whereas some treatments had no effects, severe isotope shifts were observed after immersion in Feig's solution or contamination with certain epoxies. The majority of tested treatments conducted with the carbonate powders and contaminants added to them caused only minor to moderate isotope offsets. In conclusion, pretreatment of bivalve shells with an intended use for isotope analysis should be kept at an absolute minimum and contamination with adhesives etc. should be avoided. Specimens from museum collections may be of limited value for isotope studies, unless the
history of sample treatment is known. Although only a few of the tested substances and methods strongly biased the isotope signatures, even small changes can accumulate to levels that are unacceptable for environmental reconstructions.

Schott, Amy (University of Arizona, Petrified Forest National Park) [87] Using Soil Geomorphology to Understand Dry-Farmed Agriculture in Eolian Sediments in Northeastern Arizona

The Petrified Forest National Park in northeastern Arizona has a long record of prehistoric occupation, including within extensive deposits of semi-stabilized dunes and sand sheets. It has been hypothesized that during the Pueblo periods, inhabitants farmed these eolian soils. Eolian sands are not typically conducive to dry-farmed agriculture; however, dune farming is known ethnographically, and has been inferred in archaeological contexts on the southern Colorado Plateau. This paper investigates underlying geology to better understand landscape conditions that may have allowed eolian deposits to be conducive to dry-farmed agriculture. Soil geomorphic studies have shown very weakly developed soils with high clay content. This paper uses clay mineralogy and micromorphology to further understand the source of the high clay content, which may have increased water holding capacity of eolian sediments. This research will contribute to a better understanding of how the area's early farmers interacted with a dynamic eolian environment.

Schoville, Benjamin (University of Cape Town), Jayne Wilkins, Kyle Brown, Simen Oestmo and Terrence Ritzman [40] Functional Implications of Backed Piece Variability for Prehistoric Weaponry in the Middle Stone Age

MSA backed pieces are often thought to be components of projectile armaments; however, our limited understanding of their functional characteristics as projectiles precludes understanding the adaptive problems they may have solved. Despite widespread acknowledgment of raw material differences and inter- and intra-assemblage morphological variability, whether backed piece morphology reflects functional, economic, or stylistic variation has a paucity of empirical support. Here, the functional differences in backed piece morphology and hafting configuration when used as projectile armatures are examined. Hypotheses that relate backed piece function to morphology and hafting arrangement are tested using experimental and actualistic projectile replications against animal and gelatin targets. The results of this study show that the morphology of backed pieces plays a relatively limited role in their performance as long-range projectile armatures. However, hafting orientation has very different performance characteristics for arrows shot at ballistics gelatin compared to animal targets. Our results suggest that MSA backed pieces hafted as armatures were unlikely to have been used with small, low-powered bows, but would have been lethal with a high-velocity delivery system.

Schreiner, Nina and Kathleen M. S. Allen (University of Pittsburgh, Department of Anthropolo) [52] Early Contact Period Shell Trade and Bead Manufacture at a Cayuga Iroquois Site

During the early contact period in Northeastern North America, Native groups traded with both other Native groups and a variety of Europeans. Early trade began on a small scale with all parties eager to gain goods. Investigations at Carman, a Cayuga Iroquoian (Haudenosaunee) site occupied in the late 1500s, produced a quantity of shell beads, along with a small number of metal items refashioned from European copper and brass fragments. This paper is an analysis of the worked and unworked shell from the site. The majority of shell beads found at Carman are discoidal, likely used for personal ornamentation, and the standardized shapes of these beads hint at manufacture using shell column blanks traded west from the Atlantic coast. In addition, the large quantity of shell material (more than 50 beads and 675 g of unworked shell) found at this domestic site, along with apparent bead blanks, suggests that shell bead manufacture occurred at Carman. The shell and shell bead data situate the Cayuga within local and regional trade networks. This analysis also sheds light on changing processes of trade, manufacture, and adornment in the early contact period.

Schroeder, Sissel (University of Wisconsin-Madison) [163] Travels and Traverses, Pilgrimages and Passages: Alternative Concepts of Interaction

When confronted by the presence of nonlocal ceramics and stone tools, variations in artifact styles, the spatial distribution of settlements and settlement hierarchies, and evidence thought to indicate intergroup conflict, archaeologists typically turn to the general concept of “interaction” to explain these material residues. Furthermore, interaction scenarios sometimes are premised on the notion of inequities in resource access. When cultural behemoths like Cahokia are implicated in scenarios of interaction in distant locales, the interactions often are described as unidirectional moments in time, in part as a byproduct of interpretive constraints placed on us by the coarse-grained chronologies that currently exist for much of the Eastern Woodlands. In this paper, I unpack these issues, particularly looking at the question of how interaction registers in the archaeological record, problems of equifinality in the interpretation of behavioral origins of material culture, and I advocate for models that consider interactions in multidirectional and serial terms.

[153] Behavior Change in Hunter-Gatherers of the Namib: A Reanalysis of the Terminal Pleistocene Lithic Technology at the Mirabib Hill Rockshelter, Western Namibia

Originally excavated in the early 1970s by Beatrice Sandelowsky, the Mirabib Hill Rockshelter is located roughly 250 km southwest of Windhoek, Namibia, in the Namib-Naukluft National Park. This poster describes our reanalysis of the lithic technology recovered from Mirabib during the Sandelowsky excavations. The lithics examined in this poster were recovered from the lowest levels of the Sandelowsky excavation, just above bedrock, and date to around 19.5ka. This poster discusses the knapping strategies, patterns of tool design, and technological organization inferred from the Mirabib lithic assemblage in relation to shifting settlement systems between the last glacial maximum (LGM) and the termination of the Pleistocene. When other sites in the region are considered, we argue that the millennia surrounding the LGM were a turning point in the lifeways of hunter-gatherer populations in the Namib Desert. In this respect, we propose a model in which ecological and demographic changes induced local populations to move around the landscape in increasingly extreme ways and to occupy residential sites with greater intensity. Finally, we discuss some ways in which Namib Desert foragers may have coped with problems caused by increasingly extreme mobility patterns through the organization of their technological systems.

[160] Mississippian Communities in the Appalachian Summit of North Carolina

Three Mississippian villages from the Pisgah period (AD 1200–1600) in western North Carolina are reviewed and discussed—the Cane River Site (31Yc91), the Warren Wilson Site (31Bn29), and the mound and village at the Garden Creek Site (31Hw1). The elements of each community’s built environment, household architecture and domestic practices are evaluated and considered along with new radiocarbon dates from each site. These three Pisgah communities are situated in an unusual mountain environment for Mississippianization, reflecting the often overlooked variation in incorporation along the Mississippian frontier. This Pisgah tradition demonstrates how the environment within the Appalachian Summit influenced the late timing, tempo, and extent of adopting Mississippian practices. This region therefore provides a significant insight in discussions of variability in the processes of expansion and integration along the expanding edge of the Mississippian world.

Schuldenrein, Joseph (Geoarcheology Research Assoc)

Geoarchaeology is increasingly concerned with the analysis of perishable remains related to both the geological and archaeological components of a sediment matrix. Geological components range from measuring the age of 14C to quantifying and classifying the organic content of an ancient soil, to identifying the source of organic materials in anaerobic (poorly drained) landscapes. More recently, organic matter studies have been applied to historic artifacts and the deposits in which they are found. Both physical and chemical processes account for the mobilization of organic matter and its disaggregation at an archaeological site. An understanding of these processes is pivotal to reconstructing the site formation history of an archaeological location. We review the origins of progressively more sophisticated analyses of “archaeological organics” through time. We identify the processes of organic disaggregation in a variety of environmental and cultural settings. Organic matter analyses can take a variety of forms from visual assessments, to geo-chemical testing and microscopic inspection and probing at high levels of resolution.

[330] Explaining Isotopic Variability among the Hunter-Fisher-Gatherers of Lake Baikal

Lake Baikal is unique in continental northern Eurasia for the size of its large hunter-gatherer cemeteries with good preservation of human bone. Many hundreds of stable carbon and nitrogen measurements are available on human bone collagen, made over the last two decades. The isotope ecology of Lake Baikal is very complex and highly variable, showing one of the largest ranges of δ13C values in the world. Thus, it is not surprising that the human results show considerable variation. This contribution attempts to account for this variation, exploring factors including location, date, individual mobility and within-group differential access to aquatic resources. A model is proposed linking the complexity of the local/regional isotope ecology with the standardized range of variability observed in human datasets.

[164] Silver Production and Inka Expansion in the South Central Andes

Silver was an important component of the Andean prestige economy with bestowal and display of silver and silver-alloyed objects constituting a vital tool of Inka statecraft. The quest for mineral wealth was thus a motivating factor for Inka conquest of the South Central Andes. Nonetheless, the impacts of imperial incorporation on the organization and technology of metal production differed across this region of the empire. Focusing on the purification of silver ores, we present two case studies of Late Horizon metal production: the Puno Bay of northwestern Lake Titicaca, and the Tarapacá Valley of northern Chile. Each study combines regional survey data on the distribution of sites related to metal production with excavation at specific metallurgical sites and analyses of silver production debris. We document the spatial organization of the production process, from mining to refining as well as the
technologies involved. We show that Inka silver production in each location was shaped by the practical demands of the silver production chaîne opératoire as well as a combination of imperial goals and local circumstances.

Schulze, Niklas (FCSyH-UASLP)

Metallurgy in America: What Do We Know about Its Development and Diffusion?

Academic interest in “New World” metallurgy is more than a century old and has come a long way. New analytical technologies have allowed us to understand in ever greater detail the composition and structure of metal objects found in archaeological contexts. This makes it possible to identify raw materials, study production processes and life histories of artifacts. While our progress in questions of detail is indisputable, the opinions concerning the general development and diffusion of metallurgy in America have not been revised or questioned until now. This presentation will try to assess if it is necessary to change the current discourse and formulate new questions.

Schurr, Mark (University of Notre Dame)

Nitrogen Stable Isotopes and Infant Feeding Practices: Taking a Long View

Over the past 20 years, nitrogen stable isotope ratios have been used to explore infant feeding practices in ancient populations. In spite of many productive studies, uncertainties remain about how to interpret juvenile isotope ratios in regard to comparing feeding behavior across different populations, and the relationships of infant feeding practices to health, subsistence modes, environment, and social organization. Infant feeding practices are likely to be constrained by the biological demands of infants and mothers, but may vary within those constraints based on factors such as degree of sedentism, population size, fertility, class and ethnic variations, and the presence or absence of foods that can be substituted for breastmilk. Juvenile and adult stable nitrogen isotope ratios from six sites in the midcontinental USA, which span almost 5,000 years, provide an opportunity to examine the relationships between infant feeding practices as reflected in nitrogen stable isotope ratios across many dimensions. Subsistence practices ranged from hunting and gathering, through agriculture without domesticated animals, to early industrial agriculture. The intersite comparisons provide an opportunity to assess the range of infant feeding practices that are possible in a single environmental zone and how they systematically varied with biological constraints and cultural practices within and between populations.

Schwadron, Margo (NPS-Southeast Archeological Center)

Climate Change and Threatened Paleoeological Landscapes of South Florida

South Florida contains millions of acres of wetlands, subtropical estuaries and prehistoric waterways interconnecting thousands of tree islands and shell work islands, comprising one of the largest and most complex prehistoric maritime landscapes worldwide. Recursive human and natural dynamics shaped these landscapes over deep time, but will soon be lost by rising sea level. Integrated archaeological and paleo-ecological studies are critical to understanding the long term impacts of humans on the development, emergence, evolution and future of these landscapes before irreplaceable data is lost by climate change impacts. We present case studies for site protection and mitigating site loss, which include integrating ecosystem restoration, building living shorelines, and engaging locals in citizen science for heritage stewardship and resource management.

Schwartz, Christopher (Arizona State University)

Exploring the Deposition of Fauna in Public Spaces in the Tonto Basin, Arizona

The nature and performance of public rituals and have long interested archaeologists studying the prehispanic U.S. Southwest. The frequent deposition of animals in public spaces suggests that certain animals were important parts of public rituals and the broader activities surrounding them. In this poster, I explore the deposition of ritual fauna in the Tonto Basin area of central Arizona. Typically considered “Hohokam,” the Tonto Basin exhibits influence from the neighboring Sinagua region and the Puebloan northern Southwest. The emergence of the “Salado phenomenon” and socially integrative architecture in the region is evidence of broad sociopolitical and religious change involving specific treatments and storage of fauna. I use ethnographic evidence and faunal analyses to ask whether ritual fauna cluster in socially integrative spaces and what implications these patterns had for integrating migrant Puebloan populations with local people. I find that ritual fauna cluster in room contexts specifically associated with platform mounds. While faunal diversities in public spaces are normal given sample sizes, non-socially integrative architectural contexts fall below expectations, suggesting a centralization of ritual practice and storage. Ultimately, specific taxa were targeted by Tonto Basin communities for the enactment of public activities, which aided in the integration of nonlocal communities.

Inequality in the Academy: An Intersectional Analysis of Young College Men in Nineteenth-Century Lexington, Virginia

What can intersectionality offer to a study of an all-male antebellum dormitory? While this approach has typically been used to identify and combat race- and gender-based discrimination, this paper argues that intersectional theory can also illuminate subtle class- and age-based inequalities among historic individuals of the same gender and race. Archaeological investigation of Graham Hall, a combined dormitory/classroom space/chapel located on the campus of Washington and Lee University in Lexington, Virginia, has revealed a diverse array of material culture representing multiple activities, individuals, and social statuses. Viewed through an intersectional lens, Graham Hall becomes a locus of intersecting identities and hierarchies: as young men from disparate places and classes negotiated their positions within the student body, age-based hierarchies contributed to tensions and occasional power struggles between students and older community authorities. In engaging intersectionality in an atypical way, this research highlights the antebellum student body (and their associated artifacts) as not a single homogeneous whole, but as a spectrum of multivalent and multilayered axes of identity.

Schwartz, Lauren E. (UC, Riverside)

Understanding of Household Architecture at Night in the Middle Chamelecón Drainage, Honduras

Interpretations of Mesoamerican households tend to focus on activities that might rightly be associated with daylight hours and mostly informed by material culture that is moveable and multipurpose. However, intensive examinations of the non-moveable or architectural composition of household settings have recently revealed even more about these diverse and socially complex domestic spaces. This examination initiates an analysis of the interaction between humans and their built-environment as it pertains to shifts in use and meaning of household settings from day to night within the Middle Chamelecón region of NW Honduras. In particular, building designs and uses of interior and exterior spaces are examined for their similarities
and variations within and between different sized households. The importance of private and public spaces, socializing and utilitarian spaces, and the architectural adaptation of these over time will be explored as their practical and communal significance transitions once daylight fades. Adding the element of natural changes of illumination to what have mostly been interpretations of daytime household activity, further highlights the complexity of these social spheres of daily life and the challenges of interpreting the entanglement of the sacred and secular, as well as the mundane and extraordinary practices they comprised.

[96] From Biochemistry to Bone: Exploring the Stress Response in Archaeological Skeletal Remains
Bone is the foundation of the human body. In an archaeological context, the skeleton is the primary piece of evidence with which to explore past peoples and cultures. Because the skeleton adapts and changes over the life course, bone acts as a record-keeper, capturing specific periods of skeletal disturbance that we are able to observe and interpret. While the research potential using skeletal remains seems limitless, the primary challenge is that changes associated with poor health take time to manifest in skeletal tissues, inherently limiting what we are visually able to assess in osteological remains. However, through the integration of innovative biochemical methods that can identify the earliest stages of skeletal disruption, it will be possible to pinpoint changes in health not yet visible in the bone. This research compares visible skeletal changes associated with stress to biochemical fluctuations in protein (osteocalcin) and steroid (cortisol) levels to assess if these elements preserve in ancient bone and their relationship to gross macroscopic changes. Combining the interpretive power of these two chemicals in a novel and innovative way will make it possible to track periods of stress from the moment of onset through to visible skeletal change, leading to new interpretive possibilities.

Scott, Ann (Terracon/University of Texas at Austin)
[68] The Politics in Places: An Ethnographic Picture of Highland Maya Use of Caves and Other Landscape Voids in Guatemala
Caves and other sacred landscape features such as clefts in rocks and mountain voids embody special powers controlled by earthen, spiritual entities. To the Highland Maya that power personified by the earth owner needs to be maintained, appeased, and managed, even on a daily basis. This maintenance comes in the form of elaborate ceremonies utilizing a number of special items deemed suitable for pleasing the ancient entities. Mayan ritual specialists or daykeepers, who perform the ceremonies, are leaders in handling not only communication with earth owners, but also in coping with the politics of that leadership whether from the potent powers in the sacred space or modern challenges from communities, religious groups, or tourism. Our ethnographic work will present a case study of contemporary Highland Maya use of sacred space, both below and above ground, and how daykeepers manage the challenges from competing powers within that space and their struggle to keep the balance of the universe despite pressures from outsiders. Insider pressures will also be explored, as use of these sacred spaces for “dark” side practices is contested by the “light” side practitioners. We detail a number of strategies invoked to curtail site pollution, both physical and spiritual.

[96] Protein Modification in Fermented and Cooked Horse Milk: Taphonomic Implications for Archaeological Chemistry
Archaeological chemistry continues to expand by adopting taphonomic experimentation as a means to identify the effects of particular processes and conditions on the preservation of biomolecular remains. Analysis of ancient proteins through mass-spectrometry based proteomics requires that archaeological chemists observe and record protein modifications that occur related to processing and use behaviors. We conducted cooking and fermentation experiments using horse milk; we then assessed protein modifications in comparison to fresh horse milk. Such taphonomic studies are essential for developing rigorous targeted approaches in archaeological chemistry.

[151] A Comparison of Elemental Analysis Methods for Sediment Geochemistry
This poster will present preliminary interpretations from a study comparing different techniques of elemental analysis for sediment geochemistry, the goal of which is to determine the “best” technique to answer the questions at hand. “Sediment geochemistry” here refers to the collection of sediment samples and the elemental analysis of these samples in order to map activity areas across archaeological sites. This study used sediment samples collected from a modern, abandoned village called Eski Haciveller, located in the Marmara Lake Basin in Western Anatolia. The elemental composition of the samples was measured using three techniques—loose powder X-ray fluorescence, glass bead X-ray fluorescence, and inductively coupled plasma mass spectrometry—to determine which technique represents the ideal balance between sensitivity of analysis and the cost/labor of analysis. In addition, this poster will be presented as one part of a larger study of multiple sites in the Marmara Lake Basin, both modern and ancient. The poster will briefly cover both field and laboratory methods, as well as preliminary results and interpretations.

Scott, Lindsay (Department of Anthropology, University of Montana, Missoula MT), Anna Marie Prentiss (Department of Anthropology, University of Mon) and Matt Walsh (Department of Bioscience—Arctic Research Center)
Cultural transmission is an evolutionary process that involves the transfer of information between people that over time can lead to the establishment of cultural traditions. This approach permits development of hypotheses regarding the cultural evolutionary process in a variety of contexts. In this paper we examine cultural transmission between generations by analyzing the effects of vertical and horizontal inheritance using archaeological data from the Bridge River housepit village. The Bridge River site offers a unique opportunity to examine cultural inheritance across generations spanning the past 2,000 years. In this paper, we present the results of a phylogenetic study of projectile points drawn from the deeply stratified floor sequence of Housepit 54 at Bridge River. This permits us to assess variability in cultural inheritance between the many floors and potentially also between housepits.

[31] Exploring Intersectionality through Osteobiography: A Case Study from Early Medieval Ireland
Over the last decade, social identity has become well established as an area of bioarchaeological research. Although bioarchaeologists now examine a variety of identities in past societies (such as gender, age, and disability), it remains challenging to discuss the ways in which multiple identities intersect in the creation of individual lives. The construction of osteobiographies provides a means of investigating these intersections, in particular the interrelation of age with other aspects of social identity. Telling the life stories of individuals allows researchers to consider how aspects of identity affected the individual’s pathway through life, as well as whether the salience of particular identities changed over the life course. To demonstrate the value of osteobiography for exploring intersectionality in the past, this paper focuses on a case study drawn from the early medieval period in Ireland (c. AD 400–1200). The analysis integrates multiple lines of evidence, interweaving human skeletal, archaeological, and historical data, in order to reconstruct possible pathways through life. The resulting narrative highlights the interrelation of age, gender, status, and religion in the lives of the early Irish.

[174] Ritual Smoking: Evidence from Archaeological Smoking Pipes
Answering the question of what was smoked in prehistoric pipes benefits from a multi-proxy approach. Partially charred residue (dottle) provides more answers than does the black carbon that often lines the interior of archaeological pipes. Pipes examined from the American Southwest and Great Basin attest to use of a variety of plants, sometimes including ground maize, as smoking mixtures. Remains within the partially burned dottle are identified by pollen, phytolith, starch, macrofloral, and anthracological studies and also chemical (FTIR) signatures, then are compared with historic documents that indicate use of specific mixtures of plants in smoking pipes. Mixtures are documented to have included soft- and hardwood charcoal, conifer needles and lignin, tobacco, grass seeds, and/or maize (pollen or starch). The archaeological record suggests differences across cultural groups and through time.

[43] Diving into the PAST: Public Engagement with Florida’s Historic Shipwrecks
Florida’s historic shipwrecks are a natural draw for divers from all over the United States and the world. Many are located in warm, clear water, and all are home to an amazing variety of aquatic life. Capitalizing on the popularity of shipwrecks with sport divers, the Florida Bureau of Archaeological Research developed the Florida Underwater Archaeological Preserve program of interpreting historic shipwrecks for divers and snorkelers. Now numbering twelve shipwrecks, these “museums in the sea” have proven popular heritage tourism destinations, and effective vehicles for promoting the preservation of submerged cultural sites. Recently, the Florida Public Archaeology Network developed the PAST (Public Archaeological Shipwreck Tours) diving program to add another layer to historic shipwreck visitation and preservation. Focusing on the Preserves and other significant historic shipwrecks, the PAST program incorporates a presentation on the shipwreck to better describe its history and archaeology, and then an archaeologist-led tour of the site. Reflections on this program include a discussion of the successes of initial PAST events, participant feedback, and plans for the future to enable more divers to “Dive into the PAST!”

[237] Sourcing Basalt from the Santiago Quarry in Chihuahua, Mexico Using XRF
During survey in 2013, we identified the only known vesicular basalt quarry in the Casas Grandes region in northwestern Chihuahua, Mexico. Using XRF, we analyzed basalt from the Santiago Quarry and compared the results to the chemical characterization of formal tools (mostly mano and metate fragments) recovered at the site of Paquimé in order to determine if this quarry was one of the sources exploited by prehistoric stoneworkers during the Medio period (AD 1200–1450).

Sears, Erin (University of Kentucky/Smithsonian Institution)
[320] You’re Not from Around Here, Are You? Ceramic Figurines and Interregional Interaction in the Tres Zapotes Region
The multiyear study of the ceramic figurines of Tres Zapotes recovered from archaeological explorations at the site center and the surrounding area indicate patterns of interactions throughout the development of the region. Supplemental museum specimens from past excavations at Tres Zapotes, residing in the National Museum of Natural History of the Smithsonian Institution, were also incorporated into laboratory analysis. The data are examined for evidence of exchange with other communities, particularly in central and southern Veracruz, the Teotihuacán core area, and the Maya region. While the Drucker and Weiant classificatory descriptive systems are still useful, they fail to capture some technological and aesthetic features reflective of interregional interaction. The aggregation of figurine material permits new interpretations of how the ancient Tres Zapotes community related to others through time.

[141] Grounding Futures in Pasts: Eastern Pequot Community Archaeology in Connecticut
Collaborations between archaeologists and Native communities have expanded significantly in the past 20 years. For most, this is recognized as an important and healthy development on methodological, theoretical, practical, and political grounds, especially when anchored deeply in the communities themselves and designed to address political as well as professional issues. We have worked together in different capacities for more than 13 years on the Eastern Pequot Archaeological Field School, a joint venture between the Eastern Pequot Tribal Nation and the University of Massachusetts Boston, to find ways to better orient archaeology to contemporary heritage and political concerns, community participation across generations, land management, and historical and cultural preservation. This effort has involved an equal emphasis on both process and product; careful attention to the linking of methods and materials with local knowledge and social memory; and a comparative and ever-changing perspective on the potentials and pitfalls of collaborative practice.

Improving Radiocarbon Dating with Ancient DNA Analysis

Recent advances in ancient DNA (aDNA) analysis have helped to shed new light on long-standing archaeological questions. Researchers can now study how elites and commoners may have been genetically related, the genetic heritage of the first migrants to a particular area, how ancient populations are related to modern groups, and more. While such revelations have been of critical importance to archaeology, results from recent analyses have implicated that ancient DNA analyses can also be applied to methodological issues in archaeology. In particular, by identifying the relatedness of two or more individuals, aDNA analyses can sometimes be used to improve the dating of specimens and/or sites. This paper discusses recent aDNA research that has identified multiple sets of ancient individuals who are first-degree relatives (parent-offspring or siblings), but have a difference of 100 years or more in radiocarbon age ranges. These case studies are then used to examine how aDNA analysis can be used to supplement radiocarbon dating in three particular ways: by identifying the need for the re-dating of samples; to help tighten the radiocarbon age ranges for individuals and sites; and possibly help calibrate the radiocarbon curve.

Shifting the Interpretation of Ohio Hopewell Copper Use

The dramatic uses of copper by Ohio Hopewell social networks have been studied for over one hundred years and have resulted in a diversity of archaeological perspectives. Our recent physiochemical study of particular Hopewell artifact classes is the most extensive to date and has resulted in source identifications that require that extant models be revised in light of our findings. Particular attention will be given to the implications that: 1) a diversity of Lake Superior outliers were utilized; 2) the use of sources along the "Mica Road" to the southern Appalachians has been demonstrated for the first time; and 3) that copper source usage clearly differed from other recently sourced exotic Ohio Hopewell materials, notably silver and pipestone.

Vestigial Religion: The Legacy of Byzantine Christianity in Ottoman and Venetian Greece

This paper offers a glimpse into the roles played by religion during the decline of one empire and the emergence of another, from the perspective of a historical case study: the Mani Peninsula. Mani is a peripheral region in the Peloponnese, Greece, that converted to Orthodox Christianity under the Byzantine Empire, and its occupants maintained this religious identification throughout the subsequent periods of Ottoman and Venetian rule. This unbroken religious continuity, which can be traced in both the archaeological and historical records, can help us to understand the perseverance of a state religion even after its collapse, particularly in marginal and rural landscapes. The paper begins with a review of previous research on the Byzantine churches in Mani and offers new interpretations as to how religion functioned in the everyday lives of the rural population. Data are presented from recent fieldwork in the region, detailing what happened to the churches following Byzantine collapse, and in particular how they functioned in relation to
the people living in nearby communities. Finally, the paper explores the contentious relationship between local residents and the emerging Ottoman Empire and suggests that Orthodoxy was a key element in undermining the new state’s power in the region.

[101] *The View from Above: The Semi-Autonomous Elite Maya Hilltop Complex of Escalera al Cielo*  
Escalera al Cielo (EaC) is a Terminal Classic Period Maya elite hilltop complex located 1.5 km to the west of the site of Kiuic in the Puuc Region of the Northern Lowlands. Previous research on the hilltop focused largely on investigating the organization and day-to-day activities associated with the northern residential architectural group. The southern group, located atop the highest spur of the hill and consisting of four vaulted masonry structures accessed by a grand staircase, was believed to be the civic-ceremonial center of the complex. Excavation data from the 2008 and 2016 field seasons suggest that the southern group served a residential function in addition to a civic-ceremonial one. The presence of at least two distinct residential areas with vaulted architecture atop EaC suggests the presence of multiple elite families. The impressive architecture of these landholding families, their reverence for a distinct patron god combined with other factors suggest that the residents of EaC maintained a degree of semi-autonomy from the political center of Kiuic. This paper presents findings from the 2016 excavations in combination with preliminary excavations from 2008 to discuss the implications of semi-autonomous elite groups for the sociopolitical and economic organization the Terminal Classic Kiuic polity.

[310] *Ancient Zapotec Material Culture and the Antiquities Market*  
While the growth of the Internet market in precolombian antiquities is of great concern to the countries of origin and law enforcement, we should also recognize that the Internet is a crucial tool in the fight to protect cultural materials. In particular, online databases that were once created for purely scholarly purposes, can be effectively used to track stolen, lost or exchanged artifacts. This talk will focus on my own experience, for over a decade now, of managing a database that catalogues Zapotec urns, a coveted ceramic object among museums and collectors. From this vantage point I hope to expose the double-edged sword located between the scholarly pursuit of knowledge and the requirements of the art market.

Semon, Anna (University of North Carolina)  
[377] *Examining Small-Scale Variations within Late Mississippian Complicated Stamped Pottery from St. Catherine’s Island, Georgia*  
Late Mississippian (AD 1300–1580) ceramic typologies on the Georgia coast broadly group pottery based on 1) temper (coarse grit) and 2) surface decoration (incising, stamping, and rim decoration). Recently, Late Archaic and Mission period pottery studies focused on small-scale ceramic variations, which reflect micro-styles, were successful in identifying patterns related to past pottery communities of practice. Using a similar approach, I present data on three Late Mississippian village ceramic assemblages recovered from St. Catherines Island, GA. In this presentation, I focus on Irene Complicated Stamped wares as a case study and characterize the small-scale variations in temper, paste, and design motif from each site. In addition, I compare patterns between sites and explore various pottery communities of practice. More broadly, these data contribute to our understanding of Late Mississippian pottery practices and social interactions along the Georgia coast, on the cusp of European contact.

[152] *Ostrich Eggshell Taphonomy and Distribution at Knysna Eastern Heads Cave 1*  
Analysis of ostrich eggshell (OES) fragment distribution at Knysna Eastern Heads Cave 1 (KEH-1) revealed taphonomic patterns. The variation of OES features and its distribution indicates that the OES was being used and processed differently in temporal and spatial context. KEH-1, a cave on the southern coast of South Africa, was inhabited by early modern humans throughout the Middle and Late Stone Age. Hearth features are prevalent throughout the sequence, providing evidence of occupational intensity and material processing. The abundance of OES found at KEH-1 allows a comprehensive analysis of OES modification and distribution. OES found at KEH-1 was coded according to color, texture, size, and whether or not it had been burned. The observed features of the OES, along with the stratigraphic context, was then used to interpret distribution patterns, which indicate that human exploitation of OES changed throughout the late Pleistocene. Analysis of the distribution correlates a correlation between the variation of features with hearths and stratigraphic aggregates. Early humans at KEH-1 left distinct taphonomic indicators on the fragments of OES left behind after processing. Further experimental taphonomic research may allow more detailed conclusions about the variation in human exploitation of ostrich eggs in South African prehistory.

North/South Archaic Mobility in Dry Puna: Hunter-Gatherers from Upper Azapa Valley Basin, Northern Chile

The different models of hunter-gatherer mobility in South Central Andean area, despite its theoretical and conceptual factors, normally emphasize for the Archaic Period the complementarity between vegetation belt for various biotic resources, depending on availability, location and seasonality. Here we complement such models at a meso-scale level, based upon results from surveys and excavations in upper Azapa valley basin, a region located at the foothills of the Northern Chile Cordillera. Our dataset includes open-air and rockshelter sites and the chronological attributions are based on relative and absolute dating. The characterization of site’s function and the analysis of raw materials allows us to precise a north/south mobility, between the Peruvian southern highlands and Chilean northern ones, between 2,500 and 4,000 m above sea level. Without excluding direct mobility of these groups to the high Puna to the east or to the Pacific coast to the west, or the acquisition via exchange of raw materials and products of foreign origin, we argue that settlement patterns between ~ 9500–1500 years BP, would correspond to a greater territorial reach over time associated to a significant rock art practice.

Liturgical Textiles from the Spanish Colonial Reducción of Santa Cruz de Tuti, Colca Valley, Peru

A highly visible symbol within the church, liturgical cloth plays an important role in the communication of ideas about the wealth and authority of the Catholic Church. During the colonial period in the Andes, the influence of liturgical textiles extended to reinforcing ideas about the power of the Spanish Empire as well as the role of indigenous populations within it. Although cloth production during the period of Spanish colonization is a subject discussed to some extent by art historians looking to better understand the garments and tapestries found in museums and churches across the Andes today, very little research has been conducted on colonial textiles recovered from archaeological contexts. This paper presents a discussion of textiles recovered in the laboratory. In the actual poster, I will explain the excavations techniques that we used at Gualupita Morelos, a Preclassic site, and the information recovered from a household.

Prehistoric Pipe Replication and Analysis: A Deeper Look into the Bowl

Smoking pipes have played an integral role for many American Southwestern groups. My research project conducts a thorough investigation into the construction of prehistoric ceramic and stone pipes. Using only stone tools, I conduct construction and use-wear analysis on the tools used to create pipes as well as the pipes themselves. I analyze the two materials most used among Southwestern Native American groups, local Southwestern clay (from the Tucson Basin) and vesicular basalt. Measuring the time spent using different techniques such as drilling, pecking, grinding, and clay shaping I investigate the most efficient methods for producing stone and ceramic pipes. Analyzing tool use wear also provides insights into different wear patterns from different techniques. This research helps us understand the efforts prehistoric groups took to create objects of spiritual importance and aids in the understanding of their construction.

*Ritual and Rag Trees in Contemporary Ireland*

In Celtic countries, early Christianity was synchronized with preexisting religious beliefs and rituals, some of which were maintained and modified through the centuries, while others were subsequently adopted but understood as ancient or essential. One ritual practice inhabiting the border of Christian and non-Christian tradition is seen in the Irish rag tree, a hawthorn with strips of cloth hanging from the branches, often located at holy wells or other Early Medieval ecclesiastical sites. People burdened with ailments, or worried about those of their loved ones, tied a bit of cloth to the tree, said a prayer, and believed that when the rag disintegrated so too would the affliction. This practice may be no older than the nineteenth century, but the association of supernatural powers with trees in Ireland dates to the pre-Christian era. Although the practice had been waning, rag trees are currently experiencing a resurgence as manifestations of diverse and fluid belief systems. Rag trees are prominent at numerous archaeological, historical, and natural sites and are understood in different ways by Christians, neo-pagans, Irish Travelers, and foreign tourists, necessitating a complicated and nuanced academic understanding of this practice and the motivations of those who engage in it.

*Crystal Creek Water Ditch: From Past to Present and Future*

The Crystal Creek Water Ditch, located within Whiskeytown National Recreation Area (NRA) west of Redding, California was built between 1852 and 1859 for the purposes of gold mining and conveying water to the nearby Tower House Hotel that was situated along the historic travel corridor between Shasta and Weaverville during the California Gold Rush. The ditch provided water for the hotel gardens, orchards, and for small-scale gold mining along the creeks. The ditch consists of two sections which total 2.5 miles and include headworks, crossovers, retaining walls, wooden gates, as well as a levy, silt trap, overflow float, power generator, cut-out shed, inverted siphon, storage tank, and down drain. The levy has been continuously utilized as a trail, first by the ditch tenders and later as a hiking trail by the National Park Service. Most components are still present and were working until 2013 when an unanticipated water release damaged large sections of the lower portion of the ditch. This has provided an opportunity to fortify the ditch and rehabilitate deteriorating constituents using period-appropriate construction techniques for increased interpretation and visitor use opportunities.

*Going beyond Science: The Tangible and Intangible Contributions of Community Archaeology*

It is widely recognized that archaeologists have the potential to contribute in meaningful ways to local communities. However, it is also important to consider the tangible and intangible nature of these contributions given the diverse and, sometimes, competing interests among various stakeholder groups along with the seasonal nature of academic archaeological and heritage research. Multiyear collaborative projects often facilitate greater general awareness of local heritage, open new opportunities for heritage tourism, and contribute toward reflections of local, regional and national identities. In this presentation, we draw examples from nine years of the Cultural Landscapes of the Irish Coast (CLIC) project, centered on the islands of Inishark and Inishbofin, off the west coast of Ireland, to examine how archaeological projects (broadly defined) contribute in tangible and intangible ways to heritage construction, island identity, and a sense of value and importance of local history and archaeology.

*Burned Earth without Cooking Stones: Cultural or Natural? Feature Deposition, Ethnobotany, and Analysis in Upland Puget Sound, Western Washington*

Concentrations of burned earth, cooking stones, a shallow basin profile, and sometimes faunal remains are often associated with Puget Sound hearth features which were commonly used for open-air cooking. Discrete areas of burned earth lacking concentrations of cooking stones have not received as much cultural feature recognition or interpretation. This poster explores the function of one in situ concentration of charcoal adjacent to a dense area of cooking stones at an upland camp in the Puget Sound basin of northwest North America to determine one of three scenarios. Is this feature a steaming pit in two parts, a dismantled pavement with a primary and secondary context, or a naturally burned tree near a secondary deposit of cooking stones? Deposition, ethnobotany, and feature analysis are used to examine the function of Feature 1 at 45KI1176.

**Sharapov, Denis (University of Pittsburgh)**

*Early Polities in the Steppes: Sintashta Communities of Southern Russia*

First polities in the Eurasian steppes are documented by the Greek and Chinese historical accounts of the Scythians (ninth–third centuries BC) and the Xiongnu (third century BC–first century AD). Archaeologically, these entities manifested themselves in complex settlement networks, consisting of fortified sites, dispersed farmlands, and mobile pastoral camps. Earlier roots of political organization in the Eurasian steppes are largely limited to funerary and ceremonial monuments, which presumably served as aggregation points for dispersed populations. In this context, more than twenty Middle Bronze Age (MBA) (2100–1700 BC) nucleated fortified settlements, concentrated in the Southern Ural steppes of Russia, commanded particular attention of archaeologists. Given that integration of settlements at a supra-local scale has been considered a hallmark in the emergence of complex societies, the isolated and completely centralized nature of MBA sites precluded viewing them as centers of early polities. However, a recent systematic regional survey recovered diagnostic MBA material from a number of unfortified settlements located some distance away from the fortified centers.

*A Week in the Life of the Mousterian Cows Hunter: A Mousterian Hunting Location on the Banks of the Paleo-Hula Lake*

Eight excavation seasons (2007–2014) at the Mousterian site of Nahal Mahanyeem Outlet (NMO) on the banks of the Upper Jordan River offer a glimpse into the lifeways of MP people during a hunting expedition in the Upper Galilee. This open-air site, OSL dated to ca. 60ky BP, is interpreted as recording a series of short-term hunting events. The NMO horizons, with their small number of lithic artifacts, unique typological composition and evidence for task specific hunting and butchering activity fit within Binford’s (1980) definition of a “task location.” The NMO findings include excellently preserved organic material, including animal bones, both micro and macro-fauna and botanic remains. We have now acquired information and data that enable us to suggest models that reconstruct the nature of the site and human behavior reflected in its layers and finds. Issues of cognitive abilities, hunting praxis and subsistence strategies, site function and group mobility all are in need of new, high resolution data that NMO can provide.
Moreover, the high resolution stratigraphy and, above all, the excellent preservation of botanic and pollen remains can achieve a comprehensive picture of the Late Pleistocene environment and its impact on human diet, subsistence and survival.

Sharp, Emily (Arizona State University) and Rebecca E. Bria (Vanderbilt University)

**Ritual Violence or Simply Ritual? Evaluating the Evidence for Child Sacrifice in Late Formative Period Peru**

Highland mortuary practices during the Andean Late Formative Period (900–500 BC) in Ancash, Peru are poorly understood, in part because burials from this period are rarely encountered. Excavations conducted in 2009 at the archaeological site of Hualcayán uncovered a primary interment of a juvenile aged 5–6 years at time of death, dated in the range 806–540 cal BC. The individual was buried with a necklace strung with bone and shell beads and bone spools. Bioarchaeological analyses indicate the juvenile sustained possible perimortem trauma to the basicranium and the second cervical vertebra. A differential diagnosis of perimortem and postmortem trauma will be completed to evaluate this individual’s status as a possible ritual sacrifice. Determining the etiology of these fractures, whether resulting from a violent act or more accidental behavior, is complex and requires knowledge of the burial context. Drawing on insights from forensic analyses of trauma and archaeothanatology, this paper will assess how taphonomic processes impact interpretations of skeletal fractures and the burial environment. It will subsequently explore how these issues affect the juvenile unearthed at Hualcayán. This relatively complete burial provides important insights into the treatment of children and their role in ritual activities during the Formative period in the north-central Andes.

Sharp, Kayleigh (Southern Illinois University Carbondale) and Juan Martinez (Bruning Archaeological Museum)

**Multi-crafting in Coexisting Gallinazo-Moche Contexts at Songoy-Cojal, North Coast, Peru**

Over the past few decades, it has been recognized that craft studies often overlook the social significance of crafts practiced concurrently. How does the selection of certain types of materials inform on the relationship between manufacturers and consumers? Does multi-crafting imply broader social relations? Or does multi-crafting imply locally meaningful social relationships through the various types of crafts produced? This paper explores the multi-craft traditions practiced in coexisting Gallinazo-Moche contexts at the Songoy-Cojal site in the mid-Zaña valley, North Coast, Peru. In this presumably multiethnic setting, evidence of pottery, stone, metalworking and metallurgical traditions are suggestive of complex social interrelationships that may help to define key aspects of social organization within the site and in the Lambayeque region more broadly. In particular, I explore the relationship between users and manufacturers of stylistically Gallinazo (or Virú) and Mochica artifacts, testing the hypothesis that this mid-sized center may have held a disproportionately high significance within the broader Lambayeque region.

Sharpe, Ashley (University of Florida)

**Lead (Pb) Isotope Analysis as a Means of Tracking Animal Migration and Trade in Mesoamerica**

This study examines the first use of lead (Pb) isotope analysis as a means of tracking animal movement and exchange in the Maya area. Strontium and oxygen isotope ratios have been previously used to track animal and human movements archaeologically in Mesoamerica. Lead has been used to track movement and exchange in other parts of the world, and its application to Mesoamerican archaeology holds great potential for refining sourcing strategies. This study identifies local and nonlocal fauna at the Maya site of Ceibal, Guatemala, which has one of the longest occupational sequences of any Maya community (c. 1000 BC–AD 950), allowing for a long-term examination of animal use and exchange. Nonlocal animals identified at Ceibal are sourced to their potential place of origin using a new lead isotope baseline map for the Maya area. The study reviews the advantages of using the three lead isotope ratios (208, 207, 206Pb/204Pb) in conjunction with strontium (87Sr/86Sr) in Mesoamerica, and examines potential sources of error from modern lead pollution.

**Contrasting Communities: Relationship Change in the Western Isles of Scotland**

The paper is an examination of the cultural differences that exist within the Western Isles and how these relate to similarities and differences with other areas of the North Atlantic, such as the Orkney and Shetland. It will focus on the changes that occur in the first and second millennium AD; the relationship with the Picts and Scots, the transformation brought about by the Vikings and the integration of the islands into the Kingdom of the Scots. These political changes can be compared and contrasted with changes in architecture and material culture that express a much more nuanced pattern of cultural transformation.

Sharratt, Nicola (Georgia State University)

**Rejection and Reinvention: A Diachronic Perspective on Ritual and Collapse in the South Central Andes**

Scholarship on Tiwanaku (AD 600–1000) emphasizes the ceremonial nature of its capital city and the role of ritual practice in incorporating diverse groups as the state’s influence expanded across the south central Andes. Although debate continues about its cause, recent research indicates that the Tiwanaku state’s political collapse played out over several centuries. In this paper, I draw on data spanning that period of fragmentation to take a diachronic perspective on the ways in which ritual, which had been so tightly intertwined with state politics and elite authority, was impacted following collapse. Examining both community ceremonial activity and funerary rites I propose that, during the height of the Tiwanaku state, ritual practice played an important role in the shifting sociopolitical landscape brought about by collapse. In the short term (AD 1000–1250), many Tiwanaku rituals were maintained but subtle shifts in funerary rites and the resituating of collective ceremonies reveal how populations confronted intra and inter community tensions. I then examine the longer term rituals (post AD 1250), and explore why Tiwanaku collective ceremonial practice ultimately disappeared from the archaeological record, but elements of funerary ritual endured.

**Beyond Radiocarbon: Using AMS Samples to Assess Woody Plant Use at Tse-whit-zen**

**Chair**

Shaw, Jennie (Salix Archaeological Services LLC) [228]
Paleoethnobotany, while not a nascent field, is still an underutilized research framework in Pacific Northwest (PNW) archaeology. But increasingly, PNW projects have incorporated macrobotanical analyses as a precursor to radiocarbon dating. Analysts provide taxonomic identifications of woody fuel remains and assist in selecting fragments from short-lived genera that will mitigate the old wood effect, thereby increasing the accuracy of dates. This paper assesses the utility of an anthracological study of over 400 charred wood fragments from the Tse-whit-zent site, a large coastal village in northwest Washington State. At least 15 genera of trees and shrubs were burned at Tse-whit-zent, including plants traditionally harvested for foods, fuels, medicines, and tools. Radiocarbon “pre-analyses” such as this one offer a convenient opportunity to access botanical knowledge at a smaller scale than grand paleoethnobotanical research initiatives and, with appropriate caveats, can contribute to the greater understanding of local fuel selection, household activities, and plant management practices.

Sheets, Payson (University of Colorado) [80] Darkness at Noon and a Whole Lot More: The Temazcal at Ceren

When people entered the temazcal at Ceren and shut the door, they created utter darkness at any time during the day. Their preparations were elaborate, involving obtaining permission from members of Household 2, who had a service relationship in maintaining the structure. They provided pine firewood and water in ollas for creating steam and as well as for ablutions after partaking. Creation of a fire in the domed firebox heated and smoked up the interior; then a plug was removed from the roof to clear out the smoke. Next, water was poured over the firebox to create steam, and when all were inside, darkness rose as they shut the door. Copal was burned to access spirits, deities, or other supernaturals. Our usage of the 1:1 replica of the temazcal has been instrumental in revealing unanticipated consequences of the darkness: we were stunned with how the dome transformed our verbal communication. Whether words were spoken or sung, voices were greatly amplified and tones were significantly lowered. This soundscape must have played a major role in the supernatural powers invoked by participants. Interior size allows for at least a dozen people, indicating that the temazcal probably served various functions for different groups.

Shelach, Gideon (Hebrew University) [26] A reexamination of Bronze Age trans-Eurasian interactions

Bronze artifacts from different parts of the Eurasian steppe zone have been used to argue for prehistoric interactions among the societies that lived in this region during the late second and early first millennia BCE. Indeed, similarities among such artifacts as knives and daggers with animal heads are telling. But what was the nature and intensity of such interactions and their effects on the local communities? In this paper I will address those questions by looking at specific well dated contexts and by correlating the bronze finds with data relevant to our understanding of the subsistent and political organization of the local societies in the eastern part of the Eurasian steppes.

Sheldrick, Nichole (University of Oxford) [57] Endangered Archaeology in Arid Lands: Remote Sensing and Heritage Management

The Endangered Archaeology in the Middle East and North Africa Project (EAMENA) uses satellite imagery to record damage and threats to the heritage of the MENA region. We are recording these data in an open-access database to create a useful platform for the management and protection of heritage in these countries. A remote-sensing approach to heritage management has many advantages and is particularly effective in the arid MENA region due to limited vegetation and development. The availability of satellite imagery via platforms like Google Earth makes it possible to identify and monitor sites remotely in a swift and cost-effective manner. In addition, as a result of ongoing conflicts, it is increasingly difficult to gain access to many sites in the region, making remote sensing an ideal alternative. Using case studies from Egypt, Libya, and Saudi Arabia, I will present EAMENA’s methodology and demonstrate its potential for heritage management in arid regions. Many sites in these regions are under threat from factors including development, mining, and agriculture. Although not all disturbances to sites in these regions can be prevented, by combining remote sensing with the work of local archaeologists, we can mitigate the effects of these problems in the future.

Shepard, Ben A. (UCLA), Vladimir Ivanovich Bazaliiskei (Department of Archaeology and Ethnography, Irkutsk), Olga Goriunova (Department of Archaeology and Ethnography, Irkutsk), Michael Richards (Department of Anthropology, University of British) and Andrzej Weber (Department of Anthropology, University of Alberta) [330] A Geochemical Investigation of Sociopolitical Structure among Holocene Hunter-Gatherers in the Cis-Baikal’s Little Sea Micro-Region

We present the results of a large-scale comparative study of individual life histories among hunter-gatherer groups inhabiting the western coast of Lake Baikal (Russian Federation) during the Late Neolithic (5700–4900 cal BP) and Early Bronze Age (4900–3700 cal BP). More specifically, we employ data on stable strontium isotope (87Sr/86Sr) values from tooth enamel collected from human molars (M1-M3), along with associated data on variation in isotopes of carbon (δ13C) and nitrogen (δ15N) to provide a glimpse into individuals’ long-term mobility practices and subsistence activities. Using these data in conjunction with archaeological data on grave goods and the placement of interments at cemeteries (single/multiple interments, grave rows, grave clusters), we suggest that the Late Neolithic-Early Bronze Age transition featured changes in group structure that are broadly consistent with a hypothesized decline in corporate political economic strategies during the Early Bronze Age.
Southwest and northwestern Mexico (SW/NW). Because they occur earlier in Mesoamerica and are the most Mesoamerican-like of the SW/NW blue-green stone creations, we propose that the production and use of these artifacts in the SW/NW was derived from Mesoamerica. We describe the degree to which mosaics manufactured in the SW/NW resemble and differ from those crafted in Mesoamerica. Using examples from Chaco Canyon, the Mimbres region, and Paquimé, we discuss how the mosaics are revealing of Mesoamerican-like practices and adapted for use in distinctly SW/NW ways. Their rareness and this association with distant places imply high value and restricted access. Thus, mosaics seem likely to be associated with architecture of power. This distributional hypothesis is tested through analysis of the spatiotemporal distribution of blue-green stone mosaics in the Hohokam region. Finally, we discuss the implied uses and meanings of mosaics in the SW/NW based on both their depositional contexts in powerful ritual structures and ethnographic analogy. We propose that the mosaics, rich with ideological associations related to their blue-green color, embodied the concentration of ritual power derived from distant sources.

Blue-Green Stone Mosaics in the U.S. Southwest and Northwestern Mexico: Origins, Spatio-Temporal Distribution, and Potential Meanings

Intricately-crafted mosaics are prevalent among blue-green stone artifacts created in prehispanic Mesoamerica, but are rarer in the prehistoric U.S. Southwest and northwestern Mexico (SW/NW). Because they occur earlier in Mesoamerica and are the most Mesoamerican-like of the SW/NW blue-green stone creations, we propose that the production and use of these artifacts in the SW/NW was derived from Mesoamerica. We describe the degree to which mosaics manufactured in the SW/NW resemble and differ from those crafted in Mesoamerica. Using examples from Chaco Canyon, the Mimbres region, and Paquimé, we discuss how the mosaics are revealing of Mesoamerican-like practices and adapted for use in distinctly SW/NW ways. Their rareness and this association with distant places imply high value and restricted access. Thus, mosaics seem likely to be associated with architecture of power. This distributional hypothesis is tested through analysis of the spatiotemporal distribution of blue-green stone mosaics in the Hohokam region. Finally, we discuss the implied uses and meanings of mosaics in the SW/NW based on both their depositional contexts in powerful ritual structures and ethnographic analogy. We propose that the mosaics, rich with ideological associations related to their blue-green color, embodied the concentration of ritual power derived from distant sources.

The Settlement Patterns of the Mid-Fraser Region of British Columbia: A Statistical Analysis of Housepit and Village Sizes

This poster presents a settlement pattern analysis calculating the relative size distribution of housepit villages along the Mid-Fraser Region of British Columbia. The precontact settlements in this study area, along the Fraser River plateau between Yale and Big Bar, are among the largest hunter-gatherer communities anywhere in the world. While previous studies in the region have concentrated on the Keatley Creek, Bell, and Bridge River housepit village sites, the research presented in this poster greatly expands on these analyses by utilizing a sample size of over 1,000 housepits from 49 villages in the region. In addition, while previous studies on settlement sizes in the area have focused on either the number of housepits or the size of individual housepits—the research in this poster uses a calculation of total roof area as a means of analyzing both housepit and settlement size and their potential statistical size classes. Investigating discrepancies in housepit and settlement size classes can give insight into potential hierarchies among settlements and can be used to infer social stratification. This method, of using site size as an index of use for a settlement location, has previously been used in the American southwest to document social stratification.

Hybrid Cultures: The Visibility of the European Invasion of Caribbean Honduras in the Sixteenth Century

Archaeological excavations in Caribbean coast Honduras explored the site of Ticamaya, described in sixteenth-century Spanish documents as the seat of a leader of indigenous resistance. Yet despite testing confirmed deposits from the period covering initial conflict with the Spanish, roughly 1520–1536, these excavations produced no use of European goods until the late eighteenth century. Contemporary with Ticamaya, the site of Naco to the west hosted troops sent by Cortes, and at least one majolica vessel was discarded there. The contrast could lead to the conclusion that Ticamaya was unaffected by the Spanish encounter until it was conquered. In our presentation we offer an alternative: emphasizing the novel construction of defensive walls at Ticamaya and its allied sites as likely material traces of innovations mediated by Spanish knowledge mobilized for indigenous resistance by a shipwrecked sailor turned strategist against Spanish invasion. Our proposal seeks to blur apparently firm lines between native and foreign materialities and define a third option of hybrid cultures.

Investigating the Nature and Timing of the Earliest Human Occupation of North America Using a Novel Integration of Biogeochemistry and Micromorphology

Paisley Caves, Oregon, is one of the key sites in current debates surrounding the peopling of the Americas. Ancient DNA evidence for human occupation of the cave has been debated, and coprolites have been said to be visually dissimilar to human faeces. This has implications for how we understand early occupation and migration in this part of North America. Our project will contribute to this debate, using a novel integration of biogeochemistry and sediment microstratigraphy. The aim is to assess the taphonomy of fecal biomarkers within the cave sediments, alongside secure dating through compound specific 14C of lipid residues. By analyzing lipid biomarkers, this project will identify the species of a large collection of coprolites from the cave, as well as investigating the dietary evidence contained within them. Compound specific 14C will provide very precise dates for dating through compound specific 14C of lipid residues. By analyzing lipid biomarkers, this project will identify the species of a large collection of coprolites from the cave, as well as investigating the dietary evidence contained within them. Compound specific 14C will provide very precise dates for occupation, which can be linked with the dietary evidence to assess seasonality of occupation and resource use.

Nested-Context Perspective of Craft Production: Middle Sicán Metallurgy

Different facets and stages of craft production commonly occur in different spatial loci regardless of differences in medium, technology, intensity and/or scale. Locational differences may be relatively minor with different facets or production stages being practiced concurrently, or masters and apprentices occupying different areas of a given room or workshop. While sheet metal preparation and alloying both require constant heat sources, the former...
requires a clean area protected from winds and dust. Locational differences can also be major, involving different settlements as with the case of primary smelting and subsequent metalworking; the former being heavily influenced by natural/material factors and close to ore and fuel sources and reliable winds. The latter is much more dependent on social/human factors such as the nature of artisans involved and intended use and users of products. Accordingly, clarification of spatial dimensions of craft production requires what I call nested-context approach and an accompanying multi-scalar and dynamic, processual perspective. Based on data garnered over nearly four decades of holistic research on the Sicán metallurgy, this paper will illustrate how the approach and perspective can be applied for valuable understanding of the spatial dimensions of this complex craft.

Shiratori, Yoko (Graduate Center, CUNY) and Timothy Pugh (Queens College and The Graduate Center, CUNY) Exemplary Centers as Quintessential Places: Migrants and Architectural Quotations in Late Postclassic Petén, Guatemala
Exemplary centers are physically schematized archetypes which represent and communicate social realities and political orders. Such exemplary centers are quintessential places, as they represent identity and memory. Migrating populations frequently reconstruct exemplary centers that replicate homelands through materials and images demonstrating their identity. Such “architectural quotations” help the migrants to legitimate social and political positions in the new locations. Members of groups perform commemorative ceremonies to demonstrate social memories at the exemplary centers. In so doing, a sense of collective identity is reinforced through the past. The Late Postclassic (AD 1250–1525) Maya groups in Petén, Guatemala, claimed origins in Yucatán, Mexico, and constructed exemplary centers representing the great city of Mayapán, in Yucatán. This paper investigates exemplary centers in Petén through the examination of ceremonial architecture and associated materials and images. We argue that the Late Postclassic exemplary centers were constructed to legitimate social identities in Petén.

Shock, Myrtle (Universidade Federal do Oeste de Pará), Laura Furquim (Universidade de São Paulo), Jennifer Watling (Universidade de São Paulo) and Eduardo Neves (Universidade de São Paulo) Extinct Mid-Holocene Maize from the Monte Castelo Shell Mound, Rondônia, Brazil
In the Brazilian Amazon, mid-Holocene maize (Zea mays) grains have been found in archaeological deposits of the Monte Castelo shell mound. The morphological differences are pronounced between these and grains from both modern maize races of the Amazon and those found beginning around 1,500 years ago at other sites in the region. Our research explores the history, from 3900 BP, and use of this extinct maize. The presence of cultivars rich in carbohydrates in the Amazon has traditionally been interpreted in light of their potential caloric contribution to the diet and the economic levels of alluvium. But these challenges present improvement opportunities to the lidar prospecting technique both in terms of hardware and data analysis developments. This presentation will cover lessons learned dealing with the challenges during a lidar survey project that was conducted in the region in 2014.

Shrestha, Ramesh (University of Houston/NCALM) and Juan C. Fernandez Diaz (University of Houston/NCALM) Challenges and Opportunities to the Lidar Mapping of the Tres Zapotes Region
The Olmec polity of Tres Zapotes, which developed on the southern gulf lowlands of the present day state of Veracruz in Mexico, is nestled between the Papaloapan river delta and the Tuixla Mountains. Topographic, geological, ecological and cultural context of the region presents unique challenges and opportunities to archaeological prospecting using airborne lidar mapping due to extensive cultivation of sugar cane which can hinder the capability of the lidar to map the ground beneath it; cultural features which are very similar to natural topographic features and in some cases are buried under several levels of alluvium. But these challenges present improvement opportunities to the lidar prospecting technique both in terms of hardware and data analysis developments. This presentation will cover lessons learned dealing with the challenges during a lidar survey project that was conducted in the region in 2014.

Agent-based computer simulation is an approach that models the behavior of individual agents, allowing for the observation of emergent phenomena created by the aggregate effects of individual actions. This presentation builds on a recent series of agent-based computer simulations exploring the development of wealth inequality as a function of environmental change in pastoral nomadic societies. When simulating a pure pastoral nomadic economy, it was found that wealth inequality increased under favorable environmental conditions. This presentation reports on the results of new simulations incorporating urban centers into this environment to examine their effect on the distribution of wealth. The relevance of these results for understanding the growth and stability of the Mongol empire will be discussed, with particular reference to historical sources dealing with the relationship between pastoral nomadic populations and urban centers.

The Cultural Kaleidoscope in the “Island of Guiana”

The Guiana Shield is an island demarcated by the massive river systems of the Orinoco and Amazon and the northeast coastline of South America. Numerous Amerindian groups with distinct identities have occupied the region for thousands of years. In the contexts of maintaining distinct identities and active processes of ethnogenesis, well-established webs of relations and exchange exist across the region. Relations of production and distribution long documented ethnohistorically and ethnographically, are now mediated and (re-)negotiated through the lens or filter of the twenty-first century globalized world. In this paper, we address postcolonial experiences of three interacting Amerindian groups: Trio, Wayana, and Waiwai. People, things, and ideas move between the Trio, Wayana, and Waiwai through social networks with varying degrees of formality. Two overarching questions inform our study: Are legacies of colonial encounters resulting in forms of ethnogenesis that might better be called ethnocidal? Are village communities that are comprised of people from different ethnic groups an artifact of globalization or part of an indigenous design that social anthropologist Peter Rivière called a “cultural kaleidoscope”?

Task, Activity, and Context: Integrated Approaches to Use-Wear Analysis

Use wear has often been used to try to understand stone tools and tool types themselves. By focusing on lithics as used in specific tasks within activities that are part of larger contexts, relationships can be demonstrated and mapped using concept mapping tools. Use-wear studies deriving from complex agricultural sites in the Midwest are coupled with looks at activities performed by modern Native Americans.

Taking Archaeology to Heart: Reflections on Passions and Politics

Talking about “heart-centered archaeology” is not necessarily easy, but it is easily necessary. Those of us who work with descendant communities know the power of the personal in making those projects possible, desirable, and enjoyable. As analytical as we must be, we must also have open hearts to those who experience the past(s) in more palpable, less academic, more heart-centered ways already. These can be profoundly transformative and positive, as they require more emotional and personal elements than archaeologists might normally engage. On the other hand, there are other non-archaeologists who seek discriminatory pasts to handle their own anxieties, nostalgias, and agendas. These are still heart-centered approaches, but much darker ones that we must confront with evidence and with stronger, more just hearts. All of these circumstances have changed my own engagements and passions. I entered archaeology decades ago because “I loved it” and the way it blended body and mind, but it has been important for me to engage not just body and mind but also heart in this long-term process. The heart that now propels my work is less the personal one about passions and more the social one about anger and rights.

[281] Ancient Maya Salt Making Activities as Revealed through Underwater Excavations and Sediment Chemistry, Paynes Creek National Park, Belize

Underwater excavations at Early Classic Chan b’i (AD 300–600) and Late Classic Atz’aam Na (AD 600–900) ancient Maya salt works in Paynes Creek National Park, Belize, reveal activity areas associated with a substantial salt industry for distribution to the southern Maya inland inhabitants. At these sites, wooden architecture and salt making artifacts are abundantly preserved in a peat bog composed of red mangrove. We describe the excavation methods at this shallow, submerged underwater site, screening, analysis of recovered material, and collection of sediment for chemical analysis. The artifacts are overwhelmingly briquetage—pottery used to evaporate salty water by heating over fires to make salt. These excavations coupled with the results of sediment chemistry at Chan b’i indicate additional activity areas inside and outside of wooden buildings some of which are not evident from the artifacts recovered during excavations. The spatial distribution of briquetage and chemical analysis is evaluated in relation to interior and exterior of buildings and lines of palmetto palm posts. An abundance of briquetage and charcoal and the scarcity of domestic artifacts indicate that the sites were specialized salt works and not physically attached to households adding a new interpretation at the place of production.

Natural Processes and Anthropic Action: Compromising the Archaeological Heritage in the Southwest of the State of Goiás

Studies performed in the southwest of the state of Goiás indicate that natural processes and anthropic action are impacting and jeopardizing the conservation of archaeological sites in the region, namely GO-JA-13 and GO-CP-16, both of which are part of two important archaeological areas in the Brazilian Central Plateau—Serranópolis and Palestina de Goiás respectively. These sites are of high scientific and cultural significance and, together with the intense landscape alterations over the last decades, require a management plan. In this sense, the main purpose of the mitigating measures presented in this work is to stabilize the erosive processes which are compromising the archaeological sites more than anything else.

Culture and Battle: An Epistemological Approach to Warfare

The continuum of behaviors associated with war stretches from the act of killing to the profound ideology justifying the act. Thus the study of warfare encompasses a constellation of behaviors ranging from the ideological roots of political solidarity to the physical mechanics of death. Of the many aspects of war, the union of political and individual motive in a seminal action that often leaves a salient archaeological imprint, is circumscribed in space and time. However, bias, introduced by the veil of time and the sometimes ephemeral residues of war, meld with the bias embedded in the cultural context of the researcher. In this paper I present case examples of warfare studies I have conducted in Mesoamerica, Egypt, and with the POW/MIA recovery effort of the U.S. government. The studies, however, will be examined not merely from the archaeo-historic contexts of the conflicts, but through the introspective lens of my sociopolitical environment.

Why Colonize? A Case Study of the Early Neolithic Colonization of the Island of Cyprus

Why humans colonize unoccupied lands, such as islands, has always intrigued scholars. Over the past few decades, researchers working on the Mediterranean island of Cyprus have documented both a Late Epipaleolithic occupation and a more substantial early Neolithic colonization episode. The number of such sites remains limited, but is growing with continuing research. For the Neolithic, both Pre-Pottery Neolithic A and PPNB occupations are now well-documented, and are as early as mainland sites. These defy earlier beliefs that the Mediterranean islands were not occupied until much later in the Neolithic. Most, but not all, sites are coastal, reflecting these new immigrants’ sea orientation. Thus, we now know that early colonization occurred, but the question of why this happened remains largely unanswered. This presentation first examines characteristic elements of early Cypriot Neolithic settlements. Then, from a circumb-Mediterranean framework, it looks at reasons why colonization may have occurred in the first place, at a time when the greater region was undergoing major social and economic shifts. Issues such as over-population, resource stress, economic or religious opportunity, internal dissent, or simply the urge to explore are all addressed. Some of these topics are especially relevant given the current immigration crisis in the Mediterranean.

Maya Metals: A Comparative Analysis from Tipu and Lamanai, Belize

Investigations at the southern Maya Lowland sites of Lamanai and Tipu, Belize have yielded diverse assemblages of metal artifacts. These metals are from the Postclassic and Colonial (twelfth to seventeenth century) occupations at Lamanai and Colonial (mid-sixteenth to early eighteenth century) contexts at Tipu. As a rare occasion to look at the similarities and differences between artifacts made of the same material from different sites, this research compares the forms, contexts, and technologies of metal artifacts from two sites having somewhat similar histories. At both sites metal objects...
were recovered primarily from human burials and midden deposits. A program of typological study and compositional analysis revealed forms shared between the sites but evidence of on-site metallurgy only at Lamanai. The assemblages from these sites will be discussed in the larger contexts of metallurgy in other parts of the Maya world and ancient Mesoamerica as a whole.

Simms, Stephanie [5] see Bey, George J.

Simon, Rebecca L. [155]  When Pots Walk: Reverse Archaeology at a Chaco Outlier Site in the Central Mesa Verde Region
More often than not, cultural resources on private land experience development and/or intentional disturbance. Data from sites are often lost or compromised during these activities. Occasionally, landowners keep notes on material culture that may be passed on to archaeologists. Incorporation of these data is important to understanding the site and maximizing interpretations of the past. As Crow Canyon Archaeological Center embarks on a new multiyear research project, the Northern Chaco Outliers Project, consideration of what happened in the recent past is crucial. The focus of the project is the Haynie site, which experienced mechanical disturbance in the 1980s when the previous landowners sought out whole vessels to sell. Tracking down these artifacts using the landowners’ notes will contribute to our understanding of social networks, the Chaco regional system, and the role of great houses as community centers in the northern Southwest. Data collection will utilize a reverse archaeology approach by organizing the notes from previous landowners in a database, interviewing previous landowners and others with knowledge of the site, contacting individuals who purchased artifacts, and conducting artifact analyses and data collection with permission from the artifacts’ current owners.

Simova, Borislava (Tulane University), E. Christian Wells (University of South Florida) and Lisa LeCount (University of Alabama) [274]  Exploring the Changing Roles of Maya E-Groups: Geochemical Analysis of E-Group Plaster Floors at Actuncan, Belize
E-Groups were among the first monumental spaces constructed in Middle Preclassic Maya centers and served as important venues for negotiating social interactions and political integration of newly settled peoples. Starting in the Late Preclassic period, their roles began to shift. At some sites, such as Tikal and Uaxactun, votive offerings signifying communal ritual were replaced with dedicatory stelae or royal interments marking exclusionary practices and political appropriation of these spaces. Excavations within the eastern platform of Actuncan’s E-Group lend evidence to suggest a different trajectory. Rather than exhibiting practices of exclusionary kingship seen at central Petén E-Groups, the Maya of Actuncan continued to cache ceramics and erect a variety of wooden features interpreted as temporary altars, shrines, or world trees. To help further understand the kinds of activities that occurred at Actuncan’s E-Group and how they might have changed through time, we conducted geochemical analysis of five sequential occupation surfaces spanning the Late Preclassic Period (300 BC–AD 250). Results indicate the nature and distribution of activities during this period with implications for understanding the role of E-Groups in the evolution of Actuncan’s site core.

Simpson, Bethany (UCLA) and Emily Cole (NYU) [132]  Results from the 2016 Excavation of a Qarah el-Hamra, a Graeco-Roman Village in Fayum, Egypt
This paper presents the results of the 2016 field season at the Graeco-Roman Village of Qarah el-Hamra. Located along the north shore of Lake Qaroun, the site was discovered in 2003 by the UCLA Fayum Project, and a magnetic survey in 2004 revealed the presence of an extensive settlement. Excavation that same year confirmed the existence of Graeco-Roman remains, however the site remained otherwise unexplored until the start of this new field project in 2016. The new Qarah el-Hamra Excavation Project, directed by myself and Dr. Emily Cole, expands upon the earlier excavation and explores the relationship of the small site to its surrounding environment. Qarah el-Hamra is positioned between two much larger ancient town sites, Soknopaiou Nesos and Karanis. These towns have been heavily excavated and studied as independent sites, yet little is known about their connection to other settlements within the spatial and social network of the northern Fayum, and the role of small sites like Qarah el-Hamra are even less well understood. Our work at Qarah el-Hamra addresses the site’s significance, its chronological development under Greek and Roman administrations, and socioeconomic strategies used by the inhabitants at both local and regional levels.

Sinensky, R. J. (University of California Los Angeles) and Kellam J. Throgmorton (Binghamton University) [368]  Indexing Mobility in the Western Puerco Region of Arizona using Paleoethnobotanical and Architectural Evidence
The Western Puerco Region of East-Central Arizona contains a staggering diversity of architecture and material culture eluding to complex mobility practices that varied across time and space. Although archaeologists in the U.S. Southwest/NW Mexico have explored the sociocultural and ecological underpinnings that influenced household mobility, and have identified numerous lines of evidence that indicate increasingly mobile or sedentary habitation strategies, archaeologists have not developed robust quantitative methods for measuring and comparing mobility between individual households at the intrasite or intersite level. This poster presents results of an exploration of household residential mobility using indices developed with paleoethnobotanical and architectural data. We applied these indices to households in the Western Puerco Region dating between Basketmaker II and Pueblo III (500 BC–AD 1300) to chart long term and short term changes in mobility through time and space.

Sinensky, R. J. [266] see Throgmorton, Kellam J.
The Paleoindian occupation at Templeton is reconsidered based on research conducted since the site’s initial study by Dr. Roger Moeller in the late 1970s. This poster describes the intrasite spatial patterning at Templeton gleaned from the 2016 excavations at the site and the reanalysis of the Paleoindian materials recovered by Moeller. Aspects of intrasite spatial patterning ascertained via ground-penetrating radar surveys of the landform, lithic microwear analyses, micromorphological sediment analyses, and analyses of phytoliths recovered from sediments also will be reported.

Some Thoughts on Altar 3, Pacbitun, Belize

The rise of public monumental architecture in the Maya Middle Preclassic (900–400 BC) and the eventual development of divine kingship during the Early Classic (AD 250–550) constitute social processes that remain comparatively obscure. Nevertheless, they are increasingly illuminated as new empirical evidence is uncovered from research projects such as the Pacbitun Regional Archaeology Project. Ongoing work at Pacbitun, Belize, has brought to light considerable new information that can clarify these processes, in the form of early architecture in Plaza A, associated artifacts, and particularly carved monuments. Discovered during the 2016 field season, in Structure 25, within the palatial group, a new fragment of Altar 3 prompts us to reconsider the dating, stylistic attributes, iconographic program and epigraphy of this important monument. Here, we present a new drawing of the monument and comment on the temporal incidence of the iconography’s stylistic attributes and touch on paleographic features of the epigraphy.

BC “Rock” Stars: The Next Generation

This presentation will showcase a cultural rediscovery and ethnoarchaeology project taking place in Kitasoo/Xai Xais Nations’ traditional territory on the Central Coast of BC in the town of Klemtu. In 2016, First Nations youth created a pictograph in their community using traditional materials and subject matter. The first painting of its kind in this area for approximately 100 years, it is a significant statement on the landscape. By encouraging youth to engage with archaeologists and embrace practices of their ancestors, the concept of conserving the very art form of creating rock art will be explored.

Education and mentorship will be considered as core values which encourage conservation and stewardship. From sourcing pigments, researching designs and testing paint recipes, this project is the culmination of three years of youth-driven research. The archaeology and conservation approaches of North America differ significantly from European rock art conservation measures because of the cultural-continuity and contribution of the Indigenous descendant communities archaeologists are privileged to work with. As with the example of totem pole decomposition in BC, conservation, in this
specify instance, does not necessarily mean direct preservation of the archaeological record, rather, by preserving the practice, knowledge is conserved for future generations.

[342] Finding the Past in the Paste: Variance in Woodland Ceramics at Woodpecker Cave (13JH202)
Five field seasons of excavations by the University of Iowa field school have recovered hundreds of ceramic pottery sherds from the Woodpecker Cave site. Previous typological analysis of the ceramic assemblage has supported the hypothesis of a multicomponent site that was host to seasonal occupations spanning hundreds of years. Woodpecker Cave provides a unique opportunity to study variation in ceramic technology within Midwestern human achievements. These technologies are given such prominence because they changed human history in significant ways. Never mentioned, however, is the cooking pot. Yet this common, inexpensive, utilitarian tool was an important part of profound, worldwide changes in cooking and food. Boiling or simmering opened up a whole series of new foods such as cereal grains, rice, potato, cassava, and other plants that are an important part of today's worldwide diets. Cooking food over a fire may have made us human, as Wrangham notes, but boiling, according to Levi Strauss, made us civilized. The cooking pot was part of a whole suite of sweeping worldwide changes that ushered in the Neolithic Revolution. In this paper I discuss the great advantages of boiling/simmering, and I make the case that the cooking pot should be listed as one of the greatest technological innovations of all time.

Skibbe, Adam [342] see McGrath, James

Skibo, James (Illinois State University)
[21] The Joys of Boiling
The list of the greatest technological innovations of all time include the wheel, bow and arrow, stirrup, and the controlled use of fire among other great human achievements. These technologies are given such prominence because they changed human history in significant ways. Never mentioned, however, is the cooking pot. Yet this common, inexpensive, utilitarian tool was an important part of profound, worldwide changes in cooking and food. Boiling or simmering opened up a whole series of new foods such as cereal grains, rice, potato, cassava, and other plants that are an important part of today’s worldwide diets. Cooking food over a fire may have made us human, as Wrangham notes, but boiling, according to Levi Strauss, made us civilized. The cooking pot was part of a whole suite of sweeping worldwide changes that ushered in the Neolithic Revolution. In this paper I discuss the great advantages of boiling/simmering, and I make the case that the cooking pot should be listed as one of the greatest technological innovations of all time.

Skinner, Dougless and Kristen Barnett (Bates College)
The Togiak Archaeological and Paleocological Project (TAPP) is a collaborative project driven by the Togiak community of southwest Alaska and their interests in documenting past lifeways at the Old Togiak Village. During the summer of 2015 The University of Montana conducted field work at the site using surface and sub-surface mapping to guide a noninvasive core sampling technique across the village, led by Dr. Kristen Barnett (Bates College). Thirty-five core samples were collected from a series of pithouse structures targeting high probability areas such as features and hearths. A range of data was recovered during analysis including lithics, faunal remains, botanical, charcoal, pollen, and a variety of other data allowing for C14 dating, and establishing a long history of village occupations ranging the past 1,250 years. This research utilizes results of the analyses along with localized Yup'ik perspectives in order to inform our understanding of the nuanced past at Togiak, promoting an equal and collaborative relationship between the indigenous community and archaeologists. In this research I will explore the importance of cultivating respectful relationships in archaeology, low-impact versus high-impact field techniques, ecological variation, and subsistence practices throughout the past 1,250 years at the Old Togiak site.

[151] Landscape Archaeology and New Technologies at Tel Akko and in the Plain of Akko
Excavations at the ancient port site of Tel Akko in 2010 were codirected by Ann E. Killebrew (Pennsylvania State University) and Michal Artzy (University of Haifa). Located on the only natural bay in the southern Levant, Akko is frequently mentioned in historical sources ranging from the Bronze Age through the present time. Among the Tel Akko Total Archaeology Project’s primary goals is the development and implementation of new technologies devoted to 3D documentation and to a high resolution investigation of the environs of Tel Akko and the site within the context of the Plain of Akko. These include sophisticated and effective 3D recording of the ongoing excavation of on the tel, an intensive test-pitting survey of the mound, and a regional survey of the Plain of Akko utilizing lidar, 3D photogrammetry, and pedestrian survey. This poster presents the results of our 3D documentation from the excavation, the test-pit survey on the mound, and the application of lidar and photogrammetry to interpreting the Plain of Akko’s ancient landscapes.

Skoglund, Peter (University of Gothenburg)
[28] Animated Ships
The rock art of southern Scandinavia includes a variety of images and among these are ships, humans and animal images. The ship is the most common motif and appears in various constellations. The ship may appear without associated images, it can be seen with a row of lines indicating a crew, and it can be associated to rather detail human and animal images. The process of adding humans and animals to the ships changed the significance of these images. In this paper I will go through some of the constellations in which the ship images appear, focusing on the addition of humans and animals to ships, as a mean of animating these objects.

Skousen, Benjamin (University of Illinois)
[157] A Relational View of Pilgrimage: Movements, Materials, and Affects
In this paper I discuss three tenets of what I call a relational view of pilgrimage. Overall, this perspective sees pilgrimage as a means through which people, things, places, and more move and converge in ways that instigate what Eliade (1959) called “hierophanies.” The first tenet is that movement is...
crucial—indeed, the nature of a pilgrimage depends on what, where, and how entities (human and nonhuman) move and assemble. The second is that objects and landscapes (e.g., relics, offerings, shrines, monuments) have histories and vitalities that influence these journeys. The final tenet is that pilgrimages are uniquely affective—they impact the senses, emotions, and sensibilities in ways that other activities do not. I explore this perspective and these particular ideas—movements, materials, and affects—through a narrative of the pilgrimage shrine at Lourdes, France. This example shows that a relational view encourages archaeologists to move beyond identifying pilgrims’ traces and relying on functional and structural theories; it also enlivens, enriches, and better conveys the complexity of a pilgrimage. Perhaps most importantly, it illustrates that archaeology, with its focus on materials and space, has much to contribute to studies of pilgrimage.

[296] **Modeling Water Routes through a Divide: Retracing Movement from the Greater Antilles to the Lesser Antilles in the Late Ceramic Age**

This paper focuses on modeling hypothetical sea routes between islands within the Caribbean Sea to try and redraw the map of social mobility and material exchange that existed during the Late Ceramic Age (AD 1250–1400). With the emphasis for modeling canoe pathways more focused on uncovering possible colonization routes, this map has yet to be thoroughly explored. However, analyzing the back and forth of travel between two sites known to be occupied during the same period can open up ideas on who was in contact due to the ease of connection between them. There are still many questions surrounding the specifics of difficulty and general progression of movement between the Caribbean Islands, in particular the connection between communities living in the Greater and Lesser Antilles during this period. Computer models of routes can provide more insight. The approach to modeling these pathways utilized a least-cost isochrone method to highlight time as a route cost. Additionally, as the models are based on environmental data—specifically current and wind—it is possible to evaluate seasonal trends.

[386] **Reverential Termination of Sun Pyramid Cave, Teotihuacán: Round 2**

The predominant view is that the paucity of material remains from the cave under the Sun Pyramid is attributable to looting, often described as exhaustive. This paper disputes that speculation, based on lack of evidence and, more convincingly, on a paucity of material remains from contexts that could not possibly have been looted any time after Teotihuacános applied concrete to the cave in the mid-third century CE. I present evidence for timing, termination ritual, sealing of termination contexts, and paucity of material remains from sealed contexts to argue that the dearth is explainable as part of a ritual of reverential termination.

Slocum, Diane (Northern Arizona University), Doug Tilden and Jaime Awe (Northern Arizona University)

[204] **Xunantunich Reloaded: Examining the Sociopolitical Significance of Structure A9**

Recent excavation of Structure A9 at the site of Xunantunich, Belize, confirmed that the mound represents the remains of a medium-size temple dating to the Late Classic period. Sub-surface excavations along the central axis of the mound revealed a large, vaulted chamber containing the remains of an elite individual. Two hieroglyphic panels flanking the building’s front staircase identify a link between Xunantunich and three other Classic Maya polities: Caracol, Naranjo, and Calakmul. Exploration in front of the structure and at the base of an uncarved stela led to the discovery of two dedicatory caches comprised of obidian and chert eccentrics. The tomb, the monuments, and the caches provide evidence of Structure A9’s ritual significance. In particular, the tomb is not only a unique find at Xunantunich, where no burials in tombs have previously been discovered in the site core, but its exceptionally large size makes it an unusual feature in the western Belize region. This paper discusses the significance of this temple in the context of Xunantunich and the eastern Maya lowlands.

Slotten, Chelsi (American University)

[19] **Engendering the Bioarchaeology of the Viking Age**

Gender roles within Viking society are generally considered to be strictly binary. Some recent research has begun to challenge this assumption using textual and archaeological evidence. This paper will explore the ways in which an engendered bioarchaeology can contribute to a fuller understanding of gender during the Viking Age. Specifically, I will discuss what assumptions have been made in the past, and the importance of engendering bioarchaeological research. I argue that the application of gender theory can provide a more nuanced view of women’s actual roles during the Viking Age and should be considered in all bioarchaeological analysis.

Slotten, Venicia (University of California, Berkeley)

[80] **Mesoamerican Plants of the Night: A Paleoethnobotanical Perspective**

The ancient Mesoamerican landscape has been extensively researched archaeologically, with the field of paleoethnobotany allowing for a better understanding of what plants the ancient people valued agriculturally and in their economic, ritual, medicinal and other daily practices. Typically, archaeologists interpret the archaeological record in terms of how the ancient peoples interacted with the artifacts and navigated through the landscape during the daytime. What about nightly practices? How have nighttime activities left their mark on the paleoethnobotanical record in Mesoamerica? The ancient Maya associated much of their environment to various night-related practices. The ancient nightly landscape can even be imagined through nocturnally active plants that either bloomed, were fragrant, or visibly illuminated in the dark. Mesoamerican interpretations of their environment can be understood, enriched, and better conveys the complexity of a pilgrimage. Perhaps most importantly, it illustrates that archaeology, with its focus on materials and space, has much to contribute to studies of pilgrimage.
Dung through the Microscope: A Close-Up View of Sample Origin

In the 1980s, Naomi Miller’s seminal publications detailing the use and identification of dung fuel within archaeobotanical samples at Malyan provided archaeobotanists with an alternate explanation for the source of plant remains preserved archaeologically, allowing for considerations of ancient fuel use and pasturing practices. Since then, archaeobotanists have generally relied upon wood to weed seed ratios or the composition of weed assemblages to support the use of dung fuel within flotation samples. However, some disagreement exists within the literature on how certain assemblages should be interpreted. If remains do originate from dung fuel, they hold the potential to inform us about use of the local environment, pasturing practices, and seasonality, but if samples represent mostly clean crop processing debris, the questions that can be reliably addressed relate to agricultural choices and organization of labor. Consequently, reliably identifying sample source is essential. This study examines experimentally charred caprid pellets, cattle dung, and wood fuel using scanning electron microscopy to help develop objective criteria for confirming the presence of dung within archaeobotanical samples. These criteria are then used to evaluate traditional interpretations of dung fuel use, wood fuel use, and agricultural processing activities within archaeobotanical samples from Southwest Asia.

Ground Stone Technology in the Late Pleistocene Horn of Africa: An Assemblage from Mochena Borago Rockshelter, Southwest Ethiopia

Ground stone technology is an early component of the African Middle and Late Pleistocene hominin behavioral package. However, very little attention has been paid to quantifying Pleistocene ground stone variation in Africa. This paper describes a ground stone assemblage from the site of Mochena Borago in Southwest Ethiopia. The assemblage plays a key role in testing the hypothesis that the highlands of Southwestern Ethiopia acted as a refugium for hunter-gatherer populations looking to escape environmental degradation associated with MIS 4 (73.4–60 ka BP). Ground stone is found interspersed throughout the assemblage with noteworthy concentrations below the earliest dated occupational horizons at ~54 ka BP. The ground stone component is composed primarily of expedient tools, or outiles a posteriori, likely shaped through use rather than intentional design. A number of ground stone artifacts preserve ochre residues adherent to their working surface. Considered in light of previously analyzed ochre pieces from younger deposits at the site, these artifacts suggest that pigments were being processed throughout the site’s occupational history. These analyses provide a platform to launch comparative studies of Pleistocene ground stone technology throughout the Horn of Africa.

Exploring the Effects of Stabilizing Riverine and Lacustrine Environments on Archaic Faunal Exploitation in the Great Lakes and Prairie Peninsula

The interplay among changing environmental forces affected the configuration of lake and river drainage systems after 6000 BP and the abundance, composition, and productivity of aquatic animal communities available to Early, Middle, and Late Archaic groups of the interior Eastern Woodlands. These environmental changes have long been suggested as powerful influences on selection strategies of animal resources during the Archaic period. Using the integrative applications of the Digital Archaeological Record (DAR) to examine faunal databases, this paper considers the role of variability in resource availability and selection among sites in different aquatic settings, specifically the dendritic Saginaw River Valley of Michigan, the Mississippi and Illinois Rivers and their upland tributaries in the Prairie Peninsula of Illinois. These comparisons allow us to examine the influence of environmental and resource changes on subsistence change and variability. Potentially related changes and variability in demography, mobility, and cultural practices,
identity and interactions can then be considered in order to gain a more thorough understanding of the factors that influenced variability and diversity among Archaic peoples in these parts of the Eastern Woodlands.

Smith, Byron (Humboldt State University)
[44] Land and Society: Evaluating Diversity in Land Use Strategies among the Classic Lowland Maya through Terrace Design and Maintenance
Agrarian production in the Central Maya Lowlands during the Classic period was comprised of a variety of techniques that were used to satisfy dietary needs and to stimulate its subsistence economy. Rainfall totals and intensity along the variable topography of the region may have predisposed areas with less vegetative structure to soil erosion. Previous research suggests the application of terraced features by the Maya as a means to lessening the effects of surface runoff while also supplementing existing growing schemes. Increased labor investments during the construction of retaining walls, and throughout the cultivatable life of the growing fields (which includes maintaining soil quality) would have been essential to the production of a sustainable crop. The nutrient requirements of grain and legume yields demand adequately sustained levels of available (P) phosphorus to ensure growth. This research seeks to analyze levels of commitment through an appraisal of retaining wall design, as well as through the measurement of available (P) within the soil’s matrix. The effects of past land use and management will be examined through the excavation of terraced features and though the chemical analysis of the soil’s mineral content.

Smith, Claire (Flinders University), Ines Domingo (University of Barcelona), Didac Roman (University of Barcelona) and Gary Jackson
(University of Toronto, Mississauga)
Much of the research done on weaning practices among ancient societies is directed toward biological aspects of the weaning process. Some researchers have, for example, attempted to identify a “natural” weaning age determined by human primate origins. Surveys of weaning age among modern and ethnographic populations, however, demonstrate that weaning age is highly variable across diverse economies and categories of social organization. This pattern (or lack of pattern) suggests that a range of contingent factors impacts weaning practices. This paper will explore economic, social and cultural influences that may affect weaning practices within the context of a localized cultural niche in northwestern Cuba.

Smith, Erin M. (Washington State University, Pullman)
[393] Interactions and Social Change in California: A Perspective from the Far West
People in California have interacted with groups near and far for thousands of years. Here we take a big picture approach by looking at how interactions between people across time and space affect the histories of adjacent regions. In this paper, we first establish connections between people in California to the Northwest, Southwest, Mexico, and afar to demonstrate the scale of meaningful interactions. Second, by considering wide-ranging and long-term interactions, we better explain the agency and structure of the relationships forged between diverse people. These relationships are not static; they have been negotiated, redefined, and sometimes have been dissolved. Using archaeological and ethnographic data, we more closely examine the rise and demise of some of these relationships. Finally, we apply large-scale and long-term perspectives to address social change and issues of structural instability today.

[169] When Lithics Hit Bones: Evaluating the Potential of a Multifaceted Experimental Protocol to Illuminate Middle Paleolithic Weapon Technology
Recent zooarchaeological and isotope analyses have largely settled the debate surrounding Neanderthal hunting capacity. The vast numbers of Middle Paleolithic sites containing the butchered remains of large ungulates demonstrates the ability to obtain and, often, highly process these carcasses. Nevertheless, evidence for the effectiveness and ubiquity of Neanderthal hunting technology, specifically composite hafted tools, has not been illustrated across either their entire spatial or temporal range. In-depth studies have focused mainly on a small subset of lithic artifacts from assemblages emphasising features of breakage patterns, retouch, shape and use wear. While most studies have focused on damage to lithic material this study uses a multifaceted experimental program of controlled experiments in both a laboratory and more realistic setting. Such a two-fold approach allows for investigation of both the projectile delivery system and the resulting damage to both animal and projectile. Central to this research is whether diagnostic impact damage on both types of material can be identified and used in turn to infer Neanderthal hunting behavior. Evaluating the incidence of lithic and faunal damage signatures from such experiments will improve recognition of these signatures in the archaeological record and allow for a better understanding the mechanisms of Neanderthal hunting.

Smith, Geoffrey (University of Nevada, Reno)
For more than a decade, the University of Nevada, Reno has conducted archaeological survey in the northwestern Great Basin, searching for Paleoindian sites under the auspices of the Great Basin Paleoindian Research Unit (formerly the Sundance Archaeological Research Fund). Our work has identified a rich record of early occupation in southeastern Oregon and northwestern Nevada. Additionally, we have reanalyzed existing collections of Paleoindian artifacts from Last Supper Cave and Hanging Rockshelter. I review these efforts, focusing on the archaeology of Warner, Guano, and Hawksy Walksy valleys, Five Mile Flat, Last Supper Cave, Hanging Rockshelter, and the Black Rock Desert. I discuss the concept of “Lithic Conveyance
Zones," made popular in the Intermountain West by Charlotte Beck and Tom Jones, as well as site location and assemblage composition. I consider these data within broader patterns of settlement-subsistence, land use, and toolstone procurement in the northwestern Great Basin.

Smith, Heather L. (Eastern New Mexico University) [226] Fluted-Point Technology and the Nature of Its Transmission in the Western Canadian Ice-Free Corridor
Recent analyses suggest that Paleoindian stage technology in the archaeological record of the Western Canadian Ice-Free Corridor—fluted projectile points—can provide valuable evidence of the dispersal of Clovis and descendant groups northward as early Americans spread throughout the New World. This paper discusses recent geometric morphometric and technological evidence for fluted-point variation in the Ice-free Corridor, which possibly represents a variety of typological specimens spanning over 2,000 years of fluted-point use. Major factors of variability reflect the presence of Clovis-point morphology in the earliest deposits of the central Corridor, as well as specimens from the Great Lakes region and Folsom at other sites. Trends in the frequencies of technological characteristics suggest directional changes that may explain the nature of the transmission of fluting information into and throughout the Corridor and its adaptive context in late-glacial Arctic and Subarctic ecosystems. Conclusions address whether patterns in such technological trends between points from Alaska and northern Yukon, Canada, the Ice-free Corridor, and Clovis suggest that cultural transmission occurred between groups that met in the Ice-free Corridor during the terminal Pleistocene.

Smith, J. Gregory (Northwest College), Lawrence Todd (Park County Historic Preservation Commission) and Brian Liesinger (Heart Mountain Interpretive Center) [394] Community Archaeology at the Heart Mountain Relocation Camp, Park County, Wyoming
Heart Mountain was one of ten confinement camps established by the U.S. government during World War II to incarcerate Japanese Americans living on the West Coast of the United States. Located in northwest Wyoming, the camp had a peak population of nearly 11,000 incarcerees, making it the third largest settlement in the state at that time. The Park County Historic Preservation Commission recently partnered with the Heart Mountain Interpretive Center to carry out mapping and test excavations at Heart Mountain. The bulk of the labor for the project was provided by some 45 community volunteers who worked a total of 627 hours. An in-kind matching grant procured from the State Historic Preservation Office provided funding to rehabilitate an original barrack at the Interpretive Center. Archaeological work focused on two 95 × 15 m root cellars at the site. In our week of fieldwork, we managed to create a topographic map of the two root cellars, test excavate one of them, and extensively photograph the vicinity using a drone. The positive feedback from community members will almost certainly lead to further work at the exceptionally rare and nationally-significant historical resource at the Heart Mountain National Historic Landmark.

Smith, Karen (University of South Carolina), Vernon J. Knight, Jr. (University of Alabama), Julie G. Markin (Washington College) and Keith Stephenson (University of South Carolina) [365] Trend and Tradition in South Appalachian Carved Paddle Stamps
The nature of Swift Creek design style has been a research focus of the lead authors for a number of years. In this poster, we broaden the discussion to include the full range of carved paddles, originally identified by W. H. Holmes as integral to the South Appalachian pottery tradition. Within the context of the stylistic principles of Swift Creek, as previously defined, we chart paddle stamping from its earliest beginnings ca 600 BC to the ethnographic present. Our concerns include establishing the emergence of Swift Creek out of the visually modest, but geographically more expansive, carved simple and check stamped paddles, to the timing of the de-evolution of the design style into a limited number of core elements with no complex elaboration by ca AD 800. We delineate the characteristics that set peripheral (e.g., Pickwick Complicated Stamped) and subsequent (e.g., Etowah Complicated Stamped) styles apart from the style at its most complex. We also offer ideas for the persistence of this multimillennia long paddle carving tradition and specific changes observed therein.

Smith, Kevin (Haffenreffer Museum, Brown University) [133] Dependent Independence? Identity, Interconnection, and Isolation in Iceland (AD 870–1800)
This paper will explore intersections among international trade, domestic economy, and identity in Iceland from the time of its settlement shortly before AD 870 until its quest for postcolonial, independent nation status in the late nineteenth century. Focusing primarily on three periods—the Viking Age: AD 870–1050, the medieval/Sturlung period: ca. AD 1150–1300, and the Early Modern era: ca. 1500–1800—this presentation will integrate archaeological data gleaned from a range of recent projects with historical source materials to query standard models of this North Atlantic island’s integration, isolation, or dependency through this 1,000-year span. Rather than focusing on models that have conceptualized Iceland and other North Atlantic Scandinavian outposts as passive actors on the periphery of dynamic European economic and cultural networks, this paper will consider Icelanders’ agency in building, maintaining, or molding those networks as integral elements in the changing construction of Icelandic identity and society.

Smith, Maria (Illinois State University) [185] A Multi-Site Analysis of Intergroup Violence in East Tennessee of 1300–1600 CE: Temporal and Regional Patterns
A meta-analysis of deliberate violent trauma (i.e., inflicted projectile points, antemortem blunt force cranial trauma, scalping, body element dismemberment and retrieval) in the human skeletal assemblages of twenty late prehistoric sites (N = 1,300+ individuals) was undertaken to determine temporal (Dallas phase [1300–1540 CE], Mouse Creek phase [1400–1600 CE]) and/or regional patterns within the Ridge-and Valley physiographic province of East Tennessee. The site samples were retrieved from what are now six reservoirs that impound either the main channel of the upper Tennessee River (Chickamauga and Watts Bar Reservoirs) or its tributaries (the rivers of Clinch-Powell [Norris and Melton Hill Reservoirs], Little Tennessee [Tellico Reservoir], Hiwassee [Chickamauga Reservoir], and French Broad [Douglas Reservoir]). The results indicate distinct regional differences in pattern and prevalence of violent trauma that co-associate with population density. Additionally, lower East Tennessee, despite evidence of sociopolitical change (Dallas phase to Mouse Creek phase), has the highest prevalence of intergroup (i.e., lethal) and interpersonal (i.e., nonlethal) deliberate trauma. The interregional differences parallel previous archaeological assessment of mortuary patterning that identified ‘ethnic’ differences in east Tennessee and, are apparently coincident to the descriptions by the Hernando de Soto Entrada of 1540 for the (elusive) boundary of the Coosa polity.

Smith, Michael (Arizona State University) [277] Why Settlement Scaling Research Is a Good Fit for Archaeology
Although initially developed to understand contemporary urban systems, the method and theory of settlement scaling are particularly appropriate for archaeological data. The scaling framework can be seen as an outgrowth of existing archaeological research on demography and settlement patterns.
Although developed independently, the “social reactor” model that explains observed patterning is in fact well-grounded in anthropological and archaeological theory. The key process that drives change is “energized crowding,” or the social interactions among individuals within the built environment. The scaling framework is general enough to apply to settlements in all types of human societies; it does not require the institutions or behaviors of the contemporary capitalist economy. This is a thoroughly empirical line of research that generates propositions that can be rigorously tested against archaeological data. Our positive findings to date contribute to a richer and broader fundamental understanding of human settlements, their generative character, and their changes over time.

Smith, Michele (Haffenreffer Museum of Anthropology)

Globalization, Trade, and Magic: Weaving the Threads of Iceland’s Viking Age Textiles

Icelandic Viking Age (ninth–eleventh-century) textiles are less frequently reported than their medieval counterparts, yet mineralized pseudomorphs adhering to copper alloy objects from burial contexts and a small number of items that survived in their organic forms suggest that this North Atlantic colony’s textiles filled multiple roles and were produced through technical approaches with diverse origins. In the North Atlantic’s Viking Age, some textiles were used as a form of currency within a commodity-money system that had continental Scandinavian counterparts and, perhaps, origins. Others were produced through approaches that integrated techniques linked not only to Scandinavia but also to other parts of the North Atlantic, including Scotland. Textiles dyed with plants brought from continental Europe, silks imported from the Mediterranean area as luxury items, and prestige textiles were used as a form of currency within a commodity-money system that had continental Scandinavian counterparts and, perhaps, origins.

Smith, Monica (UCLA)

Does the Site-Size Hierarchy Concept Mask the Complexity of Urban-Hinterland Relations?

The site-size hierarchy concept was born of a marriage between a long-standing interest in the emergence of the state and the mid-twentieth-century development of systematic regional survey projects. The assumption of equivalence between sites and territorial complexity facilitated an intellectual investment in survey data beyond a mere tally of sites toward an analysis of the way in which political administrations functioned at the landscape scale. The resultant easy equivalence of four-tiered site size hierarchies as characteristic of states, and three-tiered hierarchies as indicative of chiefdoms, has become a standard taste of current, even popular, description so much so that the original formulators of the concept are no longer cited. Yet everything about the site-size rubric, from the reliability of surface-survey data to the recognition that small sites are sometimes quite powerful political entities, should prompt a reevaluation. Using evidence from eastern India where surveys and excavations have focused on social and economic relationships among different-sized sites, the paper examines the way in which visible areal dimensions are only one measure of regional political integration. Territorial interactions among population centers are likely to be more varied than simple hierarchical models allow, encompassing the potential to identify heterarchical, corporate, and situational-network configurations.

Smith, Ryan (University of Pittsburgh)

Understanding an Alternative Pattern of Coalescence: A Study of Architecture and Organization at a Non-fortified, Pre-Inca Town in Highland Peru

This study presents an analysis of the architecture and spatial organization at Maukallacta de Núñoa, a prehispanic site within the highlands of Peru dating to the Late Intermediate Period (AD 1000–1450). Within the northern Titicaca Basin where the site is located, hillforts dominate the archaeological landscape during this time as a result of increased political fragmentation and social discontinuity. While these hillforts often display very little architectural investment other than their fortification walls, Maukallacta boasts over 300 well-preserved house structures along with dozens of chullpa burial towers, slab-cist tombs, and other structures which are unevenly distributed throughout the site. The organization and spatial relation of these
structures in addition to the site's non-fortified nature provide important clues as to the exceptional use of this space during the Late Intermediate Period. Preliminary results based on site-wide architectural mapping and further GIS analysis demonstrate fundamental differences between the planning, use of space, and nature of social life at Maukallaqta and that of contemporaneous hilfts.

Smith, Sarah (Amec Foster Wheeler), Cara Brendzy (Sto:lo Resource and Research Management Centre) and Lisa Dojack (Sto:lo Resource and Research Management Centre)

In 2014 Amec Foster Wheeler, in partnership with the Sto:lo Resource and Research Management Centre, conducted an archaeological investigation of rockshelter site DiRj-34 in response to a proposed development. The site was documented ethnographically by Wilson Duff in 1949 as the Restmore Caves and recorded as spiritual site Uwqw'iles by the Sto:lo Nation. The rockshelter is comprised of large boulders at the toe of the Canadian Cascade Range, adjacent to Hunter Creek on the south side of the Fraser River in S’olh Temexw. The site is located between Hope and Chilliwack, in southwestern British Columbia, Canada. The identification of stratified cultural layers, archaeological features, diagnostic lithic tools and the analysis of radiocarbon data provides a framework for placing the site into the oral and ethnographic history of the Sto:lo. The results of systematic data recovery and radiocarbon sampling are presented in the context of ethnographic and traditional use information. By comparing ethnographic information recorded on the rockshelter site, the cultural narrative associated with the Uwqw'iles spiritual site, and data collected during preliminary archaeological excavations, we provide a glimpse into the cultural landscape of the area, focusing on changing site-use and settlement patterns over time.

Smith, Stefanie (New South Associates, Inc.)

Data recovery excavations at Site 1Mt504 in the downtown section of the City of Mobile, Alabama produced a large assemblage of faunal material relating to the nineteenth century occupation of the surrounding city blocks. By the 1840s, the area was occupied as a residential block including the private homes of merchants, doctors, and other professionals, as well as boarding houses for similar professional classes. In the 1910s, land use began to shift from residential to commercial. By the 1950s, businesses outnumbered residential houses. Faunal material from the site was mostly recovered from the privy features attributed to the original residential occupation of the neighborhood. Zooarchaeological analysis of the recovered faunal material indicated that the average diet was heavily reliant on domestic animals. The consistent presence of wild birds and both freshwater and marine fish suggests that these animals were included as supplementary foods. A comparison of faunal material from privy to privy shows some variety in consumption practices between households.

Smith, Tara (Texas State University)

Entangled Lives: Intercultural Interactions in the Nubian Borderland

Anthropological theories of cultural interaction, in particular entanglement, can help shed light on how individual choices drove intercultural interaction between Egypt and Nubia in the context of a colonial borderland. This paper explores how recent archaeological work in Nubia is breaking the simple Egyptian-Nubian dichotomy that has characterized previous discussions of interactions between the two African cultures. Taking their cue from Egyptian ideology, Egyptologists have often depicted Nubia as inferior, dominated both militarily and culturally by its northern neighbor. Similarly, the Third Intermediate Period in Nubia has been seen as a dark age, a boundary between civilization and a return to barbarism. This process of cultural and political regeneration in Nubia eventually led to the rise of the Nubian 25th Dynasty, whose pharaohs ruled Egypt for nearly a hundred years (c. 747–656 BCE). Recent archaeological work reflects a much more complex picture of intercultural interactions that were by no means unidirectional. Understanding this complicated transition requires a nuanced approach that avoids simple explanations based upon the deeds and pronouncements of kings in favor of an archaeological focus on the accumulation of subtle shifts in local interactions and the cultural and biological entanglements that led to regional change.

Smith, Stuart (UC Santa Barbara)

Cosmic Ventures of the Olmec Dwarf: An Analysis of the Dispersal and Transformation of Dwarf Imagery within Olmec Iconography

The formative period dwarf imagery in Mesoamerica offers an exemplary opportunity to further our understanding of the Olmec cosmovision and how their ideology spread throughout the region. This study specifically compares the three monumental sandstone dwarfs at La Venta to the portable dwarfs carved in stone and sculpted from clay found elsewhere within the Olmec exchange network. I discuss the origin of Dwarf imagery within the Olmec artistic style through an analysis of stylistic trends and by upstreaming from the Maya. Ultimately, I present evidence that shows dwarfs as transformative beings, likely associated with creation events and cosmic travel; a transformative sequence can be identified when viewing the corpus as a whole, further alluding to the ritualized nature of dwarf imagery. Moreover, the evidence suggests, and I concur, that the phenomenon of dwarf representations originated in the periphery regions of Olmec influence and was later incorporated into the heartland, manifesting in the monumental sculptures at La Venta.

Snead, James (California State University Northridge)

Water Wars: The St. Francis Dam Disaster and Resource Competition in the American West

Euro-American experience in the western states has been profoundly shaped by the fight for resources, among which water ranks extremely high. Traditional histories of such struggles focus on policy, macroeconomics, and large-scale social transformation. Historical archaeology, in contrast, offers the opportunity to emphasize the quotidian manifestations of these conflicts, particularly as they shaped the lives (and deaths) of local residents. Current fieldwork conducted by California State University, Northridge (CSUN) emphasizes landscapes associated with the Los Angeles Aqueduct, constructed between 1908 and 1913 and one of the most “iconic” features of the struggle over resources. In particular we have focused on the St. Francis Dam disaster of 1928, an aqueduct-related catastrophe that took hundreds of lives and destroyed vast swaths of countryside. This work, involving survey, excavation, and extensive engagement with stakeholders, offers a new look at the “water wars” from the perspective of those most directly engaged.

Snitker, Grant (Arizona State University)

Snitker, Grant (Arizona State University)
Proteins and DNA can be trapped in the microcracks on the surface of stone tools, which can then be extracted and analyzed to aid in inferring the use of the tool (Shanks et al. 2001, 2005). This nondestructive method involves the use of sonication to release DNA from the microcracks, then amplification of regions of mitochondrial DNA that are species specific. This technique was applied to ground and chipped stone from the Bridge River site in British Columbia. Focus on groundstone was of particular interest, due to debate over its use in either food preparation or bone tool creation. If used for bone tools, the potential to identify which species, such as deer or bear, was also addressed. Scrapers were also analyzed in order to surmise the species the tool had been used on. This technique provides an interesting new avenue of investigation into the use of lithics from archaeological sites.

Snyder, Brian
[184] An Examination of Variation in Hafting Configuration among Early Paleoindian Projectile Points
In this paper I use a combination of experimental replication, microscopic use wear analysis, and morphological analysis to investigate questions about the differences in hafting technology between Clovis, Folsom, and Midland projectile points. The transition from Clovis to Folsom culture is still poorly understood, and changes in hafting technology are part of the transition. In addition, the question of why fluted (Folsom) and unfluted (Midland) projectile point forms are found in the same temporal contexts at Folsom-age sites looms large. These questions have implications for how technology can be used to overcome environmental stressors, such as the climatic changes at the end of the Pleistocene. My research uses a behavioral ecological approach aimed at understanding change through time and cost/benefit decisions related to technologies of varied effort-cost. I examine these problems in a pilot study using a combination of experimental replication of impact-related use wear using a calibrated crossbow and ballistic gel targets, combined with morphological and use wear analyses of existing prehistoric collections. My research seeks to develop new knowledge on the differences in early prehistoric technologies and cost/benefit decisions about subsistence technology in the early cultures of the Plains and Southwest.

[190] Molecular Markers in Keratins from Hair and Baleen for Species Identification of Archaeological Artifacts
In this paper, we present a methodology to identify organic remains from Arctic and Subarctic origin. Peptide mass fingerprinting (based on the characterization of specific peptides from proteins) is a rapid and efficient method for species identification, which requires little material and provide results on processed and degraded material. Recent studies of ancient marine mammals’ remains has used collagen peptides in bones and skins for species identification. Here we demonstrate the application of peptide mass fingerprinting in hair and baleen; both materials are made of alpha-keratins. Baleen, or whalebone, has been harvested for thousands of years from Mysticeti whales. It was appreciated for its horn-like, flexible properties and used for tools and cultural objects. Baleen constitutes a rich source of biomolecular information with potential to contribute to studies of conservation and the exploitation of Mysticeti whales in past and recent times. We examined baleen from ten different species of whales and determined specific molecular
markers for all species. The methodology was used to successfully identify baleen scraps from an archaeological assemblage from Labrador that span up to 1,500 years of aboriginal whaling. Hair remains from these sites were also identified to species from a build database of keratin markers.

[118] Integrating Lidar with Pedestrian Survey at the Ancient City of Angamuco, Michoacán, Mexico

Remote sensing techniques have enhanced studies of ancient urbanism particularly because they have improved the speed of data collection and our abilities to identify the extent of urban sites. Data derived from airborne laser scanning such as lidar have been rapidly incorporated to study settlement patterns in order to accelerate the survey process, but also to produce innovative and higher quality data. In this paper, we discuss the use of lidar and traditional pedestrian survey data at Angamuco, an ancient city within the Purépecha imperial heartland in Michoacán, western Mexico. Between 2009 and 2011, the Legacies of Resilience Project mapped over 7,000 architectural features that comprise roughly 17% of the 26 km² Angamuco urban core. We explore how the integration of these datasets helps us to better understand urbanism and demography in prehispanic Mexico and how these data can be used to document archaeological heritage that is impacted by modern development and looting.

[245] Strontium Stable Isotope Ratio Analysis of the Loma Sandía Archaic Period Mortuary Site of South Texas

Models of hunter-gatherer territoriality are derived from the ethnographic record but have rarely been directly evaluated with archaeological data. Mortuary sites on the Texas Coastal Plain have long been thought of as a product of hunter-gatherer territoriality. Strontium stable isotope ratios from human bone enamel can be used to estimate the origin of individuals and can evaluate evidence for territoriality. This paper will report the results of strontium stable isotope ratios analyzed from 54 human teeth from the south Texas mortuary site of Loma Sandía dating to 2850–2550 BP. Strontium bio-availability is preliminarily assessed with fauna from two nearby geological regions. The data analysis of this NSF-funded dissertation project evaluates the variability in the geographic origin of individuals designed to assess the degree of territoriality. Differences between males and females may indicate mobility related to post-marital residence rules.

Solis, Reyna (Museo del Templo Mayor-INAH) and Emiliano Melgar (Museo del Templo Mayor-INAH)

The archaeologist of INAH recovered hundreds of lapidary items at Tantoc and Rancho Aserradero. Among these pieces, there are glossy greenstone objects restricted to the burials of both sites. The chemical composition and mineralogical characteristics of them with Micro-Raman, XRF, and FTIR, allowed us to identify two exotic raw materials, jadeite and green quartz from the Motagua Valley in Guatemala. Also, with the technological analysis of their manufacturing traces with Experimental Archaeology and Scanning Electron Microscopy, these objects showed a foreign lapidary style that shares the tools and techniques detected on Mayan jewelry, especially jadeite pieces, and differs with the Huastec lapidary technology. Based on these results, we could infer the symbolic employment of these exotic greenstones in the burials as long-distance prestige goods for the elite members. Also, these are the northernmost confirmed jadeite pieces found in Mesoamerica, opening new researches about the acquisition, production, and distribution of luxury items in Ancient Mexico.

[138] The Revival of Gut-Skin Parka Production among the Siberian Yupik

The Siberian collections at the American Museum of Natural History (AMNH) are one of the world’s most important collections of cultural artifacts from Northeast Siberia. These artifacts were created as a result of the historic Jesup North Pacific Expedition (1897–1902), which sought to study the cultures framing the Bering Sea. In 2014, the Conservation Department at AMNH began a two-year project to stabilize and rehouse 100 items from this collection, including 14 gut-skin parkas attributed to the Siberian Yupik people. The project involved research of gut-skin properties to understand processing and manufacture, and to develop suitable treatment methodologies. Consultations regarding material processing and cultural significance of the parkas and gut skin were conducted during a visit to source communities in July 2016. Information sharing about the current state of the Siberian collections and research was also a vital part of the work. Due to political and ecological factors in the region, the tradition of manufacturing gut parkas is at risk of disappearing. There is an expressed interest among local community members to revive the technology. Access to the AMNH collection and outreach as a result of the Siberia project play a key role in the revival.

[281] Spatial Analysis of the Preserved Wooden Architectural Remains of Eight Late Classic Maya Salt Works in Punta Ycacos Lagoon, Toledo District, Belize

In 2005, eight Late Classic Maya sites with the remains of wooden posts were found beneath the surface of Punta Ycacos Lagoon in southern Belize. The presence of briquetage on the surface and embedded among the clusters of wooden architectural features implies association with salt production activity. This research employed a rigorous field survey, combined with mapping, sampling, and building a GIS. Detailed analysis of the spatial distribution of wooden posts was conducted to determine if comparisons could be drawn to ethnohistoric examples of wooden architecture reported among the Maya and in Mesoamerica. This research found that there are patterns in post distribution, some of which compare to ethnohistoric examples of wooden architecture. This study emphasizes that there are rectilinear patterns in the placement of posts. This research did find positive results from the use of in-the-field GIS analysis to recognize patterns and predict missing data. This study was part of a larger ongoing project “Mapping Ancient Maya Wooden Architecture on the Seafloor” that will continue to address these problems and build upon this research.

[104] Analysis of Perishable Artifacts from Conejo Shelter, Texas

Conejo Shelter (41VV162) is a perennially dry rockshelter in the Lower Pecos region of southwest Texas. This shelter was excavated in the late 1960s by the Texas Archeological Salvage Project, an offshoot of the joint Smithsonian and National Park Service River Basin Survey program, as part of...
mitigation efforts during construction and inundation of Amistad Reservoir. As is common among the rockshelter habitation sites in this region, the artifact assemblage from Conejo Shelter is largely composed of perishable artifacts. While the perishable artifacts from several other shelters and caves in this and other parts of western Texas have been studied quite extensively, very little is known or published about the remarkable assemblage of perishables from Conejo. Current efforts are working to close this dearth of research through recording and analysis of all perishables, particularly the sandals in the assemblage. Sandal analyses have included conservation, comparative studies of size, structure, and manufacturing techniques—particularly among anomalous forms, and acquisition of direct radiocarbon dates from the sandals themselves. Results of these analyses expand current understanding of perishable technology adaptations and artifact use-life behaviors and align the sandal assemblage at Conejo within existing typologies and chronologies.

Our Collections at Risk: Climate Change Threats to NPS Museum Property

Over the past 15 years NPS Collections from Texas to Maine have faced devastating impacts from hurricanes and other climate related events. During this time, Hurricanes such as Isabel, Ivan, Katrina and Sandy have wrought havoc on NPS museum collections. Although not subject to direct impacts from these recent hurricanes, National Capital Region (NCR) parks have been heavily damaged by their collateral impacts, typically in the form of flooding along the Potomac Valley. It is simply a matter of time before a major hurricane strikes right at the heart of the Nation’s Capital. Our recent brush with Hurricanes Joaquin and Hermine highlight the risks we face in NCR from a devastating Hurricane event and its related impacts. Over the past two years the NCR Museum Management Program has been gathering data and developing an assessment of park collection vulnerabilities due to climate change in NCR. This brief presentation will discuss those threats and highlight how some NCR parks are addressing those threats.

Research on Faunal Remains at Geduling Site, Muping, Shandong Province

Animal remains excavated from Geduiding can be divided into two stages: 1) the earlier (5925–5880 BP), and 2) later (5880–5530 BP) periods of the Early Dawenkou Culture. In both stages, identified animals include: mollusk, fish, amphibian, bird, deer, dog, pig, raccoon dog, rabbit and rodent. Crab and sand badger are also found in the later period. The identified fauna indicate that the environment around the site did not change much in the few hundred years between the early and later periods. According to the quantity of animal remains, the use of aquatic animals, especially marine mollusks, increased in the later period. This indicates that ancient peoples’ abilities of cognition and exploitation of marine resources increased as time went by. Most of the excavated pigs from the site are domestic pigs; and wild boars are also present. In the view of the total mammals composition, pigs take up more than 50% (NISP and MNI) in both earlier and later periods. This shows that ancient people fed domestic pigs in order to obtain a stable meat source. They also hunted wild mammals, especially deer, and caught aquatic animals as important supplementary sources of meat.

A Study on Trade and Behavior through the Analysis of Exotic Lithic Debitage and Artifacts at the Tule Creek Site (CA-SNI-25), San Nicolas Island, California.

This study examines lithic debitage and artifacts on exotic raw materials from the Tule Creek Village (CA-SNI-25), a late Holocene site (3500 cal BP to the Mission Era) and one of the last occupied villages (500 BC–AD 1700) on San Nicolas Island. In contrast to the shell bead trade off the island, little is known about what materials were brought to the island. Excavations yielded over 100 objects or components at CA-SNI-25 with the majority consisting of imported obsidian, chert, and soapstone. In this study, we compare the attributes of the lithic debitage to the formal artifacts made on nonlocal raw materials found at the site. Results suggest that the Nicoleño acquired finished artifacts as part of a large and intricate trade network.

Soto, Gabriella (University of Arizona)

Microhistories of the “Funnel Effect”: Tracing the Banal Materialities of U.S. Border Enforcement, 2000–Present

Nearly two decades have passed since the strategic border security paradigm known as “preservation through deterrence” took root in the landscape of Southern Arizona. The aim is to deter illicit migration by strategically amassing border security forces to funnel migrants into a treacherous landscape of increased risk. Thousands of undocumented migrants have died when confronting those risks in an outcome known as the “funnel effect.” This paper draws upon dissertation research that studied the local and microhistories of the funnel effect using ethnoarchaeological methods and GIS technology. This work ultimately reveals the limits of state control of people and landscapes. Networks of migrants’ spiderwebbed clandestine trails exhibit a history of changing but repeat use, all while the state’s tools and spending to control the border have continued to amass. Similarly, one can trace the institutionalization of migrant “trash” cleanup by Arizona land managers, and the trend of migrants endeavoring to leave no material trace. Motivating this work are applied questions about the effectiveness of state-based aims to control the border, and theoretical questions pertaining to the role of contemporary archaeology to understand the banal material realities of state-based power in dialectical engagement with the collective effects of informal survival strategies.

Soto, Selena

On the Road Again

National parks and their cultural identities have changed their meanings to visitors throughout time. The significance of national parks in the United States to visitors during the nineteenth and twentieth centuries was to experience the nation’s heritage, admire natural resources, and/or gain monetary value. One method in understanding past visitors’ behaviors and how they viewed the significance of national parks is to analyze historic roads. Roads help determine the most frequented places whether for tourism, travel, and/or trade. One national park specifically, Petrified Forest National Park, exhibits these behaviors due to its historic background of having roads for a mail route, guided tours from nearby towns, and for being one of the only national parks to have Historic Route 66 preserved within it. With the amount of history that is found within Petrified Forest National Park, I used Google Earth Pro to map historic roads within the national park and utilized previous site assessments to confirm the dates and purpose of the roads. By
examining the historic roads found within Petrified Forest National Park, I determined the significance the park held for past visitors and how its identity has changed throughout time.

[89] Clovis to San Pedro: Projectile Points and Land Use in the Southern Colorado Plateau
Recent research done by the University of Arizona at Rock Art Ranch, located on the southern Colorado Plateau near Winslow, Arizona, yielded a wealth of information on preceramic land use in an area where prior research had not been conducted. Survey of a 6-square-mile area recovered more than 140 projectile points ranging from Clovis to San Pedro, 50 bifaces, and 88 sites. Multiple canyons crosscutting the ranch carry water that results in a diverse range of flora and attracted animals to the area. Additionally, cobble accumulations in two areas along Chevelon Canyon, where over 3,000 preceramic petroglyphs have been carved, provided local populations with ample lithic raw material. This poster looks at these resources to understand their role in explaining extensive use of the study area for over 10,000 years. Samples of raw material from the local quarries will be compared to the materials used in the manufacture of the preceramic projectile points and bifaces to determine local and nonlocal procurement. This research will add new data to prior studies to provide an understanding of the broader patterns of land use and social interactions of the mobile occupants of this region.

Sparaga, Joseph (Western Washington University) and Laura Phillips (Burke Museum of Natural History and Culture)
[228] Specialization, Standardization, and Opportunity: A Design Theory Perspective on the Production of Cultural Necessities at Tse-whit-zen Village
Lithic artifacts recovered from the Tse-whit-zen village, a large settlement on the coast of the Strait of Juan de Fuca inhabited for 2,800 years, assist in portraying the choices made by people for adapting to the surrounding environment through tool development. Analysis of the lithic assemblage is based on a design theory approach that addresses material selection and reductive manufacturing strategies to understand efficiency, expediency, and reliability in forming the end products. The assemblage is dominated by fabricating tools such as flakes, anvils, hammerstones, and abraders. Mobiliary art in the form of stones with incised designs occur in significant numbers, while tools specific to food procurement such as projectile points, net weights, and fishhook shanks constitute a very small percentage. In contrast, manufactured bone items are almost entirely specialized, standardized components for fishing gear. Cutting, engraving and incising tools were required to produce both the bone tools and the socially significant incised stones but high quality flaking material is not common in the area. Rather than importing exotic material, the artisans developed techniques for producing reliable, standardized cutting tools such as quartz crystal microtools and large spall flake tools from local materials that were less than optimal.

[194] Buried Archaeological Sensitivity Modeling in the Pacific Northwest
ICF assisted the Washington State Department of Transportation (WSDOT) with the preparation of a buried archaeological sensitivity model in support of a client-sponsored research project in Seattle, Washington. ICF approached the model development from a statewide scale and employed geologic landform and soil age as main model inputs. Surface geology data was not available at a large enough scale to support the entire effort so ICF combined national resource conservation soil data attributed with soil parent material with surface geology units at a scale of less than 1:100,000 to cover soil data gaps. After statewide data coverage was achieved, landform and parent material types were normalized based on geomorphic origin, and then assigned to a target geologic epoch (Holocene or Pleistocene and older). ICF then tested this model with 200 previously recorded archaeological site locations. This presentation presents the methods and results used to develop and test this model, and discusses the potential of this model to be an efficient and practical modeling approach for modeling buried archaeological sensitivity across larger regional areas.

[366] A Case Study of Engaged Archaeology within Graduate Education
This poster presents a collaborative archaeological project between the Pueblo of Acoma Historic Preservation Office (HPO) and the University of Arizona, School of Anthropology. The project began as an internship that fulfilled a requirement of the Applied Archaeology MA program. The internship was designed to better understand the Tribal Historic Preservation Program in residence at the Pueblo of Acoma, while providing professional archaeological assistance to the HPO by compiling a database of archaeological sites that may be impacted by an upcoming infrastructure project in the San Juan Basin. This database will be used to inform an upcoming ethnographic study of the project area. The internship quickly morphed into an ongoing collaboration that is assisting the HPO in developing a program plan for submittal to the NPS to become a federally recognized THPO, and a comprehensive preservation plan that the HPO will use to frame their goals and objectives. This results of this ongoing project are being compiled as a Masters Report. This project is an example of a mutually beneficial collaborative project and demonstrates an engaged archaeological approach within graduate education.

Speer, Charles (Idaho State University)
[91] Knapping Precise Porcelain Replicas
The experimental replication of lithic artifacts commonly encounters issues of standardization and control. Two major issues are how to accurately sample a population and how to sample from specific stages of artifacts and control. Knappable stone is unpredictable due to inclusions, cracks, and differences in size, texture, and fracture toughness. It is necessary to create knappable facsimiles of either artifacts or knapped replicas by experts at specific stages. This allows for observation of specific behaviors at critical stages in the production process; such as notching, fluting, pressure flaking, or late stage bifacial thinning. A new method is presented that provides several advantages over traditional approaches to flintknapping experiments: flaking of precise facsimiles of actual artifacts, recording and replication of critical stages in the reduction process, and the production of a large number of these precise replicas at a relatively low cost. The method presented here uses a micro-CT scanner to record the artifact form, a Fused Deposition Modeling 3D printer to produce a copy of the artifact form, a plaster mold of the printed artifact form, and then lastly casting, production, and firing of the artifact form in the plaster mold from porcelain slip.

Speller, Camilla (Department of Archaeology, University of York) 

Molecular Solutions for the Taxonomic Identification of Archaeological Whale Remains

Several large cetaceans appear on the IUCN Red List, and in most cases their endangered status is considered to be the result of relatively recent industrial overhunting. Archaeological studies, however, suggest that preindustrial whaling may have had a significant impact on whale behavior and ecology. Documenting the impact of natural and anthropogenic factors within the archaeological records is difficult because whales are big and their bones are friable. The larger the whale, the less bone is transported from shore to settlement, decreasing the likelihood of finding diagnostic pieces of the skeleton, and identifying either the species or number of animals present. A variety of molecular methods are now available identifying the taxonomy of highly fragmented remains, including collagen peptide mass fingerprinting (ZooMS), mitochondrial DNA barcoding, and whole genome sequencing. Through a case study focused on the Mediterranean, we discuss the relative advantages and limitations of these molecular techniques, and highlight the importance of molecular identifications in reconstructing former cetacean species distributions and behavior.

Digital Documentation of Ancient Ritual Landmarks: Modeling Senses of Place with Photogrammetry, Lidar, and Virtual Tours

Ritual karstcape archaeological research at the prehispanic Maya site of Pacbitun, Belize, by the Pacbitun Regional Archaeological Project (PRAP) has included experimentation with a range of digital recording technologies. The overall goal of these experiments has been to better document ritual landmarks and the archaeological materials within them than has been possible with traditional recordation methods such as hand-drawn maps, photographs, and written descriptions. Our efforts have centered on three-dimensional digital photographic modeling (photogrammetry) in a variety of contexts, including landmark mapping, unit and archaeological feature modeling, and recording a rock art panel. We have also experimented with terrestrial laser scanning (TLS) for landmark mapping and modeling. In this presentation, we discuss the benefits and the frustrations we experienced using these technologies, discuss avenues for moving forward with them, and offer some preliminary interpretations of the archaeological data we collected with them over the past several field seasons. We will also demonstrate the ease with which cave archaeologists can use some of these technologies, in conjunction with inexpensive immersive three-dimensional digital viewers to convey the grandeur of the places we investigate and make them broadly accessible to interested audiences.

Memento Mort: Scalar Reference, Architectonic Persistence and the Continuity of Ritual Memory at Huaca Colorada, Jequetepeque Valley, Peru

This paper examines the temporal dimensions underwriting relationships linking humans, architectural representations and the meaningful places they reference in past Andean life-worlds. I argue that for the Moche of the North Coast of Peru, acts of symbolic compression and miniaturization served to reanimate specific times, known ceremonial locales, and the social identities created and reaffirmed in these places. The ritual efficacy of architectural simulacra rests in their mimetic power to condense and transfer the potency of ritually charged spaces and their human and other-than-human attendants across time. I interpret the numerous scalar representations of ceremonial spaces ubiquitous to the Moche ceramic corpus as playing an important role in rites of death and renewal as well as serving as chronometric markers of temporal breaks. However, a comparison of such representations in relation to a remarkable sequence of ritualized reconstructions of architecture found at the Late Moche site of Huaca Colorada (AD 650–800) in the Jequetepeque Valley reveals that they served much more than as passive mementos of deceased leaders and revered places. Instead they condensed latent temporal or generative energy that at once stored but could potentially reanimate ritually charged landscapes as active timescapes throughout the phases of their occupation.

Evolution of Elite Residence at San Martín Ticajete, 500–100 BC

Between 1995 and 2014, we directed 11 seasons of horizontal excavation in and around the main plazas of two Formative Period sites, El Mogote and El Palenque, near San Martín Ticajete in the Oaxaca Valley. Our results indicate that major changes occurred in public architecture and elite residence between the Early Monte Albán I phase (500–300 BC) occupation at El Mogote and the Late Monte Albán I phase (300–100 BC) site of El Palenque. In view of the evidence of fundamental cultural continuity between the two sites, we submit that the observed changes represent a case of “descent with modification,” amenable to analysis and interpretation from an evolutionary perspective. We argue that the data reveal a major increase in the centralization and segregation of political and religious institutions between the Early Monte Albán I and Late Monte Albán I phases. Of particular relevance to this symposium is our discovery at El Palenque of a 1,700 m² palace complex, comprising both residential and governmental components, as well as a 5,000 m² temple precinct, containing three multroom temples associated with two specialized priests’ residences; these architectural forms made their first appearance in the Late Monte Albán I phase.
Spengler, Robert (Institute for the Study of the Ancient World, New York University)

**Evidence for Dung Burning in the Archaeobotanical Record of Central Asia**

In the early 1980s Naomi Miller changed the way paleoethnobotanists in several parts of the world approached the interpretation of their data. With her research into whether the ancient seed eaters of southwest Asia were human or herbivore, she opened an ongoing debate over what impact the burning of animal dung had on archaeobotanical assemblages and how researchers can differentiate between human and animal food remains. As the number of systematic paleoethnobotanical studies across Central Asia increase, we are continually confronted with the topic of dung burning. Herb animal dung is the dominant fuel source across much of Central Asia today and the high densities of wild seeds in archaeobotanical assemblages seem to suggest that people were using dung as fuel across Inner Asia for millennia. Seed assemblages that represent herd animal dung are helping scholars in Central Asia understand paleoecology and herd animal diet in the past.

**A Method to Extract Collagen from Archaeological Leather for Species Identification with ZooMS**

Zooarchaeology by Mass Spectrometry (ZooMS) is a rapid peptide fingerprinting technique capable of identifying species provenance in several archaeological materials of biological origin, and most commonly used on bone. Leather has proven resistant to analysis not only by ZooMS, but also to DNA extraction due to the tannins that are present in the material. We have used alkali (NaOH) to increase the solubility of the tannins and thereby extract them before enzyme digestion. This has allowed us to make several species identifications on samples of archaeological leather in varying different states of decay and mineralization. The ability to identify leather opens up the possibility of a larger study exploring the production and use of a wide range of leather artifacts. Developing this method could provide advantages over visual examination of follicle patterns where these have been destroyed by the manufacturing process or degradation, and where even with good visual evidence two species are difficult to distinguish from one another (e.g., sheep and goat).

Splitstoser, Jeffrey (George Washington University)

**Wari-Style Khipus from El Castillo de Huarmey**

Archaeological evidence suggests that khipus—devices made of wrapped and knotted cords—were used by people living in the Wari Empire at least as early as Middle Horizon 1B. These Wari-style khipus, like their later, more famous, Inka descendants, likely carried and conveyed information using color and knots. Wari khipus differ from Inka khipus, however, in many respects including their use of colorful wrapping to make bands and patterns to convey information. Wari-style khipus survive in far smaller numbers than their Inka counterparts. In fact, until 2013, the total number of Wari-style khipus known to be in museums and private collections throughout the world was less than thirty, but excavations conducted between 2013 and 2016 by Milosz Giersz and Roberto Pimentel at the site of Castillo de Huarmey changed all of this when they uncovered the largest number of scientifically excavated Wari-style khipus ever found: approximately fourteen khipus and khipu fragments, many from undisturbed contexts. Some of these khipus are nearly complete; others are remnants, consisting of single cords to multi-cord assemblages that include pendants and subsidiaries. This talk will detail this important find, presenting the entire collection for the first time with its archaeological associations and contexts.

Spores, Ronald and Laura Diego Luna (Insitucional de Antropología e Historia, México)

**Power and Settlement in Prehispanic and Early Spanish Colonial Yucundaa-Pueblo Viejo de Teposcolula, Oaxaca**

Yucundaa-Pueblo Viejo de Teposcolula, Oaxaca, Mexico, is the urban capital and power center of a Prehispanic and Early Colonial Mixtec state, occupying 4 km² from AD 1000 to 1550. This research utilizes a convergent archaeological, ethnohistoric, and biological methodology, and focuses on the evolution and transformation of the city and its surroundings until the time of its relocation to the adjacent lowlands in 1550. Of particular concern was identification and analysis of archaeological and infrastructure pertaining to major social classes, political institutions, and ritual activities as they evolved from Prehispanic to Spanish Colonial times. What were originally conceived as separable residential, administrative and civic-ceremonial elements (*"palace," tecpan, tecpancalli, anafe or yuhullau, plaza, mounds, platforms, courts, patios, etc.) through data collected from intensive excavations, survey, and ethnohistorical and biological studies, were determined to be functional components of an integrated urban-political urban capital and should
be properly treated as such. This report considers those findings and conclusions and provides recommendations relating to research in the Mixteca, Oaxaca, and in other regions of Mesoamerica-New Spain with reference to the grand transformations taking place in the area before and after the Spanish Conquest.

Sportman, Sarah P. (Archaeological and Historical Services, Inc.) and David Leslie (Archaeological and Historical Services, Inc.)

Underwater, Terrestrial, and Intertidal Core Extractions at the Walk Bridge, Norwalk, Connecticut: an Alternative to Traditional Phase I Survey

The CTDOT Walk Bridge Replacement Project in Norwalk, Connecticut presented several challenges, making it unsuitable for a traditional Phase I archaeological survey. The urbanized Area of Potential Effect (APE) has been heavily industrialized since the mid-nineteenth century. The pervasive ground disturbance, land making, and hazardous soil contamination that characterize the APE presented obstacles to typical survey methods such as hand-excavated shovel test pits. Documentary research identified several areas of potential archaeological sensitivity in the APE, including the possible location of a Late Woodland Native American fort. To overcome these obstacles and better assess the archaeological potential of sensitive portions of the APE, AHS chose to employ a testing strategy that combined terrestrial geoprobe, underwater vibrocores, and intertidal push-cores. This sampling strategy allowed AHS to evaluate the presence of and/or potential for intact soils and subsurface cultural materials; to collect data to reconstruct local paleogeography and paleogeomorphology, evaluate depositional environments, and record changes in historic-period land use; and to provide recommendations for further investigations or mitigation based on an overall assessment of underground and underwater archaeological potential within the APE. Underwater, intertidal, and terrestrial core extractions provided AHS with cost-effective and information rich alternatives to traditional survey strategies.

Different but Similar? Colonization Processes on Islands and Continents Compared

As discussed elsewhere (Spriggs 2008) the ‘islands as laboratories’ trope can be overblown, and factors beyond size, circumscription and vulnerability have to be taken into consideration. Indeed none of these are concerns uniquely limited to islands. In this paper I stress too that colonization on its own may be too limited a concern. We need to examine longer archaeological sequences for a truly comparative archaeology, where what happens after initial colonization is also key to understanding. I compare aspects of the Lapita colonization and its aftermath in the Southwest Pacific islands, the Linearbandkeramik and Cardial Ware cultures of Continental Europe and the Mediterranean coastline, and the Neolithic spread across Mainland Southeast Asia to show that islands are not always what they are cracked up to be.

Leading Each Other to Water: Queer Archaeology and Consciousness Raising in New York’s Adirondacks

In 1903, white middle-class women founded Wiawaka Holiday House in New York State’s Adirondack Mountains for “working girls” to have an affordable vacation away from unhealthy factories and cities. In 2013 and 2014, I and dozens of community volunteers (ages 18 to 70) excavated on the grounds of the still-operating Wiawaka Holiday House (now the Wiawaka Center for Women). Underpinning all of the conversations and instruction about interpretation and excavation at the site were the queer archaeological approaches of challenging assumptions and recognizing the deeply intersectional nature of identity. For many participants, the idea of identities not being fixed characteristics was transformative, and they readily engaged with examining how gender, class, and race were (and continue to be) created and enforced, often using their own life histories as examples. In this paper, I discuss how the project was structured to facilitate these conversations; give examples of how participants (and myself) were changed by the experience; and present how the excavations at Wiawaka continue to challenge the status quo.

Houses, Territory, and Tenure: An Archaeological Case Study of Territoriality in the Salish Sea

The multifamily, above-ground, post-and-beam plankhouse looms large in our understanding of ancestral Coast Salish households that populated the coastal regions of southwestern British Columbia and northwestern Washington State. In addition to their practical role as shelters, plankhouses were both social fields of daily practice and ceremonialism, and imposing physical structures that communicated presence and the territorial and tenurial interests of the household. In this presentation, I examine the purported adoption of this house type over other architectural forms (e.g., in-ground houses) as the primary dwelling circa 2400–2000 years BP among the coastal populations of the Salish Sea. Drawing on Coast Salish structuring principles of bilateral kinship and group exogamy in conjunction with cultural values associated with autonomy and collectivism, I argue that an increasing territoriality in the region necessitated previously dispersed families aggregating into larger, mutually beneficial collectives that were best served by the modular design of the above-ground plankhouse.

Time to Take a Rain Check? The Social and Practical Implications of Weather and Seasonality on the Cremation Rite in Early Anglo-Saxon England

Cremation was one of the primary funerary rites employed in early Anglo-Saxon England (fifth to seventh century AD). Open-air pyres were used to cremate the dead alongside an array of pyre goods, including personal objects and faunal gifts. The resultant remains were subsequently collected and interred in pottery urns. Despite the fact that this mortuary rite has been subjected to extensive research over recent years, archaeologists often overlook the challenges faced by communities that practiced cremation during this period. Weather and seasonality would have undoubtedly played a major role in the success of an open-air cremation. This paper will explore how early Anglo-Saxon communities dealt with fatalities during winter months and periods of inclement weather. The effects of a death under these circumstances would have impacted populations on a household and communal level. Funeral preparations, interactions between the living, and post-mortem treatment of the dead will each be considered as a means of establishing how communities overcame periods of adversity. An examination of the hardships faced by cremation practicing groups on both a practical and social level can further illuminate how the living interacted, not only with each other, but with the dead in early Anglo-Saxon England.
Assessing Human-Animal Interactions in Mesoamerica: Ancient Maya Use of the Black-Throated Bobwhite (Colinus nigrogularis)

Stanchly, Norbert (AS&G Archaeological Consulting), Stephanie R. Orsini (Coastal Environments Inc. and Moore Archaeological C) and Marcus England (Bloom Biological Inc.)

This paper examines human-animal interaction between the ancient Maya and the black-throated bobwhite (Colinus nigrogularis), a small quail resident to Central America. We provide a literature review of the occurrence of bobwhite remains in Maya faunal assemblages. Unpublished faunal analyses by the primary author, in conjunction with the published literature, suggest that the bobwhite, like many animals in Mesoamerica, was of greater importance to the Maya than as a mere dietary food. We examine its social, political and economic importance to the Maya and explore several forms of interaction such as wild or captive management or rearing of the bird. Finally, the paper will suggest avenues of future research to help reconstruct and elucidate its function within ancient Maya society.

Osteoarthritis and Implications for Economic Lifestyle Change in Two Prehistoric Skeletal Populations

Stanco, Alyxandra (Louisiana State University)

Numerous studies have been conducted regarding the influence of activity-related stress on postcranial elements such as the upper and lower limbs, but few studies have considered the vertebral column in relation to interpopulational variation. This study examined the vertebral columns of two prehistoric skeletal populations. The Indian Knoll site (n = 98), representing a population of hunter-gatherers, is located in Ohio County, Kentucky along the Green River and thus increase mound size. Satellite images and ground exploration were also used to examine the relationship between wind and other constructed features across the valley. This approach enables a semi-automated land classification process capable of identifying sites similar to Los Morteros that may lie hidden beneath the large coastal dunes of the region.
River and is dated between 2558 and 4160 BC. The Moundville site (n = 56), a chiefdom of early agriculturalists, is located in the Black Warrior River Valley in west-central Alabama and is dated between AD 1050 and 1520. Data were collected on type and location of pathologies to determine if economic lifestyle is associated with interpopulational differences in vertebral pathologies. Vertebral scores were compared from 0–3 based on severity of osteoarthritic development. Results show that Indian Knoll had higher prevalence of osteoarthritic when compared with Moundville. Additionally, osteoarthritic was more frequent in the lumbar region followed by thoracic and cervical. Results indicate a relationship between changes in economic lifestyle and development of vertebral pathologies.

[3] Olmec of the Periphery: The Dawning of Creation in the Central Mexican Highlands during the Middle Formative

By 900 BCE, a middle formative Olmec influence projected into the central highlands of Mexico. This became apparent with the 1930s discovery of the regional center of Chalcatzingo and its monumental architecture created in the Olmec style. Additionally, Olmec style symbolism appeared in the modern Mexican state of Guerrero with outstanding examples like the monumental architecture of Teopantecuanitlán and the cave paintings of Oxtotitan and Juxtlahuaca. This paper will iconographically analyze the four aforementioned middle formative periphery centers, whose Olmec style architecture, base-reliefs, and cave paintings link this highland region back to the Olmec heartland. On the one hand, my hypothesis is that these periphery centers incorporate heartland symbolism and ideology to validate and link their elites to those of Olmanc. At the same time, the same symbolism displayed at the four sites can be linked thematically, showing a unique cultural fluorescence within this highland periphery. Thematically, the highland symbolism relates to greater Mesoamerican cosmology and, specifically, the belief of the dawn of creation. This paper will attempt to further develop the scholarship of this formative cultural region, arguing that a similar symbolic sequence, or tableaux, illuminates a highland cosmology that incorporates middle formative symbolism of Olmanc.

Stanisell, Ann (CSUN)
[98] Commemoration in the Wake of Catastrophe: A Historical Archaeology Investigation of Southern California’s St. Francis Dam Disaster and its Victims

The commemoration of disasters and their victims is a product of cultural, economic, political, and social forces in human society. Southern California’s largely forgotten St. Francis Dam Disaster of 1928 provides an excellent opportunity to study this complex process of commemoration, engaging memory within different frames of reference. Previous scholarship related to the disaster has been focused within the fields of civil engineering and geology, with the singular goal of determining the cause of the dam’s collapse; little, if any attention has been given to the 400 victims or how they have been memorialized. Evaluating how and why this catastrophe has been forgotten on a state and national level, but tenuously remembered within the local geology, with the aim of understanding the commemorative processes involved in the construction of memory and heritage related to major catastrophes and can help reveal the spatial and temporal scales of memorialization efforts. This investigation synthesizes archival research, Internet resources, and archaeological survey data to discern how the disaster and its victims have been commemorated through state monuments, community memorials, grave markers, museum exhibits, and memorabilia and the legacy of their memory.

Stantis, Christina, Hallie Buckley (University of Otago), Amy S. Condellador (Idaho Museum of Natural History) and John Dudgeon (Idaho State University)
[123] Using Stable Isotopes to Identify Childhood and Infant Feeding Practices in Prehistoric Taumako

Though many ethnographic sources in the tropical Pacific recount chiefly feasting events, few describe the feeding practices of children despite the impact childhood nutrition has on morbidity and mortality throughout an individual’s life history. The Namu burial ground (circa 750–300 BP) on the island of Taumako in the southeast Solomon Islands provides a direct means of understanding prehistoric life on a Polynesian Outlier. Twenty individuals from the 226 excavated were sampled as part of a pilot study. We investigate infant and childhood feeding behavior in prehistoric Taumako by creating δ13C and δ15N profiles using collagen horizontal dental sections of permanent molars. The high-resolution data in those individuals who survived to adulthood is supplemented with skeletal evidence of nutritional disease and grave goods suggesting relative wealth to create a combined approach and offer insight into breastfeeding and weaning practices in the absence of documentary evidence.

[329] Using LIDAR and Ground Survey to Understand Regional Settlement Patterns in Terminal Classic Central Yucatán

The first research performed by the Proyecto de Interacción Política del Centro de Yucatán centered on understanding the impact of Chichén Itzá in the region to the southwest of this Terminal Classic city. Working in an area of roughly 500 km² around the site of Yaxuna we performed traditional ground reconnaissance and mapping at numerous centers in the region from 2007 to 2013 to better understand regional settlement patterns and how they changed with the establishment and growth of the Itzáe center. In 2014, we conducted a lidar survey of a 48 km² area that included Chichén Itzá, Yaxuna, and a 1 km wide transect between the two sites. In this paper we report on the results of this survey, as well as an intensive ground-truthing sample along the transect between the sites of Yaxuna and Popola. The combined data suggest that rural settlement decreased when Chichén Itzá was urban leaving primarily scattered small hamlets throughout most of the region.

[11] Excavations at Group P of the Medicinal Trail Community in Northwest Belize and Its Implications for Agricultural Processing
Excavations of a circular depression and adjacent mounds at Group F have revealed functional data to support the hypothesis that this area was used as a processing center for agricultural material. The evidence stems from excavation of the depression itself, as well as two chich mounds on the northwest and northeast sides. The limestone bedrock of the depression appears to have been manually shaped for use, as indicated by cobble fill found roughly a meter down in an excavation trench bisecting the depression. The two chich mounds appear to have no uniform structure to them and appear to be used as debris piles related to field clearing. This paper will aim to analyze the evidence uncovered and perform an interpretive analysis of the data presented at Group F during the 2015 and 2016 field seasons and to assess the probability of agricultural activity taking place.

Khmer Stoneware Ceramic Production and the Angkorian State

The Angkorian Khmer (900–1500 CE) manufactured an array of goods that materialized and celebrated political authority, from temples and religious statuary to ornaments and domestic tools. Khmer stoneware ceramics were one of the least spectacular and most ubiquitous of these, yet their distributional pattern deftly maps the geography of ninth–fifteenth century Angkorian rule. Archaeological research at Khmer stoneware kiln sites in the last two decades, coupled with excavations in Greater Angkor, have resulted in a growing database of production centers and a better understanding of the range of stoneware products. Our paper presents morphological and geochemical results from eight Cambodian stoneware kiln complexes. Examining kiln design and geochemical variability, evident at different scales, allows us to better problematize and contextualize the relationship between stoneware production and the state.

Spatial Differences in Site Use at the Middle Paleolithic site of Lakonis (Peloponnese, Greece)

Lakonis is a Middle Paleolithic rockshelter on the coast of the Mani Peninsula of southern Greece. It is well-known for the preservation of a Neanderthal tooth in the late Middle Paleolithic layers, which is one of the few Pleistocene hominin remains from Greece. The site preserves several occupation areas spanning 120,000–40,000 BP. Lithic and faunal remains are abundant, though the faunas are highly fragmented due to heavy concretion of the sediments. During excavation, researchers defined at least three distinctive areas of the site: a rich hearth complex, Upper Bone brecchia, and Lower Bone brecchia. Analysis of the lithic assemblages suggests a number of key differences between the three contexts. The hearth complex is characterized by small numbers of unspecific artifacts. In contrast, the Upper and Lower Bone brecchiadas are richer and characterized by higher proportions of retouched and broken tools as well as cores, some of which were heavily utilized. Cutmark frequencies and degree of bone burning also differ between the three areas. In this paper, we attempt to define different activity areas across Lakonis by comparing bone taphonomy to differences in the composition and the main technotypological characteristics of the lithic assemblages between the three distinct contexts.

Stastney, Phil (University of Reading)

Heaps of Time: Methodological Considerations for Dating Earthen Mound Construction

Establishing a robust chronology is fundamental to consideration of the ritual significance of mounds. This can be as simple as placing a mound or group of mounds into their chronological and cultural context, exploring the chronological relationships between mounds and the pacing of mound construction, through to unpicking sequences of construction, use and reuse of a single mound. Fixing the act, or acts, of "mounding" in time is no less important than fixing them in their place in the landscape. Dating mounds may not be straightforward. There are several important methodological considerations that not only have an impact on the interpretation of dating evidence from earthen mounds but may also impact on our understanding of the ritual and symbolic nature of mounds. The act of mounding involves the collection and redeposition of material that is, by definition, older than the mound itself; whether this is the deliberate remolding of old material, or merely an accidental side-effect, this raises important considerations. Case studies from a number of morphologically similar but chronologically diverse mounds in England are presented, illustrating the insights as well as the practical and methodological challenges posed by dating large earthen mounds.

Stauffer, John (Washington University in St. Louis)

Greeting the Dawn: Investigations of Cahokia’s East Plaza

This paper provides an investigation of Cahokia’s East plaza and its associated architectural remains. Defined here as the area bounded by Mounds 31, 36, 38 (Monk’s Mound), and 51, the plaza was initially distinguished by an absence of surface debris, noted during controlled surface collection efforts in the Ramey Tract by Elizabeth D. Benchley and Barbara J. Vander Leest. Based largely on ceramics that were acquired by these investigators, the proposed time of construction has been placed between the Lohman and early Stirling phases, around the same time as the West, North, and Grand (South) plazas are believed to have been completed. As a relatively early construct that was overshadowed by the rise of Cahokia’s other forms of monumental architecture, the area in which the East plaza was established became a palimpsest for the site’s pioneering architects. Nevertheless, it comprised an essential component of the site’s cosmologically oriented layout. As such, it retained its own architectural nuances and metaphors, some of which are celebrated in our fragmentary understanding of Native oral histories.

Steele, Laura (University of New Mexico), Emily Lena Jones (University of New Mexico) and Jonathan Dombrosky (University of New Mexico)

Rebound, Stress, Persistence, or Subsistence? The Pre-Pueblo Revolt Fauna from Isleta Mission Convento

Although the Spanish documentary record from seventeenth century New Mexico describes challenging environmental conditions, faunal analyses from this time and region largely suggest a period of environmental amelioration. However, many of the assemblages that have been used to argue for improved conditions are from indigenous sites. Here, we present data on taxonomic relative abundance from the seventeenth century zooarchaeological assemblage from the Isleta Pueblo Mission Complex, and then use those data to test questions about environmental rebound or, conversely, stress in a Spanish mission environment in the period immediately after Spanish colonization.
Steele, Teresa (UC Davis)

**Testing for Mass Processing in Archaeological Ungulate Remains**

Archaeological applications of ethnographic models require that variables derived from the activities of living people be translated into archaeological terms. Enloe suggested that processing caribou (Rangifer tarandus) carcasses for food storage should be recognizable in patterns of bone fragmentation. He predicted that relatively uniform and large-sized bone fragments would result from mass processing for marrow as part of logistic collector subsistence strategies, compared with smaller and less uniform bone fragments typical of individual consumption practices by foragers. He tested this expectation with caribou remains derived from known activities in historic village sites. When I applied this model to a faunal sample from the Croxton Site, the expectation that late Holocene prehistoric occupants of northern Alaska were logistic collectors that mass processed bones for marrow was not supported. This result indicates either that site occupants were not logistic collectors, that mass processing did not occur, or that mass processing is not decipherable in the bone sample. Most likely explanations are offered and some implications of this study are discussed.

**Archaeological Chemists and Chemical Archaeologists: Working Together in the Lower Pecos Canyonlands, Texas**

This research is a collaboration between chemists and archaeologists to study the ancient mural paintings of the Lower Pecos. Using two independent methods, we are able to provide reliable age estimates for rock paintings. To obtain direct dates, we oxidize organic material in paint layers using plasma oxidation followed by accelerator mass spectrometry radiocarbon dating. For minimum and maximum ages, we isolate calcium oxalate in overlying and underlying accretion layers for combustion and radiocarbon measurement. Direct dates for three paint samples at Eagle Cave are statistically indistinguishable, suggesting the mural was painted as a single composition. In addition, chemical analyses identified rockshelter accretions as well as the mineral pigments used by ancient painters. Methods used include Fourier transform infrared spectroscopy, X-ray diffraction, and portable X-ray fluorescence spectroscopy. The combination of archaeological observations with physical science techniques offers a comprehensive recording methodology. As new high-resolution excavations are underway at Eagle Cave, the rock paintings can now be studied alongside excavated cultural deposits to provide a more complete understanding of this hunter-gatherer society.

Steeves, Paulette (UMASS Amherst)

**Indigenous Method and Theory in Archaeology**

Indigenous Archaeology has been described as archaeology with, for, and by Indigenous people. The differences between with and for, and by Indigenous people are critical to Indigenous peoples and society in general. Research framed in Indigenous method and theory is built within frames of respect, relationship, and reciprocity. It is praxis that weaves through institutional and public spaces to create social change. Such social change addresses the past real world consequences of colonial archaeology and addresses colonialism in the present. The impacts of colonization, including Eurocentric archaeological discussion of Indigenous communities are best understood through the lived experience of colonized populations. Research framed in Indigenous Method and Theory and carried out by Indigenous scholars and communities is most often, if not always a political act of resistance and rhetorical sovereignty, a reclaiming and reviving of Indigenous ways of knowing, being and doing. It is a weaving of knowledge, oral traditions, and science, reflecting a praxis that Indigenousizes the academy and education. Indigenous methods work to foreground Indigenous voices, counter dominant discourses, open paths to healing, and strengthen the community. In mitigating their predecessors' past, archaeologists are responsible for creating open and safe spaces for Indigenous scholars within the academy.

Steffen, Anastasia (Valles Caldera National Preserve) and Rachel Loehman (USGS Alaska Science Center)

**Wildfires, Forests, and the Archaeological Record: Investigating Complex and Persistent Human-Landscape Legacies**

Recent wildfire fires of western North America are occurring in some landscapes at intensities, severities, and extents that are far outside the historical record. These fires and their ecological and social consequences are highly-reported, and there is emerging awareness of the potential for large and severe wildfires to alter or destroy cultural legacies in fire-prone landscapes. Contemporary anthropogenic land use and management have contributed to altered wildfire regimes, but this can be better understood in the context of complex and persistent human-landscape legacies. The archaeological record is a potent source of information on how past occupations influenced ecosystem functioning, information that is needed for successful adaptation planning and climate change response in the coming decades. We discuss several projects that are ongoing in the Jemez Mountains of northern New Mexico, each designed to examine wildfire dynamics and human-landscape interactions across spatial and temporal scales. We consider the conceptual and practical tools needed to examine long-term human-ecosystem dynamics within seemingly natural areas; how fire effects can serve as secondary “artifacts” to be used to examine past fires; and how cultural and natural resources managers and researchers can work together to anticipate and offset the potential damage of wildfires.

**The Business of “Becoming”: Community Formation and Greek Colonization in the Northwestern Mediterranean**

Archaeological applications of ethnographic models require that variables derived from the activities of living people be translated into archaeological terms. Enloe suggested that processing caribou (Rangifer tarandus) carcasses for food storage should be recognizable in patterns of bone fragmentation. He predicted that relatively uniform and large-sized bone fragments would result from mass processing for marrow as part of logistic collector subsistence strategies, compared with smaller and less uniform bone fragments typical of individual consumption practices by foragers. He tested this expectation with caribou remains derived from known activities in historic village sites. When I applied this model to a faunal sample from the Croxton Site, the expectation that late Holocene prehistoric occupants of northern Alaska were logistic collectors that mass processed bones for marrow was not supported. This result indicates either that site occupants were not logistic collectors, that mass processing did not occur, or that mass processing is not decipherable in the bone sample. Most likely explanations are offered and some implications of this study are discussed.
In the early first millennium BCE, Greek communities sprang up around the Mediterranean, and the West was no exception. As the story goes, Ionian Greeks arrived in southern France and a legendary marriage to the local chieftain’s daughter ensured their acceptance as settlers. From their base at Massalia, they spread their trading foothold to Emporion on the Catalonian coast, cementing a relationship that was long-attested by the presence of Greek goods on western shores. Whereas rapid ‘Hellenization’ was the narrative that often followed such colonization, the situation in the West was quite different. Historically-identifiable Greek settlements are sparse, and even at those known sites, the makeup of populations and nature of communities is still being called into question. This paper examines the processes of community formation in southern France and northeastern Spain—how community identities took shape, shifted, or resisted when newcomers and locals came into contact—through the lens of repeated and daily practice in court and domestic contexts. It examines the role played by local communication and connectivity between settlements, and argues that the lack of overt ‘Hellenization’ in this region was in part due to a high level of shared social experience with newcomers far from home.

Steinbrager, Aubrey (ASM Affiliates) [103] Monte Cristo’s Gold: A Case Study of a Hard Rock Gold Mining Town in Washington’s Cascade Range at the Turn of the Twentieth Century

In the 1890s, the town of Monte Cristo, located deep within Washington’s Cascade Range, promised to be one of the state’s most profitable mining towns. Gold was first discovered in Glacier Basin in 1889, and Monte Cristo, assisted by a railroad that ran directly from the town to the city of Everett, developed nearby to support local mining endeavors. Unfortunately, the mines were not as profitable as originally hoped. By 1905, mining had mostly seized, and the town was eventually abandoned. In 2015, ASM Affiliates, Inc. conducted archaeological monitoring during a CERCLA project targeting the Monte Cristo Mining Historic District. During the project, 385 artifacts largely dating to the mining period were collected from 6 individual sites. This paper documents the results of research into the artifacts collected from the site which reveals details about the industrial and private activities undertaken within this important but short-lived Washington gold mining town at the turn of the twentieth century. It also details the international mining networks of the late 1800s which prompted the spread of new mining technologies into the American West and provided the impetus for hard-rock mining in Washington’s Cascade Range.

Stephenson, Birgitta (In the Groove Analysis Pty Ltd/University of Queensland) [42] Is that Roo on the Barbeque? Using Use Wear, Residue Analysis, and Biochemical Staining to Identify Varied Subsistence Practices in Aboriginal Archaeological Sites in Australia

Environmental factors associated with open context sites are frequently considered to negatively impact on the survival of archaeological residues on lithic artifacts. This report challenges these views and documents how the simple combination of three lines of evidence enabled the identification and characterization of significant and varied subsistence practices from two sites on opposite sides of Australia. The identification of use-related residues was facilitated by using a specifically developed suite of biochemical stains to provide visual support/evidence for the stories that have been passed down through generations of Aboriginal people. The results challenge the uncritical use of artifact morphology to assume function and demonstrates the value of analytical techniques to understand wide-ranging practices across various contexts. The first study documents investigations carried out on two open context grindstones from the site of Serpent’s Glen in the Western Desert of Western Australia. The second study examines flaked stone artifacts from a late Holocene open context site in the Lower Hunter Valley of New South Wales, in eastern Australia near Sydney.

Stephenson, Keith (USC Institute of Archaeology and Anthropology) [163] Aspects of Carved Paddle Stamped Designs from the Middle Mississippi Period
Complicated stamped pottery vessels, and the carved wooden paddles used to stamp them, were produced in Southeastern North America beginning early in the first millennium AD and continued in some quarters well into the nineteenth century. Much of the research on paddle designs has focused on the highly decorative and diverse Woodland Period expressions, with little attention given to later, more repetitive paddle stamps. In this paper, I bring the methods of analysis used to study Woodland paddle designs to bear on thirteenth-century paddle stamps from the Sandy Hammock site in southern central Georgia. By examining design variability at the scale of the individual paddle, inferences about household level production and, ultimately, social interaction can be made.

Sterling, Sarah L., Sarah K. Campbell (Western Washington University) and Virginia L. Butler (Portland State University) [228] Introduction to the Tse-whit-zen Site: Landform Evolution and Chronological Structure

Tse-whit-zen, a large ancestral village of the Lower Elwha Klallam Tribe, located on the southern shore of the Strait of Juan de Fuca, Port Angeles, WA, was excavated in 2004 as part of a transportation project. Its location on a protected bay adjacent to open marine habitats, and inland highlands gave rise to a diverse marine and terrestrial resource base. The site site is situated on a series of beaches representing relict shorelines, which generally prograde seaward over time. The site's geochronology is derived from finely defined cultural and geological deposits, with ages spanning the period from ca 2,800 years ago to contact, based on 52 radiocarbon ages from the original 2004 excavations, and 50 high-precision radiocarbon ages, taken from short-lived organic material, funded by the current project. Using excavation records, radiocarbon dates and ArcGIS we have defined seven chronostratigraphic zones and identified the remains of two structures, the occupations of which overlapped between 1250–450 BP, allowing for comparison of resource use between two households. In situ geomorphic evidence indicates impacts of two tsunami inundations; and the site was occupied coincident with known great Cascadia earthquakes. The occupation spans the Medieval Climatic Anomaly and the Little Ice Age.

Sternberg, Evan (Office of Contract Archeology, UNM), Justin Lowry (George Mason University) and Jason Paling (Plymouth State University) [326] Contemplating Trade Corridors: Cost and Pathway Analysis around Managua, Nicaragua

Trade and intercommunity connections are keys to understanding how the ancient region around the modern city of Managua, Nicaragua, interacted and participated in the larger Central American and Mesoamerican trade corridor. This paper will present potential interpretations of long distance and local connections through a cost and pathway analysis using ArcGIS. This study will incorporate recent research on obsidian and ceramic sourcing studies from the site of Chiquiutilagua into the model of interactions. Adapting site catchment areas, using trade and pathway data, and incorporating sourcing analyses will enable us to identify potential connections between sites and regions. These models may then be tested in future excavations around Managua, Nicaragua, to evaluate their utility.

Sterner, Katherine (University of Wisconsin-Milwaukee) [264] Examining the Use Lives of Archaic Bipointed Bifaces: Cache Blades from the Riverside Site

During the Late Archaic to Early Woodland transition, caches of blue gray chert bifaces were deposited throughout the Midwest, often in association with burials. Their utility between manufacture and deposition has long been the subject of speculation, but never compellingly demonstrated. Comprehensive use-wear analysis of these bifaces demonstrates that they were, in fact, used prior to deposition. Unfortunately, use-wear data in isolation tells us little about the actual role these bifaces played in the lives of the people who produced, used, and deposited them. Relatively few of these caches have been recovered as a result of systematic excavation, so other datasets that can be used to contextualize use-wear data are scarce. The Riverside Site is a Red Ochre affiliated burial and habitation site in the Upper Peninsula of Michigan, excavated by the University of Michigan, the Milwaukee Public Museum and the Oshkosh Public Museum. Excavations in the 1950s and 1960s uncovered a total of 83 bipoited bifaces. Use-wear analysis of a sample of these bifaces allows us to expand the conversation about their significance to include not only information about their depositional context but their active social and economic context as well.

Steuber, Karin (Saskatchewan Archaeological Society), Tomasin Playford (Saskatchewan Archaeological Society) and Biron Ebell (Saskatchewan Archaeological Society) [246] Saving the Best 'til Last (Day in the Field): The Farr Site Community Archaeology Project

Over 30 years ago, Biron Ebell reported the existence of a probable Cody Complex site near Ogema, Saskatchewan, situated about 100 km south of Regina. Since then, numerous artifacts have been recovered and a discrete scatter of bison faunal remains identified. Like most Paleoinid sites in the region, the Farr site had been recorded as a surface collection with artifacts and observed features exposed by cultivation, wind and water erosion. In 2014, the Saskatchewan Archaeological Society worked with Mr. Ebell to develop a community-based research program for the site. The goals of the project were to establish site boundaries, survey and map artifact and feature distributions, establish site integrity, confirm site age and interpret the site within the context of Paleoinid occupations on the northern plains. Local school groups, members of the local community and the general public assisted with pedestrian surveys, shovel testing and full-scale excavations in 2015 and 2016. This presentation will report on the results of the past two field seasons and showcase the community involvement in the project.

Stevens, Chris (Institute of Archaeology, University College London) and Dorian Fuller (University College London) [27] Agricultural Diversification, Perennials, and Complex Societies in Mesopotamia and the Yellow River

Mesopotamia and the Yellow River of China had long trajectories from early farming through to primary urbanization, but to what extent do the archaeobotanical records indicate parallel developments in terms of agriculture? In both areas agriculture diversifies during the late Neolithic, with an increasing range of annual field crops as well as evidence for the cultivation of some perennials (tree fruits or vines). However, diversity was much
higher in western Asia, from both a highly diverse Neolithic package of staples (multiple cereals and pulses) and co-staples to a range of livestock, craft-related/cash crops (e.g., flax, carthamus), and fruits (olive, grape, fig). In China a cereal-focused Neolithic was slowly augmented by beans, fiber, drugs, and a few fruits, but evidence for regional specialization and trade in crop products is lacking. Thus, while secondary crops may indeed have been important in the agricultural rise of complex societies, a more crucial common denominator would appear to have been simple agricultural expansion to provide more land for more staple crops to support larger overall populations and larger population centers.

Stevens, Chris [177] see Fuller, Dorian Q.

Stevens, Nathan (CSU Sacramento) [383] Bedrock Mortars as an Indicator of Territorial Behavior in Late Holocene California

Bedrock mortars were an integral part of intensive acorn economies in Native California and are a prominent feature of the Late Holocene archaeological record. Construction of these milling features also indicates a strong investment in particular locations on the landscape. Ethnographic evidence suggests the importance of local acorn crops led to ownership and defense of property rights in many areas. Human Behavioral Ecology offers a framework for examining the conditions that may have initiated these processes and their broader effects on Native culture. When and where bedrock milling features occur may provide evidence for evolving territorial behavior during the Late Holocene and further insights into how prehistoric Californians used technology and behavioral changes to solve the difficult problem of making a back-loaded resource both palatable and profitable.

Stewart, Christina (University of Oklahoma) [155] Reading between the Lines: A Biscuitware Analysis in the Lower Chama Valley

Archaeologists have long understood that the Lower Chama Valley in New Mexico was home to a large Tewa population during the Classic Period (AD 1340–1540) but the area underwent dramatic depopulation by AD 1600. The precise timing, motivation and movements of people are unclear due to the lack of chronological control in the region. One way to address this chronological problem in the Lower Chama Valley is through analysis of the abundant archaeological record. Construction of these milling features also indicates a strong investment in particular locations on the landscape. Ethnographic evidence suggests the importance of local acorn crops led to ownership and defense of property rights in many areas. Human Behavioral Ecology offers a framework for examining the conditions that may have initiated these processes and their broader effects on Native culture. When and where bedrock milling features occur may provide evidence for evolving territorial behavior during the Late Holocene and further insights into how prehistoric Californians used technology and behavioral changes to solve the difficult problem of making a back-loaded resource both palatable and profitable.

Stewart, Kathlyn, Grant Keddie (Royal British Columbia Museum—Archaeology), Susan Crockford (Pacific Identifications), Gay Frederick (Vancouver Island University) and Rebecca J. Wigen (University of Victoria—Department of Anthropology) [46] The Maplebank Site: New Findings and Reinterpretation along the North American Northwest Coast

Most discussions of the ‘complex’ fishing-gathering-hunting peoples of the Northwest Coast (NWC) focus on the Marpole Phase sites around the Fraser River Delta, BC. These contain evidence of developed social structures, an economy based on huge salmon runs and storage, and sophisticated art/architecture, and discussions of contributing factors to these traits usually focus on the perennial access to the Fraser River salmon runs. In contrast to Marpole sites are nearby ‘Islands’ sites, located along the Salish Sea. ‘Islands’ sites lack most Marpole traits, and are characterized as cultural laggards with non-specialized economies, attributed largely to lack of access to perennial salmon runs. However, new faunal data, based on 100,000 animal bones and updated stratigraphic information from Maplebank, a large, stratified Vancouver Island site, indicate that salmon comprised a greater percentage of the fauna than at Marpole and most NWC sites. This finding refutes (again) the link between salmon abundance and developed social and cultural NWC institutions. Further, an enigmatic hiatus in cultural deposition at Maplebank, coinciding with development of Marpole on the mainland, indicates widespread population displacement from Maplebank and other Islands sites. We discuss these and other findings, and their ramifications for change along the Northwest Coast.

St-Germain, Claire (Ostéothèque de Montréal, Université de Montréal), Christian Gates St-Pierre (Université de Montréal), Krista McGrath (BioArCh, University of York), Keri Rowsell (BioArCh, University of York) and Matthew Collins (BioArCh, University of York) [385] Black Bear among the St. Lawrence Iroquoians: Food, Tools, and Symbols

Bear bones have been identified in the faunal assemblages of Iroquoian sites of the St. Anicet cluster near Montreal, Quebec. Three village sites will be the focus of this presentation: McDonald, Droulers, and Mailhot-Curran, with comparisons with other Iroquoian sites, especially Hurons and Iroquois. Bear bones are few in the St. Anicet faunal assemblages, but a ZooMS analysis indicates a high frequency of bear bones used in the production of bone projectile points. This unexpected result will be explained using a blend of archaeological, ethnohistorical and ethnographic data, including Iroquoian mythology and ethnonyms, providing a glimpse of the economic and symbolic importance of black bear for St. Lawrence Iroquoians.

The Longue Durée of Malta (Mediterranean) and Lismore (Argyll, Scotland) Compared and Contrasted, and Set within Concluding Remarks  
The author has undertaken fieldwork on both of these two limestone island systems, one in the Mediterranean, one leading into the Atlantic. The paper will reflect on the longue durée development of these two contrasting contexts, in terms of the rhythms of settlement organization and interaction. The first, Lismore, an area of only 23.5 km$^2$, is set within an enclosed maritime zone close to shore, off the western seaboard of Scotland. The second, Malta, a larger area of 316 km$^2$, is set within the broader enclosure of the Mediterranean, but not sufficiently isolated to maintain the ideology of communication would have made a very great difference, particularly in prehistory. Occupation of both islands bridges the transition from prehistory into a globalized literate world. Both have important phases of monumentalization and strikingly different relationships to their near continents, according to the political contexts of the seas in which they are placed. The differences and similarities will be brought out in the discussion, allowing broader reflection on the papers that compare the Atlantic with the Mediterranean. The paper will conclude with a comparative analysis of the earlier examples presented, as a link to the discussants that follow.

Ballgames and the Social Networks of the Sierra Sur: What Can Ball courts Tell Us about Political Negotiation in Southern Oaxaca?  
As a specially marked category of public architecture, ball courts were both socially-integrative and socially-divisive spaces through hosting games and other important ritual activities. Moreover, research has shown that ballgames in Oaxaca acted as mechanisms of social mediation within and between different ethnolinguistic communities. The distribution of ball courts is therefore significant and expresses underlying social and political relationships. The Nejapa region is a frontier zone between the different ethnic territories of the Zapotec, Mixe, and Chontal-speaking peoples in the Prehispanic and modern era. It is also an important stop on interregional trade routes connecting the central valleys to the isthmus, and the altiplano of Mexico to the Soconusco region. Over the course of three field seasons, 16 ball courts were recorded in the Nejapa region, the majority of which are found within a 20 km$^2$ area. Outside of Nejapa, recent research in the quiechapa and Chontal regions to the south documented significantly fewer ball courts, while the Mixe region presents a different situation altogether. This presentation examines ball court features and distribution in Nejapa and surrounding regions in order to understand the political relationships between the different communities of the southeastern Sierra Sur through the medium of the ballgame.

Buried in the Sand: Investigations at Uchelliungs Cave, Palau, Micronesia  
Remote Oceania was one of the last major regions colonized by humans prehistorically. While there has been an increasing amount of archaeological and genetic research in the region in recent years, many parts are sorely un- or understudied. This is particularly true of Micronesia, where many questions remain as to how and when these early inhabitants settled and adapted to the area. The Palauan archipelago, which comprises hundreds of smaller uplifted limestone “Rock Islands,” hosts identified mortuary sites dating back to between ca. 3000–1500 BP. With some occasionally used as camps to harvest marine resources. To expand our understanding of Rock Island cave use over the last three millennia, we present the results of new test excavations at Ulchiulings Cave, a site that had been previously identified as an early burial cave containing purported small-bodied humans. In contrast to previous research—which reported only human remains and few artifacts—our results indicate that there is an abundance of faunal material and artifacts present. New radiocarbon dates suggest long-term use of the cave for both mortuary activity and small scale marine foraging that is contemporaneous with or even slightly before the earliest accepted known human occupation of Palau.

Central Andes Kotosh Religious Tradition, Third Millennium BCE: Hearth Designs as Andean Portals between Worlds  
On top of Caral Peru’s amphitheater mound, an entry passageway opens to an inner sanctum—tiered benches surrounding a sunken floor and a central ceremonial hearth. This concentric design recessed into the earth repeats in diverse ways throughout third millennium BCE Kotosh Religious Tradition temples in the central Andes. Whence the concentric sunken design and hearth? I propose the hearth functioned as Andean portals for communication with unseen worlds, giving offerings, remembering ancestors. Details of archaeologists’ findings in smaller mountain communities—one-room temples, offerings, and burial relics—complement Caral temple hearths amid stairs and entries, art and carvings. For long-term context, archaeologists noted varied and widespread sunken court designs through five millennia, and Spanish colonizers recorded portal sites for the unseen world. Today the design continues to be used in ancestral sunken courts, offering openings, and ritual fires of Lake Titicaca communities. This proposed model sheds light on central concerns of the earliest complex societies of the Americas, a regional scale society where archaeologists noted that social cohesion was created through religion not war, a society that endured a millennium and provided the foundations of major Andean prehistoric societies. This model would correspond with the long-lived Andean worldviews of cyclic life/death/rebirth and communication with ancestors.

Living and Dying a Bioarchaeological Analysis of Human Remains Recovered by Earl Morris at Aztec Ruins  
Aztec Ruins, an Ancestral Pueblo site in northern New Mexico, is recognized as a large and socially complex site. Aztec Ruins is typically considered in relation to the Chaco Phenomenon, although connections to Mesa Verde have also been made. Combined these relationships suggest close ties to other temporally occupied sites. Excavations of Aztec Ruins were undertaken between 1916 and 1923 by southwestern archaeologist Earl Morris.
Among his many finds he reported excavating 186 sets of human skeletal remains with a higher concentration of burial appearing in the West Ruin area of the Aztec Ruins complex. Unfortunately, only a third of these remains were collected, and fewer have been curated. In this paper we will discuss the politics and laws that impacted what was excavated versus what was curated. In our reanalysis of some of the curated human skeletal remains, we examine markers of stress, pathological conditions, activity, and nutrition, as well as consider the potential connections between Aztec and the Chaco and Mesa Verde complexes. Combined we offer a window into the lived experiences of these Ancestral Puebloan people, and their relationships to the greater Southwest.

[376] Betwixt and Between the Long and Short of It: The Pequop Projectile Point Type Site in Goshute Valley, Northeastern Nevada, and Implications for the Long and Short Chronology Debate in the Great Basin

In a 1995 study of the chronological patterning of Elko Series and Split-stemmed projectile points, Bryan Hockett concluded that neither type entirely matches the patterns of the Bonneville or Lahontan Basins; and that neither area represents good chronological analogues for northeastern Nevada. Dart points recently found in the well-dated context of an Early Archaic stratified open site in the northern Goshute Valley exhibit characteristics of both early side-notched and corner-notched types. Comparison of these points with projectile points found in Early Archaic contexts in the Bonneville Basin and other regions suggest that many of the points may have been routinely misidentified as Elko Series points and not an earlier transitional point type. In this paper, we propose a new temporally diagnostic projectile point type and explore the implications that the identification of what we term “Pequop points” may have on the Long and Short Chronology of the Great Basin.

Stoner, Wesley (University of Arkansas)

The Altica Project, which began in 2014, is an important step in addressing the limited problem-oriented research at Formative sites in the Basin of Mexico for over two decades. Altica is the earliest-known settled village in the Teotihuacán Valley and one of the only first-farming village sites in the Basin of Mexico that has not been engulfed by the urban sprawl of Mexico City. Despite its small size and remote location, Altica was an important piece in Early and Middle Formative exchange networks as it played a role in the early trade of Otumba obsidian and imported other goods from distant places in Mesoamerica. In this presentation, we frame the research project and outline major goals. Survey and excavation results are introduced. Finally, we prep each of the presentations to situate them within the framework of the general project goals.

Storey, Rebecca (University of Houston), Gina Buckley (Pennsylvania State University) and Douglas J. Kennett (Pennsylvania State University)

Altica is the earliest-known settled village in the Teotihuacán Valley, and perhaps the only first-farming village site in the Basin of Mexico that has survived to modern times. Thus, it provides a rare glimpse into life during the Early-Middle Formative period. While only four burials comprising four individuals were recovered from pits dug into bedrock, each tells a unique story. Two individuals are older-aged females, the third, a middle-aged male, was accompanied by prestigious nonperishable goods. The final individual presents a mystery. This individual was a young male buried in a deviant manner, suggesting possible foul play. While all individuals have indicators of periods of poor health, stable isotopic evidence of carbon and nitrogen paint a more complete picture of the types of food these individuals consumed over their lifetime. In addition, radiogenic strontium and oxygen isotope analysis of tooth enamel help us to understand from where these individuals originated and then lived throughout late adolescence. In addition, AMS radiocarbon dating completes this story, by providing a chronology of occupation in this early farming village.

[33] Dirt, Dynasties, and Devastation in North China: Geoarchaeological Perspectives from the Luoyang Basin

Anthropogenic disturbance of alluvial systems is increasingly influential through time, but the interplay of climatic systems and basin hydrology complicate attempts to fingerprint how humans influence these systems. We evaluate the importance of climate change, fluvial dynamics, and anthropogenic environmental modification in forming the Holocene sedimentary record of the Luoyang Basin, a tributary of the Yellow River, located in western Henan Province, China. Our fieldwork indicates that an unconformity found within the basin is roughly coincident with a major, human-caused, change in the lower course of the Yellow River in AD 1128. For the first time in the late Holocene, the Yellow River took a southern course, flowing out to the Yellow Sea. This course change not only had dramatic environmental consequences for the lower Yellow River valley, but may have also changed the fluvial dynamics of upstream tributary basins, such as the Luoyang Basin, from aggradation to incision, potentially destabilizing the area for hundreds of years. Although many paleo-environmental studies imply that anthropogenic environmental change is a gradual process involving climate and environmental change. This study demonstrates that historically contingent decisions of human agents can result in sudden, long-lasting, environmental impacts.

[182] Thirty Years after La Mojarra: Epi-Olmec Writing Revisited
Almost a century after William H. Holmes published the first study of the incomparable Tuxtla Statue, the La Mojarra Stela was recovered from the Acula River in Veracruz, Mexico. In the three decades that followed, the hieroglyphic script that pours over these objects has been scrutinized and debated, named and renamed, both deciphered and declared undecipherable. This paper reflects on the status of Isthmian studies and explores the intricacies of Epi-Olmec visual culture as it is understood today. Drawing connections to the Late to Terminal Formative contexts of the Pacific coast and highlands, as well as the other great script traditions of ancient Mesoamerica, this paper aims to move Epi-Olmec epigraphy from the realm of theoretical firebrand to its rightful place as an integral field of study within early Mesoamerican visual culture.

Strawhacker, Colleen (National Snow and Ice Data Center, University of Colorado), Grant Snitker (Arizona State University), Keith Kintigh (Arizona State University), Ann Kinzig (Arizona State University) and Katherine Spielmann (Arizona State University)

Marginal environments present risks to food shortfall, prehistoric small-scale societies, which create and rely on social and environmental strategies to mitigate those risks. One piece to understanding the vulnerability to failing to produce enough food is identifying the risk factors that may limit food procurement on a given landscape — in our case, the U.S. Southwest. Using large archaeological, historical, and ecological datasets, we present results from the Salinas region of central New Mexico, where Dr. Spielmann has devoted much of her research career.

[249] Dendrochronological Dating of a Burned Native American Structure at Fort Ouiatenon, Indiana

While dendrochronology has been used successfully to date standing historic period structures in the Midwest, its application in archaeological contexts has been limited. Recently, a large Native American structure was partially excavated from a village area adjacent to Fort Ouiatenon, in Tippecanoe County, Indiana. The wigwam-like structure was circular and 6.2 m in diameter. Though Native American occupation of the Fort Ouiatenon vicinity is known from ca. 1709 through 1791, very few artifacts were found in association with the structure, making it quite difficult to determine its approximate occupation date. One item, however, that was found in abundance was charcoal, as the structure had burned down. Some of the fragments were relatively large, containing as many as 43 annual growth rings. Recent efforts at developing a preliminary dendrochronological sequence for Indiana have made it possible to estimate the construction date for this structure. Through cross-dating (comparing the pattern of large and small tree rings in individual samples) a 43-year-long hickory and a 35-year-long maple chronology were developed. While additional data are still being collected in order to refine our estimates, preliminary results suggest that the structure was built in either 1776 or 1798.

[74] At the Intersection: Destabilizing White Creole Masculinity at the Eighteenth-Century Little Bay Plantation, Montserrat, West Indies

Guided by contemporary humoral theory, eighteenth-century Europeans believed climate and bodily humors to be mutually influential and correlated in their effect on human temperament, appearance, and behavior. Resettlement to a new climate was understood to create humoral imbalances fundamentally affecting an individual’s character and even physical appearance including skin color. Subject to the effects of tropical climate British settlers to the West Indies thus transformed were viewed as contaminated, degenerate, and culturally distinct by the metropole, their whiteness and Britishness called into question. Born in the colonies of British descent, the white Creole was inherently discrediting. Disrupting the notion that whiteness and masculinity are stable social categories, intersectionality as an analytical concept makes space for the relational aspects of white Creole masculinity situated at the intersection of the distinct social systems and power structures of the metropole, the Montserratian planter class, and the emergent racialized violence of the plantation. Looking at the way the architecture of the planter’s dwelling house offset the deleterious effect of climate and his clothing asserted his white, British masculinity, this paper explores the fluid, relational, and intersectional aspects of race, gender, ethnicity, and class as they informed the complexities of white Montserratian Creole planter identity.

[241] The Effect of Raw Material on Technological Organization and Recycling Practices in a Late Woodland Rockshelter

This paper attempts to synthesize the influence of raw material quality and abundance, mobility patterning, and social organization on the lithic assemblage. Each factor has been shown to have significant effects on the chaîne opératoire of lithic technology; acquisition of raw material, discard, and recycling. Following a literature review, distinct archaeological correlates to a wide variety of behaviors are used to analyze the lithic assemblage from Woodpecker Cave, a multicompartment rockshelter. The analysis shows that while raw material quality and abundance affected lithic production at Woodpecker Cave, the organization of technology correlated closely to lifestyle and mobility. By understanding this locality of production as one of many along a larger landscape, no single factor, such as raw material quality and abundance, or mobility, gains primacy over the others. Using the archaeological correlates described above provides a more holistic understanding of production processes.

[121] Lithic Technology and Reduction Strategies at Shishan Marsh 1
The 2013–2015 excavations at Shishan Marsh 1 have revealed an impressive array of stone tools at this Middle Pleistocene Oasis. More than 7,000 stone tools including: hand axes, scrapers, modified and utilized flakes, burins, Levallois points and flakes, cores, small pebble tools and debitage associated with tool manufacture and refurbishing, have been analyzed. Analysis was conducted on all tools and debitage using the lithic attribute analysis method, and low and high power magnification to examine edges and surfaces for wear associated with use. Forty-four tools were then selected and submitted for CIEP protein residue analysis. Based on the lithic attribute analysis, microscopic tool analysis, and results of the CIEP analysis, a model of hunter-gatherer lithic reduction strategies at this Middle Pleistocene Oasis will be presented.

Stumpf, Tyler (University of Kentucky), Vanessa Hanvey (University of Kentucky) and Richard Jefferies (University of Kentucky) [87] Searching for Spanish Footprints: Recent Geophysical Prospection on Sapelo Island, Georgia
The Sapelo Island Mission Period Archaeological Project (SIMPAP) has been conducting research on Sapelo Island, Georgia since 2003 in search of the Mission San Joseph de Sapala. Previous test excavations have produced potential architectural features and Spanish artifacts, while previous geophysical feasibility surveys hint at the presence of unique anomalies warranting further investigation. During the summer of 2016, University of Kentucky personnel conducted new ground-penetrating radar and magnetometry surveys across the site with the goal of locating and defining architectural anomalies associated with the suspected Mission structures. The survey focused on areas north of and adjacent to previous test excavations where evidence of architectural features and Spanish artifacts were located. This poster presents the results of the GPR and magnetometer surveys and discusses the results, in combination with previous archaeological evidence, to suggest the locations of Mission period structures.

Sturm, Camilla (University of Pittsburgh) [213] Evaluating Structural Change in Neolithic Economies: Social Network Analysis of Utilitarian Pottery Exchange in the Jianghan Plain
The emergence of walled town settlements of the late Neolithic middle Yangzi River region are widely associated with the development of a complex form of social organization. While significant attention has focused on the structure and organization of individual walled settlements, little is known about the nature of social and economic interactions between communities. To address this issue, I combined geochemical analysis of pottery with formal social network methods to investigate changes in utilitarian economic networks across a 1,500-year period. These economic networks were traced between the neighborhoods of two Neolithic walled settlements, Taojiahu and Xiaocheng, over a 56 km² region during the Quijialing (c. 3300–2600 BCE) and Shijiahe (c. 2600–1900 BCE) periods. Preliminary findings indicate that networks were less centralized and better integrated in the Shijiahe than in the Quijialing period, suggesting that economic interactions between these communities became less regulated through time.

Sturm, Jennie (University of New Mexico) [130] Recent Advancements in Remote Sensing Studies in Chaco Canyon
Remote sensing has been an integral part of Chacoan archaeology for several decades, helping to identify and map the broader landscape in and around the canyon. Early remote sensing studies, while pioneering, were often experimental and limited by the available technology. As the technical aspects of remote sensing continue to improve with advancements in computer power and data processing, it is now possible to move beyond experimental studies and broad characterizations of the Chacoan landscape to high-resolution, spatially accurate representations of localized areas. Furthermore, the products that can be generated from these new remote sensing investigations are often robust enough to use directly in the interpretation of a specific area’s cultural history. In this presentation, results from recent remote sensing investigations (including ground-penetrating radar and aerial photography mapping) from several areas within the canyon are discussed. The analytic methods used to collect and process the data are highlighted, as well as some of the archaeological interpretations that are possible using these data.

Styles, Bonnie (Director Emeritus, Illinois State Museum), Mona Colburn (Illinois State Museum) and Sarah Neusius (Indiana University of Pennsylvania) [61] Exploring Comparability of Archaic Period Faunal Datasets for the Interior Eastern United States
The Eastern Archaic Faunal Working Group uploaded nearly 60 faunal datasets for 21 archaeological sites in the interior Eastern United States into the Digital Archaological Record (tDAR) to address hypotheses about changing human reliance on aquatic resources during the Archaic Period. As an important prerequisite for our integrative study, we examined comparability of data. To ensure comparability of datasets developed by different researchers, we addressed variable structure and mapped key faunal attributes to existing and new tDAR ontologies. We analyzed variables related to bone preservation and destruction for eight pilot sites and developed a final taphonomic protocol based on evaluation of fragmentation, burning, and bone density-mediated attrition for use on all sites. We also developed a protocol for examining comparability for site type, context type, and recovery method. Assessments of bone destruction and recovery helped us identify problematic datasets. Taphonomic biases and recovery strategies affect bone representation for all sites, but most of our datasets appear to be relatively comparable. Informed by examination of biases, we proceeded with comparisons of human use of aquatic fauna within and among sites at multiple scales and are exploring the influences of cultural preferences, population size and demography, and environmental conditions.

Getting Accustomed...

Pueblo Indians have successfully managed social and environmental situations for thousands of years by moving our villages. However, after the Spanish invasion and the Anglo imposition, we were no longer as free to move. We’ve had to engage foreign ideas at our home villages in some cases very rapidly. Those in the 1950s were unlike anything we had seen in my pueblo. Seventy years’ changes in America happened in ten years not giving us much time for careful thought as to what side effects these carried. Among the many were paving the road that increased contact with tourists and the cash economy. Subsistence farming, our mainstay went to the wayside. The automobile, electricity, our diet and much more changed. This new trajectory in life threatened old values that sustained us over time as a people. Life became more individualistic and stressful in order to have regular cash to support the American Dream. It pulled us from our strong cooperative orientation. Evening gatherings and storytelling gave way to television. The English language overshadowed Keres right in our homes through the radio and television. Today we struggle to revive our language and many other culture gifts of our ancestors.

Eccentric Caching Practices of the Belize Valley

The ancient Maya expressed complex ideological and cosmological systems through diverse material practices. The ritual caching of objects, particularly offerings of chert and obsidian eccentrics, was a common manifestation of this integrated worldview throughout the Maya Lowlands. The study of these caches allows archaeologists to explore elements of ancient Maya ideology, which were shared across broad temporal and spatial landscapes. With over 100 years of previous archaeological research, the Belize Valley is an ideal locale for understanding regional caching practices. At the major civic-ceremonial center of Xunantunich, recent work by the Belize Valley Archaeological Reconnaissance Project revealed the presence of several dedicatory caches from the Late Classic Period, adding to the corpus of known caches in the valley. An examination of eccentric morphology and cache context from the Belize Valley elucidates the manifestation of strong regional traditions and pan-Maya ideology, as well as provides insight into access and consumption of local and long distance trade commodities.

Sullivan, Lauren (University of Massachusetts) and David M. Hyde (Western State Colorado University)

Social, Economic, and Political Changes: An Integration of Ceramic and Lithic Data from the Three Rivers Region

Archaeological research in northwestern Belize indicates a long history of occupation beginning in the Middle Preclassic and ending with abandonment in the Terminal Classic. The collection and analysis of ceramic and lithic data on a broad regional scale and across the entire range of settlement hierarchy allow for a comprehensive examination of social and political changes that occurred across the region. Stylistic changes in the ceramics, the continuity of lithic forms, and depositional patterns of both artifact classes provide information on the activities that occurred between the Late and Terminal Classic in the Three Rivers Region.

Oral Health and Dental Attrition of Human Remains from Tianli Cemetery, Xinzeng (ca. Eighth–Fifth Century BC)

Oral health (caries, antemortem tooth loss (AMTL), enamel hypoplasia, and dental attrition were assessed in human remains from Tianli cemetery, Xinzeng, Central China (Zhou Dynasty, ca. eighth–fifth century BC). This study explores diet and eating habits in a population practicing dry land agriculture. Males exhibited greater frequencies of enamel hypoplasia than females. In contrast females suffered more from caries, AMTL, and tooth wear than males. Heavy wear on the upper anterior teeth is remarkable when compared to other regions and other subsistence strategies in pre-Qin China. Higher frequencies of oral health markers for females than males suggest that diet followed gender division, with more cereals such as millet in the diet of females. Stable isotope analyses from other human skeletal samples in Xinzeng suggest males might have had more access to meat than females. Furthermore, the much higher frequencies of enamel hypoplasia, cribra orbitalia, and porotic hyperostosis in males suggest that males generally were exposed to more stress than females. In addition, heavy wear on the anterior teeth at Tianli, especially in males may be related to teeth being reduced in strength by enamel hypoplasia, crops machined roughly, and/or frequent use of teeth as a third hand.

Risk in Collaborative Archaeologies of Place as Engaged Scholarship
Drawing on examples from my community-engaged work in post-apartheid South Africa and post-annexation New Mexico, I want to talk about the kinds of risk my community partners navigate in our collaborative archaeologies. Both communities are focused tightly on colonial-era processes that have translated into dimensions of racialized inequalities, against which we hope archaeological partnerships might be employed and produce tools that do more good than harm.

What Makes Us Beat? Toward a Heart-Centered Practice in Archaeological Research
Within the discipline of archaeology, we conventionally employ rational, science-based analyses to examine ancient cultures. Yet the lives of archaeological practitioners, contemporary descendent communities, and the ancient peoples we study, are more than just minds and bodies. In this paper, we outline a framework for a heart-centered archaeological practice that draws from foundational literature on feminist, Indigenous, and community-based archaeologies. We posit that a heart-centered archaeology will allow us to bring our whole and integrated selves to our practices and will broaden our understanding of and relation to the lives of the people we study. Like the organ we draw inspiration from, an archaeology of the heart flows through four main channels: 1) care; 2) emotion; 3) relationality, and 4) rigor, strengthening and feeding the structure of the discipline. Heart-centered practice, guided by these principles in the past and present, opens new avenues of research and pedagogy in which the relationships we build with ourselves, other humans, and the broader world inform our understanding of the material record and shift the ways we teach and learn about the past. Using examples from our experience, we work to discover how these principles can be applied to archaeological research and pedagogy.

“I Could Feel Your Heart”: The Transformative and Collaborative Power of Heartfelt Thinking in Archaeology
As anthropologists we know that the heart is considered a source of strength in many cultures. Yet in Western society and the culture of science, an epistemology of the heart or heartfelt thinking is generally feminized and as a consequence, devalued. Guided by Feminist and Indigenous theory, I have established an archaeological practice that foregrounds heartfelt thinking as part of community-based heritage work. Importantly, I strive to train the next generation of archaeology professionals to recognize the role of the heart in promoting an effective multivocal research perspective. There are many challenges to such an approach, not least of which is the perception that inclusive and reflective practice is a sign of weakness. I will discuss the personal challenges I have experienced in operationalizing an “archaeology of the heart” and explore why it is imperative to overcome these problems to reinvent our discipline.

Reconstructing the Historical Abundance and Importance of Large Whales in Northern British Columbia
Whales obtained through various combinations of hunting and scavenging have long provided coastal communities worldwide with sustenance and many raw materials. However, global whale populations have been severely depleted by commercial whaling. This study combined historical abundance reconstruction with ecosystem modeling to investigate the effects of whaling on the abundances and ecological roles of five large whale species (blue, fin, sei, humpback and sperm) in northern British Columbia waters. Unexploited local whale abundances were reconstructed using population models based on recorded catches and entered into an Ecopath food web model. The changing ecological role of these whales was examined by comparing two Ecopath models representing pre-whaling and current ecosystem states. The results revealed massive changes in the absolute and relative local abundances and ecological importance of these whale species during the twentieth century. Combined with habitat modeling in Ecospace, these results indicate a vastly greater availability of both live and drift whales (particularly fin and humpback) to coastal foragers prior to the depletion of whale stocks in the early twentieth century. These results demonstrate the historical importance of whales in northern British Columbia, as well as the utility of linking population and ecosystem models in the study of whaling.

High-Precision Mapping of Human Behavior in Ethnographic Contexts, a New Tool for Ethnoarchaeology
Ethnoarchaeological studies attempt to link human behavior to the material residues they produce for the purpose of developing archaeological method and theory. Traditional studies in spatial ethnoarchaeology, however, have focused on the mapping of material remains, but the spatial distribution of the behaviors that produced them, the thing that interests us most, has gone largely undocumented and for good reason. Until recently, it was not technically possible to map people in space in a way that is simultaneously accurate, precise, and unobtrusive. In this paper, we discuss the use of time-lapse photography and photogrammetry for the direct, frequent, and high-precision mapping of human behavior in ethnographic contexts. We illustrate the use of this method using a case study from campsites of nomadic Dukha reindeer herders in Khövsgöl Aimag, Mongolia. It is argued that this method not only provides much needed data on how humans use space but also that abundant ancillary behavioral data are collected. As such, time-lapse photography and photogrammetry could become part of the standard tool kit for ethnoarchaeological research.

Quintessentiallyizing the Power of Place in the Ancient Andes
The co-extension of peoples, places, and things as interdependent social actors were fundamental to Andean spatial ontologies. For instance, the “multiflex” Paria Caca of the Huarochiri Manuscript was manifested as five eggs, five falcons, five brothers, and a great mountain that still bears his name. In this paper, I argue that quintessential locales in the ancient Andes were often places where wholes and parts, microcosmos and macrocosoms, interiors and exteriors, and complementary opposites either converged or became materially differentiated. Living landscapes uniting or animating essential life-forces were thus sites of heightened semiosis entailing the intensified materialization and interchangeability of different sign modalities (Peirce’s modalities of firstness, secondness, and thirdness). Although reminiscent of traditional theories on the “center” as an axis or imago mundi, a comparison of unmodified wak’as and built landscapes in the Jequetepeque Valley of the North Coast of Peru will demonstrate considerable variation in how the structure of underlying social networks leads to the emergence of social complexity in past middle-range societies. Archaeological proxy data for each of the relationships defined above are analyzed using methods derived from complex systems and small world network science. Using the Prehistoric Bronze Age on Cyprus, a transitional period on a Mediterranean island with clear indications of changes in complexity from small egalitarian communities to those with social and economic leadership, the emergence of complexity will be tested at multiple scales across both space and time. These results are compared to Gini coefficients for scaling wealth inequality, and diversity metrics for understanding how wealth and diversity covary with different kinds of social network arrangements and identify inequality thresholds for changes in social networks. The presented results will highlight a nonlinear trajectory for social complexity in middle-range society.

Swanson, Edward (University of Toronto)
Social Complexity and Wealth Inequality in Middle-Range Society: A Complex Systems and Network Science Approach to the Prehistoric Bronze Age on Cyprus
Economic leaders create and maintain unequal or dominance relationships within and between communities by controlling labor, and limiting access to technological, material and ideological resources, and trade networks. Through these kinds of actions and interactions, social networks are structured and restructured altering the flow of goods, services and information. From this bottom-up process, social complexity emerges. To understand how the structure of underlying social networks leads to the emergence of social complexity in past middle-range societies, archaeological proxy data for each of the relationships defined above are analyzed using methods derived from complex systems and small world network science. Using the Prehistoric Bronze Age on Cyprus, a transitional period on a Mediterranean island with clear indications of changes in complexity from small egalitarian communities to those with social and economic leadership, the emergence of complexity will be tested at multiple scales across both space and time.

Tewa Place-Based History
Tewa history is the story of places. The narrator emplaces a story within the context of Tewa time by naming the place at which the story takes occurs. By using a Tewa place-based approach to narratives of the past, I demonstrate three important points. First, that history is an ethical act. Tewa history helps reproduce the values of good humanness. Second, that Tewa place-based history reconnects the narratives of the past with people’s relationship with land and linked responsibilities. As such, it serves as guidance for long and ongoing relationships with place. Finally, place-based history emplaces the past within a cultural landscape and de-universalizes history.

Precolumbian Diet and Subsistence Strategies in the Aconcagua Valley of Central Chile, from the Early Ceramic to Late Periods: Evidence from Stable Carbon (Δ13C) and Nitrogen (Δ15N) Isotopic Analyses
This research documents past diet and subsistence strategies of the precolumbian ceramic societies in the Aconcagua Valley of central Chile. We aim to characterize the late Holocene cultural, social and economic interactions of this geographically strategic zone between the semiarid north and more fertile central Chile. Dynamic changes over the past two millennia include the establishment of culturally heterogeneous enclaves from the north alongside local populations. The broader region of central Chile was also the southernmost limit of the Inka Empire as well as part of the southernmost frontier of maize agriculture in the Americas. We are resolving variations in diet with complimentary analyses of dental paleopathologies coupled with stable carbon (Δ13C) and nitrogen (Δ15N) isotopic analyses of bone using human skeletal remains from the collections of the Museo Histórico-Arqueológico de Quillota (MHAQ). These changes are evaluated in the context of the coeval economic and political transitions, including the adoption of new technologies and domesticates and the expansion of different cultural influences.

Applications of Rat Bone Collagen Stable Isotope Analysis toward Investigating Long-Term Island Socio-Ecosystem Dynamics: Case Studies from Mangareva (French Polynesia) and Pemba Island (Zanzibar)
Stable isotope analysis of small commensal fauna provides a novel approach to paleoecological reconstruction and investigations of human site activities. The human translocation of rat species, especially the black rat (Rattus rattus), brown rat (R. norvegicus), and Pacific rat (R. exulans), has significantly—and often deleteriously—impacted native floral and faunal communities, particularly within island ecosystems. Rats are small-bodied omnivores with limited home ranges and highly generalized diets, and thus can provide a localized picture of landscape change and resource availability. On small islands in particular, rat diet has proven sensitive to island-wide changes in ecosystem dynamics. This paper compares bone collagen carbon and nitrogen stable isotope data from two rat species (R. exulans and R. rattus) recovered from archaeological sites within two separate island regions (Mangareva Islands, French Polynesia and Pemba Island, Zanzibar). Results demonstrate the efficacy of rat diet as a paleoenvironmental proxy for investigating human-environment dynamics, including species extinctions and nutrient flows within human-centered food webs.

Szymanski, Ryan (Washington State University) [154] Human Landscape Modification and Environmental Change in the Western Kenyan Highlands

Interpretative changes involving concepts of equilibrium and causation can chronically hamper environmental reconstruction efforts, as numerous physical, environmental, or anthropogenic processes may potentially be responsible for creating observed raw data patterns. Nested multi-proxy and multi-scalar analyses offer potential means of approaching these difficult conceptual issues which can plague interpretations reliant on single lines of proxy evidence. A dataset comprised of multiple paleoecological proxies, including pollen, phytoliths, and fungal spores, derived from a sediment core from Kingwal Swamp, Kenya, is presented in order to illustrate these issues and means of resolution. Using the different origin points, production, distribution, deposition modes, and associations of these proxies, I argue that discord in data between these sources can aid in isolating some of the possible environmental scenarios which may have produced particular data patterns, and may enable researchers to more effectively separate anthropogenic versus climatic impacts on past environments. It is proposed that more intensive study of the microbiotanical content of sediments is critical to improving paleoecological, and by extension, archaeological knowledge of ancient landscapes and their inhabitants.

Typological and Archaeometrical (pXRF) Study of Final Bronze Age Ceramics of Cuccuruzzu, Corsica

The construction of large stone fortresses, the casteddi, is a defining phenomenon of the Bronze Age period of the Mediterranean island of Corsica (France). However, the function and the precise chronological setting of these structures are still debated. The summer 2015 preventive intervention at the fortress of Cuccuruzzu has revealed some new information on the socioeconomic context of ceramic production during the Final Bronze Age (1200–850 BC). The typological study of the material indicated the existence of two distinct categories of ceramics, a fineware and a coarseware. In order to determine if these two types of ware corresponded to differential patterns of production and distribution, a portable X-ray fluorescence spectrometer (pXRF) was used to establish the chemical composition of sixty-seven artifacts and compare it with local clay sources. Multiple spots were analyzed on each sample, and multivariate statistics applied to trace elements Rb, Sr, Y, Zr and Nb. The results suggest that while most of the coarseware sherdswas present a chemical composition and were presumably manufactured with local clay, a large proportion of the fineware was made with imported or unusual raw material.

Taber, Emily C. (Portland State University) and Virginia L. Butler (Portland State University) [194] Toward Developing an Economic Model of Fish Rank for Late Nineteenth-Century Pacific Northwest Households

Considerable research has been conducted on archaeofaunal food remains as a proxy for consumer practices in Euro-American historical archaeology. Such research often incorporates price-driven meat rankings, in which the historical cost of a meat cut determines its rank. Archaeological fish remains also present an opportunity to examine how historical communities engaged with fish that could be acquired through subsistence practices, leisure activities, or market purchases. However, the social-economic rankings of fish have rarely been considered, even in the Pacific Northwest where fish were central to human lifeways. When fish remains are incorporated into rankings, they may be included only as one ranked item ('fish') and a single cut ('whole'), which fails to recognize the cultural and economic importance of fishes in historical Pacific Northwest communities, as well as the biodiversity of fishes that can vary greatly in size, abundance, seasonality, and so forth. This pilot study is part of a research effort to establish a price-driven meat ranking for Pacific Northwest fishes between 1860 and 1910. Pricing data for local fishes has been systematically collected from late nineteenth-early twentieth century newspapers, with prices averaged and adjusted to reflect stable rankings during the late Victorian era.

Tache, Karine (CUNY Queens College) [319] Early Pottery and the Quest for Fat in Northeastern North America

Accumulating evidence point toward hunter-gatherer communities as the first inventors of ceramic containers in many parts of the world, but the incentives behind this technological innovation remain elusive. In this presentation, archaeological information and biomolecular data from organic residues analyses are combined to support a scenario in which preagricultural communities in Northeastern North America used early pottery as a fat rendering device, whether the fat came from fish oil or bone grease. Rather than a sine qua non for extracting nutrients from specific resources, however, the invention of pottery is best understood as part of broader developments featuring seasonal gatherings and a new articulation of social relations.

Taffere, Abebe (University of Florida) [55] Terminal Pleistocene Lithic Technology and Adaptation from Bulbulia River B1s4 Site, Ziway-Shala Basin, Ethiopia

Archaeological excavation which had been conducted in 2009 and 2010 in the Ziway-Shala Basin, close to the Bulbulia River Canyon at B1s4 site, has yielded lithic assemblages and few faunal remains. Two human occupation horizons (PS1 and PS2) were identified which are separated by an occupational hiatus at the very end of the terminal Pleistocene. Analysis of debitage on both unit levels indicates the presence of similar features that lead us to assume that B1S4 industry was oriented toward the production of blades and bladelets. But, this site shows strong technological and industrial variabilities to early Holocene sites which are very close to B1S4. The microliths, which are widely discovered at early Holocene sites and to a lesser extent sites dated to Pre-Glacial Maximum, are hard to find at B1s4. Alike Paleoenvironmental records in the Ziway-Shala basin and other parts of Ethiopia and Eastern Africa, B1s4 has proved that terminal Pleistocene was characterized by fluctuating weathering conditions that might have forced hunter-gatherers in the region to practice diverse adaptive strategies.
Esta ponencia explora el espacio arquitectónico de la sacristía ubicada en la reducción de Santa Cruz de Tute, en el valle del Colca, Arequipa. A Consideration of Totemism in Late-Latest Jomon Age Based upon Archaeological Records

Recent advance in anthropology have resurrected the term totemism from earlier the theories developed by such scholars as Robertson Smith and E. Durkheim at the beginning of twentieth century. The crucial features of totemism are: 1) it represents total emblems of the descent groups; 2) it functions to support solidarity of the group; 3) it has as exogamic function; 4) it invokes taboos against killing certain animals and eating them; 5) it constitutes intimate relationships between human being and specific animals and plants; and 6) it strengthens the special bound human groups and their ancestors by means of ceremonial feasts and rituals. From an archaeological perspective, some elements of totemism are present in the Late to Latest Jomon age culture in Japan, including evidence of zoomorphic clay figures and ceremonial feasts and rites, animal sacrifice, polite attitude for special animals, identification animals for human. Those features were diagnostic in northern Japan in Late Jomon age.

The Colonization of the Southern Ryukyu Islands, Japan

The Ryukyu Islands are located in the western Pacific between the islands of Kyushu and Taiwan, stretching approximately 1,200 km. The focus of this presentation is the Southern Ryukyu islands, which consist of the Miyako and Yaeyama archipelagos. Until recently, the Miyako Island was the only island in this region which yielded fossil human remains dating to the late Pleistocene. Recently, human fossil remains dating to the same period has been unearthed from the Yaeyama islands. During this period, these islands were not connected to the mainland of Taiwan or China, indicating they crossed water gaps at this stage. This presentation first introduces these late Pleistocene data, and then examines the Holocene colonization processes. While it has been not well understood, many scholars believe the first colonization to the area took place not from the north (from the Okinawa archipelago) but somewhere from the south such as Taiwan and/or Philippines. Furthermore, there seems to have been another colonization to the islands at the beginning of the Gusuku period. This time, the colonizers appear to have come from the north.

Nukubalavu: An Examination of Fijian Mid-Sequence Ceramics on Vanua Levu, Fiji

This paper reports on excavations from field seasons in 2013 and 2014 when major excavations on the main landmass of Vanua Levu, Fiji were conducted at the beach site of Nukubalavu. This site is positioned on a small peninsula in the island’s southeastern Natewa Bay region. Nukubalavu produced ceramic assemblages that extend to all of Fiji’s known culture history. The team also documented a deeply buried probable house floor with diagnostic artifacts that indicate intensive occupation during Fiji’s Mid-Sequence (ca. 2800 BP–500 BP). The assemblage includes Late Lapita rim fragments with dentate stamping, body sherds and rims of large Fijian Plainware vessels, and fragments from the Navatu phase. With such a diverse representation of Fijian material culture and approximate dates via Radiocarbon AMS, Nukubalavu presents a rare opportunity to inspect in detail changes that may have occurred between the Plainware and Navatu phases of the Fijian Mid-Sequence. A detailed examination of the assemblage is underway, which will help to determine if stratigraphic variations, corresponding with our Radiocarbon AMS dates and Bayesian models, demonstrate clear correlations with the distribution of ceramic types.

High C4 Plants Consumption from the Late Intermediate Period in the Cuzco Region

Maize was one of the important crops for Inca political economics as a ritual and a staple food. In previous study of sacrificed children mummies found at Mt. Llullaillaco, the individuals particularly consumed C4 resources (such as maize, amaranth and domestic animals raised with C4 plants) in ritual activities. Contrary, the dietary compositions of Machu Picchu skeletons have shown diversity. The individuals from Mt. Llullaillaco and Machu Picchu were most probably immigrated from different regions and may not represent the diets in the capital city of Inca. Therefore, it is important to reveal inherent diet of the Inca group which had been emerged in Cusco region to get better understanding of their maize usages in their economy.

We conducted dietary investigation on the five sites of Cuzco region using carbon and nitrogen isotope ratios. Our data revealed that high C4 resource consumption started by the Late Intermediate period. Meanwhile, nitrogen isotope ratios of Sacsayhuaman in Cuzco city were the highest. Estimation of marine resource consumption using 14C date suggested that their high nitrogen isotope values were derived from C4 plants. Inca may have had an agricultural system using guano as the fertilizer or putting a priority on the amaranth cultivation.

Uso de un espacio sagrado: Excavaciones de la sacrístia de una reducción colonial en la Sierra sur del Perú

Los espacios rituales han sido desde siempre lugares importantes dentro de las comunidades humanas pues son la expresión material de sus creencias y su fe. En el caso del Virreinato del Perú, la invasión española del siglo XVI significó un cambio radical en la concepción y materialización de la religiosidad practicada, donde la construcción de edificios de carácter religioso encarnó el cambio de vida y costumbres de los pueblos conquistados. Esta ponencia explora el espacio arquitectónico de la sacrístia ubicada en la reducción de Santa Cruz de Tute, en el valle del Colca, Arequipa. Las excavaciones realizadas dentro del Proyecto Arqueológico Tuti Antiguo durante la temporada 2016 han permitido distinguir los diferentes usos de este recinto y su transición hacia un espacio sagrado y de culto. Una serie de remodelaciones arquitectónicas, la presencia de objetos de culto y contextos funerarios de infantes, señalan el uso variado de este espacio para el desarrollo de actividades rituales durante su ocupación y su posterior abandono. Estos indicadores nos dan luces sobre la vida religiosa en las reducciones durante la Colonia y nos permiten entender la relación que la población de entonces mantenía con estos espacios sagrados.

Modeling the Relationship between Riverine Resource Exploitation, Technology, and Social Organization in the Sacramento River Basin

Isotopic studies allow for a more refined look at variation in diet and mobility among individuals. These studies have been used in California as a proxy for analyzing human behavioral adaptations. In this study we use stable isotope analyses of human bone collagen and apatite to evaluate diet of...
individuals from sites within the Sacramento River basin over time. Ethnographic accounts from this area emphasize the importance of mass salmon procurement and describe high levels of social organization, trade, storage, and specialized fishing and preservation technologies. However, archaeofaunal assemblages from this region often lack evidence of intense salmon exploitation, limiting knowledge of the time depth of these practices. For this study, we examine specific dietary indicators of riverine versus marine protein resource exploitation and use this to model the relationship between diet, technology, and social organization through time. Site location and chronological context are used as proxies for technological constraints and population size.

[249] Removal of Coal Contaminants from Chaco Canyon Radiocarbon Samples

Micro-flotation, a specific gravity separation technique, was successfully used to remove coal contaminants from radiocarbon samples obtained from profiles, unit excavations, and sediments cores in Chaco Canyon, New Mexico. Coal from the Cretaceous Menefee Formation occurs throughout Chaco Canyon in aeolian, alluvial, colluvial, and anthropogenic sediments. The Menefee Formation contains carbonized broadleaf angiosperm and gymnosperm plants and, as such, paleobotanical analysis was not effective in the identification and removal of coal contaminants. The effectiveness of micro-flotation as a pretreatment procedure was evaluated by 1) comparing AMS radiocarbon ages on processed and unprocessed samples from the same archaeological contexts; 2) comparing a processed sample of carbonized hardwood charcoal with a sample of uncarbonized hardwood from the same archaeological context; and 3) comparing radiocarbon ages on a split sample of processed bulk carbon. The comparisons confirmed the effectiveness of micro-flotation in processing samples for radiocarbon dating in Chaco Canyon and would be applicable for similar locations elsewhere in the world.

[308] The Pinta Ceramic Phase: Explaining a Paracas Ceramic Phase from Cerro del Gentil

During the last five years, we have developed an archaeological research program in the southern Peruvian coastal valley of Chincha. This project focuses on the rise of the Paracas society ca. 800–200 BCE. We excavated the monumental Paracas site of Cerro del Gentil located in the Chincha mid-valley where we recovered an important ritual context in a sunken court related to the Pinta phase. The Pinta phase was defined by Dwight Wallace in 1950’s but not has been systematically described. In this paper, we describe the Pinta assemblage and contextualize it in a regional context of Paracas emergence.

[164] An Evaluation of Stingless Bee Wax as a Pattern Material in Mesoamerican Investment Casting

Mesoamerican metal objects have been studied in-depth in terms of alloys and production techniques, but little work has been carried out on the foundry materials used in the prehispanic casting process. In modern foundry practice, synthetic waxes, paraffins, or processed European honeybee wax (from the Apis genus) are commonly used as pattern materials. One possible ancient Mesoamerican pattern material is the wax of the stingless bee Melipona beecheii, a species known to be cultivated by the Maya. Ethnohistorical sources attest to the widespread practice of meliponiculture in prehispanic Mesoamerica at Spanish contact. Meliponiculture was particularly common in Northern Yucatán where its products, honey and beeswax, were commonly exchanged as commodities, and were staple products used to pay provincial taxes. Archaeological evidence, including metallurgical ceramics and production debris, suggests that lost-wax casting formed an important component of Postclassic period Maya metallurgical technologies at the urban centers of Mayapán and Lamanai. This paper examines the efficacy of stingless bee waxes as a foundry wax, particularly as a component of the copal-wax mixture described in the Florentine Codex. The thermal, mechanical, and rheological properties of these waxes and blends will be evaluated in order to assess their use in a foundry context.

Museums display archaeological human remains to educate visitors about past people’s lives, beliefs, and customs, and to encourage reflection. However, over the past fifty years, political changes, including civil rights, decolonization, and repatriation movements, have driven some museum professionals and academics to reevaluate the authority of museums and their ethics. These developments have inspired discussions about the ethical treatment of both Indigenous and non-Indigenous human remains, which are now reflected in professional guidelines and accords emphasizing ‘respect.’ The display of Indigenous human remains is usually considered unethical. However, when it comes to other institutionalized human remains, the definition of ‘respect’ is unclear. A number of museum professionals have experimented with methods of displaying non-Indigenous archaeological human remains with respect. They attempt to tackle this ethical issue and create public dialogue by displaying remains in new ways, or by removing existing displays. This presentation will review recent developments in museum ethics pertaining to the treatment of human remains, with a focus on novel approaches to displaying archaeological human remains. It will highlight public and professional reactions to such displays, and discuss what may be learned from these examples about ethical display practices for the future.
Equine Dentistry and Early Horse Husbandry in the Mongolian Steppe

Although nomadic horse pastoralism remains an important way of life in eastern Central Asia, the origins of horse herding in the region and their relationship to key social developments are poorly understood. Recent work indicates that late Bronze Age people of Mongolia’s Deer Stone—Khirigsuur (DSK) Complex herded horses, and used some of them for transport by circa 1200 BCE. This paper presents evidence that DSK people practiced equine dentistry and veterinary care, removing or modifying incorrectly erupted deciduous incisors that may have interfered with feeding. Results indicate a sophisticated knowledge of equine anatomy and behavior during the late Bronze Age, which would have contributed to the success of nomadic societies in Mongolia during the first millennium BCE.
Toward Complexity in the Osseous Raw Material Work at the Beginning of the Early Upper Paleolithic in Eurasia: The Manot Cave (Israel)

Osseous Tools in the Aurignacian Emergence and Diffusion Context

The Early Upper Paleolithic in the Levant plays an important role in understanding the emergence, dispersal, and adaptations of the first anatomically modern human populations in Eurasia. The exploitation of osseous raw materials for technical and conceptual behaviors is recognized as one of the several innovations that have occurred both in the Levant and in Europe during this time. Previous works demonstrated that the complex and innovative working of osseous materials in Europe is restricted to antler working, around 40 Ka cal BP, and are thus chronologically coincident with the emergence of the Early Aurignacian. Conversely, bone exploitation shows a continuity through the Mousterian, the Proto-Aurignacian and the Early Aurignacian, invalidating the argument that osseous material exploitation represents a radical difference between the Middle and Upper Paleolithic in Europe. We present the results of a technological analysis on the bone/antler industries from the EUP (Aurignacian) layers at Manot Cave, Israel. Comparing the technical concepts of the bone/antler working, through the operational sequence, between the European and the Levantine Aurignacian allow us to discuss the significance of the osseous raw material exploitation in the framework of the different proposed hypotheses on the emergence/diffusion of the Aurignacian techno-typological tradition over Eurasia.

Establishing Provenance for Chert from Southern Baffin Island: a Multi-Scalar Approach

Difficulties in physically or chemically distinguishing between chert from closely situated quarries have made a multi-scalar approach to chert provenance analysis necessary in some regions. We present the preliminary results of a multi-scalar chert provenance project focused on the eastern Canadian Arctic. On a regional scale, we examine ICP-MS trace element results for chert from two quarries and five archaeological sites on southern Baffin Island. Chert from the quarries and archaeological sites is chemically similar. However, provenance assignments based on these data alone must be viewed as highly provisional, given that the chemical signature of the materials analyzed may be representative of chert deposits throughout the eastern Arctic. We augment these data with ICp-MS trace element results for chert quarry and archaeological samples from the Churchill region of the westernmost coast of Hudson Bay, which diverge significantly from those of the Baffin Island quarries. These results support placing the Baffin Island quarries into a regional quarry group to which provenance for the Baffin Island archaeological material can be more confidently assigned.

Covering Ground: Spatial Relationships of Prehistoric Sites on Black Mesa, Arizona

Modern applications in spatial analysis are reinventing the way archaeologists view spatial relationships in the prehistoric Southwest. Building on the extensive research conducted by the Black Mesa Archaeological Project (BMAP), this poster presentation presents new insights into spatial relationships and social dynamics on northern Black Mesa, Arizona using ArcGIS applications, as well as predictive modeling. Recently conducted pedestrian survey on Peabody Western Coal lease areas on Navajo and Hopi tribal lands provide spatially accurate data to address lingering questions within Black Mesa archaeology, such as the relationships between primary and secondary Ancestral Puebloan habitation complexes.

Late Pleistocene Campsites of the Transbaikal, Siberia

Late Pleistocene settlement systems in the Transbaikal Region of Siberia were established by 21,000 cal BP, and underwent key changes as climates ameliorated into the Holocene by around 12,000 cal BP. During this time the area was characterized by construction of characteristic stone-outlined circular structures, or dwelling features, with activities situated around central, stone-outlined hearths, in riparian environments of major waterways. A few produced as many as six hearth features. With warming climates and increasing forests, inhabitants diversified and intensified their consumption of small mammals, birds and fish, aided by emerging technologies including bone harpoons and possibly ceramics. We explore the developmental variability of these unique structures along the Menza and Chikoi Rivers in the southwestern Transbaikal. Several key sites such as Studenoe and Ust'-Menza where complexes of remarkable late Pleistocene dwellings are highlighted emphasizing numerical chronology, formation processes, and associated artifact assemblages.

Learning from Scratch What the Environments Were Like as the Complexities of Societies Changed in Eastern Tigrai

Home to Aksum and other highly-developed polities, the Tigrai Plateau is a leading contender for sub-Saharan Africa’s richest center of ancient state formation. This and its susceptibility to environmental (climate and land cover) variation make the region compelling for evaluating whether environmental changes affected the trajectories of polities. Soils exposed by gullying are the longest continuous archives of environmental proxies in the region. Many proxies are affected by both climate and land cover. Results indicate that stable hydrogen isotopic (δ2H) analyses of specific land-plant derived n-alkanoic acid (n-alk) molecules in soil organic matter are most affected by precipitation. Furthermore, the rainfall inferences from δ2H n-alk values can clarify whether changes in other proxies were due to climate or land cover. Our isotopic, elemental, and micromorphological analyses of gully soils suggest that Pre-Aksumite and Aksumite polities emerged during wetter intervals but that anthropogenic influences on land cover may have been very different during each period. Our present challenge is to understand possible relationships between the complexity of settlements and their
immediate environments. To meet this challenge, we are building local records of environmental change and coupling them to the emerging archaeological record of settlement characteristics in Mezber and Ona Adi.

Testard, Juliette (Paris 1/UMR 8096 Archéologie des Amériques) [369] Mesoamerican Figurative Plaques: Elites’ Legitimization Strategies during the Epiclassic Period (AD 600 to 900)
Few authors have analyzed figurative plaques from Late Classic and Epiclassic contexts even though they are considered as prestigious artifacts and exhibited as prominent pieces in Museum collections all over the world. Several examples from Epiclassic city states of Cacaxtla (Xicocotitlan and Xochicalco) (Morelos) will be analyzed. Contexts, morphologies and iconographies reveal continuities of sociopolitical and religious practices with contemporaneous Maya sites. We will propose hypotheses concerning the manufacturing, circulation and functions of these peculiar artifacts. They highlight political strategies of legitimation in which elites are represented as mediators between different beings both human and nonhuman.

Teufer, Mike [221] The Bronze and Iron Age Sites Saridjar and Karim Berdy, Tajikistan
The Late Bronze Age site of Saridjar was discovered during a survey of the northern Yakhsu valley in 2010. Excavations in 2012, in 2013, 2015 and in 2016 prove that we are dealing with a 200 x 200 m large settlement with at least three construction phases. The proportion of the hand-made ceramics in all levels varies between 80% and 90%. Only occasionally wheel-made ware appears. Andronovo pottery of the Federovo phase is present in small numbers. At Karimberdy nearly all the pottery was handmade. The continuity is obvious not only in the production process but also in terms of typological development of pottery forms: small bowls with S-shaped rim are abundant at Saridzhar, and they continue in painted handmade ware in the Yaz I period of Karimberdy. Therefore Saridzhar is a transitional site between the Late Bronze Age and the Early Iron Age (Yaz I-period).

Thacker, Paul (Wake Forest University) [389] The Importance of Short Duration Archaeological Sites for Contextualizing Forager Organization: An Argument from the Middle and Upper Paleolithic of Central Portugal
The majority of Late Pleistocene archaeological sites in central Portugal resulted from short-term forager activities on the scale of days or weeks. This paper explores the analytical and theoretical significance of these small, ephemeral sites for understanding Middle and Upper Paleolithic organization of technology and settlement strategies. The interpretive context provided by short term site assemblages is essential for developing robust regional hypotheses of Paleolithic behavior, including the local scale of MP raw material selection, a complex Gravettian settlement strategy for the Río Maior region, and increasingly reliable and standardized technological organization during the Magdalenian. The variability in formation processes at different activity duration scales is an often neglected line of evidence for evaluating anthropological models of prehistoric forager adaptations, an oversight that creates a large-site bias and frequently leads to erroneous archaeological conclusions.

Confronting the existing challenges of archaeological collections management amidst increasing threat from environmental disasters Museums, Curation facilities, and Repositories worldwide are struggling to preserve irreplaceable cultural heritage. At the same time researchers and government agencies are also struggling to mitigate loss of valuable cultural heritage threatened outside of existing facilities. All involved clearly want to increase opportunities to learn valuable lessons and collect new data from material remains of the human past. This paper considers opportunities for researchers, government agencies, and museum professionals to develop new strategies to preserve the research, education, and outreach value of archaeological materials already in collections as well as new materials being excavated from threatened sites.

Tharalson, Kirsten (University of Iowa) and Matthew E. Hill Jr. (University of Iowa) [344] Bison, Dog, and Deer, Oh My! Faunal Analysis of the Lovitt Site, Western Nebraska
The Dismal River complex is a protohistoric archaeological complex likely representing an early Apache occupation on the Central Great Plains of North America. A key Dismal River complex site is the Lovitt site (25CH1), located in southwestern Nebraska. Excavations at Lovitt in 1939 revealed the site as a small residential locality with three ephemeral house structures and more than 150 pit features. Recent radiocarbon dating at the site suggests it was likely occupied either in the first half of AD 1500s or during the middle of AD 1600s. This study analyzes the faunal material from the site. Our study focuses on reconstructing prey choice decisions and patterns in carcass utilization. Finally, we compare our results from Lovitt to patterns of faunal use at other Dismal River sites in order to better understand early Apachen subsistence practices.

Therrien, Monika (Director) [327] Satisfying Needs and Negotiating Freedom in Colonial Spanish American Cities
Unlike archaeological studies that seek to focus on the relations of power and elites, that by means of physical violence and symbolic exerted their domination over other groups assumed to be passive, an approach from practice theories and spaces of contact in which daily practices took place is proposed. It is in these spaces and through everyday activities that curiosity, knowledge and consent made it possible for the majority to survive under the colonial regime, without this implying an unconscious submission. With this purpose two spaces of practices are examined, 1) the production of ceramics, in which techniques and ways of doing converged with new decorative styles and forms, that made artisans with different historical and geographical backgrounds aware of the conditions of life imposed on them, and 2) the shops and market places, where the ceramic wares acquired various uses and meanings, both between natives and settlers. The crafts and trades exercised by artisans and merchants as they satisfied domestic and daily needs lead them also to find a place in colonial society, which, by being considered exclusionary and repressive, these groups and their practices have been made invisible in the studies of power.

Therrien, Monika [36] see Cohen, David
The Evaluation of the Labor Costs of Stone Boiling Dried Maize during the Early Agricultural Period in the Southwest

The Early Agricultural period (2100 BC–AD150–500) in the Southwest begins with the presence of maize and ends with the advent of ceramic vessel use. It is assumed maize was dried out and stored for future consumption. Once dried, maize required extensive processing to gelatinize the endosperm starch, or transform the polysaccharides back to a digestible monosaccharide, through techniques such as: parching, steeping, grinding, and/or boiling (Hard et al. 1996). Little, however, is known about the exact methods of dried maize processing during the Early Agricultural period. The addition of slaked lime to cook dried maize in boiling water, or nixtamalization, can boost digestive breakdown and the nutritional availability of the maize (Katz et al. 1974). Some Southwest archaeologists postulate nixtamalization could be achieved with an indirect firing technique termed “stone boiling” (Ellwood et al. 2013). This poster presents the results of seven stone boiling dried maize experiments. This research addressed the following questions: what are the labor costs of stone boiling dried maize and would this technique be a viable approach for daily consumption? These experiments demonstrated that the labor costs of stone boiling dried maize would be too high to be a preferred processing technique by early maize agriculturalists.

Imperial Authority and Local Agency: Investigating the Interplay of Disruptive Technology, Indirect Authority, and Changing Ritual Practice at Dos Cruces

The Chimu smelting site of Dos Cruces is located along the Zaña River in the middle valley of the greater Lambayeque area. Dos Cruces is located at the intersection of two major trade routes and nearby several rich sources of copper ore. The smelting of ore at Dos Cruces utilized wind powered smelting technology, a new innovation for this region. Despite its obvious Chimu affiliations, Dos Cruces lacks an audiencia, or indeed any indication of Chimu administrative oversight. The denizens of Dos Cruces appear to have engaged in a campaign of site fortification unique among known Chimu crafting centers, restricting access even among the residents themselves. The ritual behavior at Dos Cruces is also distinct both from other Chimu crafting sites and other Andean smelting sites, featuring the ritual killing and burial of furnaces and the rebuilding of the entire smelting terrace at least three times over the life of the site. This paper investigates the nebulous relationship between Imperial power and local agency at Dos Cruces in the context of indirect imperial authority as well as the role of wind powered smelting in the formation of new economic and ritual understandings of copper smelting.

Great Basin Incised Stones and the Shoshonean World

More than 1,500 incised stones have been documented from the Great Basin. By defining object itineraries of individual artifacts, it is possible to animate the archaeology from static to active by emphasizing motion and interaction, fragmentation and accumulation. Tracing both provenience and provenance, we can learn how these objects moved through time and space, intertwining with people and places. It is possible to craft a cartography sufficiently powerful to tease out an underlying, basic, formal structuring of ritual behavior that has epitomized Shoshonean epistemology for more than five thousand years.

Archaeology in 3 Minutes: Multimedia Storytelling in Public Archaeology

In 2014 the Florida Public Archaeology Network began producing a webisode series titled “Archaeology in 3 Minutes.” These three-minute videos are designed to highlight archaeology in the state of Florida and feature the research of faculty and students at the University of West Florida. In 2015 one of these videos was awarded First Place Winner and People’s Choice Award for the Video Category in the Archaeological Photo and Video Festival Competition hosted by the Society of Historical Archaeology in Seattle, Washington. The overall goal of this project is to educate the public about the archaeological process and communicate the importance of preservation and protection of cultural resources through multimedia storytelling. Video has long been used a medium to present archaeology to the public. The digital revolution and availability of less expensive high-quality digital equipment, however, have empowered anyone to tell their own stories and reach much wider audiences than previously. This paper offers some lessons learned from the field for creating digital videos that present archaeology to the public, and covers a wide range of multimedia storytelling, from basic equipment needed to how to best conduct interviews with subjects.
Settlement Development and Social Landscapes at the Classic Period Maya center Uxbenká

Using a Human Behavioral Ecology (HBE) framework, the social and environmental factors that influenced community development have been modeled at Uxbenká, a Classic period Maya center located in the southern foothills of the Maya Mountains. This study focuses on settlement decision making dynamics using a chronological assessment of the expansion of settlements based on radiocarbon dating and ceramic typologies in conjunction with statistical analyses to test which factors influenced patch selection of early colonizers of the Uxbenká landscape. We found that over time the social construction of the community shifted from an Ideal Free Distribution, where individuals had free-choice of where they settled, to an Ideal Despotic Distribution, in which despotic elites’ influenced settlement choice of hinterland residents.

Thompson, Ashleigh (University of Arizona) and Anna Jansson (University of Arizona)

The Integrity of a Surface Collection and Its Value to a Tribe

What is the value of a large surface collection? Surface finds are often dismissed by archaeologists as having little or no integrity. Our work uses data from 24GL304 (The Billy Big Spring Site) to speak to two different types of value for a surface collection: one being its archaeological integrity and the other the value placed on these artifacts by their descendant community. During modern times, the area around our study site has been used as rangeland, which has resulted in animal trampling causing the disturbance of the near-surface deposits. Three research questions guide our work: 1) What has been disturbed? 2) Is there any primary depositional patterning preserved among the surface artifacts? We use GIS analysis to calculate patterning among the artifacts. 3) What do the surface finds from this site mean to the Blackfeet community and tribal members who were involved in this project? Through ethnographic interview, we ask how this project interacts with the Blackfeet identity, their history, and their connection to the land. By following these research questions, we attempt to speak to value of the surface finds at our study site, as both a resource for archaeological data and as a monument to tribal identity.

The Forgotten Significance of the Later Stone Age Sites near Hora Mountain, Mzimba District, Malawi

In 1950, J. Desmond Clark led excavations at a Later Stone Age rockshelter at Hora Mountain, a large inselberg overlooking a modern floodplain in the Mzimba District of northern Malawi. At the Hora 1 site, he recovered two human skeletons, one male and one female, along with a rich—but superficially described and undated—cultural sequence. In 2016, our renewed excavations recovered a wealth of lithic, faunal, and other materials such as mollusk shell beads and ochre. Our reexamination of the skeletons also produced the first ancient DNA from the central African region, which together with previous morphological analysis demonstrates that the LSA foragers of the area cannot be readily fit within the known genetic and phenotypic parameters of living foragers. The significance of the Hora 1 site was made further clear by the relocation of several previously known sites also at the mountain, the discovery of four new rock art sites, and the discovery of four very rich new archaeological sites in the mountains adjacent to the floodplain. Here, we describe our renewed work and how it fits with the original findings to offer unprecedented promise for understanding the lifeways of Holocene foragers in central Africa.

Thompson, Kerry (Northern Arizona University)

Materiality and Movement: Indigenous Concepts in Archaeological Analysis and Interpretation

As investigations of cultures' material pasts, archaeology's units of analysis are tactile. The concepts we employ need material referents in order to be accessible to archaeological analysis and interpretation. To bring together the scientific method of archaeology with Indigenous frameworks, material referents of Indigenous concepts necessarily require theorizing the dynamic relationship between culture, time, and place in concert with Indigenous perspectives. In scaffolding theoretical structures that are useful to archaeologically understanding Indigenous pasts and building a more inclusive archaeology, our interpretations must account for the movement inherent in many Indigenous worldviews and attempt to work without strict adherence to traditional ideas of static moments in linear time.

Thompson, Lenore and R.C.P. Doonan (University of Sheffield)

Biographies of Northwest Coast Copper: A Material Investigation

This paper explores indigenous use of copper metal on the Northwest Coast of North America, and the impact of colonial contact on established cultural practices. Prior to contact (late seventeenth to early nineteenth century), native copper was collected, traded, and manipulated by indigenous communities that considered the material animate and powerful. Following the introduction of foreign trade materials, copper continued to be used to create culturally significant artifacts, however, strict frameworks of interaction with the metal shifted to accommodate the new materials and social relations brought by contact. This investigation adopts a biographical approach, placing indigenous artifacts and the relationships within which they are entwined at the center of the study, allowing us to address particular associations and practices with materials, objects, and assemblages. Analysis includes the combination of archaeological, ethnographic, and traditional indigenous data coupled with a detailed investigation of individual objects, including nondestructive material characterization, to identify procurement, production, and consumption strategies. In this way, it is argued that the study of copper in the Pacific Northwest aids the understanding of aspects of social, economic, and political change set in motion by the contact period.

Thompson, Victor (University of Georgia)

Plummets, Ritual Dance, Individuals, and Macro-regional Interactions during the Woodland Period in Florida

Community making during the Woodland period in Eastern North America manifested itself in a variety of material forms, most notably in the wide distribution of elaborate artifacts dispersed as part of Hopewellian related exchange. In this paper, we examine the role that one particular class of artifact, plummets, played in community making during the Woodland period in Florida. Often interpreted as fishing gear, we suggest that instead such artifacts played a large role in community style dances and can be used as indicators of regional and macro-regional exchanges among varying communities. By tracking the various styles and material types found at sites in Florida through a typological and network analysis, we argue that certain sites, such as Crystal River, played a larger role in connecting subregions in Florida, and may have served as cultural brokers across the macro-region due to their connections to Hopewell sites throughout the Eastern Woodlands. Furthermore, it appears that such connections were limited in time and given the prominence of plummets buried with certain individuals, we suggest that specific persons were entwined with some of these larger scale processes.

Thompson, Victor [81] see Krus, Anthony
Thompson, Alston (Texas A&M University)  
[21] Learning from Earth-Oven Baking Experiments
Ethnographic and ethnographic accounts attest to the dietary importance of wild food resources (i.e., geophytes) and a diversity of earth-oven baking techniques among hunter-gatherer populations in the Maya Lowlands. Recovery of charred bulbs and tubers, as well as their microfossils, from ancient earth ovens and fire-cracked rock features illustrate that dependence on wild geophytes and earth-oven technology was widespread by the early Holocene and continues to the historic era. It is readily apparent, however, that observations and studies of living hunter-gatherer populations attest to far more variability in oven morphologies, baking times, and food types than has been identified archaeologically. To better understand relationships between historical accounts and archaeological observations, we have conducted a series of actualistic experiments, including baking geophytes for 20–40 hours in large ovens, with and without rock heating elements, and baking meats and geophytes in a variety of small earth ovens for 2–3 hours. Another important aspect of this kind of research is its potential contribution toward bridging persistent gaps between scientific and humanistic approaches to archaeology by calling attention to ancient foodway revolutions and related changes in behavioral systems that accompanied worldwide transitions from paleo to modern diets.

Thornton, Erin [5] see Emery, Kitty

Thornton, Christopher (National Geographic Society)  
[70] Funding “The Human Story” at National Geographic
For over a century, the National Geographic Society has provided field research grants to archaeologists and anthropologists from around the world, and then told their story through our media. Over the past few years, National Geographic has gone through a tumultuous period of financial instability and schizophrenia between the nonprofit and for-profit arms. The new joint venture created with 21st Century Fox in the fall of 2015 created a fully nonprofit National Geographic Society with a sizable endowment and a 30% share in the for-profit NG Partners (e.g., Channel, Magazine, Travel, Books, etc.). With great wealth comes great responsibility, and National Geographic is looking to make a broader impact in “The Human Story”—i.e., research, preservation, education, and storytelling in anthropology, archaeology, and paleoanthropology—beginning in 2017. A summary of the recent changes at NGS will be presented as well as a first look at our plans for the future.

Thornton, Erin (Washington State University), Richard Hansen (FARES Foundation, Mirador Basin Project) and Edgar Suyuc-Ley (FARES Foundation, Mirador Basin Project)  
El Mirador (Petén, Guatemala) is among the largest Preclassic settlements in the Maya lowlands. The site has attracted attention due to its size and antiquity, but also for its location within a region containing few permanent or perennial water sources. This study presents a preliminary analysis of the site's faunal remains to assess diet, ritual, habitat use and exchange. Comparison of the El Mirador data with other Preclassic faunal assemblages allows us to assess the degree to which animal use patterns were shaped by local environmental conditions or larger pan-Maya Preclassic dietary and ritual traditions. Although a large portion of the faunal remains date to the Late Preclassic (350 BC–AD 150), remains associated with a Late Classic (AD 600–900) resettlement provides an additional opportunity to address diachronic variation in animal use, and how the local environment may have changed or recovered after nearly 500 years of human abandonment. The dataset is thus significant to documenting the timing/tempo of potential wildlife resiliency in the Maya Lowlands.

Thornton, Taylor (University of Toronto), Jason King (Center for American Archeology), Jason Herrmann (Eberhard Karls Universität Tübingen) and Jane E. Buikstra (Arizona State University)  
[241] Marking and Maintaining Empty Spaces: A View from the Golden Eagle Site
The Golden Eagle (11C120) site enjoys unique status among prehistoric sites of the Lower Illinois River Valley due to its large earthen enclosure. This elliptical ditch and embankment circumscribes a number of mounds assumed to be of Middle Woodland origin (ca. 50 cal BC–cal AD 400); however, other diagnostic Middle Woodland attributes are absent. Magnetic survey and three seasons of excavations with field crews from the Center for American Archeology in Kampsville, IL, have thus far revealed no significant concentrations of artifacts or other cultural residue within the enclosure. Compared to other Middle Woodland mound sites in the Lower Illinois River Valley, this pattern appears anomalous, though not unprecedented. The Kamp (11C12) and Mound House (11GE7) sites, for example, each include relatively debris-free spaces enclosed by earthen structures. Incorporating evidence both from within and beyond Illinois and the Middle Woodland period, we discuss possible motives for the creation and maintenance of spaces free of material culture.

Throgmorton, Kellam J. (Binghamton University)  
[266] Measuring Mobility: Comparing Indices Developed from Architectural and Paleoethnobotanical Datasets
Thirty years of research on mobility and sedentism shows that population movement occurred for reasons both ecological and social. Population movement could occur over short or long distances, could occur seasonally or generationally, and could involve both small and large groups. While archaeologists have theorized mobility in a variety of ways, they have not developed a robust body of methods for measuring and comparing mobility between households at the intrasite or intersite level. This paper uses architectural and archaeobotanical datasets to create indices of residential mobility. We apply these indices to sites within the Western Puercos Region of east-central Arizona and west-central New Mexico dating between Basketmaker II and Pueblo III (500 BC–AD 1300) to explore long-term trends in mobility. In addition, we discuss the degree of congruence and discrepancy between the indices developed using architectural and paleoethnobotanical data. The research has relevance for research on architecture and residential movement more broadly.

[301] see Schachner, Gregson
Local Scale Cultural Transmission: How Are Neutral Artifact Traits Manifested at Neighborhood Boundaries?

Archaeologists are paying increasing attention to prehistoric social organization using learning theory, social networks, and the distributions of artifact variation. A starting assumption is that artifact variation will present an isolation-by-distance distribution, a concept developed by Sewall Wright to explain population genetic distributions. Here we extend Wright’s work and adopt his neighborhood model as an analog to explore the small scale interactions between two groups making different variations of the same artifact. We examine the boundary conditions and explore three hypotheses of human behavior that would result from interactions of two groups: blending the shape of both artifact variants, blending of the minority shape, and exaggeration of shape differences to assert ethnic identity. We test these hypotheses against the null hypothesis of no effect with new statistical methods using the shapes of set of Early Archaic projectile points from Florida, defined using landmark-based geometric morphometrics (LGM). The results show no difference in the distribution of artifact shapes that support any of the hypotheses. We conclude the pattern of shape variation was due to long-term residence of males from outside the neighborhood.

Thurber, Hali (American University) and Justin Uehlein (American University)

You Sleep Alone: Away from People: Understanding the Movement of Hobos and Other Transient Laborers (ca. 1880–1940)

Throughout the late nineteenth and early twentieth centuries, hobos and other transient workers crisscrossed the nation, taking temporary jobs wherever capital demanded labor that exceeded local resources. Despite their contingent status as surplus laborers, hobos were cast as morally bankrupt deviants, insane, and sexually ambiguous men by media outlets across the nation. State laws and county and town ordinances were summarily passed barring hobos from entering towns, cities, and otherwise populous areas. As a result, hobos were effectively pushed into the margins. Yet, their labor was still a requisite factor in the continued functioning and expansion of U.S. economic networks. In this paper, we utilize ArcGIS platform to build on the results of excavations conducted in the summer of 2016 at a Great Depression Era hobo camp in South Central Pennsylvania—the Delta Trestle Hobo Jungle. In particular, we use GIS to explore the formation of a transient community in proximity to an expanding railroad network that not only linked industrial centers and natural resources across the Mid-Atlantic, but facilitated the mobility of laboring individuals to sources of employment and sustenance at the turn of the twentieth century.

Thurston, T. L. (SUNY Buffalo)

Reversals of Fortune: Understanding Shifts in Political Power from Above and Below

Current social theories from a variety of disciplines offer ways through which we may understand when and why citizens of a polity or subjects a ruler are likely to protest or rise in response to problems in the relationship between governments and those they govern. Some forms of asymmetry and inequality serve as good general predictors of when protest, rebellion, or civil war are most likely to occur, while the ways in which these issues are framed and resolved vary from society to society. In case studies from early historic Europe, both general predictors and unique contexts can be examined using collective action theory, cultural dimensions theory, and the theoretical concepts of political peoplehood and reiterated problem solving as keys to understanding the power of those ‘above’ and ‘below’ and the outcomes of different kinds of conflicts.

Housepit 54: Dogs and Their Changing Roles

Excavations at the Bridge River site, British Colombia have been ongoing since 2003. The careful study of these housepits have significantly increased our understanding of the communities that inhabited the Middle Fraser Canyon over 1,000 years ago. The completion of the Housepit 54 excavation has provided further evidence of the many facets of indigenous life at Bridge River; among these is the role of dogs. The possession and many uses of dogs framed and resolved vary from society to society. In case studies from early historic Europe, both general predictors and unique contexts can be examined using collective action theory, cultural dimensions theory, and the theoretical concepts of political peoplehood and reiterated problem solving as keys to understanding the power of those ‘above’ and ‘below’ and the outcomes of different kinds of conflicts.

Tilley, Lorna (Australian National University)

Extending Osteobiography: Disability, Care, Agency, and Emotion

Based on evidence in human remains suggesting survival despite functionally-limiting disability, the bioarchaeology of care approach infers provision of health-related care; identifies likely elements of this care; then explores the implications of care practices and outcomes for increased understanding of both the subject of care and their community. A comprehensive osteobiography of the care-recipient (framed within the individual’s life course and lifeways, and acknowledging the centrality of individual agency in managing disability) is used reflexively throughout this process to interrogate aspects of the subject’s experience. So far, however, this analysis has neglected the role of emotion in shaping behaviors associated with disability and care. Most archaeological discussion of emotion to date has been curiously impersonal, concentrating either on generalized reactions to significant events (ritual sacrifice, violence) or landscapes, or on the ‘emotional identity’ invested in specific artifacts. In contrast, the impacts of serious disease—frightening, restrictive, demanding, unpredictable—evoke intensely personal emotional responses in sufferers and caregivers alike, and an archaeological focus on emotion in this context may be particularly rewarding. Using case study illustrations, this presentation looks at what happens to osteobiography when the bioarchaeology of care meets the archaeology of emotion.

Forensic Techniques to Investigate Museum and Archaeological Samples

Forensic biologists utilize the latest DNA technologies to deal with low level, difficult, and degraded samples on a regular basis. In fact, forensic testing is specifically designed and validated to be robust under conditions that would cause most other genetic testing to fail. It is therefore no surprise that forensic genetic techniques can assist museums with research questions regarding their collections. Here we discuss how, using forensic techniques and testing, we were able to analyze museum exhibits/samples to determine either species, in the case of nonhuman samples, or, in the case of human samples, genetic profiles including ancestry markers, using Next Generation Sequencing.

An Alpine Archaeological Landscape in the Greater Yellowstone Ecosystem, Wyoming

The alpine archaeological record above 3000m of Greater Yellowstone Ecosystem has received much less research attention than the adjacent plains, basins, and foothills. We have been working in an area of NW Wyoming where dense surface stone tool scatters, stone features (including some of the highest elevation habitation stone circles in the region) are associated with dwindling ice patches that have yielded both perishable artifactual material and an array of wood and bone that provides information on past environments. Since 2014, a 175 ha area at elevations from roughly 3,200–3,500 m has been inventoried from the artifact-based documentation perspective. Locational and descriptive data on nearly 20,000 items have been recorded and provide a glimpse of the complexity and diversity of this high elevation landscape. While there is indeed evidence of big game hunting, there are also indications that the area was used by residential groups in addition to task-specific hunting parties. Data from this inventory are examined in the context of regional landscape distributional patterns.

Copan Reloaded: A New Look at the Ante Step and Its Context

This presentation reassesses the chronology and meaning of the inscription on the hieroglyphic step of the Ante structure at Copan, Honduras. The analysis was made possible by a high-resolution 3D scan of the step produced in 2011. The new interpretation indicates that the city of Copan underwent a re-foundation event upon the accession of its eighth ruler, W’il Ohl K’inich. The known contexts of similar statements are discussed along with the implications of several possible translations for our understanding of the sixth-century history of Copan during the crucial transition between the Early and the Late Classic. The textual information is compared to other data from the same period.

Artisan Production and Morphological Changes in Skeletons from San Jose de Moro (North Coast of Peru)

The study of occupational stress markers was an attractive investigation field some years ago, due to the alleged possibility for the identification of ancient activities through skeletal changes. Nevertheless, a critical vision of the issue evidences that this relation is not so easy to establish, because bone biology is complex and also because different activities may produce similar changes. This does not mean that this type of studies should be abandoned. On the contrary, it is a call for more rigorous methodologies and for the building of a corpus of information about changes occurred on skeletons from individuals with known activities in life. In this presentation we show the results of the analysis of four skeletons from different epochs that were excavated in the prehispanic cemetery of San Jose de Moro (North Coast of Peru). These skeletons were associated to elements related to metal and textile production. We searched the processes performed by modern artisans in the region to produce metal and textiles, and we explore if there is a congruency or not between the observed changes in the skeletons and the activities suggested by the funerary goods.

Local Food, Exotic Sacrifices: The Tentative Summary of the Animal Management in Castillo de Huarmey.

Even through the majority of faunal remains so far recovered at Castillo de Huarmey site derived from ceremonial contexts (i.e., main mortuary mausoleum and adjacent palatial complex), studies demonstrate that at the very least, the site’s elite inhabitants extensively exploited local resources, and simultaneously benefited from developed trade connections. At the core of animal management was the extensive camelid husbandry. The standard zooarchaeological analysis and mortality profiles indicated that camelids served as a source of meat, pelts, and material for bone tools. Stable isotopic analysis, together with research on bone pathologies confirm the local origin of most animals, but not of all. Distinctive isotopic ratios and vertebrae pathologies suggest usage of few camelids as beasts of burden. Scarcie marine birds and sea lion (Otaria flavescens) findings suggest limited utilization of marine resources as well. Additionally, the presence of exotic and non-consumable species such as: monkey (f. Atelinae), condor (Vultur gryphus) and parrot (Amazona aestiva) in the sacrificed assemblage possibly reflects long-distance trade and is a sign of Castillo’s importance as a local Wari capital.

**Searching for the Lost Marines of Guadalcanal**

In early 2016, Garcia & Associates conducted forensic archaeological investigations for the Defense POW/MIA Accounting Agency (DPAA) on Guadalcanal, Solomon Islands. DPAA (formerly JPAC) is the Department of Defense agency tasked with providing the fullest possible accounting for missing American service personnel from past wars. During World War II, the Battle for Guadalcanal lasted from 7 August 1942 to 9 February 1943 and included intense ground fighting to secure the airstrip known as Henderson Field. Not including sea battles, more than 1,200 Marines and 26,000 Japanese soldiers were killed during the six-month battle in the Solomon Islands. As part of its continued effort to recover and identify missing U.S. war dead, DPAA has increased its effort to foster public-private-partnerships (P3) to maximize the number of missing personnel accounted for through search and recovery operations. GANDA was fortunate enough to participate in one of the first P3 operations. The GANDA team, working closely with DPAA personnel and local informants, conducted investigative and data recovery excavations at a suspected war-time burial site possibly associated with one of the more than 500 Marines that remain missing in action in the Solomon Islands today.

**[380] Beyond Impressions: Systematizing Sherd Identification Using the Yale Khabor Basin Project Collection**

Clam gardens, anthropogenic rock-walled terraces built at the lowest intertidal, are part of an ancient system of mariculture of the Indigenous people of the Northwest Coast of North America. The construction of clam gardens increased shellfish production by increasing ideal clam habitat and creating substrate preferred for clam growth. On Northern Quadra Island, where there is a dense concentration of clam gardens, we assess bivalve productivity of clam gardens by 1) calculating how much clam habitat is created by constructing clam garden terraces; and 2) comparing the growth rate of clam shells from clam gardens with those from non-cultural contexts. In Kanish Bay, over 80 clam garden features result in an increase of 20,000 to 34,000 m$^2$ of clam habitat. Butter clam (Saxidomus gigantea) specimens spanning 11,500 years allow us to analyze patterns of clam growth throughout Holocene. By expanding our ecological understanding of clam gardens, this analysis enhances our understanding of the extensive ecological knowledge of marine environments held by coastal First Nations.

**[193] Ancient Clam Gardens and Ecological Enhancement on Northern Quadra Island, British Columbia**

The first step in ceramic analysis is typically to determine the age or cultural affiliation of the sherds. Traditionally, this process is done through comparisons of superficial attributes to those of sherds that are already known. This task is difficult to do without years of region-specific experience and knowledge. Using the ceramics collected from over 300 sites, ranging over 5,000 years through surface collecting survey in northeastern Syria by the Yale University Khabor Basin Project (KBP), we plan to systematize this identification process using a method akin to that used in biological keys. We aim to determine the age of an unknown sherd through a system of observations, rather than just impressionistically. Such a systematic approach should improve consistency among analysts, particularly those without firsthand knowledge of ceramics from the various periods of this region. This poster shows the first attempt at developing such a system, using an example of bowls from the KBP. Beyond the superficial inspection of sherds, we plan to carry out additional modern technical analyses to augment the macroscopic observations with other aspects such as paste, temper, clay, and firing.

**[177] Developing a Legacy Collection of Traditional Rice Cultivation: Implications for Archaeobotanical Study**

Legacy ethnobotanical collections have untapped potential to elucidate human-plant relationships through time and space. This paper examines a subset of a comprehensive ethnobotanical collection undertaken in 1979–1981 in northeast Thailand. The subset comprises 43 traditional rice cultivars and wild forms, each collected along with detailed information about cultivar-specific uses and growing conditions. Our study includes morphometric examination of grains and spikelet bases with the objective of documenting variability within both individual spikes and across the species continuum. Ultimately this examination provides a platform for thinking about domestication processes in the past and interrelationships between wild and cultivated forms, particularly when considering harvesting times and field conditions. These data and this legacy collection can be used as a comparative for archaeobotanical assemblages as well as future genetic studies.

**[90] The Eye in the Sky: Use of an Aerial Drone to Record Landscape Alteration in the Malloura Valley, Cyprus**

The use of unmanned aerial vehicles or drones on archaeological projects has proliferated over the past few years. As with many new technologies, the use of drones has gone through several phases. Initially, there is the fascination with a new instrument, followed by more sober assessment of how the equipment can be used to address questions of scholarly interest. In an effort to record the changes in the local landscape of our study area in central Cyprus, the Athienou Archaeological Project used a drone to take aerial still shots and video. One issue that drone users increasingly face is the development of new regulations. Because of our location in the UN buffer zone, we obtained permission from national and local government offices and the Cypriot National Guard. In seven flight episodes we took aerials of an Archaic-Roman Sanctuary, buildings from the adjoining Roman-Medieval settlement, two groups of tombs to the north, remnants of an early twentieth century house, a stone basin production site, and an Aceramic Neolithic quarry. Comparison of these images with aerial photos from the 1960s allows us to monitor the evolution of the Malloura Valley and the impact on archaeological sites of agricultural transformation of the landscape.

*Proyecto Arqueológico Cochasqui-Mojanda*

El Parque Arqueológico Cochasquí se encuentra en las estribaciones sur orientales del macizo montañoso de Mojanda, en la provincia de Pichincha a 52 Km al norte de Quito. El sitio está conformado por 15 pirámides truncas, casi todas conservando sus rampas que facilitan el acceso a la parte superior. En el mismo espacio se puede encontrar varios montículos circulares. En 1932 Max Uhle—el primer arqueólogo en realizar excavaciones dentro del sitio—concluyó que las pirámides fueron sitios ceremoniales y rituales. 30 años más tarde, una misión arqueológica alemana bajo la dirección de Udo Öberem, establecieron dos fases de ocupación del sitio: Cochasquí I, de 950 DC hasta 1250 DC; y, Cochasquí II, de 1250 hasta el 1550. El proyecto arqueológico Cochasqui—Mojanda ha iniciado con la búsqueda de nuevos datos que permitan ampliar la comprensión global de la estructura del sitio así como su posición regional. Para ello se ha recurrido a la aplicación de recursos tecnológicos no intrusivos como el uso de ground-penetrating radar (GPR), así como modelamiento 3D a partir de fotografía área con drones, e información LIDAR.

*Cookbooks as Documentary Sources: The Material Culture of Kitchens and Tables from Nineteenth-Century Puerto Rican Households*

Puerto Rico’s culinary history is characterized by a blend of the different ethnicities that settled in the island after the Spanish Conquest, as well as the incorporation of precolombian food ways. This ethnogenesis can be studied through the culinary traditions that conform what we now refer to as criollo. This presentation uses *El Cocinero Puerto-Riqueño*, the only cookbook available from the nineteenth century in Puerto Rico, as a primary source to address the material culture associated to activities related to kitchens and food consumption. First, by applying research methodologies previously proposed and used by Elizabeth Scott and Mary Beaudry, we will demonstrate the research potential of cookbooks to establish the utensils used for both food preparation and serving. Then this data will be used to outline the type of objects that could have been found in certain nineteenth-century Puerto Rican households. Lastly, we will like to address the social context in order to pose questions regarding who might have had access to the book, as well as how culinary traditions might have been passed from one generation to the next.

*Establishing the Nature and Scale of Ritual Behavior at La Quemada, Zacatecas, Mexico*

The northern frontier region of Mesoamerica is partially defined by its ceramic traditions (i.e., red-on-buff, incised-engraved, and resist); however, observed variation in the types belonging to decorated wares suggests these types are likely local materializations of a regional ideology. Testing this hypothesis requires first determining the provenance of decorated ceramics recovered from a northern frontier site and then exploring the intrasite distribution of local and nonlocal ceramics through the lens of different social mechanisms. The case study for this project is La Quemada in Zacatecas, Mexico, which was the focus of the Malpaso Valley polity during the Epiclassic period (AD 500–900). La Quemada lacks evidence supporting the existence of an elite class or marketplace, but does possess traits associated with pilgrimage centers. Therefore, this paper uses an ethnographic model of prehispanic ritual practice based on northern frontier descendant communities (i.e., the Huichol and Cora) to evaluate if ritual ideology was the mechanism responsible for regional ceramic traditions. The conclusions of this research will establish the nature and scale of ritual behavior that may have occurred in northern frontier centers (e.g., La Quemada, Alta Vista, and Cerro Moctehuma), as well as the impact of this behavior on intraregional social networks.

*Hemish Migration, Movement, and Identity*

We examine migration, travel, landscape, and place names as key elements of Hemish (Jemez) identity. Language is a key element of Hemish identity, and place names figure prominently in Hemish historical and cultural discourse. The place names that define the footprint of Hemish ancestral territory are associated with the migration that culminated in the occupation of Walatowa and with pilgrimages and land use that take Hemish people back into areas where their ancestors formerly lived. Jemez migration involved movement from the north to the Jemez Mountains, with a few groups later moving from the Jemez Mountains to areas to the south and back, and finally the entire Hemish population moving from large villages in the mountains to Walatowa. The many Hemish ancestral archaeological sites and trails that mark the landscape are physical expressions of past and present land use that figure prominently in the formation and transmission of Hemish identity.

Where Condors Reign: Methodological Challenges in the Bioarchaeology of Chachapoya Cliff Tombs in Peru

Traditional archaeological practice involves horizontal mapping and excavations of ancient settlements and cemeteries, but bioarchaeological research of mortuary practices in the Chachapoyas region of northeastern Peru is stymied by the challenging vertical slopes, almost constant rain, and the placement of burial structures on seemingly impossible to reach ledges on exposed rock escarpments. Exploring and registering archaeological vestiges of these cliff cemeteries requires the combination of “vertical archaeology”—using rappelling and rope technology to reach tombs as directly as possible to engage in traditional methods of recording using meticulous photography and drawings—and 3D photogrammetry as well as long distance and aerial drone photography. This paper discusses the methods used at the site of La Petaca and Diablo Wasi and the major challenges faced including natural and technological impediments. We attempt to identify and reconstruct how and why the ancient Chachapoya people created and placed their dead using both up close and personal observations as well as remote recording techniques. Many archaeological details cannot be seen from a distance and yet many locations could not be physically reached safely. We continue to explore how to combine these datasets in meaningful and accessible ways for both local and scientific communities.

The Ancient City of Dos Hombres: Material Expressions of Power

Investigations at the ancient Maya city of Dos Hombres have been guided by an interest in social, political and economic organization, based on architecture and material culture remains. Excavations in the civic ceremonial center of Dos Hombres have been focused in the northern plaza, a very public space that likely was a place of commerce, public ritual and sacred space, thereby the prime backdrop for publicly legitimizing authority. Newly excavated data, especially architectural exposures as well as material culture deposits are presented. These new data are rich with information about public activities and architectural programming at the ancient city. New material culture analyses, including that of the ceramic deposit unearthed from a range structure in the northern plaza are presented. Recent XRF data reveal that most of the obsidian found thus far at Dos Hombres originated at El Chayal, both in the Early Classic and in the Late/Terminal Classic. The resulting lines of evidence delineate various expressions of power by the Dos Hombres polity and elucidate social and economic relationships, both individually and collectively, of the ancient Maya at Dos Hombres and northwestern Belize.

Life and Death in the Southeastern Maya Periphery: Bioarchaeological and Isotopic Analysis of the Uxbenká Burial Population

The southern Belize region is typically considered geographically and culturally peripheral to the primary activity areas of the ancient Maya. Although researchers have documented the development of a “southern Belize style” in terms of architecture and material culture, to date very little systematic work has been undertaken to understand health, diet, and mortuary behavior in the region. Ten years of excavations at Uxbenká have yielded rich evidence of a continuous occupation spanning from the Late Preclassic to the Terminal Classic, with evidence of human activity at least as early as the Archaic period. Human burials were recovered from a diverse range of civic and residential contexts, providing substantial insight into life and death among the ancient Maya of southern Belize. This paper draws on skeletal, dental, mortuary, archaeological, and isotopic data as a means to investigate health, diet, and mortuary trends at Uxbenká during the span of its occupation. We also identify continuing evidence of ancestor veneration and status disparities reflected in burial practices and mortuary traditions. These studies expand our understanding of the biological consequences of increased social complexity as the Uxbenká polity transformed from a small agricultural community into an important regional geopolitical center.

Remodeling the Liturgical “Backstage” of the Parish of Santa Cruz de Tutí, Colca Valley (Arequipa, Peru)

The Toledan resettlement during late decades of the sixteenth century in the viceroyalty of Peru involved a series of changes in the territory for Andean people at different levels, from household to the public and religious spheres. In the case of the reducción (planned colonial town) of Santa Cruz de Tutí, the religious sphere was transformed and materialized into a new core of buildings and spaces: the church, its parish, and plazas. The parish and casa cural (rectory) was a liminal space in terms of a very particular form of combined domestic/private/public/sacred functions for clergy and laity. In these terms, its internal organization depended on the set of ideas (a discourse) which to orchestrate people’s daily and liturgical praxis. This paper explores the changes around the parish as a backstage area in this orchestration, and what was involved its spatial remodeling over nearly three centuries of occupation. To approach this context we use three sources: ecclesiastical text documents, the preliminary results of excavations, and architectural analysis to better understand the physical links between elements and spaces and the modification of movement into and through the parish complex.

Tratebas, Alice (Bureau of Land Management)

Conservation and Preservation Issues Post Fire

Wildfire damage to rock art can have long-term effects. Panels may continue to spall over time from the fire damage or from the effects of soluble salts that were activated and spread during the fire. Rock outcrops and slopes may become destabilized after fire denudes vegetation. Panels can be buried or have ashy sediments washed down from the cliff tops above. What happens over time after wildfire kills lichen growing on rock art? Observations and studies following two large wildfires that damaged an extensive petroglyph site provide insights into long range issues in site preservation.

Trautwein, Emily, Stephen Nash (Denver Museum of Nature & Science), Michele Koons (Denver Museum of Nature & Science) and Deborah Huntley (Denver Museum of Nature & Science)

The Reserve Area Archaeological Project

Since 2014 archaeologists from the Denver Museum of Nature & Science’s Reserve Area Archaeological Project (RAAP) have conducted survey work in the greater Reserve, New Mexico region. They examined numerous tracts in a range of biomes to better understand the highly variable topographic setting and archaeological settlement patterns, documenting dozens of new sites in the process. After spending a week in the New Mexico site files in Santa Fe in March 2016, the team also spent substantial time and effort re-locating and re-recording many previously (and often poorly) recorded sites in the region. The team’s future research will focus on the Torriete Lakes region north of Reserve, where a single isolated great kiva exists within a broad, high-altitude meadow. Small pueblos scatter the landscape like satellites around the great kiva and appear to encompass both the Reserve and Tularosa Phases. Survey work in 2017 will focus on a more detailed survey of the Torriete Lakes region, hopefully allowing us to parse the comparatively ephemeral Reserve Phase occupation from the more substantive Tularosa Phase occupation. All of this will be done with an eye toward initiating an excavation program in 2018.
Traxler, Loa (University of New Mexico) [39]
Foundations to the Late Classic Kingdom: Copan in the Sixth Century CE

Historical and archaeological data support interpretation of Classic Maya polities as centralized states—strongly integrated organizations with stratified and hierarchical political structures led by rulers wielding coercive power. Yet archaeology is often hard pressed to identify changes instigated by individuals or events, or to define watershed moments when particular sites or regions coalesced into states. By the early sixth century CE, the kingdom of Copan had established itself as a dominant player in the southeastern frontier of the Classic Maya world. With control over subordinate polities and trade relations, the royal house had wielded power for over a century laying the foundations for the Late Classic dynasts and their detailed histories. Prior to the strengthening of the state under Ruler 11 (reigned 578–628), Copan’s history records a succession of rulers who managed internal growth and likely faced regional population movements and the political challenges that accompanied them.

Trein, Debora (University of Texas at Austin) [83]
Power, Space, and Place in the Heart of La Milpa

La Milpa was one of the largest ancient Maya urban centers in the eastern Maya Lowlands during the second half of the Late Classic to the Terminal Classic periods, its influence extending over communities throughout the Three Rivers Region of northwestern Belize. La Milpa’s rise to regional prominence is associated with a series of upheavals during this period, including increased political dynamism following the decline of Tikal at the end of the Early Classic period, and a dramatic rise in the population of the Three Rivers Region. In this presentation we provide a synthesis of the research conducted over the past ten years at La Milpa, utilizing multiple datasets to chart the cultural trajectory of this large urban settlement. Further, we explore ways in which the residents of La Milpa and surrounding communities may have articulated their position in the region through the design, access, and use of the built environment of La Milpa. We suggest that La Milpa’s architecture provided an arena for members of the La Milpa polity to interact with one another and negotiate changing social, political, economic, and environmental conditions in the region, through both extraordinary events as well as mundane activities. [83]

Tremain, Cara G. (University of Calgary) [310]
The Many Lives of Maya Antiquities: Tracking Distribution and Redistribution through Auction Catalogues

Glossy sales catalogues published by high-end auction houses present a seemingly endless supply of antiquities for purchase from around the world. These catalogues offer insight into market trends and allow the volume of antiquities being bought and sold at auction to be monitored. At a time when the internet auction market is growing, and the publication of information in catalogue form is declining, it is important to record and share data from available sales catalogues. This paper presents the results of a systematic study of Maya antiquities at auction, using sales catalogues that cover a period of more than 50 years. Quantitative studies of auction catalogues are useful for understanding the volume of antiquities that have been bought and sold at auction; the types of antiquities that are more vulnerable to looting and forgery; and whether the market is becoming more or less opaque with respect to provenance. Studies such as these, although time consuming and hampered by the difficulties of accessing information, are important for an understanding of the past and current market in antiquities. [310]

Tremain, Andrew H. (National Park Service) and William Brown (University of Washington) [190]
Mid-Late Holocene Population Trends and Maritime Resource Intensification in Western Alaska

Population growth has long been argued to play a critical role in promoting cultural evolution, operating both through adaptation to population pressure and increasing social network size and transmission frequency. We present a model of mid-late Holocene Alaskan population size based on a temporal frequency analysis of 902 site occupation episodes dating between 6000 and 1000 radiocarbon years BP, with two objectives: 1) identify factors that influenced Alaskan population dynamics over this interval, and 2) bring these to bear on our understanding of the cultural transition from the Arctic Small tool tradition (ASTt) to the Norton tradition. To evaluate the influence of environmental factors and population size on future population growth and cultural change, we regress growth rates derived from our population model on 1) GISP2 temperature data; 2) the 3600 cal BP Aniakchak eruption; and 3) the population model itself. Paradoxically, the ASTt-Norton transition, which apparently increased cultural complexity, transpired during a sustained low-population interval driven by the eruption and extreme temperatures. We tentatively resolve this paradox by suggesting that severe subsistence stress entailed by these environmental factors encouraged late ASTt communities to shift focus from terrestrial to marine resources, promoting technological innovations to better exploit the marine habitat.

Tremblay, Anna (Pennsylvania State University) and Daniel E. Ehrlich (Dickinson Excavation Project and Archaeological Su) [234]
7 × 105 Dimensions of Pottery: Multivariate Analyses of Pottery Assemblages from the Lower Town Site of Mycenae, Greece

During excavation, it is often safer to record areas separately and later identify associations between strata across a site. Such practice waits until detailed analyses can be conducted and avoids erroneously comparing material from separate depositions. However, the process can lead to more identified strata than are truly present. This project considered relative frequencies of pottery fabrics as a multivariate dataset to characterize and analyze site formation at the Lower Town site of Mycenae, Greece. Mahalanobis distance (D2), hierarchical clustering, and principle components analysis were used in order to quantitatively assess 841 pottery units. These units, on average containing 215 sherd s, represent 41.7% of all pottery recovered during the multiyear excavation. Dendrograms and Multidimensional Scaling were used to visualize distances and clusters in order to characterize relationships between the 416 individually named strata on site. Data showed high degree of patterning and formed between 7 and 54 groups. This method proved highly effective in identifying putative associations across a large site. Importantly, this method does not require whole or decorated ceramic material, can be calculated relatively quickly, and is sensitive to detecting relatively small differences in assemblages.

Trigg, Heather (University of Massachusetts Boston) [128]  An Exploration of Indigenous Participation in Spanish Economic Activities in Seventeenth-Century New Mexico
When the viceroy of New Spain gave permission for the establishment the colony of New Mexico in the late sixteenth century, he acknowledged the importance of indigenous people to the colonial enterprise, urging the governor to treat indigenous Pueblo people kindly so that they would work for the colonists. The Spanish colonists’ economy largely consisted of the barter of subsistence goods. Throughout the seventeenth century, Pueblos and other indigenous peoples both engaged and were integrated into the colonial economic activities in various contexts and in various ways. Pueblos were forced to provide labor for construction and agricultural pursuits, and they were obliged to pay tribute in goods that were commonly used in the barter economy. Yet, the production and exchange of certain items appears to have been controlled by the Pueblos. In this paper, I address the intersection of indigenous activities and Spanish colonists’ economies. An archaeological perspective of colonists’ households along with documentary data illustrates some of the ways indigenous peoples participated, both voluntarily and coerced, in economic activities. These interactions ranged in scale from daily household activities that were informally negotiated and contextualized to more formal economic structures regulating tribute and long distance trade.

Tringham, Ruth (University of California-Berkeley) [172]  Closely Observed Layers: Small Stories and the Heart
When I tell people I’m an archaeologist, their eyes light up with a wistful look and they say “I’ve always wanted to be an archaeologist.” I could describe one reality, that it is not as glamorous as they think, work is slow and repetitive, and that leaves them disappointed. But usually I describe another reality: what I love about what I do—and they are delighted. However, I have never articulated it in a professional presentation or publication: I excavate layers of dead people’s residential debris; my trowel gradually reveals the thousands of events that have created the layers and material fragments of past lives. Meanwhile, my mind is joyfully busy inside my head, making sense of the layers, using all my senses and intuition to plan where my hands-with-trowel should go next, respectfully fearful of the responsibility of the decision. At the same time my mind buzzes with all the small stories that rise up out of the debris of the dead residents. This presentation, inspired by the writing of George Saunders, will find the heart in the specifics of the archaeological activities and the slow versioning of their myriad stories from source to sharing with the world. Trinidad-Rivera, Gelenia (University of Puerto Rico—Río Piedras Campus) [289]  The Jácanas Archaeological Collection: Laying Down the Facts
While researching an archaeological collection, it is important to trace its history in terms of its origins, what makes up the collection, where it is located, and who is responsible for it. Jácanas, a precolombian site in Ponce, Puerto Rico, was excavated during the first decade of the twenty-first century. The fieldwork was carried out by a nonlocal cultural resources management company under contract with the United States Corps of Engineers (USCE). Among the many concerns expressed by local archaeologists was the fact that the collection was taken to the United States for analysis. In 2013, the Jácanas collection was transferred to the Museo de Arte, Historia y Antropología, of the University of Puerto Rico, Rio Piedras campus. This paper will outline the history of the Jácanas collection using the records and documentation provided by the USCE to the Museum, and concentrate on the transfer process. What archaeological materials were transferred? What type of fieldwork and laboratory documentation exists? How was the collection catalogued? This investigation wants to provide the general public with an understanding of what materials are available for future research projects.

Trizzi, Nicholas, Anna Semon (UNC Chapel Hill/American Museum of Natural History) and Thomas Blaber (American Museum of Natural History) [365]  Causes and Consequences of Pre- and Protolithic Social Network Connectedness in Coastal Georgia
This poster considers social networks derived from artifact assemblages and interment types from early-Iréné and late-Iréné and protolithic mortuary contexts on the Georgia (USA) coast. Network analysis can be used to evaluate potential interactions between community members represented in mortuary contexts. The R statistical program is used to model social networks according to multiple parameters and generate statistical indices of network connectivity. I propose that these indices are a function of external forces (e.g., political and economic pressures, or dramatic changes in climate) acting on connections among individuals in a community and between geographically separated, but culturally affiliated communities. If intersite, cross-temporal, social networks can be demonstrated from artifact assemblages, then the connectivity of each network may be consequences of, or causal to micro-regional external forces. The historic, archaeological, and paleo-climatic records frame this interpretation of network connectivity.

Tripcevich, Nicholas (UC Berkeley), Lisa Trever (UC Berkeley), Chris J. Kennedy (UC Berkeley), Eric Kansa (Alexandria Archive) and Michael D. Glascoc (University of Missouri) [134]  Open Obsidian Geochemistry Visualization System for the Andes
Obsidian sourcing studies that provide valuable insights into archaeological mobility and interaction are enhanced by the availability of geochemical analyzers, and especially by the proliferation of portable X-ray fluorescence units. This year we are introducing an open-source system for analysis of geochemical datasets available in web-based repository and based on R-Shiny, a browser based analysis and visualization system built on the R project. The Andean Geochemistry data archive, a new project hosted at OpenContext, combined with the R-shiny based analysis system, allows...
researchers to explore geochemical data interactively. We have uploaded a number of geochemical datasets from the Andes to demonstrate the effectiveness of this approach when many datasets are available in a given area and to encourage more researchers to share their data in an open framework. While there remain obstacles to productive comparison of geochemical data in a given region, including problems with inter-instrumental comparability in particular, this system provides an architecture for sharing and visualizing these data in an open format to foster greater comparison between projects going forward.

Archaeological Data from Washington State Indicate That Northern Fur Seals Will Likely Once Again Be a Dominant Predator in the California Current System
Northern fur seals (Callorhinus ursinus) of all ages (pups, juveniles, bulls and adult females) dominate the mammal assemblage of prehistoric (prior to 1850) coastal middens from California to Alaska. We reviewed archaeological data, historical documents on the early fur trade, as well as more recent data on fur seal genetics and migratory patterns of fur seals—and discovered that most of the fur seal remains in Washington State middens likely originated from a very large colony of northern fur seals that Russian sealers extirpated from the Farallon Islands (California) in 1840. Additional fur seal remains likely originated from the Bering Sea (Alaska). Prehistorically, native hunters regularly traveled 50 km or further offshore in open canoes during the winter and spring migration of northern fur seals along the continental shelf break to obtain fur seals (and other species). We hypothesize that sealing likely led to the development of exceptional seamanship and was the stepping stone to whaling. The data we compiled further indicate that fur seals were once a dominant species in the California Current system, and that they are likely to again dominate this ecosystem now that they have reestablished a breeding colony on the Farallon Islands.

Why Did People Begin to Make Rock Art? A Case Study from North-Central Chile
The origin of rock art has frequently asked from an evolutionary and cognitive perspective to understand the dawn of making images in the Paleolithic. But in many regions of the world the beginnings of rock art production occurred later. North-central Chile is one of these places. In this area, the practice of marking and chipping rocks surfaces started around 2000 BCE in coherence with the transition from the Middle to the Late Holocene and the start of many transformations in the hunter-gatherer’s way of living. Our paper approaches this question, discussing how this new practice and materiality in the start of rock art in the area was a result of new relationships with the world, landscapes and the substances that composed it.

Preliminary Analysis of Archaic Lithic Material from the Murrell Home in Cherokee County, Oklahoma
In 2016, excavations at the George M. Murrell Home, a mid-nineteenth-century plantation home located in northeastern Oklahoma, yielded a number of chipped stone artifacts attributable to the Archaic period. Abandoned during the Civil War, the Murrell home is currently owned by the Oklahoma Historical Society and run as a living history museum and park. Located near the confluence of three major waterways, the site lies in an ecotone between broadleaf forests and prairie parkland. The lithic assemblage includes both finished tools and flaking debris made from local material as well as material from other locales. Agriculture has disturbed and decontextualized many of the recovered artifacts, and remote sensing failed to reveal any features which might be associated with the site. This study presents an analysis of the chipped stone assemblage in an effort to determine the role of the site, estimate the duration of occupation, and identify potential linkages to nearby contemporary sites.

Working for the Palace, Working for the House: How Households Became a Neighborhood in Late Third Millennium BC Tell Asmar (Ancient Eshnunna), Iraq
To test the value of the neighborhood concept in archaeological practice, this paper relies on a model of socioeconomically diverse, urban Mesopotamian neighborhoods and tests the model by analyzing households within a neighborhood at Tell Asmar, Iraq. Tell Asmar became one of several major urban settlements in the Diyala River region, with occupation of the site extending back into late prehistory. The dataset comprises a subset of archaeological evidence recovered from the Tell Asmar Northern Palace and Private Houses Area by the 1930s Diyala Expedition excavations and concentrates on late third millennium BC occupation levels, architecture, artifacts, and ancient texts. Using methods of household archaeology to reconstruct household wealth, this paper investigates household artifacts and their findspots within houses, making inferences about activities taking place in different household loci. An analysis of several houses compares households with life cycles spanning the late third millennium BC with late Akkadian households that appeared alongside the architectural reorganization of the Northern Palace. By reconstructing households in the context of the material culture of the Early Dynastic city-states and the Akkadian state, this paper shows how households functioned as a neighborhood, one experiencing growth, decline, and resurgence connected to broader socioeconomic and political developments.

Technological Approach to Fire-Cracked Rock
Fire-cracked rock (FCR) is an artifact category that has not received much attention, normally reduced to counts and weights. However, FCR is a dynamic material that undergoes a specific sequence of changes. In this poster, the authors propose different “stages” corresponding to different hot rock technologies and features, such as hot rock cookery, hearths, and limestone temper. An experiment is designed to identify the physical and geochemical changes that occur during hearth construction and maintenance, and a methodology is proposed to identify those changes in the
archaeological record. Using the archaeological assemblage of FCR from Woodpecker Cave, a Late Woodland rockshelter, we are able to use physical and geochemical changes combined with ethnographic analogy to show the sequence of maintenance behaviors performed on a hearth feature.

Trusler, Kate (University of Missouri) [282] Evaluating Socioeconomic Status at Maasplein Using Food Utility Indices
A number of researchers have inferred socioeconomic status using zooarchaeological data in contexts suggested by artifacts to reflect a particular status level. Cuts of meat that are of relatively high yield (“utility”) should be more economically valuable than low yield parts. A model of carcass-part utility assumes that people of high socioeconomic status will preferentially acquire greater relative frequencies of high yield parts than people of low status. The model is applied to the Roman town site of Maasplein, the Netherlands, using a food utility index for cattle (Bos Taurus). Results indicate that there are relatively more low yield parts, reflecting low status. This test of the model demonstrates that food utility indices in conjunction with other contextual data can be used to identify socioeconomic status.

Tryon, Christian (Harvard University), Nick Blegen (Harvard University) and Tyler Faith (University of Queensland) [389] The Scatter between the Scatter between the Patches: A Tephrostratigraphic Approach to Low-Density Archaeological Sites in the Eastern Lake Victoria Basin of Kenya
Among recent groups, foraging activities are unevenly distributed across the landscape. Archaeological traces of past foragers are also spatially variable as a result of multiple factors, including the redundancy of site use, a bias toward tasks that leave well-defined material traces likely to preserve into the present (e.g., stone tool manufacture), and local sedimentological factors that mediate site preservation through burial as well as subsequent recovery through erosion or excavation. Landscape-scale studies of past foragers do not provide ethnographic snapshots of the past, but rather recognize and use the time-averaged nature of the record. Widespread deposits of volcanic ash, or tephra, are particularly useful in this context, particularly as stratigraphic markers. As the products of a single eruption, tephra are chemically distinct, amenable to direct chronometric dating and can bury paleoecosystems as well as surface and subsurface archaeological and paleontological sites. We use multiple widespread Late Pleistocene tephra deposits exposed in outcrops around the eastern margin of Lake Victoria to constrain and guide our examination of spatial variability in Middle Stone Age artifacts, fossil fauna, and depositional environments in a region that, while dominated by the largest lake in Africa today, was an expansive grassland in the past.

Tsesmeli, Evangelia (Southern Methodist University) and David Eck (New Mexico State Land Office) [366] Eligible Recommended Archaeological Sites? Biases and Caveats: A View from New Mexico
Eligibility of an archaeological site in the National Register is determined on four basic criteria. This research discusses the nature of eligible nominated sites in regard to their temporal and spatial affiliation on New Mexico State Trust Lands as they are recorded in the New Mexico ARMS database. Correlations with available archaeological surveys, terrain visibility, and the way we regard and define what an archaeological site is are also examined.

Tsouras, Theodore (Logan Simpson), Michael L. Terlep (Logan Simpson), David Lewandowski (Logan Simpson) and Wesley Gibson (Logan Simpson) [301] The Site as a Moving Target: 40 Years of Change on the Dynamic Landscape of Black Mesa
In the context of surface archaeological inventory, sites are typically regarded as static entities about which numerous inferences can be made regarding function, temporal affiliation, and potential for subsurface deposits. These inferences are often the primary tool used to inform National Register of Historic Places eligibility recommendations, as well as guide testing and/or data recovery strategies ahead of various development or other federal undertakings. In many regional areas and with many site types, this process can be more or less straightforward. In areas subject to intense erosion and/or deposition, and with certain site types—specifically, small artifact clusters—the process can become more complicated. Comparing previous survey and testing data from the Black Mesa Archaeological Project (BMAP) conducted between 1967 and 1983 with almost 4,000 acres of recent survey by Logan Simpson of the same area, this poster examines the effects of approximately 40 years of erosion and deposition on the surface manifestation of small artifact clusters on Northern Black Mesa, Arizona.

Tsui, Jamie and Liye Xie (University of Toronto) [91] Quantitative Use-Wear Analysis with ImageJ
Traditional use-wear analysis is mostly subjective and requires considerable experience. Researchers have tried image analyzing software to quantify use-wear patterns; however, the cost of software and the lack of training to use the software made common adoption of the approach less practical. In this research, we tested the open-source software ImageJ for use-wear measurement in two-dimensional images. The results show that the software can reliably quantify the polish development, the polish microtopography, and the dimensions and numbers of worn areas in image samples taken from both experimental and archaeological specimens. Compared to the software previously employed in two-dimensional quantitative use-wear analysis, ImageJ has the advantage of being a free, public domain software which also allows developers around the world to create plug-ins to meet specific research needs. With this software, it is now possible to popularize quantitative use-wear analysis, even for the use-wear images taken in past, traditional use-wear projects.

Tsutaya, Takumi (Kyoto University) [330] Feeding Ecology of the Okhotsk Hunter-Gather-Fishers Estimated by Stable Isotope Analysis
Hamanaka-2 site in the Rebun Island, Hokkaido, Japan, provides a good faunal assemblage made by Epi-Jomon and Okhotsk hunter-gatherer-fishers. In this study, we reconstructed feeding ecology of the Okhotsk hunter-gatherer-fishers by applying the stable carbon and nitrogen isotope analysis to faunal and human remains from the Hamanaka-2 site. As a result of the analysis, Okhotsk humans were at the highest trophic level among the mammals, domesticated dogs indicated the similar but slightly lower isotope ratios with humans, and domesticated pigs indicated the varying isotope ratios between marine and terrestrial endpoints. Isotopic mixing model suggested that the main protein sources of the Okhotsk humans are dogs and marine mammals, those of the domesticated dogs are marine mammals and fishes, and those of the domesticated pigs are C3 terrestrial and marine food sources. Although the dogs indicated no chronological change in the isotope ratios, the carbon and nitrogen isotope ratios of the pigs appeared to increase through the time. The results of this study will provide a new insight into the feeding adaptation of ancient northern hunter-gatherer-fishers to subsist in the island environment.

[184] Younger Dryas Fluted Technologies: A Comparison of Folsom, Cumberland, and Barnes Technologies

The transition from Clovis-type techniques to the variety of later Paleoindian fluting methods and fluted-point morphologies represents one of the earliest major technological shifts currently known in North America. This transition generally coincides with the beginning of the Younger Dryas, and much speculation exists concerning potential correlations between changes in environmental factors and Paleoindian technologies. Some researchers argue that late Pleistocene ecological transitions and subsequent variation in fluted-point technologies demonstrate early stages of cultural regionalization as people began to adapt to local environments. In turn, this regionalization led to the emergence of "full-fluted" technologies during the Younger Dryas such as Folsom in the Great Plains, Cumberland in the Midsouth, and Barnes in the Great Lakes regions. Here, we present an assessment of morphological and technological attributes observed on samples of Folsom, Cumberland, and Barnes points to identify degrees of homogeneity in technological traits. Discussion will address the potential for historical relatedness, regionalization, and independent invention, as well as correlations with Younger-Dryas era environmental proxies.

[73] Excavation Narratives and Reflexive Practices at Çatalhöyük

A microcosm in itself, The Çatalhöyük Project has, in one way or another, intellectually, emotionally and physically altered the lives of its members. The project ethos, in turn, has changed through time with the dynamics that surround research and managerial practices of the individuals making its body. Further the project has been part of a local landscape enduring sociopolitical changes within Turkey. As a member of the Çatalhöyük Research Project since 1997, in this paper, I reflect on the practicalities of the Project's reflexive excavation methodologies. I explore the different narratives that have structured the excavation methodologies of the different teams engaged in the project. I bring my perspective, as a female Turkish archaeologist, to the challenges that have been faced, the opportunities that may have been missed, and the accomplishments that have been made in lieu of the competing expectations held by different team members.

[364] Documenting the Forced Migration of Enslaved Peoples at the Grassmere Plantation, Nashville, Tennessee, Using Strontium and Lead Isotope Analyses

The Grassmere Plantation in Nashville, Tennessee was established in 1810, and documents show that unnamed, enslaved peoples labored there throughout the decades until emancipation. Our research investigates whether enslaved laborers were born and raised on the plantation or were forcibly moved there later in their lives. To address that question, we analyzed strontium and lead isotope ratios from tooth enamel. Twenty burials were recovered from Grassmere, and we obtained strontium and lead isotope ratios from 12 teeth representing 10 of those individuals. The strontium isotope ratios range from 0.70963 to 0.71303 and the mean 87Sr/86Sr = 0.71097. For lead isotopes, the 206Pb/204Pb range is 18.4 to 21.5 (mean = 20.3); 207Pb/204Pb range is 15.6 to 15.9 (mean = 15.8); and 208Pb/204Pb ranges from 38.4 to 41.1 (mean = 40). Independent verification of local strontium and anthropogenic lead ratios remains to be determined; however, the observed range and cluster of these data strongly suggest there were two, perhaps three, different geographical origins represented by the 10 individuals. This is consistent with oxygen isotope data, with δ18OVPDB values that range from −2.6 to −6.1. Together, the isotope data suggest that several of the individuals were probably purchased at slave markets later in life and forcibly relocated to Grassmere.

The history between the Wupatki Basin Navajo, the National Park Service, and various local ranchers has resulted in the Navajo being driven from this area. This has led to a significant impact on their subsistence practices and cultural landscape. We will discuss the results of our research, which includes broader understandings of Chacoan expansion. Our investigations have also contributed to our understanding of the site's chronology and the use of materials from near and far. Our studies have been conducted in part to impress visiting dignitaries or merchants from distant allied or rival polities. Similarly, similarities in ballgame architecture and associated artistic embellishment could signal mutual affiliation to foreign visitors, and thus may have been prone to emulation among different cultures.

Our paper reports on our recent archaeological testing at the previously unexcavated Aztec North great house at Aztec Ruins National Monument. Standing on the river terrace behind and above the better-known valley great houses, Aztec North is out of sight of those great houses but tightly bound to them as part of the formalized cultural landscape of Aztec Ruins. It is a crucial site for understanding the development of Chaco Canyon's outliers, as it was likely the earliest great house built in what eventually became the enormously ambitious outlier complex of Aztec Ruins. Our investigations revealed architectural surprises, including unexpected construction methods that bring into question archaeologists' traditional dichotomies between Chacoan building methods and methods of local emulation. And even as the site revealed little evidence for intensive use, we found signs of significant remodeling. Our artifact analysis is also adding to our understandings of the site's chronology, of the use of materials from near and far, and of subsistence practices at this site. We will discuss our results, drawing on broader understandings of Chacoan expansion, and with consideration of how Aztec North relates to the greater cultural landscape of Aztec Ruins, to Chaco Canyon and to other regions.

Turney, Kathryn (University of Arizona) [106] Oral History and Ethnoarchaeology at Wupatki National Monument

The oral history between the Wupatki Basin Navajo, the National Park Service, and various local ranchers has resulted in the Navajo being driven from this part of their ancestral homelands. The results led to loss of land and connection to family members, some of whom were driven across the Little Colorado River and formed new settlements. My research this summer has been to chart the genealogy of the Wupatki Navajo and extended family, visit Navajo sites within the Flagstaff National Monuments and employ spatial analysis of family dwellings and sheep herding areas within the park. I want to generate a better understanding of the importance of land use and loss and how it is related to the Navajo philosophy of K’e and K’e’i.’

Tushingham, Shannon (Washington State University) and Robert Bettinger (UC Davis) [383] Diversity and Development of Property Rights and Money in the Southern Pacific Northwest Coast

At contact, property rights systems in northwestern California and southwestern Oregon were complex and diverse, and applied to a wide range of sacred places and items as well as use rights to foods and materials associated with a highly productive (yet very patchy) resource base. Use rights and possession extended from property that was commonly owned (e.g., game, line fishing locations) to individually owned property (e.g., productive salmon weir locations and acorn groves, dance rights, formulae). Individually owned items were easily negotiated with money, while other property less so. Despite similarities with the northern/central NWC, resource privatization was the norm, and household production remained on the family level operating within the “sweathouse group.” Property rights and human-environmental relationships changed fundamentally at 1300 BP when plank house villages spread throughout the region. This time is characterized by a rapid, qualitative shift in adaptive strategies—including an expansion in diet that included back loaded staples (e.g., salmon) in addition to previously intensified front-loaded foods (e.g., acorns)—and likely involved an expansion and/or formalization of money use, resource privatization, and individually negotiated items.

Tykot, Robert H. (U. of South Florida), Kyle Freund (Indian River State College) and Andrea Vianello [178] The Social Dynamics of Obsidian Use in the Prehistoric Western Mediterranean: Temporal Changes in Maritime Capabilities, Lithic Technology, and Sociopolitical Complexity

In the western Mediterranean, obsidian was an important lithic material, coming from four Italian islands and found at archaeological sites up to several hundred kilometers away. Analytical studies of many thousands of artifacts have identified their specific geological sources, and revealed chronological and geographic changes in their selective use through the Neolithic and Bronze Ages (ca. 6000–1000 BC). These data are used to assess economic and social dynamics regarding access to and territorial control of the sources, and the production and distribution of obsidian cores and tools. We specifically compare the social dynamics of obsidian usage from the large island of Sardinia with that of the small island of Lipari, for several time periods. Elemental analysis of artifacts and identification of specific geological subsources for each island is well established, while the use of a nondestructive portable XRF in museums and other facilities over the last decade has tremendously expanded the number of artifacts tested. The variables addressed include the quality, quantity, and accessibility of the raw material; technological developments and specialization in lithic artifact production; and socioeconomic changes from early farmers in the Neolithic to complex societies in the Bronze Age.

Los cambios climáticos y sociales una ecuación positiva: Los datos en el complejo arqueológico de Huacas del Sol y de la Luna

Los antiguos estudios sobre la cultura Moche, o Mochica, consideraban que un mega Niño (550–600 dC) fue la causa del abandono del sitio y el traslado de la capital Moche a Galindo. Los datos recuperados en los últimos 25 años en el complejo arqueológico Huacas del Sol y de la Luna ofrecen una secuencia ocupacional casi continua desde el siglo I dC hasta el siglo XIV. Durante este tiempo se han identificado tres grandes periodos: los dos primeros corresponden a la ocupación Moche y el tercero post-Mochica. Un cambio brusco en la estructura social y política Moche hacia el siglo VII se registra en asociación con el abandono del Templo Viejo de Huaca de la Luna y la construcción de un nuevo edificio, aunque menos imponente. Al mismo tiempo y contemporáneo con el Templo Nuevo, la Huaca del Sol pasa de ser una importante residencia a un verdadero palacio. En base a esta evidencia, este trabajo explora una reinterpretación del impacto del fenómeno El Niño, en contraposición a las hipótesis propuestas en la década de 1970, muchas de ellas aún persistentes.

Navigating through Asian Waters: Comparative Study of Seventeenth- and Eighteenth-Century Porcelain Trade in Manila, the Philippines, and Banten, Indonesia, from an Archaeological Perspective

The trade networks in seventeenth- and eighteenth-century Southeast Asia are often reconstructed by using European historical sources. As a result, Southeast Asia is frequently portrayed as a way station between Europe and China. However, the comparative study presented here between Ayuntamiento the Spanish government site in Manila, the Philippines, and indigenous palace sites in Banten, Java, Indonesia, under Dutch indirect rule suggests a far more complex picture and challenges the traditional understanding of the Euro-Asian porcelain trade as well as the Eurocentric power relationships in early modern Asia. The results of our study unveil the strong presence of Chinese merchants’ activities among the regional maritime networks. A sizable amount of Japanese trade porcelain found in Ayuntamiento suggests that the privilege bestowed to the Dutch as the sole Western trading partner in Japan was effectively violated by trade through Chinese merchants particularly via Formosa (Taiwan). Moreover, the distinct porcelain distribution patterns between the two indigenous palaces in Banten suggest the dynamic agency of the locals and help fill the gap in an under-documented aspect of Euro-Asian porcelain trade.

Variation in Large Sites from the Longshan Period of Northern China

Recent research does not support the common view that the numerous large sites from the Longshan period of northern China ca. 2500–1900 BC represent a homogeneous type of settlement with respect to developmental process, scale, and organization. Most publications regard these large settlements as cities and expect they share specific features indicative of organizational homogeneity. The focus has been on large Longshan and later, early Bronze Age settlements in Henan province. We discuss variation in scale and organization of large sites located in the eastern seaboard area of Shandong and northern Jiangsu provinces. On the basis of our collaborative excavation at Liangchengzhen in southeastern Shandong, we argue that a particular challenge for understanding the nature of large Longshan settlements is the need for more extensive excavations and diachronic data revealing changes in scale and organization over time.

Mesopotamian Megasites before Uruk

Discussions of “alternative” trajectories of urban growth are often compared to “classic” models from Old World civilizations, and most often Mesopotamia. It is said that Mesopotamian cities were dense and spatially discrete from their agricultural hinterlands, in contrast to new models of low-density urbanism. In fact, the earliest large settlement agglomerations (“megasites”) in Mesopotamia were discontinuous and far less dense than the mature cities of the Bronze Age (after 3000 BC). This paper describes two such early sites, Tell Brak and Khirbat al-Fakhar (Hamoukar), both of which...
grew to large spatial (and possibly demographic) scale centuries before Uruk. Rather than seeing them as experiments that failed, this low-density “proto-urban” phase of the late fifth–early fourth millennium BC was on a trajectory toward the classic Mesopotamian urban model, one that archaeologists have failed to recognize due to methods and taphonomic factors.

Urban, Thomas (Cornell University), Linda Chisolm (U.S. National Park Service), Sturt Manning (Cornell University), Jeffrey Rasic (U.S. National Park Service) and Andrew H. Tremayne (U.S. National Park Service) [257] Geophysical Investigations of Archaeological Sites in Alaska’s National Parks and Preserves: 2016 Field Season
Alaska’s National Parks and Preserves have seen increased use of geophysical methods for cultural resource management and archaeological research in the past several years. Here we describe the results of geophysical surveys conducted at several of Alaska’s National Parks and Preserves in the summer of 2016 as part of an ongoing effort that has span several field seasons and has now included eight parks and preserves. Examples from 2016 include research at Gates of the Arctic National Park and Preserve, Bering Land Bridge National Preserve, and Katmai National Park and Preserve. Our results include successful examples of detecting hearths and campfires with magnetic methods as well as detecting and mapping semi-subterranean houses with ground-penetrating radar (GPR). We also test the possibility of using GPR for snow and ice patch archaeology. As resource management and research tools, our work has shown geophysical methods to be highly effective in these contexts.

Uriarte Torres, Alejandro (Instituto Nacional de Antropología e Historia) [215] Consumo de bienes de prestigio y estrategias políticas: Una propuesta diacrónica para el noroeste de Yucatán en el Preclásico
Durante el Preclásico, el noroeste de Yucatán atestigua el desarrollo de grupos sociales complejos tempranos evidenciados por la aparición de una jerarquía de asentamientos y una arquitectura de función cívico-ritual. La evidencia arqueológica indica que estos grupos tenían acceso a bienes de intercambio a larga distancia de productos elaborados con diversas materias primas: obsidiana, jade y basalto, por mencionar los que aparecen con mayor frecuencia en contextos arqueológicos. En contraste, existe poca evidencia de la relación entre el consumo de estos bienes y grupos que puedan ser considerados de élite. En este trabajo se explora la relación entre el estatus social expresado en la calidad e inversión de fuerza de trabajo en construcciones residenciales y la distribución de bienes de prestigio, con base de los datos recuperados durante las excavaciones efectuado en los sitios de Caucel, Anicabil, Xaman Susula y Xanila (localizados en la periferia occidental de la ciudad de Mérida, Yucatán). Los resultados obtenidos permiten analizar la relación entre la codificación social de los bienes, acceso a ellos y estrategias políticas económicas, de acuerdo a la teoría acción colectiva, efectuando una propuesta diacrónica desde el Preclásico Medio (1000–450 aC) hasta el inicio del Clásico Temprano (ca. 250 dC).

Uribe, Mauricio [202] Repensando la verticalidad en tiempos del Inca: El caso de Zapahuira, Sierra de Arica, Norte de Chile
A mediados de 1970 surgió la conocida discusión si el dominio incaico en el norte de Chile había sido directo o indirecto, a partir de la aplicación que se hizo del modelo sobre la “verticalidad” andina de John Murra. De acuerdo con esta propuesta, la situación se dirimiría en términos de que cuán abundante era la materialidad del Inca en los territorios conquistados, especialmente arquitectónica y cerámica, y cuánto ésta se atenía al estilo original del Casuco. De acuerdo con las incipientes investigaciones de aquella época, predominó y mantiene cierta vigencia la hipótesis de la ausencia de una conquista propiamente tal y que más bien se trató de un dominio indirecto sobre la base del sistema ecológico previamente implantado por grupos altiplánicos en tierras bajas. Aprovechamos este simposio para discutir estos planteamientos a través una síntesis y actualización de nuestros estudios en los sitios Tambo y Colicas de Zapahuira, aportando con nuevos datos tecnológicos, estilísticos, funcionales y cronológicos sobre la expansión del Tawantinsuyo en las tierras altas de Arica.

Urquhart, Lela [166] Measuring the Impact of Ancient Colonization in Central-West Sicily
Studies of ancient colonization in the Mediterranean have principally been concerned with assessing the “impact” of colonization: did the colonization processes of groups like the Greeks and Phoenicians make a significant impact on local native societies among whom they settled, and if so, in what ways? Important as such questions are, they have sometimes overlooked a more basic step: how do we actually measure the “impact of colonization” in the first place? This paper offers a response to that question through the case study of ancient central-western Sicily. It argues that a good way to examine colonial-indigenous interaction is to isolate an aspect of culture that can be a) observed cross-culturally and temporally; b) measured using material correlates; and c) has interpretive salience. For ancient Sicily, religion best fits those criteria. Applying religious correlates to the archaeological record of Sicily between 900–400 BCE reveals important changes. First, colonization catalyzed shifts in the structure and scale of indigenous religion. Second, in terms of “impact,” Greek colonization influenced local religious expression more than Phoenician colonization, particularly after 550 BCE. Third, the perception of this “impact,” however, was due to religious modifications made by all groups—indigenous and colonial—to fit changing sociopolitical circumstances.

Uzawa, Kazuhiro (University of East Asia), Mai Takigami (Yamagata University) and Yuji Seki (National Museum of Ethnology) [238] Beginning of Camelid Breeding during the Formative Period at the Pacopampa Site, Peru
Our research on faunal remains from the Pacopampa and the Kuntur wasi sites has shown that Camelid breeding began during the Late Formative period (800–500 BC) in the northern highlands of Peru. However, motives for the introduction and usage of these animals remain obscure. We conducted multidisciplinary analyses of the camelid remains from the Pacopampa site to investigate breeding and utilization patterns of these animals. The Sr and O isotope values from tooth enamel showed that 17 of 18 camels from the Late Formative period had been bred and kept for their lifetimes
near the sites. Although corresponding data for the Middle Formative period (1200–800 BC) is not available currently, N and C isotope ratios were statistically different from those of the Late Formative period. It suggests Camelids were bred in different areas and then transported to the site during the Middle Formative period. Mortality profiles and pathological observations indicate that camelids had rarely been used as pack animals but were consumed as meat during ritual feasting, used as sacrifice and possibly utilized for their hair. We conclude that camelid dispersal was undertaken in connection with the development of a complex society in the region.

Vacca, Kirsten (University of California, Berkeley) [19]

The Construction of Archaeological Practice: Sex/Gender and Sexuality on the Fringe

Archaeologists have incorporated sex/gender and sexuality research in projects for decades, yet such foci have failed to become widespread as they are largely considered a specialty or niche topic. This paper first looks at why the topics in question have remained on the fringe of archaeological research. The subsequent discussion analyzes ways in which contemporary practices can counteract deeply embedded ideas about the archaeology of sex/gender and sexuality, making this approach to the record more accessible to a larger audience. The importance of examining the social structur...

Valdez, Fred (University of Texas at Austin) [83] Origins: Contextualizing the Beginning and Development of the PBAP
The introduction of a large-scale regional project in northwest Belize began as a more modest endeavor in northeast Guatemala. How the Programme for Belize Archaeological Project (PBAP) began, how it has modified through several decades, and what we anticipate as its future are discussed. A brief review of select projects within the PBAP are mentioned as examples of overall program interests. Importantly, the PBAP relationships with the Belize Government, local communities, and other entities are also presented.

Mobility Models and Caravanning during the Late Intermediate Period (ca. AD 1000–1400) in Northernmost Chile, South Central Andes
Llamas were one of the most valued animals in the Andes. Their importance has transcended the subsistence sphere as they were not only used as a source of food but also served for medicinal and ritual purposes; their fiber was fundamental for manufacturing textiles, and they were a source of symbolism and “food” for thought and ideologies. Nevertheless, their use as pack animals in exchange caravans has been prominent, stimulating intense mobility and long distance traffic between diverse ecological regions as well as mediating political alliances and social interaction. In this paper we analyze the archaeological evidence of caravan movements available in the lowlands (coast and valleys) of northern Chile and discuss the role played by local populations in the systems of interregional traffic. Until recently, it has been assumed that lowland populations relied on a mixed agrarian-maritime economy and that caravan transport was a specialization carried out by pastoralists of the Andean highlands. We discuss alternative models of mobility (with and without caravans) for explaining the regional flow of goods and social interaction by emphasizing the diversity of participation strategies that lowland populations exercised.

Valenzuela-Lamas, Silvia and Ariadna Nieto-Espinet (University of Lleida/CNRS—UMR 5140) [275] Ding Dung: Animal Enclosures, Digested Bones, and Where was the Livestock in the Archaeological Site? Evidences from Experimentation and Zooarchaeology from Late Prehistory in the Western Mediterranean
One of the most intriguing questions in many archaeological sites is to elucidate where the livestock was kept, and which and how many animals were herded. This is particularly compelling in Late Prehistory, when many sites were heavily fortified, and all the space intramuros seemed to be occupied by domestic buildings. Some disciplines, such as micromorphology and palynology, help to answer some of these questions. In this paper, we will provide a perspective from zooarchaeology, which is one of the least explored disciplines to detect where the living animals were. Together with a review of the archaeological and zooarchaeological literature for Late Prehistory in the Western Mediterranean, we will provide the results of a present-day experiment with pig dung. The objective of this experiment is to analyze whether the accumulation of digested bones could testify of the presence of pig enclosures, a hypothesis raised for the Iron Age levels of Althiburos (Tunisia; Portillo et al 2012).

Valese, Immacolata (University of Bologna) and Davide Domenici (University of Bologna)

The paper summarizes the results of six field seasons since 2011 by a joint Italian/American archaeological project on the Merrell Tract 300 m west of Monks Mound. The extensive excavations, expanding upon the area of Wittry’s 1960 salvage work on Tract 15B, revealed a complex sequence of occupations covering the entire sequence of Cahokia’s history spanning the Edelhardt through Sand Prairie phases. Throughout its history the Merrell Tract experienced important changes: first as a domestic area occupied by Emergent Mississippian residential groups; then, during the Cahokian apogee (Lower and Stirling phases), it was marked by a sequence of large wooden buildings as part of its transformation into a public space, the West Plaza; finally, it reverted back to a domestic area during the Moorehead and Sand Prairie phases, just before the city’s abandonment. The recovered data clarify many aspects of this long occupation, especially those related with the shape of a rather enigmatic Stirling-phase bastioned compound and with the unexpectedly complex Moorehead-phase occupation of the area.

Micro-Sampling Dentine to Reconstruct Life Histories of Holocene Hunter-Gatherers in Siberia

van den Haas, Victoria M. (University of Alberta), Vladimir Ivanovich Bazaliiskii (Irkutsk State University) and Andrzej Weber (University of Alberta/Aix-Marseille University)

This paper presents a contemporary method for investigating the dietary history of past peoples using micro-sampling dentine of molars from middle Holocene (~8300–3500 cal BP) hunter-gatherers in the Cis-Baikal region, Siberia. The dentine has been sampled into 1 mm strips and each is analyzed for carbon and nitrogen stable isotope ratios. Each dentine strip represents roughly nine months of developmental life while bones samples typically average over the course of ~10–20 years. Previous geochemical tests demonstrated that during the Early Bronze Age a number of individuals migrated from the north of the Cis-Baikal, the Upper Lena area, toward the coast of Lake Baikal, the Little Sea micro-region. Some hunter-gatherers appear to have retained diets typical of their homeland while in other cases they were abandoned for new local diets. Micro-sampling of dentine allows for a more
complete and informative record of human behavior in the Baikal region and a greatly improved temporal resolution of the chemical signatures obtained from human teeth.

True Potential: A Database on Osteological Material in Nicaragua

Archaeological research in Nicaragua has yielded an extensive osteological material. Excavations at sites like Monkey point on the Caribbean coast and RURD-UNAN in Managua have uncovered impressive and extensive human inhumations. These sites are among the only four sites in Nicaragua were an extensive osteological study has been done and published. Yet many more unpublished literature mentions or has documented osteological remains. What is the real extent of the uncovered osteological material in Nicaragua? What potential lies in the study of this untouched material? This study presents a database compiled of published and unpublished literature that mentioned or studied osteological human remains. The database shows in detail what osteological material is found, if any research has been done on the material and if so what methods were used. Analyzing this database shows that there is indeed an abundance of material that has yet to be studied. Furthermore it shows that there is great need and potential for expanding the science of human osteology in Nicaragua.

Chaco Canyon: Dispersed Settlement, Dialectical Tension, and the Rise of an Ancient Polity in the Southwest United States

Two dozen monumental buildings lie at the heart of Chaco Canyon, a UNESCO World Heritage site in the southwest United States. However, ancient Chaco Canyon was not a single locality but a focal point for outlier settlements spanning a region of 60,000 square miles. The canyon-outlier relationship is key to understanding the Chacoan polity. Residents of canyon and outlier settlements within a dialectical relationship gathered periodically to share resources, marriage partners, and ritual knowledge. When contradictions within this relationship reached a tipping point, a group of small-scale, dispersed farmers transformed into a centralized, hierarchical rituality where secret ceremonial knowledge legitimated elite political authority.

The study of finger flutings, lines drawn with fingers in the soft surfaces of cave walls and ceilings, allows for the identification of unique individuals within a cave’s context. In early years of research we were able to identify men, women, and children in some of the 15 caves which have been studied. These led to discoveries as to which individuals which were often found together in their movement through the caves. The intimacy of cave spaces with artists working side by side, sometimes in very small spaces, and in a variety of combinations of children and adults, males and females, allows us to begin to imagine the embodied experiences and relationships of these people. Through looking at the cave artists with a forensic approach and a relational lens we begin to shine a light on themes of intimacy, cooperation, community and play in the Upper Paleolithic. Finally, this paper considers how our discipline might be radically changed were it to focus research agendas on questions of looking for evidence of intimacy, relationships, and the invisible but powerful impact of the generosity of the human heart in something as simple as holding another’s light in a darkened cave.

Making Amber Beads: Technological Insights into a Late Neolithic and Bronze Age Craft Activity

Experimental research of different ways of shaping and perforating amber beads has provided insight into the signatures of different manufacturing techniques and the character of the tools involved. Using stereo and incident light microscopy it was for example possible to distinguish the features from the use of metal tools from the traces resulting from flint implements. Perforating amber with drills made of different raw materials like wood, metal, flint and antler, also show considerable variation in traces, with Micro CT scans further elucidating the exact shape of the perforation and allowing a close scrutiny of the production marks. This knowledge was used to study beads from Late Neolithic and Bronze Age settlements and burials, located in the present-day Netherlands. Late Neolithic coastal settlement sites have shown evidence for large scale production of amber beads, with beads being markedly different technologically from contemporary funerary sites further inland. This observation will be examined from the perspective of craft specialization and identities of the makers and users of these beads. In this paper we will discuss our experimental results and use these findings to better understand the archaeological observations on beads from Late Neolithic and Bronze Age settlement and funerary sites.

Lithic Analysis of GaJ17: A Middle Stone Age Locality in Koobi Fora, Northern Kenya

The Koobi Fora region in eastern Turkana, northern Kenya, is known for its preservation of Plio-Pleistocene hominin fossils. However, very little is known about the Middle Stone Age (MSA) from this region. Fossil and genetic evidence suggest modern humans originated in eastern Africa ~200ka, adding to the significance of this time period and region. In 2016, we excavated site GaJ17, an MSA site located in Area 104 of Koobi Fora. Here we present lithic analysis of recovered in situ and surface artifacts, building on the work of Alison Kelly (1996). These data points were used to understand the overall lithic technology and how they were affected by taphonomic forces. This research showed differences in raw material composition across the site; igneous rocks are more common in situ, and cryptocrystalline silicates (CCS) were more abundant on the surface. This may represent a disparity in
collection method, with differential weathering of surface volcanics leading to over-collection of CCS. Reduction intensity analyses indicate that both were produced in the early stage of reduction. Finally, we document the presence of in situ Levallios technology.

Van Horn, Mark (Pennsylvania State University), Adi Eliyahu (University of Haifa), Naama Yahalom-Mack (Hebrew University of Jerusalem) and Anne E. Killebrew (Pennsylvania State University)

Recent excavations (2010–2016) at the Mediterranean port city of Tel Akko, directed by A.E. Killebrew and M. Artzy, have uncovered abnormally large quantities of iron slag and remnants of iron working spanning the sixth–fourth centuries BCE. This mid-first millennium smithy, which smelted iron on an industrial scale, is the only known iron working facility in the Levant dating to the Persian period, providing an unparalleled opportunity to explore iron production at a Phoenician maritime center. This poster presents the preliminary results of iron ore provenience studies utilizing osmium isotope analysis of iron slags and spatial distribution of slags at Tel Akko using geographic information systems (GIS) to address questions relating to sources of the ore, the reconstruction of the Phoenician iron industry at Tel Akko, and its larger economic role in the Achaemenid Empire.

Isotopes of Coastal Ecuador

A preliminary report is presented on research into the diet, health, and mobility patterns for prehistoric coastal Ecuador, based on an analysis of both modern data and archaeological data from Site 035 Salango. An assessment of dietary habits provides insight into a broad range of societal developments, such as the implementation and timing of maize agriculture. Additional insights are provided by an osteological evaluation of human remains, with a particular focus on evidence of pathologies associated with diet. Establishing whether the individuals were born locally, as well as the geographic place of origin for non-native individuals, yields insight into social and economic aspects from the past. Starting with an isotopic baseline for the coastal region of Ecuador, derived from contemporary water, soil, flora, and fauna samples, together with selected archaeological samples, we can compare the isotopic content of human remains to draw conclusions about the deceased’s diet and residences. Preliminary results are presented based on archaeological samples of four individuals and contemporaneous fauna derived from three distinct tomb burial sites at the Manteno culture. Individual teeth and bone samples from the same individual are utilized to construct a comprehensive life history to provide insights into patterns of diet and migration.

Weapons of a Spanish Colonial Road: An Analysis of Arms Found at Paraje San Diego, New Mexico

The Camino Real de Tierra Adentro served as the main conduit of transportation in New Mexico from 1598 until the 1880s, with continued regional use afterward. Situated in strategic locations along this road were stopping points, called parajes, which travelers used to rest. Parajes are usually described as campsites in literature and literature, but less attention is given to the other activities that occurred at these sites. In recent reanalysis of collections from Paraje San Diego, a historical paraje near Las Cruces, New Mexico, this significant number of arms and ammunition have been found ranging from lithics to modern firearms. The notable presence of such materials indicates some of the activities which occurred at these sites. As stopping points along lengthy, well-used roads, these sites were home to food gathering, violence, and target practice, among other uses. This paper will present an analysis of the arms found at Paraje San Diego and discuss when, how, and possibly why they were used by travelers using the paraje. Understanding the wide variety of roles these arms served to travelers on the Camino Real will lead to a better understanding of both paraje sites and their uses, as well as travel along the road.

Osteo-Grammetry: Using Photographs to Rapidly Model Large Cemeteries in Three Dimensions

Recent excavations at the nineteenth-century St Peter’s Burial Ground, Blackburn (UK) are the first to demonstrate the immense value of photogrammetry for recording human remains on a large scale. Photogrammetry is the process of using photographs to record objects in a measurable way. Recent developments have made the technique accessible and capable of high levels of detail in both geometry and texture. These attributes make photogrammetry very appealing to archaeologists and it should now be considered part of the standard recording toolbox. This paper presents the initial results of the individual photogrammetric recording of 2,000 burials. Both on-site and post-extraction processes will be discussed, demonstrating why it was by far the most appropriate technique for this type of project. The outputs have enabled a comprehensive re-stratification of the site, visualization of the density and depth of burial plots in 3D, and the spatial plotting of a wide range of osteological, artifactual and demographic datasets. The technique has clear applications on North American sites, where rapid, high-quality recording of human remains and other archaeological material is crucial. This is especially true for rescue archaeology in areas affected by high erosion or development pressure.

Past Communities in the Marginal Landscapes of the Western Taurus Mountains, Southwest Turkey: The First Results of the Derekköy Archaeological Survey Project

This paper presents the results of a new survey project in the Border Region (southwest Turkey). Previous archaeological research in southwest Turkey has until now mainly focused on the larger fertile lowland areas, which revealed numerous farming settlements from the Neolithic onward and illustrated clear distinctive periods of continuity and collapse in human occupation in these areas. The more marginal areas in the landscape such as remote, high altitude locations, on the other hand, have not been the main area of interest. The new Derekköy Archaeological Survey Project, conducted within the framework of the Sagalassos Project, aims to fill this gap in knowledge by shedding light on how different landscape units were incorporated into the...
cultural landscape. By investigating the Dereköy highlands we would like to examine how and when past communities used more marginal landscapes, and to provide a window on periods which are currently poorly known in plain areas, such as large parts of the Chalcolithic (5500–3500 BC), the Late Bronze Age (1600–1200 BC), and the so-called Byzantine Dark Age (eighth–tenth centuries AD). The unique archaeological datasets of both low and highlands allow us to paint a more comprehensive picture of the prehistoric cultural landscape in Anatolia.

[174] *Analytical Approaches for Identifying Ritual Contexts*

Paleoethnobotanists continue to push plants into the realm of social archaeology, particularly in terms of examining how plants articulated with ancient ritual practices. The connection between the prehistoric and ritual, however, is not a straightforward process—researchers must first appropriately identify special contexts and/or foods, after which they must attribute meaning to the contexts and events they have identified. This presentation focuses on the first step—identification of ritual plant deposits, using the plant assemblage as the means of definition. I discuss several analytical approaches and quantitative methods for achieving this goal while also highlighting relevant case studies.

[157] *Traveling to the Horned Serpent’s Home: Pilgrimages to Paquimé*

In the thirteenth and fourteenth centuries, a new political and religious capital expanded its influence in the North American Southwest. This settlement, called Paquimé or Casas Grandes, was the focus of pilgrimages that reflected and reinforced the social dominance of the elites living at the community. However, caches of millions of ocean shell, instances of human sacrifice, and other aspects of the archaeological record indicate that Paquimé itself was likely considered a living entity that helped control access to water in the region. The pilgrimages consequently reflected and created a reciprocal relationship in which the settlement legitimized the elites living there while the elites reinforced and emphasized the sentient nature of the settlement. The resulting pattern is largely consistent with Southwestern and Mesoamerican perceptions of animated places where human and nonhuman beings negotiated complex relationships within the larger cosmological network. These animated locations were often the focus of pilgrimages, and included living communities, ancestral communities, natural features (e.g., the Zuni pilgrimages to the Salt Lake), and symbolic representations of the heavens.

[89] *An Assessment of Prehistory at Historic Hanna’s Town*

Historic Hanna’s Town, a colonial settlement in western Pennsylvania, was founded in 1769 and quickly made history by becoming the first county seat west of the Allegheny Mountains in 1773. In 1775, Hanna’s Town made history again by signing the Hanna’s Town Resolves, stating that they would take action if British tyranny continued. Hanna’s Town soon became embroiled in the Revolutionary War and as a result was attacked and set on fire by the British and Seneca. Hanna’s Town did not recover from this attack and was dissolved as the county seat. The site was then farmed until 1969 when Westmoreland Historical Society purchased the land and placed it on the National Register of Historic Places. Since, the site has been excavated resulting in the recovery of artifacts from colonial as well as prehistoric periods. Most of the research on the site focused on the colonial period resulting in little information about the prehistoric use of the site. This research project examined the occupation of the site prior to Hanna’s Town, by classifying the bifaces recovered from the site by type and raw material to determine the time of occupation and where the material was procured.

[118] *Site-Seeing: Aeriality, Archaeological Survey, and Objectivity in Coastal Peru*

Far from being mana from the future, aerial imagery has been integral to both the practical and conceptual dimensions of archaeological survey almost from its inception. In this presentation, I argue that aerial photography captured via private and state-funded reconnaissance in the 1930s and 1940s played a transformational role in the emergence of regional approaches in Peru’s desert coast in the mid-twentieth century. I discuss how the use of aerial imagery has both enabled and constrained the interpretation of archaeological phenomena and participated in the construction of the objects of archaeological survey—sites, artifacts, and landscapes. I then consider how more recently available products—high resolution, multi-spectral satellite imagery, UAV photography and near-surface remote sensing—participate in the same processes.

[43] *How I Spent My Summer Vacation: A Model for Archaeology Camps in Service of Public Outreach*

Public outreach and education has increasingly become an essential component of archaeology. Helping the community become invested in the past can do wonders for perpetuating the archaeological ideals of cultural preservation and conservation. Instilling these values in the younger generation is one of the most effective ways to create a more culturally conscious future. The University of Texas at San Antonio’s Center for Archaeological Research aims to meet this goal through their educational outreach program titled “Legacy: Hands on the Past.” The Legacy program offers many archaeology based learning opportunities for local students, teachers, and other community members throughout the year. Within this presentation we will highlight one of the longest running methods to connect the past to the present embodied by the Legacy program. After years of fine tuning, the Legacy team has developed a highly successful model to create an annual archaeology themed summer camp that couple learning and fun for a holistic experience for students. This paper will outline the model while emphasizing the benefits, challenges, and changes Legacy staff has encountered along the way.

"Local Engagement in UNESCO World Heritage Sites: Mexico as a Case Study"

The "critical importance of involving indigenous, traditional and local communities in the implementation of the [World Heritage] Convention" (World Heritage Committee Decisions 31.COM/13A and 31.COM/13B, 2007) reflects discussions that have been taking place in WH since 1994, and has guided much of UNESCO's efforts regarding their committee in World Heritage Sites since. In 1994 social participation became a requirement in the nomination of new World Heritage Sites and since 2008 it has been expected in their management. However, the extent to which social participation has been implemented is a moot point. Inspired by the "Rapid Ethnographic Assessment Procedures" (REAP) method developed by the U.S. National Park Service (Low 2002), our team has conducted fieldwork to examine the situation in archaeological WH sites in Mexico. Methods used by our team include personal semi-structured interviews, focus groups, participant observation and archival research. We will explain some of the results obtained so far and contextualize them in the social and political processes that have taken place in Mexico in the last two decades.

Varma, Supriya (Jawaharlal Nehru University, New Delhi, India)  
"Unsettling a Region: Archaeological Landscapes and Seascapes of Saurashtra, Western India"

The peninsula of Saurashtra is a distinctive physiographical region in western India that is surrounded by the sea on all sides except the east, where it is attached to the mainland of South Asia. This square peninsula, virtually a cul-de-sac, is somewhat isolated when compared to the Gujarath plains that are located to its east. Farmers, pastoralists, crafters and traders have left behind their signatures through settling and unsettling in a region, which is characterized by shallow, unproductive soils, high seasonality, recurrent droughts and crop failures. In my paper, I will explore the region of Saurashtra to shift focus and interpret the study of sites in current and historical contexts from both North India as well the Indus Valley Civilization. I examine the archaeology of places, sites and non-sites, as mediated by economic, environmental or physical conditions as well as by social and cultural practices of past communities that have inscribed, both intentionally and unintentionally, the landscapes and seascapes of Saurashtra in the period between the third and first millennia BCE. I use the concept of "trace" to explore the residues of ordinary people that have been inadvertently left behind and now form part of the archaeological contexts.

Varney, R. A. (PaleoResearch Institute, Inc.) and Linda Scott Cummings (PaleoResearch Institute, Inc.)  
"Finding Dung on Prehistoric and Historic Landscapes: Sporormiella in the Pollen Record"

Dung fungal spores (Sporormiella) live on grazing animal dung and comprise part of the pollen record in landscape studies. Coprophilous fungi such as Sporormiella rely on a cyclic process involving herbivore ingestion of spores with foliage; germination of spores following passage through the gut; and mycelial growth within, and eventual sporulation on the surface of drying dung. Often their recovery in stratigraphic profiles is interpreted to represent megafaunal presence, thus enhancing landscape use discussions to include grazing fauna. Stratigraphic records from the American Great Plains beginning with a site in Oklahoma (21,000 BP), then moving to other locations examine faunal presence from the late Pleistocene and early Holocene until modern times. Recovery of dung fungal spores on groundstone suggests processing animal entrails. At the recent end of the time spectrum, dung fungal spores recovered from historic Iowa privies from neighboring properties suggest keeping livestock on some properties.

"Current State of Megalithic Research in Kerala, India"

Megalithic studies in Kerala started with the discovery, excavation and publication of burial site at Chattapparamba in Kozhikode district by James Babington in 1819. While a number of archaeological investigations on Megaliths in Kerala have been carried out since then, very few of them document the location, distribution and nature of these monuments. Megalithic burials are highly visible on the landscape and are often subject to excavation, yet, we currently lack an understanding of the society and the people who constructed these monuments. In recent years, large-scale construction projects and rapid growth in house construction throughout Kerala has led to the destruction of large number of Megaliths. In this context, the Department of Archaeology at the University of Kerala in collaboration with the University of Kansai (Japan) and Memorial University (Canada) is preparing a gazetteer of reported Megalithic sites in Kerala. In this paper, we discuss the Kerala Megalithic Gazetteer Project, the available archaeological data, and excavations and explorations undertaken under the project. We present preliminary efforts to better understand the density and distribution pattern of Megaliths in Kerala in relation to their physical and social landscapes.

Vashishth, Meenakshi (M.Phil., University of Delhi)  
"A Study of the Archaeological Landscape of Bairat, Jaipur district, Rajasthan"

Bairat is a region located in the present-day Viratnagar tehsil of Jaipur district in Rajasthan. So far it is known for yielding two Ashokan inscriptions in the nineteenth century and being identical with the mythological Viratnagara of Mahabharata. This paper develops a larger understanding of the history of Bairat by studying its material culture which came into light after post-Independence excavations and explorations. To understand the settlement from about seventh century BCE up to third century CE, I carefully examined ceramics in existing archaeological collections and integrated them with surface finds of a new site Khera-ki-Dhani which was discovered during the field surveys. This integration of sources of archaeological information offers insights into the history of Bairat, helping us contextualize the royal Ashokan proclamations while providing perspective view on Bairat through time—as part of the larger narratives from Mauryas to Mughals.

Vaughn, Kevin [308] see Gorman, Alicia

Vázquez López, Verónica (Yaxnohcah Archaeological Project)  
"Ritual activity at the Grazia Complex, Yaxnohcah"

Yaxnohcah is located in southern Campeche, Mexico, and had an important occupation from the Middle Preclassic to the Late Classic period (c. 600 BCE–800 CE). The focus of this paper is the Grazia complex, one of the ten major civic-ceremonial groups. Grazia consists of two monumental platforms featuring a triadic group and a ball court. The complex is located about 2 km southwest of the center of the site. Excavations began in 2016, revealing the presence of several constructive phases, including early platforms built with massive stone blocks, as well as the remains of ritual
activities. A hearth and a ritual deposit with a triadic layout—a cache vessel surrounded by three stones—might be related to the principle of centrality and creation mythology. In this paper, I discuss the importance of the findings at the Grazi complex in a broader perspective, comparing the new data on ritual activity with other contemporary practices throughout the Maya area. Public rituals seem to be related to the process of social integration and the institutionalization of power in the Preclassic period, in an area which played a crucial role in the consolidation of the Maya political landscape.

Reddish Valuable from Far Away: Spondylus princeps in the Ancient City of Tamtoc

The ancient city of Tamtoc developed in the Huastec region between 400 BC and the early sixteenth century AD. A great amount of shell objects have been found here, some of them made of freshwater mussels that live in the nearby rivers, while other are made of marine species from the relatively close Gulf of Mexico. Some pieces, nevertheless were made of species from the far way Pacific coast, one of which is the bivalve Spondylus princeps. In this paper, the results of the analyses made to the objects made of this shell will be presented. They include the study of their manufacturing techniques and their archaeological contexts of finding. On this basis aspects as the origin of their manufactures and their role as luxury items will be discussed.

Biographical Approach for Evaluating Archaeological Landscapes: A Case Study from Estonia

Since the 1990s, landscape biography as a research method has diversified. The biographical approach expects a thorough study of a certain region in various fields of landscape research, which span far beyond just geography or archaeology. In contemporary approaches to landscape, the limits of the concept of landscape biography are being explored, but also tested. What exactly is a landscape biography? What does it constitute? Is landscape biography just a narration of a specific defined place on the face of the Earth in a defined period of time or does it have a practical output? Is it possible to tell the future by narrating the past? In addition to the traditional landscape narrative, the scope of the current research concentrates on historic land use around archaeological sites and aims to create a system for assessing the archaeological heritage value of certain micro-regions. The aim of the research is to elaborate practical methodology for detecting the most essential elements of archaeological heritage landscape to create an effective concept for landscape preservation through sustainable development. The paper is illustrated by a case study from Estonia.

Red Ochre at Hohle Fels, Germany: The Use of Pigment and Space at an Upper Paleolithic Cave Site

Some of the most informative artifacts regarding early symbolic behaviors in Europe come from Hohle Fels Cave, Germany. Hohle Fels (HF) boasts a detailed Upper Paleolithic sequence, and an extensive array of ochre artifacts. In this project, we systematically investigate the ochre assemblage at HF by quantity, type and modification, and proximity to other archaeological features. The ochre assemblage includes painted limestone pieces, faunal elements, fossils, and potential grindstones with traces of ochre, raw ochre artifacts, and anthropogenically modified ochre pieces. Most un-worked ochre pieces date to the Aurignacian (ca. 44–34 cal. ky BP) layers, while important symbolic artifacts such as the Venus figurine and bone/mammoth ivory flutes were found. Almost all of the modified pieces date to the Gravettian (ca. 27–31 cal. ky BP) and Magdalenian (ca. 12.5–13.5 cal. ky BP). A central part of our investigation assesses whether clear behavioral trends related to ochre manipulation are recognizable throughout the Upper
Paleolítico. Al analizar los contextos en los que la arcilla ocurre espacialmente y temporalmente, buscamos entender cómo los primeros humanos interactuaban con y movilizaban materiales de arcilla durante la Edad del Paleolítico Superior, lo que tiene implicaciones para el entendimiento del comportamiento simbólico temprano en Europa Central y más allá.

La fotografía aérea con drone como una herramienta para el Registro del Patrimonio Histórico de Yucatán
Desde hace muchos años, la fotografía aérea ha sido de vital importancia para el desarrollo de la arqueología. Hoy en día, su uso es tan común que podríamos considerarla una herramienta elemental dentro del trabajo arqueológico, ya sea en la etapa de registro, excavación o análisis. El surgimiento de los Vehículos Aéreos No Tripulados (UAVs o drones), trajo consigo la capacidad de obtener fotografías aéreas de espacios o elementos específicos en pocos minutos a bajo costo, generando mayores facilidades en la obtención de imágenes que pueden ser procesadas en diversos programas computacionales, poniendo a nuestro alcance una herramienta innovadora para la investigación arqueológica. De esta manera, la presente ponencia tiene como objetivo mostrar las capacidades y la viabilidad del uso de la fotografía aérea con drones como una herramienta para el registro de la arquitectura histórica de Yucatán. Para ello, se expondrán los resultados obtenidos dentro del proyecto "San Pedro Cholul: geoarqueología, historia e industrialización de una hacienda henequenera yucateca de principios del siglo XX" llevado a cabo por la Facultad de Ciencias Antropológicas de la Universidad Autónoma de Yucatán.

Venter, Marcie (Murray State University)
Not So Strange Strangers in a Strange Land?
Ceramic evidence combined with obsidian and sculptural data from the archaeological site of Matacanela are beginning to paint an unexpected picture of intra- and interregional dynamics in the Early and Middle Classic Tuxtla region of the southern Gulf lowlands. These data point to an unexpectedly independent political-economic relationship with the nearby center Matacapan, but one that may have been created through elite-alliance networks that differently incorporated Teothihuacán-style symbols into local political strategies. In this poster, we consider existing models for political and economic networks in the Tuxtala, how those networks differently incorporated foreign styles in political strategies, and how new ceramic evidence, some of which includes recent NAA characterizations, addresses our evolving understanding of Classic period dynamics.

El suelo arqueológico como mercancía: Problemas actuales sobre la conservación arqueológica en la Costa del Golfo
El suelo que sólo sea visto como una mercancía que otorgue seguridad económica y sobre el cual no se regule su uso, adquiere una mayor complejidad al ser parte, además, de un contexto arqueológico. En este sentido, uno de los principales retos de la arqueología en México es conservar a largo plazo las zonas arqueológicas que la ley refiere y todos aquellos sitios de gran valor y extensión, que son investigados año con año y que requieren de un diseño de conservación como política cultural, acorde con el territorio y la organización política-económica de su región, en este caso la gran región de la Costa del Golfo.

Beautiful Virgins and Male War Captives: The Role of Sex Attribution in Ancient Maya Human Sacrifice at Midnight Terror Cave, Belize
The prurient element in the popular notion of the Maya sacrifice of "beautiful virgins" during the first half of the twentieth century (Frost and Arnold 1909; Willard 1926) appears to have made researchers wary of the topic of gender in study of human sacrifice. The interest in human sacrifice arose in the 1990s at the same time as the formulation of the warfare hypothesis for the collapse of Maya civilization (Demerast 1990) so that models of human sacrifice tended to assume that victims were largely male war captives. In reality, few large skeletal assemblages related to sacrifice exist to provide hard data on the issue. The Midnight Terror Cave assemblage, consisting of more than 10,000 bones, is one of the few. This paper reports on the detailed examination of all the pelvises in the assemblage using osteological and paleogenetic techniques to shed light on the sexual composition of sacrificial victims.

Mapping and 3D Modeling of a Terminal Postclassic Site in the Northern Yucatán
During our 2016 field season, we mapped and created 3D models of several sites in the Northern Yucatán that were scheduled for destruction due to highway expansion. We used unmanned aerial vehicles (UAVs/drones) to carry photographic equipment to collect both vertical and oblique photos of the site. The resulting photos were processed in photogrammetric software to generate an orthorectified photo mosaic and a 3D model of the entire area. These products were integrated into a GIS to facilitate analysis. In this poster, we outline the technology and data processing workflow used and display the resulting products for a Terminal Classic settlement. The settlement consists of a large platform on which approximately twelve structures are located. Our map encompasses, the platform, architectural remains visible on the ground surface, and salvage excavations from several structures and into sections of the platform.

[45] Technological Variability in the Ancient Holocene in the Central Plateau of Brazil and Border Southwestern Brazil with Uruguay

We'll present reflections about the technological variability of two regions of Brazil, the Central Plateau and the southern state of Rio Grande do Sul. Both are dated from the ancient Holocene and the results come from techno-functional analysis applied in lithic materials evidenced in sites of these regions. The Central Plateau is characterized by the Itaparica Techno-complex, composed of instruments with silhouette easily identifiable. The technical design allows a standardized hafting and organization of different functional parts. The defined spatial distribution of this material and its rupture with the Middle Holocene indicates that it is a technical phenomenon that does not exist in other sites in South America. In the area of southwestern border of Brazil with Uruguay, archaeological sites in surface and stratigraphy present a significant technical diversity. Technical systems of production were evidenced, and for each of the modes (façonnage and debitage) there are different predetermined blanks that correspond or not to specific tools. We present technological diversity witnessed in different areas and specific period, indicating multiple technical behavior where a single model is not enough to explain the occupations.

[88] Late Formative Obsidian Procurement in Xochitecatl-Cacaxtla

This study inquires into the obsidian commercial networks of Late Formative in the site of Xochitecatl-Cacaxtla employing an analysis of pXRF on 102 pieces of obsidian artifacts. In addition, we performed a technological approach of the material recovered from ceremonial and domestic contexts in order to know in which stage of the process it arrived. With this, we intend to know how each source was represented throughout the site, revealing the internal maneuvers used by two different settlements in order to better understand both intrasite economic relationships and the interregional commercial system between sites within the Tlaxcala region.

[222] Human Selection on Maize Size Traits: A Contribution from the Archaeological Record of Tarapacá, Chile, South-Central Andes

Maize from Andean region has a recognized complex history, involving ecological and human interaction. Today, while Andean maize shows high morphological and low genotypic diversities, the process involved in its production and selection is unclear. In this work we ask how the morphological and genetic diversity of maize has varied through the Formative Period to the present time in Tarapacá Region, northern Chile? To answer this we analyzed thirty morphological traits and eight microsatellites markers over archaeological cobs and kernels (dated circa 500 BC to AD 1400) and 95 modern ears maize derived from primitive races. Our results show, at phenotypic level, significant differences between archaeological and modern cobs/kernels. In contrast, low genetic diversity between samples was found. These results are consistent with a human selection directed to increase corn size during a short period of time.

[134] Formative Mobilities: Moving through the Atacama Desert, Northern Chile

Social spheres are constituted by population movements. Mobility entails not only the circulation of material goods, but of people, collective imaginary, experiences, flows of information, and knowledge. In this paper, we examine multiple types of movements through the Atacama Desert during the Formative Period (ca. 500 BCE–700 CE). Here, mobility required displacements whose variability included pedestrian travels, the movement of large llama caravans, and the use of sea lion-skin rafts to sail along the Pacific Ocean, thus involving different material means and encompassing a wide array of incentives. We offer different case studies that challenge monolithic assumptions about mobility in the south-central Andes, often seen exclusively through the lens of ecological complementarity and primarily driven by economic exchange. We question here the spatial and temporal scale of these displacements—from daily to seasonal, from micro to macro-movements—as well as its motivations, which were prompted by different social commitments (cooperation, the creation political ties, and the livelihood of communities, to name a few). Through these case studies, we approach movement and travel as a way of life, and explore how it was incorporated into the social lives of these groups.

Fishes Swimming in the Magdalena River: Villages and Summit Features in the Middle Magdalena Valley, Northwest Sonora

At the end of the 1990s, Suzanne and Paul Fish conducted a full coverage survey around the regional center Cerro de Trincheras in the middle Magdalena Valley “to clarify the role of the many smaller or secondary trincheras sites within territorial organization” (Fish and Fish 2007:168). Early Ceramic trincheras sites were located 2.5 to 4 km from its nearest neighbor; all suggest multifunctional and residential occupations in the Magdalena valley, and most of them continued in use in the El Cerro Phase (AD 1300–1450). Summit rock rings are the main architectural feature. El Cerro Phase in the middle Magdalena Valley is marked by the occupancy of Cerro de Trincheras; trincheras sites are more numerous and widespread than Early Ceramic sites. El Cerro Phase sites had corrales with a standardized form which denotes replication and institutionalization of specialized functions, creating a network of integrative trincheras nodes that increasingly interlinked populations. The Fishes interpret summit compounds at Sonora and Arizona as ideologically significant features and move into ethnography for plausible frameworks for testing interpretations. I will discuss if summit structures are a trans-regional phenomenon that include concepts taken by Northwest/Southwest societies who incorporate them in their own traditions.

Community Archaeology and Ancient Ceramics: Developing an Inclusive Research Design in San Jose Succotz, Belize

Collaborative archaeology is an approach that promotes the inclusion of modern, indigenous communities in the study of the ancient past. In the Maya area, local communities have recently become more involved with archaeological research at multiple stages, including research design, data collection, and community outreach. At the same time, advances in the qualitative and quantitative study of early ceramics have allowed archaeologists to further elucidate ancient Maya chronology, economy, and sociopolitical structure. A project design which integrates these recent developments emphasizes the incorporation of local community knowledge into the study of ancient Maya ceramics. This paper, which offers a broad overview of the history of collaborative efforts in the Maya region, serves as a preliminary discussion of a collaborative project established with a local, traditional potter in the village of San Jose Succotz, adjacent to the site of Xunantunich, Belize. The knowledge produced by this project will allow local potters to incorporate ancient techniques into their craft and advance archaeological understandings of ancient ceramics. Further, this introduction of inclusivity into the design and execution of research will help ensure that the knowledge produced is accessible to actors who have traditionally been excluded from academic discourse.

Village Aggregation and Early Cultural Developments on the Canadian Plateau: A Case Study from Keatley Creek

Understanding when and under what conditions aggregation into larger communities with large corporate house organizations, socioeconomic inequalities and specialized ritual structures occurred has been a central theoretical issue in various regions of archaeological investigations. Perhaps the biggest bone of contention in current theorizing is whether these transitions occur when hunter/gatherers accepted claims to privilege on the part of some individuals by consensus to deal with community problems due to environmental stress or population pressure, or whether people were cajoled into participating in systems creating inequality by promises of lucre and a better life. These scenarios contrast the most in terms of the resource conditions under which early cultural developments are expected. Ritual is often invoked in this context as a means of promoting community solidarity, or to mobilize and justify systems of inequality. Research at Keatley Creek has been investigating these issues through intensive radiocarbon dating and detailed stratigraphic analysis of large house rim midden contexts and ritual structures, combined with GIS modeling of ritual in village or tribal level societies drawing upon ethnographic and archaeological research. Results from this ongoing research offer significant insight to our understanding of early cultural developments among hunter/gatherers.

Satellite Remote Sensing of Archaeological Environmental Change in the Chicama Valley

As global ecological change becomes a pressing contemporary issue, it’s beneficial to also consider how long-term land use histories have affected current ecologies. Using imagery from several multispectral remote sensing satellites and field verification of detected sites, I describe how legacies from archaeological occupations impact modern industrial sugarcane production in the Chicama valley. Occupation sites and agricultural systems, both extant and remnant, continue to influence sugarcane phenological development. These anthropogenic features result from highly localized changes in groundwater and soil water potential, which in turn produce differentials in plant-available essential nutrients and moisture. In many cases, crop losses result. This remote sensing–aided approach further documents many archaeological features unrecorded in prior surveys. Settlement analysis suggests an abrupt coastward shift in populations between the Moche and Lambayeque cultures; dispersal into more, smaller sites; and an increased reliance on anthropogenic ponds (cochas) in the latter period. These shifts may be linked to changes in groundwater hydrology. Modern small-scale farming and wetlands ecology continue to benefit from anthropogenic wetlands originating in the Lambayeque periods. Both findings show the importance of archaeological land use legacies and path dependence on the modern ecological function of the Chicama Valley.

[49] Coastal Predictive Modeling for Early Period Archaeological Sites in a Landscape subject to Rapidly Changing Sea Levels, Quadra Island, British Columbia

In the Northwest Coast, paleoenvironmental context is essential in the search for late Pleistocene–early Holocene coastal archaeological sites. The dynamic and complex relative sea level history is a key determinant in site discovery. In this presentation I describe how we are using predictive modeling to help overcome the challenges of this dynamic history. This research introduces novel coast-focused variables and methodology to find early period coastal archaeological sites on Quadra Island, British Columbia. Initially, quantitative modeling is used to highlight potential areas for specific temporal and spatial archaeological site types. These highlighted areas are then evaluated by human judgment to include qualitative and subjective aspects of archaeological potential, such as human behavioral models and landform formation processes. Novel variables such as coastal sinuosity and wind fetch serve as proxy indicators for marine biodiversity and coastal exposure respectively, which in turn may be factors related to site location. Presented are preliminary survey results using this predictive modeling theoretical and methodological approach to find early period archaeological sites on Quadra Island.

[179] Classic Maya Politics and the Spirit of Place: Controlling Architectural Discourse at Uxul, Campeche, Mexico

Settlements are both product and site of innumerable, multilayered, and constantly changing interactions between humans and the material world. At any given moment, the quintessence of a place reflects the prevailing meanings that are associated with it. In this sense, quintessence is inextricably linked to power—over discourse, material, and space. This talk explores the role played by political power in defining the character of the Classic Maya settlement of Uxul, Campeche, Mexico. After establishing itself as an important regional center in the Early Classic period, Uxul fell under the control of the Kaan or “Snake-head” dynasty of nearby Calakmul in the first half of the seventh century AD. This talk suggests that the esprit du lieu of Late Classic Uxul was defined by a tension embodied in the built environment of the site. This tension originated from the juxtaposition of “local” places—sites of memory, ritual, and identity—and new public spaces that signaled the incorporation of Uxul into the Calakmul regional state.

[274] The People Who Harvest Together, Live Together: Ethnoarchaeological Considerations on a Late Chalcolithic Archaeobotanical Assemblage from Çadir Höyük, Turkey

This paper presents archaeobotanical data from the Late Chalcolithic (LC) archaeobotanical assemblage at Çadir Höyük, a mound site on the north-central Anatolian plateau with almost continuous occupation from the Middle Chalcolithic through the Byzantine period. The analysis will focus on both descriptive and quantitative data from samples dating to around 3600 BCE from a communal cooking area at Çadir. It will examine how archaeobotanical analysis can be used as a line of evidence to determine storage patterns at sites, labor organization, and fuel choice using models of plant use developed from ethnographic work. The paper will also discuss how other lines of evidence, like architectural analysis, can inform or can be informed by the archaeobotanical remains.

[175] The Shaman in the Cave? Testing for Entoptic Imagery in Upper Paleolithic Geometric Rock Art

It has been proposed that much of the rock art of Upper Paleolithic (UP) Europe can be interpreted as the result of shamanistic visions and related spiritual practices (e.g., Lewis-Williams and Dowson 1998; Clottes and Lewis-Williams 2001; Lewis-Williams 2002; Whitley 2005). This theory is based on a combination of analogy with modern hunter-gatherer groups, and recent neuroscience studies on the universality of human physiological response when in a trance state. Specific geometric signs found in UP art are frequently cited in these arguments as evidence of entoptic phenomena—abstract shapes seen during an altered state of consciousness—but what has yet to be explored is whether these particular images appear with a great enough frequency and in the appropriate contexts to verify this claim. This paper will address the question of whether the regularity and co-occurrence of geometric sign types identified as potential entoptic imagery supports the theory that UP art is the product of shamanistic visions.

**[275]** Dung Management in Medieval and Post-Medieval Brussels (Belgium)

During archaeological excavations in the center of Brussels (Belgium), often stratigraphic units containing dung—either omnivore-carnivore, including human, or herbivore—have been encountered. A multidisciplinary approach, comprising soil micromorphology, phytolith analysis and parasitology on soil thin sections, chemical analyses, including GC-MS and phosphorus measurements, was adopted to identify and characterize dung remains. In some cases dung was observed as part of the manure added to pre-urban and urban agricultural and horticultural soils. Under other circumstances, we were instead able to identify the very stable where dung was purposely accumulated for later use (“podstal” or “sunken byre”). In one site we observed the accumulation of dung in an area where waste from latrines and houses accumulated. Such contexts provide important insights on dung management practices and on the value of dung in Brussels between the tenth and sixteenth century AD.

**[279]** A Vertical Loess Cave Dwelling at Yangguanzhai?

Of all features excavated at the late Neolithic site of Yangguanzhai since 2005—including houses, hearths, postholes, kilns, child and adult burials, and ditches—pits features, known by the generic term “huikeng” or “ash pit” in Chinese archaeology, account for about 80%. Detailed studies of such features are important not only because of their sheer number, but also because their contents are often used as criteria for site dating and chronology. As our excavation of one such feature (H85) shows, understanding their deposit formation as well as the contents of the deposit is essential to deciphering the function of the pits, as well as their relationship to other features found in archaeological contexts. Our study methods include micromorphology, paleobotany, ceramic analysis, and C14 dating of the pit. This approach of the intensive study to one feature has proved to be fruitful and holds promise for future studies in Chinese archaeology.

**[91]** Measuring Gesture: Stroke Quantification in Lithic Use-Wear Experiments

The saying “different strokes for different folks” is a literal truism in the realm of lithic analysis and experimentation where stone tools were and are used by individual people whose tool use gestures vary in any number of ways. Until very recently, experimental archaeologists have largely neglected aspects of gestural variation, such as how much force is applied to a tool’s edge, and task-related gestures are most often glossed under the catch-all term “stroke.” “Strokes” are counted and then compared to other “strokes,” often without any further definition. This poster describes a method for precisely measuring tool edge loading without restricting the tool user’s gestural freedom. Using a low-cost, handheld digital force gauge made with open-source hardware and software, it is possible to precisely record and define individual strokes, and relate them to wear observed on experimental lithic tools.

**[140]** Mobility of Folsom and Late Paleoindian Occupations at the South Bank Portion of Blackwater Draw Locality No. 1

Research and excavations conducted at the Blackwater Draw Site have largely contributed to our understanding of Paleoindian era life. This study focuses on the lithic artifacts recovered from the South Bank portion of the Blackwater Draw Site to understand the mobility of Folsom and Late Paleoindian occupations. Although there has been extensive fieldwork conducted at the South Bank, the lithic artifacts from these excavations have not been studied as one cohesive assemblage. The entirety of the Folsom and Late Paleoindian assemblages from the South Bank are used to conduct a lithic attribute analysis to identify and compare the mobility of these occupations. This research also spotlights new information concerning South Bank artifacts, much of which is unpublished and unknown to the greater field of archaeology.

**Wagner, Mark and Kayeleigh Sharp**

**[175]** Portable X-ray Fluorescence (pXRF) and Photogrammetric Studies in Illinois Rock Art Research

Illinois rock art studies conducted in the nineteenth and twentieth centuries typically used drawings, tracings, and print photography to record prehistoric petroglyphs and pictographs. These types of studies have been replaced in recent years by a variety of new methods including digital photography, DStretch enhancement, photogrammetry, pXRF analysis, and other technologies. These new techniques have greatly enhanced our ability to quickly and accurately record rock art sites in comparison to older methods. In this paper we present several case studies that showcase the use of these new methods and their ability to enhance or correct information collected by earlier rock art studies. Of particular relevance are recent (2016) photogrammetric and 3D modeling studies of several large panels containing hundreds of painted and pecked images at the Pinney Creek site (11R26), which the senior author (Wagner) recorded in 2001 through the use of tracing, line drawings, and conventional photography. Comparison of the two techniques demonstrates the clear superiority of photogrammetry and 3D imaging in terms of the reduced amount of time and greater level of accuracy in regard to rock art site recording over more conventional approaches.

**[370]** Changing Interpretations of the Archaeology of Caribbean Western Panama

Recent field and laboratory archaeological findings in Bocas del Toro, Panama offer data that changes and amplifies our understanding of the prehistory of the region. Detailed paleoethnobotanical study, further zooarchaeological examination, preliminary ceramic thin-section analysis, and continuing
ceramic analysis have all produced results that call into question entrenched assumptions concerning the timing of settlement, the nature of the subsistence economy, trade, exchange and cultural complexity in the region. Bocas del Toro was settled by at least 2 kya. Its inhabitants consumed maize, a variety of tree crops, a diverse array of animals, and were fully incorporated in the greater Lower Central American Interaction Network as evidenced by the presence of diagnostic ceramics derived from Central Panama all the way to southwest Nicaragua and many places in between.

Walden, John (University of Pittsburgh), Michael Biggie (Los Angeles Maritime Institute), Rafael Guerra (University of New Mexico, Albuquerque) and Julie Hoggarth (Baylor University) [369] Investigating the Presence of Neighborhoods in Classic Maya Dispersed Settlement Patterns

Classic Maya settlement patterns can be characterized as dispersed or “low density.” Yet among the dispersed house groups scattered across the landscape, patterns of residential clustering can often be discerned. These settlement clusters likely resulted from an array of different forms of interaction which collectively acted as centripetal forces bringing people together. For this reason, Maya residential clusters probably represent extended corporate groups or neighborhoods. Unlike their nucleated urban counterparts in other early states, Maya dispersed settlement patterns present difficulties when defining cluster membership and determining where to effectively “draw the lines” around possible neighborhoods. This presentation explores ways to better delineate dispersed neighborhoods at a micro-regional level through the application of various spatial analyses which have been traditionally used to discern political boundaries and polity affiliation at a regional scale. These techniques are applied to the hinterland settlement patterns of the Late/Terminal Classic (AD 600–900) Maya polity of Lower Dover, Belize, to investigate the presence of neighborhoods and patterns of interaction between households. The results suggest the presence of several distinct neighborhoods structured around large intermediate elite residential and ceremonial centers.

Walder, Heather (Michigan State University) [341] Compositional Analysis of Copper-Base Metal Artifacts from Michigan

Compositional analysis of copper-base metal artifacts using portable X-ray fluorescence (pXRF) is an accurate and nondestructive way to identify “protohistoric” European-trade items in early contexts and to assess the continuity of native copper object use on historic-era archaeological sites (Dussubieux and Walder 2015). This poster presents new results from pXRF analysis of artifacts from two late seventeenth century archaeological sites in the Upper Peninsula of Michigan: the Cloudman Site, a protohistoric or Early Historic Anishinaabe/Ojibwe camp on Drummond Island, and the Marquette Mission site, a Tionontate village in close proximity to a Jesuit mission at St. Ignace. Copper-base metal artifacts from feature contexts were selected for analysis on the basis of other potentially temporally or culturally-diagnostic trade items from the same features. Results provide new information on the persistence of native-copper metallurgical practices in colonial contexts and the introduction of smelted-copper trade items at these sites, furthering the understanding of interactions among Native American communities as well as European explorers, traders, and missionaries in this area.

Walder-Hoge, Zoe (Simon Fraser University) [171] An Ethnoarchaeological Approach to Traditional Farmer Knowledge and Fire Ecology in Eastern Tigrai, Northern Ethiopia

This study will conduct ethnoarchaeological interviews of Eastern Tigrai rural consultants on traditional farmer knowledge, risk management and fire ecology. The data will enable the integration of farmer knowledge within an historical ecology framework to understand human-environment interactions taking place during the Pre-Aksumite and Aksumite periods (≥800 BCE–CE 700). A previous paleoenvironmental study examined extensive charcoalized wood and burned matter in the region, however an ethnoarchaeological study has yet to be conducted as to farmer’s potential use of fire. Interviews will concentrate on Elders and other community members practicing non-mechanized agriculture. The research will focus on human agency in regard to risk management and periods of resource stress, most notably from climate, soil erosion and increasing demographic pressures. Questions will probe the significance of cereals and the importance of crop diversity. The study will also document changes in land use and approaches to crop cultivation. The knowledge gained is intended to further elucidate human-environmental interactions of early complex societies in the Horn of Africa. The results will assist in generating hypotheses on the role of human intervention and decision making in past human-environment interactions.

Walker, Bethany [285] Localizing the Imperial Grain Economy in Mamluk Syria: Expressions of Village-Level Initiatives in Fourteenth-Century Transjordan

How did the medieval Islamic state realize its objectives in natural resource management? How can we distinguish the “hand of the state” from that of local initiatives in land use? This paper is an attempt to evaluate planting and watering strategies, differentiating imperial agro-policies from local practice at the village level. The focus is the intensification and diversification of grain production in fourteenth-century Syria. Grain fields were the most valuable of the agrarian iqṭa’at (grants of tax revenues) assigned to military and administrative officers; they were the financial underpinning of the medieval Islamic state. The history of grain production is one lens through which to study the development of governance in the Mamluk Sultanate (1250–1517 CE). Tall Hisban in central Jordan, a rural site that physically dominates the grain fields of the Madaba Plains, provides a case in point. Excavations there, integrated with textual and multipronged paleobotanical analyses, are revealing ways that village communities, combining traditional know-how and innovation, came to actualize state programs aimed at maximizing, and guaranteeing reliable, grain yields. Grain production is likewise compared to the sugar industry and market-oriented terrace gardening, which were also impacted by state policy and have left physical and textual traces.

Walker, Cam (Archaeological Investigations Northwest, Inc.) [121] Dining Out in the Desert: Results from Protein Residue Analysis at the Azraq Oasis, Jordan

Excavations at Shishan Marsh 1 (SM-1) have provided evidence of a unique ecosystem, along with faunal remains and over 10,000 artifacts made from local flint dating to approximately 250,000 years ago. Forty-six of these artifacts were selected for residue analysis from stratified, in situ deposits. Extractions from these lithic tools were tested for possible protein residues using the technique of cross-over immunoelectrophoresis (CIEP). The SM-1 artifact extractions were run against eight antisera, informed by the diversity of faunal remains at the site: rhinoceros, camel, deer, duck, horse, goat, bovine, and cat. In total, 17 positive results were obtained: rhinoceros (3), duck (3), horse (5), camel (3), and bovine (3). An overview of the findings, methods, implications, and the demonstrated potential for CIEP to reveal family-specific results of protein residue from deep time will be presented.

Walker, Chester [41] see Pantel, Agamemnon
Walker, Debra (University of Florida)

The principal ceramic type for the Petén Late Preclassic period, first identified by Edith Ricketson in the 1930s, and dubbed Sierra Red three decades later, has just about the widest distribution of any ceramic type in the Maya lowlands. In particular, the omnipresent simple flaring walled bowl form is virtually synonymous with the period, yet, after five years of excavation at Preclassic Yaxnohcah, Sierra Red remains an elusive minor type. Middle Preclassic Um Phase is well represented as is the Terminal Preclassic Wob Phase. Excluding a population collapse in Late Preclassic Chay Phase, which seems illogical based on massive and continuous construction data, a case can be made for more diversity in Late Preclassic ceramic production than previously recognized. This paper explores the consequences of such a reality in archaeological interpretation of the Late Preclassic era in the Central Karstic Uplands.

Walker, John (UCF Department of Anthropology)

Inequality and Taskscapes in a Precolumbian Agricultural Landscape

Raised fields and other earthworks, as parts of archaeological landscapes, can be theorized through Ingold’s related concepts of taskscapes and lines. In the Bolivian Amazon, such earthworks are the physical remains of group or community activities in the precolombian past. As such, they are both the products of community tasks, and infrastructure, or resources that in turn afford other community tasks. In conjunction with archaeological survey and excavation, mapping of raised fields and other earthworks makes it possible to characterize trends in the precolombian landscape across an area of about 10,000 km². About 37,000 individual raised fields have been measured, averaging about 0.27 ha each. When fields are grouped according to simple geographic criteria (such as proximity), groups of fields differ in terms of inequality, by area. The Gini coefficient is used to characterize this inequality, and trends across space are interpreted, in conjunction with results from excavation. Thinking of landscape as both a product of community tasks, or practices, could be useful in understanding similar patterns in the anthropogenic landscape.

Walker, Samantha

Empires and Kingdoms: A Comparative Analysis of Settlement Patterns and Social Organization among the Charter States of Southeast Asia (800–1400 CE)

The settlement component of the Socio-ecological Entanglement in Tropical Societies (SETS) project assesses the availability and quality of evidence for the structure and organization of dispersed urbanism among a sample of pre-industrial societies within the tropics. This paper compares support population distributions and organization among the kingdoms and empires that correspond to the Charter State era (800–1400 CE) in Southeast Asia. Our study area includes the Dai Viet and Cham kingdoms of Vietnam, the Early Siamese kingdom of Thailand, the Mataram, Kendi, Singhasari, and Majapahit kingdoms of Java, the Chola Empire of South India, the Sinhalese Empire of Sri Lanka, the Khmer Empire of Cambodia, and the Burmese Empire of Myanmar. We summarize the theoretical and methodological foundations of this project and present the preliminary insights of our ground surveys. Emphasis is placed upon how the geopolitical extents of these charter states—and their stability and longevity—are the product of integrative socio-ecological features. This offers a multidimensional view of how the integration of variable power relationships, social structures, and ecological circumstances influence the resiliency of urban systems in Southeast Asia.

Queering the Inuit Past: Archaeology as LGBTQ Allyship

The real-world utility of academic archaeology is frequently called into question. I address this perception by demonstrating that archaeology has unique potential in the sphere of LGBTQ activism. Because archaeology deals in constructing past narratives, it has the discursive power to naturalize or denaturalize existing social structures and identities. While archaeology has a long history of reinforcing normative social categories, archaeologists have recently begun to apply queer theory, which aims to dismantle normative categories, to their interpretations of the past. I argue that if we practice archaeology with the goal of revealing inconsistencies between past and present social norms, rather than projecting normative categories onto the past, archaeology gains the power to legitimize the identities of people living outside of the norms of their society or community. Through an investigation of nonbinary gender as a traditional aspect of Inuit shamanic identity, I have spoken with members of the Inuit LGBTQ community in order to understand how presenting a queer version of the past impacts living people. The results express the possibility and need to investigate queer pasts to gain a fuller picture of past identities and give LGBTQ communities a sense of history grounded in archaeological research.

Commoner Landscape, Ritual, and Symbolism in the Shadow of Dos Hombres: Recent Investigations at the Site of Chawak But’o’ob.
A number of seasons of research at the site of Chawak But'o'ob in the southwestern outskirts of the city of Dos Hombres have revealed an architecturally humble community characterized by dense habitation and extensive landscape modification as well as domestic and public ritual. The evidence suggests that the inhabitants of this farming community had an eye toward symbolism in decisions they made about the disposition of domestic and public structures as well as the manipulation of water and soils. The archaeological investigation of this site, which among other things, includes a ball court complex, suggests that meticulous examination of relic lowland agrarian settlement has the potential to reveal evidence for unexpectedly complex systems of meaning among the non-literate members of Maya culture.

Subsistence Economies at Morne Patate: A Zooarchaeological Analysis of a Colonial Plantation Landscape in Dominica

From the seventeenth through twentieth centuries, the Caribbean region experienced unprecedented demographic and environmental change, with the rise and fall of sugar monoculture and the institution of chattel slavery. These transformations were a result of power imbalances at many scales, and the economic, ecological and social consequences of the migrations and interactions were significant and long-lasting. During the Colonial Period, enslaved communities developed diverse socio-ecological practices to survive and adapt within the oppressive plantation structure, through the establishment of artisanal economies and creative subsistence strategies. Zooarchaeological data provide insight into these localized histories and offer important perspectives on the human-ecodynamics of plantation landscapes. This paper presents the results of the analysis of faunal remains from the site of Morne Patate, a colonial plantation in Soufriere, Dominica. As a colony, Dominica was known for its difficult terrain, absentee land owners, and its positioning as a locus of conflict between colonial empires. Through an investigation of the subsistence-based practices developed by the enslaved laborers and habitants of the plantation, Morne Patate provides a unique case study to explore the socio-ecological dimension of this contentious political and social setting.

Revisiting the Morris Bay Kayak: Analysis and Implications for Inughuit Hunting Practices before the Nineteenth Century

The Morris Bay Kayak is a unique assemblage that consists of kayak fragments and associated hunting equipment that was discovered in 1921 by chance in Washington Land, northwest Greenland. This paper documents results from a collaborative project with the Greenland National Museum to reanalyze and date the Morris Bay Kayak, and to consider how it fits in the current perspectives on Inughuit archaeology. Working with the traditional kayaking community in Greenland, the project reconstructed the kayak’s frame and life history, and then modeled the skills through which it would have been used. Comparisons of structural fragments and hunting tools with regional assemblages, along with new AMS radiocarbon dates, suggests that the kayak represents a local tradition of kayaking that was practiced until shortly before the colonial period. This paper will discuss what open water kayak hunting implies about Inughuit subsistence, and the sudden loss of the technology before John Ross’s arrival in 1818.

Jeju Island Ceramics as Evidence of Overseas Trade

The inhabitants of Jeju Island, Korea, maintained active trade routes with societies in the Korean Peninsula, the Japanese Archipelago, and mainland East Asia. These interactions are encoded in material culture, including imported pottery. Instrumental Neutron Activation Analysis provides high-resolution data on ceramic geochemistry that allows for differentiation among local Jeju clay sources, peninsular clays, and those from farther afield. Samples from the earliest known pottery-bearing sites on Jeju through the historical period demonstrate the continuing role of overseas trade in Jeju society.

Swahili Agriculture and Power Dynamics in Regional Perspective

Urbanization along the Swahili coast coincided with an increasing importance of Islam, stone architecture, and materials traded through connections built inland as well as with Indian Ocean merchants. Archaeobotanical data from the town of Chwaka on Pemba Island, Tanzania (AD 1100–1500) suggest that foodways turned toward Asian crops, including rice and legumes, during the urbanization process. Beyond subsistence, crops held political power. Jeffrey Fleisher (2010) has suggested that feasting was integral to the process of negotiating and maintaining political power among stone-patricians, and historic records report that rice and other crops grown on Pemba were mobilized for political relations in Malindi. New data emerging from further south on the Tanzanian coast at Songo Mnara (Kilwa archipelago) demonstrates a different pattern of foodways, relying less on Asian rice and more on African grains sorghum and pearl millet. Further south still, archaeological and archaeobotanical evidence from the Mkiindi region demonstrate a continued reliance on African crops and inland connections. Here we employ data from three regions using multiple archaeobotanical...
methods to consider implications for regionalism in subsistence, agriculture, and land use along the Swahili coast in light of the key role food played in supporting, or contesting, political power.

Walzer, Mariah (Hamilton College), Nathan Goodale (Hamilton College), David G. Bailey (Hamilton College) and Alissa Nauman (Hamilton College) [79] Prehistoric Mobility Patterns and Geochemistry of FGV Toolstones at Slocan Narrows Pithouse Village and the Upper Columbia River Area The work of Charlotte Beck and George T. Jones dramatically advanced toolstone provenance studies from how to conduct field survey, to how to prepare samples for laboratory analysis. Building on their pioneering work, this paper details the beginning of our efforts in sourcing fine-grained volcanic (FGV) toolstones in the Upper Columbia River area of the interior Pacific Northwest. Handheld portable X-ray fluorescence (HHpXRF) instrumentation was used to nondestructively analyze the FGV artifact assemblage from Slocan Narrows Pithouse Village. A systematic sub-sample (N = 20) of the FGV artifacts were then destroyed to form glass beads for wavelength dispersive XRF (WDXRF) analysis. In this paper we provide details on the methodology, and we compare the results of both analytical techniques. Results of WDXRF are expected to provide higher quality data that will enable us to resolve and identify toolstone sources whose compositions could not be resolved in the HHpXRF data because of the lower analytical precision that results from variations in artifact size and geometry. The data from this study supplement a broad examination of the lithic assemblage at Slocan Narrows that aims at defining past lithic procurement and use patterns in the Upper Columbia River Area.

Wandsnider, LuAnn (University of Nebraska) [325] LandUse6k North America: Report and Implications LandUse6k is a consortium of archaeologists, historical geographers and historians engaged in synthesizing land use data for various slices of time, to be used to improve the efficacy of climate models. These efforts recognize the large impact that anthropogenic land cover change has had on past climate and climate change trajectory. We report on efforts to characterize land use through time for North America describing methods and issues. We estimate how these characterizations allow for more accurate climate models.

Wang, Chunxue, Quanchao Zhang (Research Center of Chinese Frontier Archaeology), Yao Li (Research Center of Chinese Frontier Archaeology), Ningning Liang (Research Center of Chinese Frontier Archaeology) and Xing Gao (Institute of Vertebrate Paleontology and Paleoanth) [116] Archaeological Study of Ostrich Eggshell Beads Collected from Shuidonggou Ostrich eggshell beads and fragments collected from Shuidonggou (SDG) reflect primordial art and symbolic behavior of modern humans. Based on stratigraphic data and OSL dating, these ostrich eggshell beads probably date to the Early Holocene (10 ka BP). Two different prehistoric manufacturing pathways are usually used in the manufacture of ostrich eggshell beads in the Upper Paleolithic. According to statistical analyses of the characteristics of ostrich eggshell beads, Pathway 1 is identified from the SDG collections. In pathway 1, blanks are drilled prior to being trimmed to rough discs. These objects exhibit great potential for the study of the origin of primordial art and the development of ancient cultures, and provide important data for studying behavioral options adopted by hominids in the SDG area. In addition, they bear important implications for the origin of modern humans in East Asia.

Wang, Hua (Shandong University), Jing Zhou and Ruin Mao [117] Community Memories? Ritual Animal Use of “Qijia Culture,” Evidence from Mogou Cemetery, Lintan County, Gansu Province, China This study focuses on human ritual animal use behaviors of Qijia communities, with the study of animal bones recovered from the Mogou Cemetery in Gansu Province. More than 1,600 tombs have been excavated at the Mogou site. Since multiple burials with a few individuals of both sex and different ages were common and human bones were clumped together, most burials were classified as multiple and/or secondary burials. Animal offerings were also common in these burials, and animal bones were found either in the burial fills, in the side chambers, or beside the human remains. With application of different zooarchaeological methods and approaches to the animal bones, we have the following patterns and interpretations: 1) Qijia communities prefer pigs over cattle and sheep bones, although the later species may be more important for subsistence practices, 2) pigs were domesticated and pig mandibles were probably accumulated for a long time rather than mass killing before the ritual ceremony, and 3) the mass use of pig mandibles may be interpreted as community memory behaviors of Qijia Communities.

Wang, Minghui (Institute of Archaeology, CASS) and Dexin Cong [115] Migration and Diversity in Ancient Xinjiang: A Multidisciplinary Approach to the Investigation of Adunqiachulel Population The Adunqiaolu site, located in western Xinjiang, belongs to the early Bronze Age and dates to the nineteenth–seventeenth centuries BC. Archaeological evidence suggests that this group of people may have come from southern and/or southwest Siberia, north of Tianshan. Applying both cranial-metrics and aDNA analysis, this study explores regional variations in western Xinjiang and their relationships to other ancient populations. Ancient DNA analysis indicates that their genes are mainly European, specifically Spanish and German, and the same sequences recovered from human bones dating to the beginning of the Neolithic. However, in the process of migration and through time, there are small amounts of Mongolian gene admixture. Preliminary craniofacial morphological analysis shows that their physical characteristics are very similar to the ancient European type. Compared with modern Eurasian populations, Adunqiachulel ancient population is on a branch of the Europe group, having close genetic affinities with Iranians and Europeans. They show a relatively pure European genetic structure.

Wang, Qingzhu, Thomas Fenn (Yale University), Hui Fang (Shandong University), Xuexiang Chen (Shandong University) and Jianfeng Lang (Shandong University) [287] pXRF Examination of Shang-Dynasty Bronzes from the Daxinzhuang Site, Shandong
In this paper I present the preliminary results of pXRF analysis of Shang-Dynasty bronzes from the Daxinzhuang site (1400–1046 BC), Jinan, Shandong province. The Daxinzhuang site has been receiving considerable research interests since the 1930s, especially when the high elite burials were excavated in 2003 and 2010. Much research has been focused on these burials and the elaborate bronzes, but there has not been any research on the chemical composition and casting techniques of the bronzes from the site. The pXRF data from the Daxinzhuang site, together with the published data from Zhengzhou and Anyang, provides a new perspective to explore the interaction of people who lived at the Daxinzhuang site and those of the central Shang power in Henan.

[72] Tianshanbeilu and the Isotopic Millet Road: Reviewing the Late Neolithic/Bronze Age Radiation of Human Millet Consumption from North China to Europe

The westward expansion of human millet consumption from north China has important implications for understanding early interactions between the East and West. However, few studies have focused on the Xinjiang Uyghur Autonomous Region, the vast geographical area directly linking the ancient cultures of the Eurasian Steppe and the Gansu Corridor of China. Here a Bronze Age isotopic study in China is presented about the key site of Tianshanbeilu, in eastern Xinjiang. The vast range of stable carbon isotopic values on Tianshanbeilu human remains provides direct evidence of unique dietary diversity and consumption of significant C4 resources (millet). Tianshanbeilu’s results are then analyzed with respect to 52 Bronze Age sites from across Eurasia, to investigate the spread and chronology of significant human millet consumption. This isotopic survey found novel evidence that the second millennium BC was a dynamic period, with significant dietary interconnectivity occurring between north China, Central Asia and Siberia. Further, we argue that this “Isotopic Millet Road” extended all the way to the Mediterranean and Central Europe, and conclude that these C4 dietary signatures of millet consumption reflect early links and cultural interactions between inhabitants of modern-day China and Europe in the Bronze Age.

[279] Understanding the Settlement Structure of the Middle Yangshao Period (Miaodigou Phase) Based on Recent Archaeological Discoveries in the Wei River Valley

As one of the most influential archaeological cultures in prehistoric China, the Miaodigou Phase of the Yangshao Culture has been found widely in many regions. During the Miaodigou Phase, a common cultural identity appeared across China for the first time, which had great significance for the later formation of Chinese civilization. However, archaeological research has until recently been limited to the study of ceramic styles. In recent years, investigations at the Yangguanzhai site in Shaanxi have uncovered a moated settlement with a west gate, a central reservoir, and a large adult cemetery separated from the settlement, while projects at other sites in the Wei River Valley have found large single-room house foundations of the same period. These discoveries have shed light on the internal structure of Miaodigou Phase settlements, and have shown that during this period, dramatic social change occurred, large sites appeared, and a settlement hierarchy began to form. The structure of large settlements also became standardized, and symmetrical site plans appeared. The discovery of large houses also represents early social stratification, and the predominance of single burials is evidence of the appearance of nuclear family structures.

Wang, Yai (Research Center for Chinese Frontier Archaeology of Jilin University), Quanjia Chen (Research Center for Chinese Frontier Archaeology) and Chuxue Wang (Research Center for Chinese Frontier Archaeology)

[116] Zooarchaeological Research of Oracle Bones from Lower Xiajiadian Culture

Lower Xiajiadian Culture is an early Bronze Age archaeological culture (4000 BP) in Northern China, located at western Liaoion and southeastern Inner Mongolia. This study explores two different kinds of oracle bones from this cultural period: 1) made of cattle scapular was thought to have been burnt in divination, and 2) bone of a mid- to large-sized mammal hoof, thrown during divination. The latter has been scarcely mentioned in the previous research and has not usually been treated as an oracle bone. Through use of zooarchaeological methods, literature comparisons and ethnoarchaeology these two kinds of oracle bones are examined in order to explore human behavior of divination in the Lower Xiajiadian Cultural period.

Wang, Yiru and Hong Zhu (Research Center for Chinese Frontier Archaeology)

[115] Preliminary Investigations of Human Remains from the Neolithic Gouwan Site in Henan China: Examples of Trauma and Stress

Traumatic injuries and other osseous evidence of stress are important factors that reflect the health status of past populations. Human skeletal remains excavated from the Gouwan (99 human skeletal remains in total), a Yangshao culture site (ca. 5000–3000 BC) in Xichuan, Henan Province were examined macroscopically for the evidence of skeletal trauma and stress using a biocultural approach. Trauma was investigated to reveal possible types, causes and rigor of activities in this sedentary agricultural community. Additionally, systemic stress indicators such as linear enamel hypoplasia, cribra orbitalis, and osteoarthritis were also examined to explore childhood and adult lifeways. Comparing with other contemporary populations, our results suggest that inhabitants of the Gouwan site experienced elevated risk of trauma in the lower spine, especially the women, suggesting heavy physically-demanding and repetitive activities. High systemic stress in childhood also indicates harsh environmental/social living conditions at the Gouwan in the Neolithic.

[79] Early Holocene Leporidae Processing at the LSP-1 Rockshelter, Oregon

Human occupation of the Little Steamboat Point-1 (LSP-1) rockshelter in south-central Oregon began ~9,600 cal BP. Artifacts recovered from the pre-Mazama deposits include a faunal assemblage comprised primarily of leporid remains and a lithic assemblage dominated by informal flake tools. I designed and conducted an experiment using replicated obsidian flake tools to identify leporid processing strategies employed by Early Holocene occupants. I performed hide, carcass, and meat processing tasks with the replicated tools on farmed meat rabbits and documented the microscopic use-wear traces of these activities. I then compared the replicated use wear with wear present on 35 obsidian flake tools from pre-Mazama deposits and found that hide processing, including both scraping and cutting, was the most common activity performed at the site. Leporid carcass processing was the second most common activity. These results suggest that the occupants of LSP-1 not only consumed and processed leporid carcasses, but also prepared leporid hides for rabbit skin blanket production.

[282] Analysis of Bones and Objects from the Viking Age site of Hrí스brú, Iceland

At the Hrí스brú site, located in the Mosfell valley just a few kilometers outside Iceland’s capital Reykjavik, the Mosfell Archaeological Project has excavated a tenth-eleventh century farmstead including a traditional Viking Age longhouse, a farm church with an associated cemetery, and a pagan cremation site. At the cemetery and the cremation site human remains of varying degrees of preservation have been unearthed, while in the longhouse a rich material record has been uncovered consisting of, e.g., lithic tools, glass beads, animal bones, and occasional metal items such as knives, nails, and keys. In my doctoral research I am using bioarchaeological, archaeometallurgical, and conservation science techniques to analyze this material, in order to better understand the history, living conditions, level of technology, and trade interactions of the inhabitants of the Hrí스brú farmstead. Some comparisons with historic written documents are made. This paper presents a first round of results from the ongoing research.

[272] Social Memory and the Development of Monumental Architecture in the Southern Jequetepeque Valley, Peru

Numerous theoretical concepts associated with social memory have been employed by archaeologists working throughout the world as a means of explaining continuities and discontinuities in the archaeological record. These social memory-based approaches are varied and include specific avenues of inquiry such as how social memories were actively manipulated for political gain; the role played by monumental architecture in the coalescing of shared memories; and the interrelationship between social memories and architectural forms. Focusing primarily upon monumental architecture, this paper will examine the pivotal role played by social memory in the formation of the dynamic archaeological landscapes located in the southern Jequetepeque Valley, Peru.

[348] Class and Reproductive Control: Birth Control Access and Hygiene among Prostitutes in Turn-of-the-Century Northern Idaho

Excavations of two brothels in the northern Idaho town of Sandpoint presented a unique opportunity to explore the nuances of economic differences in the lives of two groups of prostitutes. Over 100,000 artifacts were recovered, providing a rich accounting of a brothel that catered to local mill workers and a brothel whose clientele was more affluent. Further, such a large volume of materials resulted in the recovery of relatively esoteric materials such as douching nozzles and a variety of products that, as a group, suggest a greater degree of reproductive control among the women working in the more affluent brothel.

[159] A View from Somewhere: Mapping Nineteenth-Century Cholera Narratives

Several scholars have explored the role of the empirical sciences in colonial contexts; far from a neutral study of the world, they were actively making and remaking material, social, and geographic boundaries. Cartography was part of these boundary-making practices, as the varying positions and views of actors engaging with the world are dissolved into the singular, authoritative view offered by the map. Studying a cholera epidemic that moved through the Caribbean in the 1850s, I consider how archaeologists might employ mapping technologies while also keeping in view postcolonial and feminist concerns for positionality, scale, and the situated nature of knowledge. Through the use of ArcGIS and its time-enabled feature, I map the ways in which primary and secondary sources describing the experience of cholera and the disease’s movement spatialize the epidemic. More specifically, I probe the scale at which these varied narratives report the epidemic to determine whether it is understood as a broad, regional event or at the level of specific colonies or islands. In exploring these cholera narratives, I raise questions about the concept of the archaeological site, problems of scale, and the power (and limitations) of maps to represent ‘views from somewhere.’

[56] Maintaining an Imperial Borderland: Inka and Indigenous Activities and Interactions in a Threatened Eastern Andean Valley

In the final decades before the Spanish invasion of the Andes, the Inka Empire struggled to maintain its eastern frontier against the imminent threat posed by the invading lowland Chiriguano peoples. Located within this sparsely populated and loosely connected borderland region was the settlement of Pulquina Arriba, an Inka tampu (waystation) strategically constructed along a preexisting indigenous road network that ran adjacent to a rich river valley. The area’s inhabitants were involved in local agricultural operations, and the tampu seems to have been an important component within the infrastructural network supporting Inka colonial activities across the eastern Andean valleys. This talk will present the results of a regional survey and targeted excavations conducted in the vicinity of the Inka site, specifically addressing 1) the Inka and indigenous settlement styles and patterns determined within the study region, 2) the types of activities (economic, military, etc.) in which indigenous groups and the Inka alike were engaged during their occupations of the area, and 3) the extent to which Inka colonial undertakings affected preexisting indigenous sociopolitical structures and the corresponding implications of these changes.

Warren, Shannon (George Washington University), Michael Ziegler, Silindokuhle Mavuso (Evolutionary Studies Institute, University of the), Tamara Dogandžić (Department of Human Evolution, Max Planck Institut) and Kathryn L. Rhom (Center for the Advanced Study of Hominid Paleobiol)

The Iléret region of the Koobi Fora Formation (KF Fm.), located in Kenya’s Turkana Basin, has historically been the focus of extensive archaeological research. Mid-Late Pleistocene units have previously lacked defined sedimentary beds due to an understudied unconformity of the upper Chari Member (1.34 Ma to 10 Ka). This represents a substantial limit to Middle Stone Age (MSA) research. Recent fieldwork (2016) incorporated a geoarchaeological survey of the upper Chari Member. Here we describe and map the associated lithologies and stratigraphic markers of this sedimentary package. We identify a major unconformity in the upper Chari and correlate the stratigraphic and structural features of this sedimentary unit across space in Iléret. Importantly, we associate the angular unconformity that defines the lower boundary of this unit with in situ and deformed MSA artifacts. This sedimentary
unit (SSM) underlies Holocene sediments and sits uncomfortably above volcanic ash, allowing a robust chronostratigraphic framework for the SSM and associated MSA artifacts. The study of SSM provides geochronological and paleogeographical context regarding tectonic setting and controls of sedimentation during this time in the stratigraphic sequence of the KF Fm. This research was supported by IRES grants 1358178 and 1358200 from the U.S. National Science Foundation.

Bears/Human Relationships in Southeastern Native North America: Creating Archaeological Models from Historical Accounts

Historical accounts and ethnographic studies of the Indians of greater southeastern North America dating from the sixteenth to twentieth centuries contain abundant information about native people’s attitudes toward black bears (Ursus americanus). These records provide a basis for inferences about changes in subsistence exploitation of bear populations in the Southeast over the last five centuries, while offering clues about longer-term non-subsistence relationships between bears and humans that developed over millennia. The unique roles of bears as liminal beings—at times other-than-human, a third gender, intermediaries between plants and animals—have barely been explored by archaeologists. Rethinking bears from southeastern Native North American perspectives opens new lines of inquiry for archaeologists.

Wasselkov, Gregory (University of South Alabama) and Lars Fehren-Schmitz (University of California Santa Cruz) [245] A Molecular Anthropological Reexamination of the Human Remains from La Galgada, Peru

The archaeological site of La Galgada is located on the eastern bank of the Tablachaca River in the highlands of Northern Peru. The site was dated to both the Preclassic period and Initial period through a combination of detailed archaeological investigation of the site complex, and the use of radiocarbon dating of material collected stratigraphically. Human remains found at the site were also categorized into these two periods based on stratigraphic location. However, recent radiocarbon dating of the human skeletal remains found at the site contradicts the initial dating results. In light of the time period discrepancies, questions surrounding the relationships between individuals, including whether individuals buried at the site were local vs. nonlocal, were addressed by reanalyzing ancient mitochondrial and nuclear DNA of the individuals dating to both time periods. Additionally, through collagen extracted from bone samples, stable carbon and nitrogen isotopes were measured in order to reconstruct changes in diet, with the goal to potentially shed light on the social organization present at La Galgada. Data from this study will provide key information into understanding the occupancy and use of this site, as well as provide insight into the possible reuse of the site as a burial location.

Watanabe, Shinya (Nanzan University, Japan) [170] Sociocultural Changes in Cajamarca Region during the Early Intermediate Period and the Middle Horizon

In this paper we discuss the chronology of the Cajamarca culture of the Peruvian Northern Highlands to consider the social dynamics during the Early Intermediate Period and the Middle Horizon. We present the excavation data from the two archaeological sites, Complejo Turístico Baños del Inca and El Palacio that correspond to the period from the final part of the Early Cajamarca Phase to the Middle Cajamarca Phase. The Cajamarca culture during the Middle Cajamarca Phase A (AD 600–750) presents maximum cultural integration as indicated by the characteristics of kaolin ceramics and settlement pattern, while we can observe the ceramic diversity during the Middle Cajamarca Phase B and C (AD 750–950). We analyze the subterranean canals of the two sites that would indicate the climatic condition of those periods. Finally we consider the character of the Cajamarca culture and society. The Cajamarca presents cultural continuity and flexibility as long as 1,600 years and it contrasts with the vulnerability of other cultures as Moche and Lima.

Waters, Michael (Texas A&M University) [226] The Emerging 13,000 to 15,000 cal yr BP Archaeological Record of North America South of the Continental Ice Sheets

Ruth Gruhn was an early advocate for a human presence in the Americas prior to Clovis. Gruhn and her late husband, Alan Bryan, excavated and reported on early sites in both North and South America and championed the Pacific coast as the route taken by the earliest people to reach the Americas. Their predictions have become a reality. Genetic and geological evidence is supporting a coastal migration route into the Americas. Recent discoveries at the Page-Ladson site, Florida, the Debra L. Friedkin site, Texas, and other sites, as well as a number of genetic studies support an occupation of the Americas by at least 15,000 cal yr BP; some 2,000 years before Clovis emerged on the North American landscape. The revision in our understanding of the timing of the arrival of humans to the Americas at the end of the late Pleistocene and the route they took has its roots in the early pioneering work of a courageous and visionary woman—Ruth Gruhn.

Watkins, Christopher (Arizona State University), Christopher Garraty (Logan Simpson Design), Travis Cureton (Logan Simpson Design), Dave Bustoz (Logan Simpson Design) and Erik Steinbach (Logan Simpson Design) [335] The Path of Hua’m A Nui: Aggrandizement among the Classic Period Phoenix Basin Hohokam

O’Odham oral histories describes the overthrow of Hua’m A Nui (Yellow Buzzard) and other arrogant rulers of platform mound villages in the Phoenix Basin. These oral histories are consistent with archaeological data that point to increasing social stratification during the Classic Period. This paper addresses the question of how the household-based egalitarianism of the Preclassic developed into Late Classic hierarchy. Leveling mechanisms that previously channeled aggrandizers into socially acceptable prestige-building began to break down during a period of instability and uncertainty of the Preclassic to Classic transition. Aggrandizers gradually reshaped Hohokam social organization to their own ends—a process that culminated in the Late Classic period with elites living on platform mounds constructed by others. An example of aggrandizement was recently identified during excavations at the village of La Plaza in Tempe. A regular alignment of several puddling pits immediately adjacent to the platform mound suggests that construction
Living at the Ritz: Investigations of the Palace Complex at Lower Dover, Belize

Palatial complexes are distinct architectural features within ancient Maya civic ceremonial centers. Maya palaces are commonly multi-roomed complexes featuring attributes such as corbelled roofing, benches, private courtyards, and other decorative attributes. Archaeologists suggest palatial complexes serve as multifunctional spaces for the elite residents. These functions include residential space as well as ritual space for events such as feasts, dances, and other social events. Excavations at the Late Classic site of Lower Dover, located in the Belize Valley, revealed the presence of many of these attributes. This paper discusses results of recent excavations conducted under the auspices of the BVAR Project during the 2016 field season in the palace complex at Lower Dover. The data recovered contributes to our understanding of the site’s occupation chronology as well as structural layout and function of the palace. This research further enhances our understanding of Lower Dover’s position within the political landscape of the Belize Valley during the Late Classic period.

Building Scholars and Communities of Practice in Digital Heritage and Archaeology

As digital methods have become more ubiquitous in archaeology, the challenge of teaching those methods has become important. Beyond the question of how and what we teach, however, there is an equally important challenge—how do we build communities of practice populated by scholars who are connected through a shared perspective on both the methods and the thoughtful application of those methods. In is within this context that this paper will explore an approach developed at Michigan State University that speaks to both teaching (and learning) digital methods and the development of communities of practice in which those methods are relevant. The approach itself is informed by the activities in three separate venues: The Cultural Heritage Informatics Graduate Fellowship Program, the MSU Department of Anthropology Digital Heritage Fieldschool, and the National Endowment for the Humanities funded Institute for Digital Archaeology Method & Practice. Ultimately, the goal of this talk is not just to discuss the Michigan State University approach, but to suggest a series of best practices for building capacity and community among students and scholars in digital heritage and archaeology that could be adapted and adopted in a wide variety of institutional, professional, or scholarly settings.

The Exotic and the Sacred: Evidence for Ritual Uses of Birds and Long Distance Exchange at Chaco and Mimbres (AD 800–1200)

Birds are key actors in Pueblo narratives of emergence and symbolize the six sacred directions in Pueblo cosmology and in some instances religious sodalities and societal divisions; bird feathers are powerful offerings to the supernatural, carrying prayers to the gods who in turn use them for adornment. Simply put, birds are central to modern Pueblo cosmology and social and religious life. Similarly, iconographic representations and the ritual treatment of avian species such as the Scarlet Macaw (Ara macao) and Golden Eagle (Aquila chrysaetos), evident in the archaeological record of Chaco Canyon and the Mimbres region, reflect the ceremonial importance of birds to Ancestral Pueblo peoples. This paper investigates the differing ritual uses of birds in Chacoan and Mimbres society through new AMS radiocarbon dates and stable isotope assays and considers the implications of these new data for our understanding of the development of long distance networks and the rise of social elites and religious specialists.

Biocultural Evolution of the Oral Complex in Coastal Atacama and the Interplay of Selection, Plasticity, and Population Histories

Indigenous groups have inhabited and exploited the coastal valleys of the Atacama Desert since Paleoindian times. Contact with the altiplano began early on but marine-based diets were eventually supplemented by agricultural adaptations as influence turned to population movement over time. We propose that the oral complex was likely subject to some degree of selection early in the sequence in response to dietary demands, but would have been relaxed as diet diversified and softened. This trend would subsequently have been disrupted by the influx of different populations from surrounding areas. We test these hypotheses by examining crown dimensions, evidence for decay and defects, and wear rates in a sample of 591 individuals (15,398 teeth) from archaeological sites in the Azapa Valley of northern Chile that span most of the precontact cultural sequence in the region. Results indicate that social changes over time, particularly diet composition and food consistency, caused steady increases in decay and defects. In contrast tooth wear was variable across time likely reflecting the continued consumption of local marine resources. Finally, fluctuating crown dimensions, enamel damage, and evidence for directional asymmetry may reflect the complex interplay between relaxing selection and gene flow.
Watson, Jessica
[319] Cultural Dimensions of Food Procurement on Martha’s Vineyard
Archaeology along the northeastern coast of the United States has often focused on island and coastal industries, with particular emphasis on shell midden deposits. Subsistence-focused research shows us that seafood played a large role in prehistoric diets, yet these studies rarely focus on the cultural dimensions of these foods. Faunal remains on Martha’s Vineyard show that early residents ate a diverse selection of land and sea animals. Identified bones reveal a broad diet of mammals, including White-tailed deer (Odocoileus virginianus) and canids; fish, ranging from inland freshwater species to marine species; and birds, including terrestrial, nearshore, and offshore taxa. These fauna have previously been studied for their basic dietary and environmental data. In this presentation they will be examined in terms of their cultural role in prehistoric settlements on the island. Analysis looks at the social aspects of food procurement, processing, and discard during the Archaic and Woodland periods. Issues discussed include the role of domestic dogs (Canis familiaris) in food procurement, gendered roles of offshore bird hunting, and trade and transportation of animals to the island. This research incorporates stable isotope analysis with traditional zooarchaeological data to better address the role of food in social identity and trade.

[272] Constructing Social Memory: Inca Politics and Sacred Landscape in the Lurin Valley
We will discuss the characteristics and scope of Inca politics in the Lurin Valley by focusing on the results of excavations carried out by Makowski (2016) in Pachacamac with its famous Imperial Inca temple and oracle, as well as in the administrative center Pueblo Viejo–Pucara. The comparison of landscape transformed by imperial infrastructure between the Highlands of Cuzco (Christie 2016) and the lower Lurin Valley allows to reconstruct the mechanisms through which social memory was channelled for political purposes which were central in both cases, even though the forms and techniques of ceremonial architecture were so different due to the separate cultural origin of the builders and users of these spaces. In Pachacamac and Pueblo Viejo, the Inca administration constructed plazas and compounds with restricted access, each one of which probably served a specific population group. The location of the plazas and communication axes maintained a direct visual connection with specific mountains and rocks which were modified and transformed into new huacas incorporated in the Imperial cult. In this new architectural setting, ritual networks of blood-related, ethnic, and ceremonial kinship as well as political compromises were sealed, negotiated, and affirmed through social performance.

[281] Attractive Salt: What the Magnetic Susceptibility and Stratigraphy of the Witz Naab and Killer Bee Mounds Reveal about Ancient Maya Salt Production and Economy
Witz Naab and Killer Bee contain some of the last remaining above-ground mounds of a once-thriving salt industry in Punta Ycacos Lagoon, a large salt-water system in Paynes Creek National Park, Belize. Documented sea level rise during the Terminal Classic has submerged the once thriving Classic period (AD 300–900) Maya salt works. Excavations and magnetic susceptibility were conducted as part of the author’s dissertation research at Louisiana State University (LSU). This excavation is part of a larger NSF funded project directed by Dr. Heather McKillop (LSU) mapping the wooden architectural remains of the large scale Paynes Creek Salt works. Magnetic Susceptibility samples were collected utilizing a technique developed by Dr. Brooks E. Ellwood (LSU) and processed by the Department of Geology. This paper will discuss the stratigraphy and the results of the magnetic susceptibility in relation to the stratigraphic interpretation. These mounds were once numerous features on the landscape prior to a sea level rise, understanding the stratigraphy of the mounds will aid in interpreting features of the associated submerged salt works and illustrate an increase in the scale of production and aid in the interpretation of the coastal Maya of this regions participated in the broader Maya economy.

[234] The Nature of Place: Changing Mortuary Traditions During the Contact Period
Community and identity among Mississippian communities were centered on cultural landscapes; reified by monumentality and complex political economies, regional interaction, and mortuary traditions. The transition at the end of the Mississippian period is marked by regional collapse, migration, diaspora, and ideological shifts. There is also a reimagining of complex religious and sociopolitical structures, creation of new cultural landscapes, and reconceptualization of collective traditions. Faced with the adversities of a changing and globalizing world, population crisis in the forms of disease and warfare, and forced migrations, latent Mississippian communities were forced to adapt and change to meet these pressures and ensure community cohesion. Changing mortuary traditions of populations at the cusp of political and social change during European contact exemplify how these important socioreligious responses to adversity affect the dynamic political interplay between colonial powers and indigenous populations during the seventeenth and eighteenth centuries. Mounds, cemeteries, and mortuary centers of Lower Mississippi Valley peoples that came under assault were also representative of an attack on that very place, cultural landscapes embedded with memories and histories of particular communities. And in the creation of new mortuary traditions and mortuary spaces, these communities sought to reimagine traditions in new and resilient ways.

Weaver, Brendan (Berea College)
[331] Supplies, Status, and Slavery: Contested Aesthetics at the Haciendas of Nasca
The coastal wine and brandy-producing estates owned by the Society of Jesus in Nasca held captive a large enslaved population in the seventeenth and eighteenth centuries. With a combined population of nearly 600 slaves of diverse sub-Saharan origins, San Joseph and San Xavier de la Nasca were the largest and most profitable of the Jesuit vineyards in the vicerealty of Peru. These estates were also home to black freepersons and itinerant indigenous and mestizo wage laborers who engaged, exchanged goods, developed intimate relationships, and even married enslaved persons tied to the estates. Enslaved actors made use of goods supplied by their Jesuit administrators along with products that they provisioned themselves, grew in their own gardens and fields, made locally by craft specialists on the estates, or obtained through exchange with free residents and visitors who connected the estates to a broader colonial market. The aesthetic worlds of the estates were contested through the ways in which enslaved actors engaged with each other and their free neighbors, provisioned themselves, and made use of material culture, often strategically manipulating their statuses and making meaning in ways reflective of their diverse origins and entanglements.

**[238] Life on the "Periphery": Pastoralism at Atalla**

Atalla, located in the south-central Andes of Peru in the province of Huancavelica, boasts a monumental temple and expansive, multi-phase domestic areas. Occupation of the site intermittently spans approximately 3,000 years, and human presence in the surrounding area likely predates this site. Recent excavations focusing on both the monumental and domestic sectors of the site have yielded faunal remains from nearly all contexts. Here, I present an analysis of the faunal remains and bone tools from all periods of occupation at Atalla, focusing primarily on the earliest occupations of the site. I integrate zooarchaeological and microbotanical data to explore the emergent pastoral economy in relation to Atalla’s potential role as both a distributor of cinnabar and a central locus of interregional exchange.

**[330] Middle Holocene Hunter-Gatherer Archaeology in the Baikal Region, Siberia: Recent Developments and Future Directions**

Over the last 20 years, the Baikal Archaeology Project has invested much effort and many resources into research on Middle Holocene hunter-gatherers of the Cis-Baikal region in Siberia (~8300–3500 cal BP). Examination of new materials excavated by the project and analysis of previously accumulated archaeological collections produced many new insights on just about every aspect of Baikal’s hunter-gatherers. We now have a very good record of spatial and temporal variation in diet, subsistence, mobility and migrations, health, trauma and activity patterns, population size and distribution, mortuary practices and some information on genetic structure. A recent breakthrough is the development of a method for building high-resolution chronologies (HRC) of decadal resolution for the region’s Middle Holocene cemeteries. The method is important because it allows examination of the entire body of data from Baikal’s hunter-gatherer cemeteries from a fresh chronological perspective. The most important discoveries facilitated by HRC include: identification of dietary trends during the Early Neolithic, identification of a substantial gap in the use of one large Early Neolithic cemetery and substantial revisions to the timing of all Middle Holocene culture historical periods. The paper reviews these discoveries and outlines future work.

**[207] Marginality in a Connected World: Consumption and Consumerism in Nineteenth-Century Rural Ireland**

Although, the rural Irish are often characterized as a geographically and economically isolated people, their material culture reveals that in the nineteenth century, they were part of a growing global economy—one that circulated both goods and people around the British Empire and beyond. While the industrial revolution and the spread of capitalism allowed for greater access to a variety of goods for the rural Irish, they also maintained a class system that perpetually confined the rural poor to marginalized positions within society. These men and women negotiated this system through their consumption of material goods to create a sense of self and a cultural identity. This paper uses archaeological and historical data to explore the economic and anthropological processes of trade, exchange, availability, and access at the local, national, and international levels.

**[37] Podcasts as Archaeological Digital Preservation**

Archaeologists are increasingly collecting and storing archaeological data in a digital format. While a lot of time and effort has been spent on the HOW of digital information collection, little time has been spent on the other side—public outreach. An archaeologist’s job is only half complete when the digital data are safely stored on multiple servers and in an archival format. If no one knows about it did it ever really matter? Podcasts are typically free and are accessible by everyone with the ability to hear. They are easy to create, store, and disseminate. The Archaeology Podcast Network has gone from a few thousand to over 30,000 monthly subscribers in just over two years—proving that the general public WANTS to know about what we’re collecting and storing. Since podcasts are inherently digital, they can be preserved as the audio record of the collected digital information.

Trepanation is defined as the intentional removal of a piece of bone from the cranial vault of a living individual without penetration of the underlying soft tissues. In China, practicing trepanation can be traced back to the Neolithic, and it can still be found today in some populations in other parts of the world. Nine skulls with lesions from four Late Bronze Age and Early Iron Age cemeteries (Yaer from Hami, Goukou from Jinghe, Yanghai from Tulufan, and Choumeigou from Changji) (4000–2000 BP) in Xinjiang were investigated macro- and microscopically. In conjunction with other information obtained through generation of bioarchaeological profiles of these skeletal assemblages, the aim of this study is to contextualize the observed trepanation cases with their archaeological settings and to explore their temporal and spatial distribution and social/cultural implications. Signs of new bone deposition, implying the short or long-term survival of all individuals after the operation, may indicate that during the Late Bronze and Early Iron Ages in Xinjiang trepanation had been a well-practiced procedure, in turn supporting the suggestion of its importance as a therapeutic method in these ancient peoples.

Wei, Qiaowei [213] Made Locally or Long-Distance Transportation? New Evidence on Ceramic Vessels from Salt Production Sites from the Late Shang Period in North Shandong
Research on salt production in Ancient China has been examining the function, typology, and chronology of a certain type of ceramic vessel, the kuixingqi (Helmet-shaped vessel). Instead of examining typology of Kuixingqi vessels from salt workshops at North Shandong region, dated to 3000 BC, I began by looking at how those Kuixingqi vessels made and transported into the salt workshops, if those vessels are not made locally. I will present the findings of the ceramic petrographic analysis conducted on Kuixingqi vessels by the low res microscope. This analysis gives us better understanding of how ceramic vessels made for salt workshops, and what was the baseline for salt workshop managed the production process.

Weide, D. Marie (University of Nebraska-Lincoln), Maria C. Bruno (Dickinson College), Christine A. Hastorf (University of California-Berkeley) and Sherilyn Fritz (University of Nebraska-Lincoln) [95] "The Decoupling of Environment" and Political Change in the Prehistoric Southern Tilica Basin
As the greater project of this symposium attests, we want to become more aware of the constraints of our historical training and try to not separate culture from nature, or politics from the environment in our study of the past. Toward that end, the authors have been working on understanding water and lake level regimes of the southern Tilica Basin, to better understand the history of this shallow lake and the people that lived around it from the Formative through the Late Horizon. Throughout this prehistoric sequence a large polity, Tiwanaku, developed in this region, clearly engaging with the landscape and waterscape of their valley. Many scholars have linked Tiwanaku’s political and economic rise to a rising lake and its fall to a desiccation and lack of lake water. The new lake data presented here clearly demonstrate how the political trajectory of the prehistoric sequence does not parallel the lake’s history, thus allowing us to better understand the impact prehistoric societies had on their environments and vice versa.

Weiland, Andrew (Ohio State University), Laura Crawford (Ohio State University) and Bret J. Ruby (Hopewell Culture National Historic Park) [53] Fires at Axis Mundi: Macro- and Microbotanical Investigations of a Hopewell Woodhenge
At Hopewell Mound Group in Ross County Ohio (33RO227), 2013 magnetic gradiometer investigations redefined the long invisible Great Circle, a 120 m diameter woodhenge. The 2016 excavation of one of four central features within the Great Circle revealed a large thermal feature. Although unusually large for this purpose, the arrangement of fire-cracked rock, clay lining, hot-burning hardwoods, and grass seed suggest a classic earth oven common to domestic sites. However, ethnographic analogy indicates that woodhenges, which are ubiquitous in eastern North America during the Middle Woodland period (AD 1–500), were used in axis mundi rituals such as the modern Sundance. In the Hopewell cultural context, there exists a dichotomy between sacred sites swept clean, and domestic debris of habitation sites. Thus, archaeobotanical analysis of an earth oven central to a Hopewellian ritual reveals a mixture of domestic and ceremonial symbolism potentially indicative of feasting. Careful archaeobotanical analysis is central to understanding the formation, function, and meaning of this feature—and Hopewell Mound Group as a whole. In this focused study on one large feature, we used seed and wood charcoal identification in conjunction with phytolith extraction to assess stratigraphy and to detect remains of removed or uncarbonized plant use.

Weiner, Robert (Haffenreffer Museum of Anthropology, Brown University) [157] Playing with Fate: A Relational and Sensory Approach to Pilgrimage at Chaco Canyon
Chaco Canyon is generally understood to have derived its regional influence by virtue of ceremonial power. But what exactly—experimentally, sensorially, affectively—was so compelling about the experience of Chacoan ritual, and how might we approach these immaterial dimensions of the ceremonial record? In this paper, I suggest that ceremonial gambling/gaming was an important practice during Chacoan gatherings that allowed participants to interact directly with supernatural forces. After briefly discussing multiple lines of evidence for gambling at Chaco, I emphasize the sensory and affective dimensions of games of chance. For example, ethnographic Native American gaming was often accompanied by fervent singing and shouting to distract the opposing team. Furthermore, gambling is primarily an endeavor that deals with The Unknown: with forces known variably as “fate,” “divine favor,” or “luck” depending on one’s worldview. To gamble is to enter a direct and highly-charged relationship with those unseen agents who make dice land heads or tails, who bring plentiful rainfall one year and not the next. I argue that the relationalities experienced by Chacoan gamblers with supernatural forces and with each other—and control over access to such experiences—formed crucial elements of the site’s allure and power.

Weiner, Robert [23] see Shepard, Lindsay

Weismantel, Mary (Northwestern University) [242] Ontologies of Water: Intensities and Magnitudes
Increasingly, the effects of global warming take the form of destructive movements of water, whether vanishing bodies of water that create desertification or floods that damage human habitation and take lives. The extensive archaeological record of the North Coast of Peru offers a place to study long-term human strategies for living with the dangerous and unpredictable movement of water. Despite frequent earthquakes, floods and torrential rains that re-shape land- and seascapes, humans flourished on the North Coast, using the region’s abundant maritime and riverine resources to construct some of the earliest monumental architecture in the Americas, and later, complex state-level societies such as Chimú. Archaeological theories about the relationship between this rich archaeological record and the region’s tempestuous waters have variously included theories of punctuated equilibrium; collapse and rebuilding; or, more recently, long-term sustainability based on strategies of mobility and flexibility. In this paper I look for the underlying indigenous ontologies that allowed humans to flourish despite the destructive yet fertile waters that periodically inundated their homes and fields. From
this perspective, our species appears as the coproducers of a fluid natureculture in which we are neither the controlling masters nor the hapless victims of water.

Weiss, Andrew (University of Pennsylvania) and Vincent C. Pigott (University of Pennsylvania Museum) [271] Here We Go Again: A New Series of AMS Dates from the Khao Wong Prachan Valley, Central Thailand
A new series of AMS dates from the Khao Wong Prachan Valley (KWPV) in central Thailand addresses several questions in the region, including the dating of the initial settlement of the valley, the duration of the pre-metal period, the first appearance of copper-base artefacts, the beginning of large-scale crucible-based copper smelting and production at the site of Non Pa Wai, the shift to a different copper production technology used at Nil Kham Haeng, and, the occupation span of the associated habitation site of Non Mak La. Defining the temporal extent of these industrial deposits allow us to estimate the production intensity of copper in the Khao Wong Prachan Valley. The dating program's strategy and results are discussed, along with the implications for the prehistory of Thailand and Southeast Asia, with particular focus on the ties between the KWPV and copper-age sites in the Phimai region in NE Thailand.

Weisskopf, Alison (University College London) and Dorian Q. Fuller (University College London) [333] Elusive Wild Foods in Southeast Asian Subsistence: Modern Ethnography and Archaeological Phytoliths
While grain crops, such as rice, are relatively easy to identify in the archaeobotanical record, evidence for early agriculture in the wet tropics can be elusive. In this region staple foods were not always grain-based and even today wild plants play an important role. So how do we identify ancient food pathways? Unlike temperate parts of the world, charred material rarely preserves, so this is where micro fossils such as phytoliths and starches come into play. I use phytoliths in combination with ethnobotany to evaluate plant remains from archaeological sites in Thailand and Vietnam and identify past arable systems.

Weiss-Krejci, Estella (Austrian Academy of Sciences, Vienna, Austria) [31] Osteonarratives in the German-Language Tradition
This paper will discuss the research history of “osteobiography” in German-language anthropology and archaeology. That the term “Osteobiographie” is actually not in use does not imply that the concept does not exist. Although German-speaking prehistoric anthropologists were and still are predominantly focused on population research, science-based stories relating to individuals have been told, for instance, about Ötzi the Iceman. On closer inspection such narratives reveal a tendency to surface under very particular circumstances: they are either triggered by a particular find context, by specific osteological characteristics or by historic circumstances under which these bodies are discovered. Hence, like all biographies, osteonarratives run the danger of being subject to manipulation in many ways. The paper analyses some of these narratives and discusses current trends and attitudes relating to osteobiographies in the German-speaking archaeological and anthropological research community.

Weitzel, Elic (University of Connecticut) and Daniel Plekhov (Brown University) [260] Contact-Period Settlement Changes in Eastern North America: A Test of the Ideal Free and Ideal Despotic Distribution Models
Archaeological and historic data suggest that prior to European Contact, Eastern North America was heavily populated. However, within a century of Contact, the indigenous population was decimated. To explore one of many behavioral changes brought about by this demographic collapse, we model indigenous settlement in Eastern North America pre- and postcontact as a function of environmental productivity. We hypothesize that if postcontact settlement differed from precontact, two scenarios are possible: settlement changes may conform to an ideal free distribution (IFD) if the average net primary productivity (NPP) of site locations improves postcontact, or an ideal despotic distribution (IDD) if average site NPP declines. Using data from the Canadian Archaeological Radiocarbon Database, we find that overall, the NPP of the average site increases after Contact suggesting settlement according to an IFD at this time. Reductions in population allowed consolidation of people in higher quality habitats. However, geographically weighted measures at least equal to precision and consistency. Keeping eyes, minds, and arms open to possibilities for unanticipated ways of seeing, knowing, negotiating meanings and values out of that haze, or for investing those meanings and values into projects with non-academic benefits and beneficiaries. Success in such pursuits, including transdisciplinary research and community-driven practice, often requires high tolerance for ambiguity in measures at least equal to precision and consistency. Keeping eyes, minds, and arms open to possibilities for unanticipated ways of seeing, knowing, and collaborating—a discipline dependent as much on relaxation as on rigor—opens archaeology to the benefits of humankind’s most potent ally, positive affect.

Welch, John (Simon Fraser University) [172] Open Eyes, Open Minds, Open Arms, and Open Hearts Open Archaeology
Archaeologists share formidable qualities of mind and temperament: observational acuity, organizational skill, perseverance. These are necessary, of course, in the sifting through of vast arrays of questions to address, evidence to harness, methods to deploy, and interpretive lenses to employ. Such rigor-making attributes may not, however, be sufficient for effective practice at hazy contacts among material pasts and intangible presents, for negotiating meanings and values out of that haze, or for investing those meanings and values into projects with non-academic benefits and beneficiaries. Success in such pursuits, including transdisciplinary research and community-driven practice, often requires high tolerance for ambiguity in measures at least equal to precision and consistency. Keeping eyes, minds, and arms open to possibilities for unanticipated ways of seeing, knowing, and collaborating—a discipline dependent as much on relaxation as on rigor—opens archaeology to the benefits of humankind’s most potent ally, positive affect.

Welker, Frido (Department of Human Evolution, MPI-EVA) [96] Ancient Hominin Bone Proteomes: Improving our Understanding of Past Human Behavior through the Study of Ancient Bone Proteins
The analysis of ancient proteins is increasingly used to study archaeological and anthropological bone specimens from prehistoric time periods. This ranges from large-scale ZooMS screening (Zooarchaeology by Mass Spectrometry) of morphologically unidentifiable specimens to the targeted analysis of ancient bone proteomes from humans through the application of LC-MS/MS. Here, some biological and phylogenetic results that can be obtained through the analysis of ancient human bone proteomes will be discussed in the light of the Châtelperronian, “transitional,” technocomplex of western Europe. This technocomplex is chronologically placed between Middle Paleolithic (MP) and Upper Paleolithic (UP) lithic industries and displays behavioral aspects interpreted as intermediate between what is typically seen in the MP and UP. Despite intense research interest, the biological
association of the Châtelperronian to either Neanderthals and/or Anatomically Modern Humans remains much debated. The analysis of a Pleistocene hominin bone proteome associated to the Châtelperronian allowed us to establish the biological affiliation of this specimen, and this will be presented together with biological insights obtained through the analysis of the same bone proteome.

Welker, Martin (Penn State University) and Rebecca Duggan (Parks Canada Agency)

[A Comparison of Dog Shoulder Height in European and Native American Contexts]

Dogs are the only domestic animal to have existed on both sides of the Atlantic Ocean prior to the Columbian Exchange. Historic documents indicate that European colonists to North America brought their own dogs and generally preferred large breeds capable of protecting livestock, hunting, and defending settlements from both predators and Native American raids. As early as 1619 the Virginia Assembly banned colonists from trading European dogs to Native Americans, and these policies were quickly adopted in many colonial legislatures, remaining in effect until the 1700s. We compare morphometric data from a sample of over 200 individuals from sites in Europe and the American colonies dating to between AD 1000–1800, and Native American contexts in Eastern North America spanning the last 6,000 years. Though many indigenous breeds were eventually influenced by admixture, our analysis identifies noticeable differences in dog’s average shoulder height, supporting assertions that many breeds introduced by European colonists were significantly larger than local Native American breeds at the time of contact.

Wellman, Hannah (University of Oregon)

[Applied Zooarchaeology and Oregon Coast Sea Otters (Enhydra lutris): Following Up on Lyman 1988]

The sea otter (Enhydra lutris) was nearly driven to extinction on the Pacific Coast in the nineteenth century due to intensive commercial hunting and the maritime fur trade. Despite some successful reintroduction efforts in North America, the Oregon sea otter population remains locally extirpated and listed as endangered. One aspect of Lyman’s 1988 study examined precontact sea otter teeth from Oregon and found they were similar in size to modern California sea otter teeth, and smaller than modern Alaska sea otter teeth. These geographic groupings were later confirmed by an ancient DNA study. I revisit this hypothesis with substantially larger sample sizes of teeth, as well as new data on humeri and femora. Sea otter tooth width and long bone dimensions vary significantly along an latitudinal clime from California to Alaska. Specific, inter-state comparisons of tooth width and long bone measurements do not support the hypothesis that precontact Oregon sea otters are more similar to those from modern California than they are to those from modern Alaska. These data show that morphometric analyses can be used to answer research questions about species distribution and demography, but with less detail regarding inter-state relationships than originally postulated.

Wells, Joanna (University of Alaska Anchorage), Kathryn Krasinski (Adelphi University), David Yesner (University of Alaska Anchorage) and Fran Seager-Boss (Knik Tribal Council)

[Traditional Dena`ina Land Use at the Cottonwood Creek Village Site, Southcentral Alaska]

The Dena`ina and Atha`na developed a sedentary socioeconomic stratified lifestyle with material inequality by the time of European contact. The development of permanent villages indicates a shift into a complex society with qeshqas (leaders) who had better food, larger houses, and more wealth. Semi-subterranean depressions at Cottonwood Creek, ranging from 802 years cal BP to modern age, are remnants of storage and house pits still present on the landscape. Geochemical testing of sediments has the potential to reveal specific storage pit contents associated with feature shape and size. In conjunction with radiocarbon ages and house style, this poster investigates the development of differences in material wealth as it relates to salmon harvesting.

Wells, Joshua J. (Indiana University South Bend)

Archaeology’s disciplinary engagement with big data is confounded by the variety of information types recorded, variability of data due to differential preservation of materials and theoretical orientations of observers, and complexity of archaeological concepts daring to be caged in explicit digital expressions. The Digital Index of North American Archaeology (DINAA) is a linked data hub, centered around the theoretically, practically, and interpretively fraught definition of “archaeological site,” nevertheless a foundational concept in archaeological science. To develop big data from hundreds of thousands of archaeological site definitions gleaned from numerous incompatible systems of nomenclature and investigative frameworks, DINAA employs strategies of aggregated ontological definitions within DINAA and loose coupling to related informational resources outside it, often achieved via fairly standard intelligence key identifiers (i.e., Smithsonian trinomials and similar). This practice requires explicit and critical consideration of what DINAA’s big data elements “mean” in their original contexts as well as what else they might “mean” in combination in DINAA or to external investigators. The intellectual labor is not trivial, but is tractable, and exemplifies a replicable process for engaging other concepts of interest to archaeologists (artifactual categories, stylistic components, cultural horizons, etc.), operationalizing archaeology’s complexity in pursuit of big data.

Welton, Lynn (University of Chicago)

[The Pre-Aksumite Period in Eastern Tigrai: The Chronology and Stratigraphy of the Site of Mezber]

The current understanding of the Pre-Aksumite period of northern Ethiopia has been heavily influenced by data originating from sites in western Tigrai, particularly those in the area of Aksum. The Eastern Tigrai Archaeological Project (ETAP), however, has also documented substantial evidence for Pre-Aksumite settlement further to the east, through both survey and excavation. This paper will summarize ETAP’s efforts to understand the Pre-Aksumite period in eastern Tigrai at the site of Mezber, a small rural center of just under 1 ha in size. Although the site was likely in use as early as 1600 BCE, there are two major Pre-Aksumite periods of construction and occupation at the site, the first dating to between 850–750 BCE, and the second from approximately the sixth–first centuries BCE. There is also evidence of limited post-occupational use of the site around the eighth century CE. By focusing on deep soundings excavated in Areas A and C at Mezber, this paper will examine the long-term history of occupation at the site and the contributions it makes to the understanding of the indigenous development and continuity of social complexity in the Horn of Africa.

Wendrich, Willeke (UCLA)

[The Hidden Costs of Archaeology]

Archaeologists have realized for a long time that in the struggle to fund field work, working on publications and the cost of publishing archaeological results are often not covered. With the increase in digital recording and digital publishing this problem is not solved. On the contrary, it is exacerbated by
a number of additional tasks and responsibilities. These range from a changing publication model, where open access is becoming increasingly important, and journals request payment to make articles freely available to payments to data archives. Added to that are the costs in time, or in paying salary for the many additional hours that need to be spent on data cleaning and the inclusion of proper metadata with the many file types that make up a modern record of an archaeological area. Publishers are experimenting with different models to include data and there is an expectation that these will be made available for free as well. The other type of costs is more virtual: all the work on collecting, cleaning and publishing data should be recognized as research in itself, and this requires an investment in time, energy and reputation from archaeologists who are in the position to do so.

Wendt, Carl (Cal State University—Fullerton)

Olmec Households in the Context of Sociopolitical Transformation

The Olmec are among Mesoamerica’s earliest civilizations and as such they provide a good opportunity to investigate household change in the context of developing social inequalities. Over the past few decades archaeologists have gathered household data that show the ways they transformed and remain unchanged during periods of social evolutionary change. Artifact assemblages and subsistence patterns are examined and together provide valuable insights into domestic reorganization and transformation. Comparing how change occurred at different scales and domains shows that social evolutionary transformations vary across different levels of society, which highlights the importance of investigating a range of domains and contexts.

Multiple Functions for an Assemblage of Middle Stone Age Points: Use-Wear Evidence from Magubike Rockshelter, Tanzania

Preliminary lithic use-wear evidence from Magubike Rockshelter, Tanzania, suggests a mixed function for an assemblage of Middle Stone Age points, including a possible projectile point role. The development of hafted hunting weapons during the Middle Stone Age is thought to have marked a major juncture in human behavioral evolution. Not only did the emergence of this technology likely have a major impact on the foraging strategies of hunting and gathering populations, many have speculated that the composite nature of these weapon systems reflects an important improvement in the cognitive abilities of contemporary Pleistocene hominins. Nonetheless, one of the primary challenges in understanding this process and its significance has been identifying and demonstrating the function of pointed artifacts. In this paper, the author makes use of a newly developed use-wear technique that relies on plotting edge damage distribution using GIS software. This method is combined with a more conventional means of high-velocity impact detection to reconstruct possible tool uses. These results reinforce the notion that pointed artifacts, sometimes assumed to be exclusively projectile points, likely assumed a variety of purposes.

Maya Architecture in the Northern Lowlands

It has long been recognized that ancient Maya architecture encoded sacred ideologies and replicated primordial landscapes through building forms and structural orientations. Many studies have focused on the architecture of the Southern Maya Lowlands, where rich textual sources exist and where an abundance of archaeological data aids in efforts to understand and interpret the meanings of architectural groups. We seek to augment interpretive frameworks with respect to the Northern Maya Lowlands, rather than just applying already existing models to new material. Indeed, northern built environments cannot be seen as carbon copies of southern ones nor can they be understood simply as late derivations from, and/or modifications of, southern ways of thinking about building. Looking at such constructs thus also has the potential to expand our awareness regional variation and specificity. In this paper, we build upon our work concerning northern architectural spaces by considering site orientations, plaza arrangements and sculptural embellishments. While we will focus on the northeastern, Puuc, region, we include sites from northwestern Yucatán and the north-south ‘buffer zone,’ which also allows us to revisit and reexamine old, conceptual divisions between the Puuc and adjacent areas in the scholarship.

Irreducible Reducción: Archaeological Microhistory at Mawchu Llacta, a Planned Colonial Town in Highland Peru

The Reducción General de Indios (General Resettlement of Indians) in the Viceroyalty of Peru brought about one of the largest mass resettlement programs ever enacted by a colonial power, forcibly displacing some 1.5 million native Andeans to compact towns (reducciones) built around plazas and churches. As a colonial utopic project, the Reducción was to remake the Andean world in the ideal self-image of Spanish civic and religious community. As materialized manifestations in the Andean countryside, reducción towns were deeply compromised and ambivalent in their significance and effects: they attempted to reduce the irreducible complexities of community. This paper presents an overview of findings from extensive excavations in domestic and ritual contexts at a large, unusually well-preserved and textually-documented reducción, Santa Cruz de Tuti (known today as Mawchu Llacta). With an occupation spanning Inka through early republican times, Mawchu Llacta promises to shed light on continuity and change in the domestic and ritual practice over more than three centuries of successive imperial rule. Through an archaeological microhistory approach, interdisciplinary research at Mawchu Llacta explores the tangible and mutual transformation of global and local practice through colonialism and the emergence of modernity.

(Re)integrating Cultures at Cacalchen: Recent Excavations at Two Rural Chapels in Central Yucatán

The arrival of Europeans to the Americas in the sixteenth century forever changed processes of cultural integration. This paper explores how small Maya communities in Central Yucatán navigated the process of integration of new religious practices and the use of preexisting structures in the landscape. This examination stems from recent excavations of two different rural chapel structures at the site of Cacalchen, located in the greater Yaxuna region between the towns of Yaxcabá and Kancabdzonot. While new permanent structures were created to fulfill the needs of a changing religious practice, spaces were chosen that already had important symbolic meaning to the local population. The remote location of these chapels likely meant that there
was not a permanent European presence at Cacalchen during their use which may have resulted in a disintegration of new cultural practices. This research illustrates how landscape participates in social disintegration, as well as integration, when occupied by two distinct cultures that had previously not been in contact. Cacalchen emerges as a space in a constant process of re-integration that continues well into the present day.

Birds of a Feather? Bird Conservation and Archaeology in the Gulf of Alaska

Gulf of Alaska islands provide habitat for substantial populations of both seabirds and migratory waterfowl, which have been under threat from mammal introductions and landscape degradation for more than 200 years. Bird management drives decisions in this island region and focuses on the eradication of invasive species and restoration of island landscapes to their “natural” state. However, given that people and climate have influenced these landscapes for thousands of years, we ask: how do we determine a baseline for this restoration? Using a combination of zooarchaeological data and contemporary bird observations on Chirikof Island, Alaska, the results of this project provide a historical perspective of changing bird biodiversity that can be used to inform contemporary conservation, landscape reconstruction, and illustrate the challenges of applying long-term archaeological data to contemporary environmental problems.

Alterations in South American Oral Health through the Colonial Period: The Story of Ancient DNA Trapped within Dental Calculus

Interpreting the evolutionary history of bacterial communities within the human body (microbiota) is key to understanding the origin of many modern diseases. The link between humans and their microbiota can also be exploited to examine and track the extent and severity of human adaptation to the environment and impacts on health. Here, we utilize a shotgun sequencing approach to examine ancient DNA preserved within dental calculus from a wide range of ancient South Americans (n = 162). Well-preserved specimens revealed remarkable microbial diversity in South Americans prior to European arrival. In fact, nearly all observed South American oral microbial diversity fell outside of known ancient and modern European diversity. The patterns observed within microbiota reflected human mitochondrial DNA distribution, and reflected cultural continuity, rather than human replacement, in several locations, similar to the mitochondrial DNA from the same individuals. We also identified unique oral microbial taxa present within South Americans, and can tracked changes within these species as Europeans arrive, with the potential downstream health-impacts. Consequently, ancient oral microbiota provides a wealth of cultural and anthropological information about the past, which is critical to identify events that altered human health and history.

Point Pueblo, a Great House Community in the Middle San Juan

San Juan College field school excavations at Point Pueblo in Farmington, New Mexico, have revealed a great house with attached great kiva constructed of both local vernacular and stylized Chacoan Type II architecture. Extensive early southern influence, AD 850–1050, is based on the dominant presence of Red Mesa Black-on-white pottery. The great kiva floors demonstrate a continuous ritual placement of artifacts subsequent to a major ritual remodeling event of the floor and roof support piers, apparently completed in the late AD 1100s. A large pit containing over 600 sherds present at the southern edge of the great kiva interior may have been used for communal offerings. A new type of great kiva floor feature was discovered on the remodeled floor wherein a horizontal arch of cobbles set in clay was constructed extending out from the northern and southern ends of the remodeled eastern Chacoan roof support piers. Numerous small to medium pit features were constructed on the remodeled floor and then capped before use of the great kiva continued through to the end of the AD 1200s. Point Pueblo exemplifies ritual complexity of the Middle San Juan region during the Chacoan time period.

The ethnographically documented Mono Lake Paiute of Eastern California regularly crossed the Sierra Nevada to procure acorns from Yosemite Valley; a total journey of fourteen days. It is not clear whether such trips are economically efficient in their own right, or were undertaken as components of social excursions to visit and trade with the Yosemite Me-Wuk, or as journeys of necessity in years with poor pithon pine nut harvests. To evaluate the economic productivity of procuring acorns from Yosemite, relative to collecting resources in the Mono Basin, we use previously published data to calculate the mean return rates for collecting and transporting basket loads of various staple foods to the winter camp location. We also calculate the standard deviation of each return rate, taking into account the variance present in published estimates of the caloric content of resources, collection and processing times, packing density, and basket volume. The results indicate that while acorn procurement trips to Yosemite are less productive than collecting pithon pine nuts and Pandora moth caterpillars in the vicinity of Mono Lake, they compare favorably to collecting small seeds. This suggests that long-distance acorn transport was a viable subsistence strategy for the hunter-gatherers of Mono Lake.

Survey in the York-Duncan Valley, Arizona: Understanding Patterns of Mogollon Population Aggregation and Dispersal

This research project examines prehistoric population aggregation and abandonment processes by analyzing how communities in Arizona’s York-Duncan Valley nucleated, and then dispersed in or abandoned the region from the end of the Early Agricultural period to the Salado period. The Upper Gila River Valley offers a unique opportunity to understand these dynamics. The research explores the interplay of ecological and demographic pressures within a resilience theoretical framework. I suggest that community aggregation initially offered competitive advantages which enhanced social robustness, but eventually introduced social and ecological vulnerabilities. This hypothesis will be evaluated, in part, by the survey and recording of sites in the studied York-Duncan Valley. Survey will focus on agriculturally productive locales most likely to have hosted prehistoric groups, based in part on results from two Geospatial Information System predictive models for prehistoric habitation in the York-Duncan Valley. Variables include a variety of ecological factors and settlement patterns from Early Agricultural to late prehistoric periods in the Mimbres, northern Rio Grande, and Upper Gila River Valleys. Model outputs are then compared to known prehistoric sites in the study area in order to evaluate the methodology.

A 1,000-Year Record of Cahokia Region Population Change through Fecal Stanol Biomarker Analysis

Naomi F. Miller’s work exemplifies the paleoethnobotanical approach toward understanding human interactions with botanical landscapes in the past using archaeological remains, rooted in theoretical traditions of American anthropological archaeology. On the occasion of her Fryxell Award in Interdisciplinary Research from the SAA, we reflect on her body of published research and active fieldwork to draw out five themes that highlight areas in which Miller has made significant contributions to the field. These include 1) interpretation of archaeobotanical deposits (best exemplified by her insights into the use of animal dung as fuel); 2) quantitative methods for archaeobotanical data analysis; 3) regional synthesis of archaeobotanical datasets to reconstruct environmental and agricultural change through time; 4) integration of botanical datasets with textual and iconographic evidence for plant use, as well as parallel lines of archaeological inquiry (e.g., faunal analysis); and 5) the conservation of archaeological sites via modern plant management strategies. We emphasize the influence of Miller’s work on the next generation of scholars in paleoethnobotany, both within and beyond Southwest Asia.

Social Boundaries and the Cultural Ecology of Artiodactyl Hunting in Prehistoric Central California

We use a model developed using Geographical Information Systems software to examine the extent to which the suitability of habitat surrounding archaeological sites in Central California affected hunting decisions for three artiodactyl taxa: elk (Cervus elaphus), deer (Odocoileus hemionus), and pronghorn (Antilocapra americana). Model findings are compared to a database of 100 archaeofaunal assemblages from the same area. We find that the model predicts the presence and relative abundance of elk fairly well but underestimates these same measures for deer and overestimates them for pronghorn. Two causes of the disagreement between model predictions and data are offered. We reject resource depression of pronghorn or elk as the cause of greater-than-expected deer hunting as there is no decline in relative abundances of either through time. However, we find that the herding behavior of pronghorn and elk, coupled with social circumscription of hunters during the Late Holocene, may have limited hunting opportunities for elk and pronghorn, leading to the ubiquity and abundance of deer bone observed in the record. The increased importance of deer as opposed to elk and pronghorn hunting is attributed to the establishment of territoriality in the region during the Late Holocene.

Whitaker, Adrian [381] see Byrd, Brian
The diet of prehistoric hunter-gatherers in the Lake Baikal Region has been extensively studied using stable carbon and nitrogen isotopic analyses. This paper extends this work, reporting new carbon and nitrogen stable isotope and AMS radiocarbon dating results from the cemeteries of Verkholensk (n = 45) in the Upper Lena micro-region; Ulan-Khada II–V (n = 19) in the Little Sea micro-region; and Fofanovo (n = 22) in the Selenga micro-region. The latter analyzes represent the first stable isotopic data from the eastern side of Lake Baikal. Our results revealed several interesting patterns: Late Neolithic and Early Bronze Age individuals from Verkholensk were significantly different from each other in δ15N (n = 41, df = 39, p = 0.000), suggesting a more terrestrial diet in the latter. Children to young adults differed significantly from mid to old adults at Ulan-Khada in δ15N (n = 12, df = 10, p = 0.009), the latter showing depleted 15N values. The results from Fofanovo appear isotopically distinct from the other micro-regions as a result of heavy reliance on the Selenga River’s resources. At Fofanovo in particular, there were discrepancies between the radiocarbon results and expected archaeological datings. In the future, it will be necessary to establish appropriate freshwater reservoir corrections for sites along the Selenga.

White, Joyce (University of Pennsylvania Museum) and Elizabeth Hamilton (University of Pennsylvania) [271] Applying a Life History Framework to Analyzing Metal Age Metal Assemblages from Thailand
Application of archaeological techniques to metals and related evidence from prehistoric sites in Southeast Asia is in its infancy. One result is that sample sizes per site have in most cases been minute or even unspecified, although in rare instances, such as Ban Chiang, sample sizes for metallicographic and elemental analyses have been more robust and representative. Small sample sizes obscure key evidence for intrasite and regional variability in technological and economic systems. Recent lead isotope analyses of copper-base artifacts from Thailand and Laos illustrate the potential for fine-grained study of metals assemblages, revealing that different sites had separate supply networks for copper at different periods of time. If our field is to contribute meaningfully toward the study of material culture in past economies and the reconstruction of technological systems in terms of chaînes opératoires, the field must raise the bar in terms of many sampling issues. Not only are larger samples required for plausible reconstructions, but complete assemblages must be assessed, not just a handful of idiosyncratically selected intact artifacts from single context types (usually graves).

White, Kirrily (University of Sydney) [20] Large, Dispersed, Occupation Aggregates in Prehistory: A Global Comparative Analysis
There is no agreement as to how very large, dispersed, occupation aggregates in prehistory such as the Trypillia megasites (fourth millennium BCE), Chaco Canyon (ninth–twelfth centuries CE) and the sprawling Neolithic settlements of the Middle Yangzi (third millennium BCE) should be classified in archaeology. Often these sites behaved very differently to the large, high-density settlements with which they are sometimes compared. The aim of this research is to look at material and spatial patterns in the formation, development and demise of these dispersed, occupation aggregate sites on a global comparative scale to understand how they fit into broad patterns of human settlement behavior in the past. By contextualizing changing occupation patterns over time in regional technological development, it becomes apparent that within this form of settlement there is very little change in local spatial and material operation when compared to their smaller predecessors and contemporaries. Comparing these patterns and technologies globally, it is possible to hypothesize that human groups used low occupation density and, in part at least, mobility within long-standing regional and supra-regional traditions of building and trade as the most common ways of managing population increase and the most extensive occupation aggregates their regions have ever seen.

White, Nancy (University of South Florida) [330] Long-Distance Connections across the Southeastern United States and Mesoamerica
Despite over a century of research, unquestionable evidence of routine and sustained interaction/communication between the U.S. Southeast and Mesoamerica remains elusive. Similarities in iconography and ritual are very general, possibly ancient. Mexican obsidian and tropical plants occur rarely and only at the outskirts of the Southeast, while earthen mounds and some Mississippian-like artifacts occur on the northern Mexican Gulf Coast. The most glaring (absence of) evidence is the lack of products such as cotton and especially alcohol in the Southeast. Both environmental and cultural processes must account for what was sporadic and limited interaction.

Whitehead, William (SWCA Environmental Consultants) [287] Recent Work in Southeast New Mexico by SWCA: The Impact of TRU Analysis on How We Define Site Boundaries
SWCA has performed seven data recovery projects in southeast New Mexico between 2015 and 2016 with TRU (Transect Recording Unit) surface survey, collections and analysis. Notable sites have included an archaic pit house structure, a bedrock mortar site and several coppice and parabolic dune sites. A summary of the excavation work will be presented, focusing on highlights from three of these sites. The results of TRU surface collection and analysis will be presented in conjunction with excavation data at six of these sites. We find that TRU surface survey and collection gives much better spatial definition for drawing site boundaries, defining activity areas, and excavation area selection. However in southeast New Mexico, with the majority of sites under some form of sand sheet, TRU analysis alone will not give perfect reconnaissance of subsurface feature areas. We propose that mechanical scraping, shovel tests, trenching and TRU surface analysis is the best way to understand surface to sub-surface site patterning. Recommendations for using TRU surface survey in relation to several New Mexico agency site definitions and reporting criteria will also be presented.

Whitesides, Kevin (University of California Santa Barbara) [212] The Highest Common Factor: Heterodox Archaeology and the Perennialist Milieu
Introducing a 1944 translation of the Bhagavad Gita, Aldous Huxley concisely described what he called the Perennial Philosophy. Despite the apparently distinct cultures of the world, he said, “beneath the confusion of tongues and myths, of local histories and particularist doctrines, there remains a Highest Common Factor.” This perception of an underlying unity among the “higher religions” of the world has led Perennialists to feel a greater sense of ownership and hence freedom in interpreting the significance of major archaeological sites the world over. Unlike alternative archaeological narratives that focus on particular geographical and cultural identities, Perennialism opens the doors to all cultures and all times, though there is a strong tendency toward reverence for the past (or contemporary “shamanic” cultures deemed to model the past). Thus the Perennialist stance undergirds much of contemporary alternative spirituality and, although it claims a timeless authority it is, itself, a temporally located and particularist set of religious positions that can be historically and socioculturally contextualized. It is, in fact, the broader “cultic milieu” in which all of these heterodox themes circulate that can allow us to make sense of the cognitive and social contexts in which the impulses to create alternative archaeological narratives arise.

Whitley, David (ASM Affiliates, Inc.)
[28]  **Agency, Structure, and the Neoliberal Turn**  
Recent theoretical over-emphasis on human agency and denial of the significance of sociocultural structure presents a radical challenge to a century of research. It implies that Durkheim, Boas, Weber, etc., are irrelevant, and that long-standing structures of inequality (e.g., of gender or race) somehow do not exist or are not important. Examination of recent human agency studies illustrates that, instead of studying human agency as action, interpretations are based on the kinds of structures whose existence is denied, meanwhile neither addressing nor resolving the analytical problems raised by this approach originally identified by Giddens, nor accommodating our current understanding of human cognition, including embodiment. Worse, the assumptions about how life mirror those promoted by neoliberal political-economic theory, introduced by Reagan and Thatcher, which portrays any kind of governmental (i.e., structural) control as necessarily deleterious, in favor of the supremacy of near-uncontrolled individual rights. This demonstrates that noncritical archaeology theory can have pernicious even if unintended consequences, in this case supporting the neoconservative ideology that has become the worldview of the West. Natural models, as durable analogical and metaphorical sources for belief and symbolic systems, are argued to be useful sources for archaeological research on religion.

[300]  **Tribal Collaboration in Heritage Management on the Carrizo Plain National Monument**  
The Carrizo Plain National Monument (CPNM) contains some of the most significant Native American heritage sites in the United States. In recognition of this, a cultural landscape, which includes habitation sites, camps, quarries and pictograph sites, has been designated as the Carrizo Plain Archaeological District National Historic Landmark. In addition to these physical features, the Carrizo Plain is imbued with intangible values that embody a sacred landscape for affiliated tribes. The Bureau of Land Management has worked closely with tribal partners during the development of management plans for the CPNM. This has included an adaptive management strategy for public visitation of Painted Rock, a sacred pictograph site. This poster will provide information on how site management at Painted Rock has been guided by this collaborative process.

**Whitley, Thomas (Sonoma State University)**  
[186]  **Droning on a Budget: UAVs, Aerial Imagery, and Photogrammetry for the Archaeologist**  
Recent changes to the FAA regulations covering the use of Unmanned Aerial Vehicles (UAVs) or “drones” have clarified their use in both research and commercial operations. This paper is intended to provide an overview of low-cost entry into the use of UAVs for archaeological projects and considerations for applications in aerial imagery, videography, and photogrammetry. Using drones for documentation and interpretation is no longer uncommon, but it has been cost-prohibitive since the previous regulations required full pilot licensing or were ambiguous. By gaining a little bit of knowledge and experience, now even graduate students with little funding can find opportunities to employ these devices on their own research projects. Some examples will be provided along with a discussion of what the future holds for UAV technology.

**Whitlock, Bethany and Kari Lentz (Sonoma State University)**  
[75]  **A Rectory Divided: Mediation of Space in a Colonial Town in the Southern Peruvian Highlands**  
During the sixteenth-century Vicerealty of Peru, Toledo ordered a series of reforms in the Vicerealty of Peru that involved the forced resettlement of the native population into planned nucleated settlements (reducciones). Toledo believed that these standardized built environments, in conjunction with ecclesiastical regulation, would produce idealized colonial communities. This paper presents the initial results of recent excavations in the rectory at Mawchu Llacta, a reducción in the Colca Valley. The rectory served as the dwelling for the parish’s clergymen during its three centuries of occupation. The interior organization of the rectory was distinct from that of other domestic structures in the settlement, and underwent significant modification during its occupation. One room, for example, was divided into clear public/reception and private spaces. As such, we focus on temporal changes in the structure and organization of the rectory, including the reuse of Inka architectural elements. We also consider historical documents pertaining to the rectory, and examine the differences between these and the archaeological evidence. Ultimately, we explore how priests, agents of colonial authority, mediated power through control of space. We also intend to investigate how the lived experiences of indigenous Andeans and colonists, such as clerics, differed during the colonial period.

**Whitney, Kristina (University of New Mexico)**  
[346]  **Landscape Use in Southeastern Ethiopia**  
The widespread availability of satellite data has opened up parts of the world that have long been inaccessible for archaeological research. One such area is the border between Ethiopia and Somalia, which has been embroiled in civil conflicts for the past 30 years. As such, little is known about the cultural heritage of southeastern Ethiopia and the greater Somalia region. This project shows how using geographic information systems (GIS) as a form of initial survey can reveal substantial results while minimizing personal risk to the researcher and maintaining cost effectiveness. The research goal was to understand how modern villages and surface anomalies relate to each other and to the landscape through analyzing satellite imagery at a scale of 1.19 m per pixel. Topographic features, such as drainages and landscape position, were analyzed in relation to identified villages and surface anomalies to analyze continuity in landscape patterning. This information was then used to estimate the length of time these anomalies may have been present on the landscape with three models. Even though ethnographic data are sparse, I conclude that longer estimates of habitation by pastoral groups in southeastern Ethiopia fit with the known data.

**Whitridge, Peter (Memorial University of Newfoundland)**  
Schematic harvesting scenes incised on tools are a stock variety of both precontact and historic Inuit graphic art. They sometimes seem to depict historically specific events, which they effectively commemorate, and have real (sometimes precise) informational content that must have been important for the dissemination of technical harvesting knowledge among a hunter’s peers, and its inter-generational transfer. However, the harvesting setups—such as a boatload of hunters on the verge of harpooning a whale—are rather conventional, even repetitive, suggesting that these depictions also acted to discursively stabilize particular sorts of relations among people, things, the environment, and nonhuman animals. This may have been an intended function, along the lines of a hunting amulet, or it may have been an unconscious effect achieved through the eidetic citation of an idealized turn of events. Although scenes of harvesting walrus, caribou, birds, fish and other species occur in this idiom, bowhead whaling was clearly the object of a special fascination. Whaling scenes are the most conventional of all, condensing these various functions—historical, educational, symbolic—as they engaged whales in a discourse on human-animal relations that embraced ritual, belief, memory, social relations, technology and economy.

[88]  **Sources of Sinagua Obsidian Points and Debitage: XRF Analysis**
Projectile points and debitage from three Sinagua sites in northern Arizona were analyzed using the XRF instruments at Missouri University Research Reactor. The rooms at Lizard Man Village, Fortress Hills, and New Caves were occupied between AD 1050 and 1250. Over 300 obsidian points and debitage were analyzed using an ARL Quant’x EDXRF Spectrometer. The primary source of obsidian is the well-known Government Mt source, with a few samples from RS Hill and other sources. The nearest sources of abundant obsidian were heavily used, but our data allow us to look at changes through time in northern Sinagua obsidian use and point typology.

Whitten, Ashley (University of Kentucky) and David Chicoine (Louisiana State University) [231]  
Architecture and Spatial Organization of Urban Cercaduras at the Early Horizon Center of Caylán, Nepeña Valley, Peru  
This poster presents architectural and spatial data from monumental urban compounds or cercaduras at the Early Horizon center of Caylán (800–1 BC), Nepeña Valley, Department of Ancash, Peru. Caylán is interpreted as the primary center of a multi-tiered polity that developed in the littoral portion of the Nepeña Valley and reached its peak during the second half of the first millennium BC. Recent fieldwork at Caylán revealed the existence of more than 40 cercaduras interpreted as multifunctional residential compounds. The cercaduras are articulated through more than a dozen streets. Area excavations and systematic pedestrian surveys provide significant data to explore the organization of the cercaduras including their size, complexity, depth, and overall variability. Results indicate that the urban cercaduras share spatial logic, in particular with respect to their access patterns and subdivisions. Here, we analyze architectural data from a spatial syntax perspective with the objective of reconstructing the size and complexity of the co-residential groups at Caylán. We present detailed reconstructions of six of the better preserved cercaduras to bring insights into Early Horizon urbanscapes and demographics. The results are discussed in light of the increased complexity and potential socioeconomic diversity of human settlements in coastal Ancash during the Early Horizon.

Wholey, Heather (West Chester University) [216]  
The Mid-Atlantic Steatite Belt: Archaeological Approaches to Traditional Knowledge and the formation of Persistent Landscapes  
in the Mid-Atlantic, steatite outcrops within the eastern talc belt, which runs from Alabama, through New England to Labrador. It is a porous, carvable stone with a mineralogical and chemical makeup that inhibits soil formation, resulting in scrub or barren landscapes that host rare grasses and wildflowers. In their natural state, these would be striking landscape features. While an array of items, such as plummet, bannerstone, and pipe, were produced from steatite throughout precolonial times, the craft of carving open vessels peaked during the Transitional Period. Though several locales may supply steatite, only some appear to have been used for extraction, and finished vessels are found up to 300 km from these source locations. Traditional knowledge about the environment is often observable to us through ethnography, local toponymy, or oral history. Much of the Mid-Atlantic region lacks access to these rich sources. Yet traditional knowledge is also manifest in the physical construction of persistent landscapes as people visit and revisit places, infusing them with meaning and memory. This work addresses how archaeology helps to understand how people developed traditional knowledge of resources in the past, and how archaeology may be a partner in the contemporary cultural reimagining of relict landscapes.

Whyte, Thomas [160]  
Big Meat Feasting in the Pisgah Phase of Western North Carolina.  
Animal remains from three late prehistoric Pisgah phase sites in mountainous western North Carolina are described and compared. The sites include a mound (Garden Creek Mound No.1) and adjacent village, and a village with no mound (the Cane River Middle School site). Deer, black bear, turkey, and box turtle remains dominate all three assemblages. Three large bones from the mound, previously reported as bones of Bison, are definitively Elk. Whole large mammal bones, recovered almost exclusively from the mound, are interpreted as evidence of lavish feasting. In contrast to Mississippian faunal assemblages from the adjacent lowlands, evidence for food resource competition or scarcity is lacking in the central Appalachian Summit highlands.

Testing Alternative Settlement Models at Las Colinas with Polychrome Dating  
An understanding of the nature of late Classic period settlement at Las Colinas is an important element in understanding the broader social changes that took place across the Phoenix Basin during this time. One perspective on settlement at Las Colinas figures prominently in the recent “core decay” model proposed for the Phoenix Basin Hohokam. In response to this model, we propose new alternative scenarios for late Classic period settlement at Las Colinas. We test these alternative settlement models through an examination of ceramic data, principally from the polychrome pottery that appears in the Phoenix Basin during the late Classic period as a sign and signature of new social arrangements. Finally, we discuss the implications of our study for broader understandings of social change and settlement dynamics in late Hohokam prehistory.

Northern Norway’s Sea of Islands: Processes of Maritime Colonization and Settlement  
Epeli Hau’ofa’s (1993) perception of Oceania as a “sea of islands” is a useful point of departure for exploring the long-term trajectories of the many thousands of islands scattered along the coast of northwestern Norway. Hau’ofa’s vision of joined islands is also instructive as a way of emphasizing seabeorne connectivity rather than insularity within maritime archaeology. This paper highlights problems related to island colonization and settlement since the Early Mesolithic (11,500–10,000 BP) in northern Norway with potential relevance for island archaeology at a global scale. A central problem is the necessity of documenting island landscape transformations as a requisite for understanding human-island interaction in a region where prehistoric shorelines may be currently submerged or elevated. A second problem related to island colonization is the pervasive underestimation of nautical expertise and sophistication of seagoing vessels prior to the Bronze Age in the archaeological literature. Evidence for island settlement among the indigenous coastal Sami is reviewed and the consequences of medieval Norse fishing settlement colonization of islands in Sami areas evaluated as a means of exploring the nature of colonization as a layered process.

Teotihuacán at Night: Lighting a Prehispanic City

Teotihuacán was a large and populous city at its height with an estimated population of 100,000 people. Since it lies in an arid landscape with neither domesticated animals as a source of dung for fuel nor oils from tree seeds these fuel sources could not have been used for cooking, lighting and to a lesser degree heating. Only wood from trees and shrubs and other plant materials could have been used for fuel. These have been identified in charcoal from archaeological deposits at Teotihuacán, indicating their possible use in lighting. Certain artifact types, such as candelarios, tapa platas, braziers, and censors, used for cooking and ritual also provide light. The demand for fuel from trees and shrubs would have been high, so these resources would have been managed and their distribution and consumption highly organized. We argue that Teotihuacán was a relatively dark and quiet city at night, and only those citizens and compounds that were wealthy enjoyed light from external fuel sources at night. We further suggest that Teotihuacán took advantage of light derived from ceremonies, rituals, and cooking and therefore performed these activities at night when light was required rather than in the day when light wasn’t needed.

Soil Micromorphology Analysis of Area D at Manot Cave, Israel: Insights into Site Formation Processes

Manot Cave, discovered in 2008 in Western Galilee (Israel), represents one of the richest Upper Paleolithic assemblages in the Levant. The site has produced a ca. 55,000-year-old anatomically modern human calvarium, as well as Middle Paleolithic to Post-Aurignacian lithic and bone artifacts. The deepest stratigraphic sequence is found in Area D, located halfway down the steep talus. This area shows continuous stratification from dolomite bedrock to an early sterile colluvium, an archaeological colluvium, and a late sterile colluvium. The aim of this work is to characterize the different stratigraphic units by soil micromorphology in order to determine their origin and correlate them to stratigraphy in the cave’s other excavation areas. Components such as relative sizes of sand particles, microstructure, coprolite fragments, and chert gravel are utilized in our analysis. In particular we found that the early sterile colluvium is dominated by fine quartz sand, the archaeological colluvium by medium quartz sand, and the late sterile colluvium by very fine quartz sand. The very fine quartz sand dominating this late colluvium is also typical of the modern terra rossa soil. The implications of these finds for site formation and use of space will be discussed.

Wicewiecki, Wiesław C. (University of Warsaw)

Bioarchaeological Research at Castillo de Huarmey, Peru

The Wari imperial mausoleum, discovered in 2012–2013 at the site of Castillo de Huarmey, Peru, brought to light remains of 64 individuals buried within the main chamber underneath and additional seven in the contexts directly associated with the mausoleum. The upper layers of the building also yielded a collection of human and animal remains. The collection of human remains brings a unique set of data for bioarchaeologists. The research performed so far include standard analyses like taphonomy, demography and health status, along with biogeochemical ones. Stable isotope analyses of strontium, oxygen, nitrogen and carbon provided insights into the geographical origins and potential mobility as well as dietary preferences of the individuals buried within that unique context. Preliminary DNA analysis widened the scope of information obtained. A lot more of analyses have to be performed to fully understand the character of the Wari presence on the north coast of Peru.

Industrial Islands: Ecological Impacts of the Steam-Powered Mills of the El Progreso Plantation, Galápagos Islands

From 1880 to 1917 “El Progreso” plantation operated on the humid highlands of San Cristóbal Island in the Galápagos archipelago (Ecuador). The plantation enterprise used steam-powered machinery for sugar refining and alcohol distillation. Despite its remote location, 1,000 km west from the South American coast, this large operation took advantage of the latest industrial technology. A number of specialized machines were used in sugar processing which were imported from factories in Scotland and the United States. The implementation of the industrial machinery required large quantities of wood for fuel, permanent sources of water, and the construction of large buildings. After the murder of the plantation owner at the hands of his workers in 1904, the machinery and the mill operated for another decade before being abandoned. Parts of the machinery were removed to mainland Ecuador but some have remained on site. This paper explores the characteristics of the technology used during the industrialization of El Progreso plantation and its effects on the local ecology of San Cristóbal Island.

An Attempt at Digitally Associating Skeletal Elements: A Study of Photogrammetry and Articular Surface Area

When excavating archaeological skeletal remains it is not uncommon to find them disarticulated and even commingled with other sets of remains. To study these remains it is paramount to first accurately and efficiently re-associate all skeletal elements. Re-association of skeletal remains is necessary before any other form of analysis (ancestry, sex, age, stature etc.) can be performed. While analog methods have been previously applied to standardize this task the advent of digital modeling provides a new medium within which new methodologies may exist. For example, photogrammetry is an accessible means of digitizing with the potential to aid in shape analysis. This study used photogrammetry to answer two questions: is photogrammetry a practical means for digitizing skeletal remains? And, is articular surface area a measurement that can be used for re-associating skeletal elements? During the study photogrammetry was found to be a practical means with which 3D models could be rendered in part due to the basic and relatively affordable tools available, even in consideration of time and learning curve. In contrast, articular surface area would require further research to demonstrate its practicality, or lack thereof, for being a means by which disarticulated skeletal remains could be re-associated.

Being a Woman in Roman Gaul: Gendered Votive Offerings in a Colonial Context

The annexation of Gaul into the Roman Empire in the mid-first century BCE spurred the development of new religious practices in that region, including the practice of offering votive figures at sanctuaries. Because each votive represents a personal decision on the part of the dedicant, analysis of votive assemblages provides unique insight into the demographics of worshippers and illuminates aspects of individual identity in this colonial context. Here, I present the results of a quantitative analysis of gendered votives, most notably female anatomical figurines—a votive type that existed neither in Gaul nor in Rome at the time of Roman conquest. Analysis of the geographic spread of the practice of offering gendered votives as well as of the differences between male- and female- gendered votives, especially when compared with the much more Roman practice of offering written dedications, provides a
means through which to study Roman colonialism as a gendered experience. These preliminary results suggest ways in which women in the Gallic provinces navigate the unique cultural landscape of Gaul under Roman rule.

Zooarchaeology and the Study of Human-Animal Relationships in Pre and Early Historic South India

The study of animal remains from archaeological sites has proven to be an invaluable approach to understanding past social, economic, and political practices. Despite the diverse behaviors and sets of relationships animal remains can index, faunal analysis has been an underutilized approach to studying Indian history and prehistory. In this paper, I present new research and zooarchaeological data to demonstrate how human-animal engagements changed throughout the Neolithic (3000–1200 BCE), Iron Age (1200–300 BCE), and Early Historic (300 BCE–500 CE) periods in South India. Using faunal remains from the site Kadebakele (Karnataka), I address how animal rearing, procurement, and consumption figured into the changing economic and agricultural regimes that ultimately laid the foundation for the emergence of urbanism in the region. In addition, I consider how a zooarchaeological study of human-animal relationships, in particular those forged through a history of animal husbandry, allow for us to critically engage with existing narratives concerning social and cultural change in South India.

pXRF Analysis of the Pylos Linear B Tablets

In 2015 and 2016 I analyzed all of the Mycenaean Linear B clay tablets and sealings from the Palace of Nestor at Pylos for their chemical composition using a portable X-ray fluorescence spectrometer. Sealings were used on containers of oil, wine, etc., and on baskets of tablets. Leaf-shaped tablets usually contain one entry or line of information. Page-shaped tablets contain several entries of related information. There are questions that these analyses may help answer:

• Did the sealings travel with material goods, or were they manufactured at the palace as materials arrived?
• When inscribed sealings are related to tablets, do they use the same or different clays?
• Do the tablet manufacturers use different clays, and were these manufacturers at the palace or located in remote areas?
• Can we gain insight as to whether the Archives Complex of the Palace was the functional economic center of the regional polity?

The answers to these questions will help us understand the controls placed on material wealth headed to the palace, how the tablet-writers interacted with goods brought to the palace, and how information entered the official record.

Markers of Time: Exploring Transitions in Artifacts and Burial Practices at Bolsa Chica, Orange County, California

The transition of artifacts recovered from the Bolsa Chica Mesa indicate changes in site use through different temporal periods. Early (9000–7500 BP) Bivalve Tivela beads give way to Olivella spire/end modified, then to Olivella Grooved Rectangle (OGR) beads (5500–4500 BP). Transitions in bead type illustrate a range of methods spanning from small bone assemblages to complete interments. Previous burial analyses have hypothesized that the Bolsa Chica burial practices found at the Bolsa Chica Mesa sites also vary by associated temporal period in addition to burial location. The burial types found on the Mesa illustrate a range of methods spanning from small bone assemblages to complete interments. Previous burial analyses have hypothesized that the Bolsa Chica Mesa was used as a ceremonial burial ground. This study attempts to assess whether the observed shift in burial practices is associated with changing coastline conditions, availability of resources, and the influx of new populations. Further, the burial types found at Bolsa Chica.

More than Just Another Number: Use of the Smithsonian Trinomial System and the Digital Index of North American Archaeology (DINAA) to Link Open Information about Archaeological Sites across the Web

Archaeological sites in the United States are often associated with alphanumeric identifiers known as Smithsonian trinomial numbers (STNs). Developed in the mid-twentieth century, STNs consist of patterned alphanumeric sequences, potentially recognizable in spreadsheets, archival records, and literature. The Digital Index of North American Archaeology (DINAA), a linked open data hub for archaeological site information, is attempting “named entity recognition” (a form of text mining) to identify STNs in archaeological literature. The grand challenge undertaken here will ultimately allow a DINAA user to browse, via map-based visualizations, cross-references between DINAA site file information and publications containing related STNs. This initiative includes human-guided cataloging of STNs from recent American Antiquity offerings, and software-enabled text mining of STNs from the entire run of American Antiquity through the JSTOR for Research program. Challenges include: variation in STN formatting, inclusion of STNs in various elements of research articles (abstract, body text, tables, figures, notes, etc.), and publication of competing identification strategies (e.g., state and museum systems). We will present results of this pilot study to inform future linked open data use of STNs in other archaeological literature, governmental records (e.g., Federal Register), museum collections, and archives.

New Insights into Old (and New) Data: Lithic Technological Organization and Evolutionary Archaeology at the St. Mungo Site (DgRr-2),
British Columbia, Canada

Results from excavations at the St. Mungo site by Len Ham and his team in the early 1980s challenged previously held ideas about the Charles Culture (5000–3300 BP) in the Gulf of Georgia region. Previous research determined the Charles Culture was represented by egalitarian hunter-gatherer societies. Several lines of evidence were cited to support this idea, including both the absence of ground slate knives for intensive fish processing and storage technology which would have allowed people to overwinter in larger groups leading to socioeconomic complexity. Len Ham and team disagreed. Their work determined that stratified collector societies occupied the region during the Charles Culture, and they had data to support their theory. New data from several research projects over the past 10 years support Ham’s conclusions, including lithic data from recent excavations at St. Mungo. A technological analysis of the new lithic data from St. Mungo suggests people had developed and organized a sophisticated lithic tool kit for processing large amounts of riverine resources, such as salmon, long before ground slate tools came into wide use in the region. Using an evolutionary archaeology framework, I assess how this tool kit was developed, modified and persisted into the Marpole Phase.

Crowdfunding, Crowdsourcing, and the Collaborative Economy: Old Wine/New Bottles, or Genuine Game Changer for Archaeology?

DigVentures was launched in 2012 as a rewards-based crowdfunding platform designed to enable participation in archaeology and citizen science projects. We were formed by a small team of archaeologists, driven to action by what we saw as the three most pressing needs affecting our sector: the necessity for heritage professionals, museums and cultural organizations to reduce dependence on grants and state funding; the development of digitally enabled alternative finance models that diversify sources of funding; and the rise of the experience economy and popularity of citizen science. Our first campaign at Flag Fen stands as world’s first-ever successfully crowdfunded archaeological excavation. Since then, we’ve repeated that initial success, crowdfunding a total of £150,000 for our projects, unlocking a further £700,000 in match funding from traditional grant-givers. Set within a broader economic trend that has seen the UK alternative finance market rise to £3.2b in 2015 (up 82% from £1.7b in 2014) and this new approach clearly offers promise. Drawing from specific examples from our project portfolio, in this short presentation I will explore the potential issues and practical steps that archaeologists can take to harness the crowd, and what differentiates this new model from anything that has gone before.

Refuge, Frontier, No Man’s Land: The Changing Nature of the Andean Cloud Forests

This paper will consider the Amaybamba Valley of southern Peru as an ecological and political frontier zone, from the late prehistoric era until the early colonial period. The Amaybamba region is a part of the cloud forest zone of the eastern Andean slopes, and is thus located where the highlands rapidly shift into the warm tropical lowlands of Amazonia. It is a region that has a complex and highly variable history, one reflecting its environmental characteristics, but often in unpredictable ways. Through a mixture of archaeological and documentary forms of evidence, the paper will discuss the occupation of the valley during the Late Intermediate Period (c. AD 1100–1400), on through to the Late Horizon (c. AD 1400–1532), followed by the post-conquest and Neo-Inca period (AD 1533–1572) and then finally the early colonial era (AD 1572–1650). As the paper will show, although there is always a strong relationship between the ecological and political frontier zones of the Amaybamba, the characteristics of this relationship were radically different across the centuries. No deterministic account of the region’s ecological and political interactions can therefore provide an adequate explanation.

Wilkinson, Patrick (University of California, Merced)

The Rock Art of Haitian Vodou

This research is part of a larger ethno-archaeological investigation of the use of caves in modern Haitian Vodou rituals in Northern Haiti. This paper explores the modern rock art left in the caves as a result of Vodou ceremonies, in particular paint and veve (veve are symbols drawn out with cornstarch used to call various spirits to ceremonies, and are an intrinsic part of Vodou). The art in question included both permanent and ephemeral works, ranging from simple graffiti to caves painted with house paint in the colors associated with particular spirits.

Paint It Black: A Geospatial Analysis of Chupadero Black-on-White Ceramics

Chupadero Black-on-white ceramics were produced in the Salinas and Sierra Blanca regions of New Mexico beginning around AD 1100. They quickly gained popularity, covering a geographic region that encompassed much of the modern state of New Mexico, west Texas, southeastern Arizona, and
northern Chihuahua. Yet, despite their popularity, little is known about the exchange mechanisms that yielded Chupadero Black-on-white’s impressive distribution. ArcGIS contains analytical applications that can be used to explore mechanisms of geospatial variation. This project uses GIS to investigate the processes behind the distribution of Chupadero Black-on-white ceramics in the prehistoric Southwest. We find that the processes change over time as exchange networks expanded during the fourteenth century.

Williams, Gareth (British Museum)

In the ninth century, Viking “armies” are recorded raiding (and in some cases conquering) in Britain, Ireland, and the Frankish kingdoms. Contemporary sources indicate that the largest of these were comprised of hundreds of ships and, by inference, thousands of men. Many of these accounts give round numbers, and historical opinion is divided between those who accept that the figures may represent approximations rather than absolute historical fact, but are nevertheless representative of very substantial forces, and those who argue that the figures are exaggerated for effect, raising further questions of what constituted an ‘army’ in this period. Archaeologically, the movements of these armies have left relatively little trace. A number of hoards and single finds can be linked with historically documented movements of specific forces, but until recently a single partially excavated winter-camp at Repton in Derbyshire has provided a paradigm for the likely size and form of such sites generally, and has been taken to support the minimalist interpretation of Viking armies. The investigation in recent years of additional sites in England and Ireland points to the presence of much larger forces, while also pointing to diversity of activity which goes beyond traditional military definitions of Viking ‘armies.’

Williams, Justin (Cultural Resource Analysts Inc.)

[89] Clovis Style Hafted Bifaces: A Pan-Regional Perspective

Many studies have made statements about the origin and method of the spread of the Clovis style hafted biface technology, but little research of late has evaluated Clovis from a Lithic Technological Organization perspective. This study examines a sample of 695 Clovis style hafted bifaces from across North America. I analyze trends in raw material use, flute length, reuse and resharpening in Clovis style hafted bifaces from across the country. I conclude that there is much variation in the types of raw materials used and the length of the flutes on Clovis style hafted bifaces. Additionally, this analysis reveals that Clovis style hafted bifaces are resharpened and retouched in an atypical manner. Finally, I use the results of this study to situate future questions that Pan-Regional studies of Clovis style hafted bifaces should pursue.

Williams, Katharine

[9] Plumbate and Imitations

Plumbate is a lustrous hard-paste ware characterized by small effigy vessels, some of which bear Central Mexican ideological influences. It was widely traded during the Terminal Classic/Early Postclassic across ethnic, political, and linguistic boundaries. Its widespread distribution and luster mark plumbate as unique among contemporaneous wares. It is sometimes found alongside locally produced wares that bear superficial resemblances, leading to the belief that they are imitations of plumbate. This research focuses on differences between imitation and plumbate wares with the goal of refining established criteria for distinguishing them. A secondary goal of this research is determining the production process of plumbate and both its luster and that of the imitations. In order to do this, compositional data (obtained via electron microprobe analysis) and recovery contexts of imitations and plumbate are compared.

Williams, Ken (Cahokia Mounds Society) and John Kelly (Washington University)

[283] Ground Truthing Cahokia’s Feature X Anomaly

A huge resistivity anomaly discovered several hundred meters northeast of Monks Mound was subjected to coring and test excavations in 2012. This testing revealed a series of major prehistoric landscape uses/modifications through time, some quite unexpected. The prehistoric sequence of events at this location, though still in need of further clarification, appear to infer significant shifts in communal priorities through time.

Williams, Mark (University of New Mexico)

[49] Shellfish Harvesting Strategies on the Northern Northwest Coast: Evidence from Labouchere Bay, Southeast Alaska

This poster presents new data from five shell midden sites on Prince of Wales Island, Alaska, in order to examine how shellfish-harvesting strategies changed during the middle to late Holocene. The accessibility and resilience of shellfish beds on the coastal margin makes them valuable resources that complement more seasonally-restricted food sources such as salmon runs. In order to meet the increasing needs of permanent settlements that emerged during the middle Holocene, shellfish management strategies would have had to adapt. Establishing specialized foraging camps and purposefully transforming sections of the intertidal zone into clam gardens would have improved the yield of shellfish beds owned by particular households. The study examines changes in the diversity and relative abundance of shellfish species within the middens at Labouchere Bay. Patterns of change are considered within frameworks of paleoecology, the priorities of individual foraging agents, and community-level settlement patterns and social organization. Analysis of stable oxygen isotopes reveals changes in environmental conditions at both a short-term seasonal scale and long-term climatic scale. Comparison with other sites in the region places these changes within the context of increasing sedentism and social organization.

[197] Social Change among the Lower Creek, the Late-Woodland to Historic Period

The protohistoric and historic periods were times of great social change among Native Americans of the southeastern United States. The era saw mass migration and shifts in political association. The indigenous tribes of the Chattahoochee River, later known as the Creek, were no exception to the cultural changes of the time. The current historical and archaeological interpretation of these changes suggests that the Creek became more closely aligned, culturally, through time. These interpretations are based on historic documents, proximity and ceramic seriation and sequencing. This paper used social network analysis to test the current interpretations and determine if the relatedness of Creek and Creek ancestor sites, in middle and lower Georgia, Alabama and north Florida, changed over time.

Williams, Patrick Ryan (Chicago Field Museum) and Donna Nash (UNCG)

[29] Radar, Lidar, Drones, and Donkeys: The Evolution of Archaeological Mapping Technologies in the South Central Andes
In this paper, we review our use of digital technologies to model archaeological landscapes over the past two decades in Peru and Bolivia. We focus on three scales of analysis in four thematic areas that leverage state of the art technology and GIS modeling as a means for understanding the archaeological record. Our scales run from the built environment of local sites and monuments to regional agricultural landscapes to subcontinental interaction spheres. We look thematically at modeling urban space in ancient cities to creating anthropogenic hydraulic networks in agrarian systems. At the broadest scale, we examine the relationship between regions through the analysis of ritual landscapes and the networks of roads that link places together and how digital technologies have allowed us to integrate these scales of analysis in our work on the Wari and Tiwanaku states of the Andes.

[204] Classic Maya Architectural Form, Function, and Urban Context in the Chenes Region, Campeche

This paper revisits Classic Maya free-standing towers and portal vaults, some of which were first reported as isolated structures in the Chenes Region during the late nineteenth century. Recent research highlights not only formal attributes, but also their particular architectural compound and urban contexts not mentioned by previous studies. More complete architectural compound and urban layout data suggest new temporal and functional interpretations for these unique masonry features at Tabasqueño, Chanchen, Nohchen, and Nocuchich. These data also shed new light on particular north–south axis site location, previously ascribed an archaeoastronomical association in the literature, and possible tower/portal vault meaning in restricted access architectural compounds at these places within the immediate region.

[196] Spatial Analysis and Sampling Techniques of Cremated Remains from Bronze Age Cremation Urns in Southeast Hungary

Since 2011, members of the Bronze Age Körös Off-Tell Archaeology (BAKOTA) Project have excavated 57 cremation urns from the Békés 103 site in Southeast Hungary. This exploratory study seeks to examine the percentages of cranial and postcranial elements present in microstratigraphic levels in order to better understand the spatial distribution of bones within the burial urns. As a way to explore new approaches, two sampling methods were employed for the analysis of three burials. The first involved a random 20% sample of each microstratigraphic level, and the second involved the entire contents of each level. Across each level, fragments were classified as cranial, postcranial, or indeterminate, and total weights of the cranial and postcranial elements were recorded. These two methods were applied to test if the 20% sample adequately represented an entire cremation urn. Preliminary results suggest that the smaller sample has a similar distribution of cranial and postcranial elements within the urn. This is promising, as it allows for data to be collected more efficiently across numerous cremations. By deciphering the spatial distribution of the cremated remains, this study aims to better understand the mortuary practices utilized at the Békés 103 site.

Willis, William (University of Nevada Las Vegas)

[155] Spatial-Temporal Distribution of Prehistoric Puebloan Settlements and Ceramic Wares on the Shivwits Plateau

During the summer of 2016, graduate students from the University of Nevada, Las Vegas conducted in-field ceramic analysis on Virgin Branch Puebloan sites found on the National Park Service portion of the Grand Parashant National Monument. Data collected from this project were analyzed in GIS in order to establish habitation site chronology in the region as well as address spatial artifact and settlement patterns through time as they relate to environmental variables. It is concluded that the land in the southern portion of the project area was favored more by the Virgin Branch during the early part of the region’s occupation. However, relating changes in settlement distribution patterns and land use through time to environmental variables is not straightforward. Finally, the findings of this study lend support to the hypothesis that Shivwits Ware ceramics were produced in the far southern portion of the Shivwits Plateau.

Willison, Megan (University of Connecticut)

Funerary objects from three seventeenth-century burial grounds were statistically associated with biological sex categories to discern what, if any, burial items were related to the sex of an individual. A handful of material objects proved to be almost exclusively associated with either sex; what also appeared from this analysis was the discovery of two burial assemblages that possessed a mixture of what are believed to be solely male or female burial goods. Utilizing archaeological and linguistic data, this paper suggests that one explanation for these two burial contexts is the occurrence of non-binary gender systems in seventeenth century southern New England. If not representative of two-spirits, this paper argues that these burial assemblages may instead reflect changes in gender roles resultant from European cultural contact and acculturation. This research has implications for broadening the scope of known non-binary gender structures in North America and discerning further evidence of indigenous cultural change and perseverance in the seventeenth century.

Willoughby, Pamela (University of Alberta)

[146] A Middle and Later Stone Age Sequence from Iringa, Southern Tanzania

Magubike rockshelter in the southern Highlands of Tanzania contains a long archaeological sequence ranging from the Middle Stone Age (MSA) through historic times. This paper describes the lithic sequence from test pit 5, which contains a 2.5 m thick cultural deposit composed of recent/historic remains, an Iron Age, a microlithic Later Stone Age (LSA), a macrolithic LSA, a transitional sequence from the MSA to the LSA and 90 cm of MSA artifacts. The later part of the sequence replicates the cultural deposits at the nearby shelter of Mlambalasi, where the microlithic LSA dates to the early Holocene and the macrolithic LSA to the late Pleistocene. The entire sequence gives a baseline for technological change at Magubike and for other sites in the Iringa region.

[130] A Three Dimensional Reconstruction of the Pueblo Bonito Mounds
There are two large mounds on the south side of Pueblo Bonito that were extensively trenched in the late nineteenth and early twentieth centuries. Data from the re-excavation of three trenches are combined with new geospatial and remote sensing information to create a three dimensional reconstruction of mound history. Although low walls were built around parts of each mound at some point, there is no evidence that the mounds were ever enclosed by architecture. The mounds consist mostly of household debris and discarded construction material that was placed over buried artificial and natural channels that directed surface flows past Pueblo Bonito until late AD 1000s. Our reconstruction emphasizes the relationship between built environment and stream dynamics during the Bonito Phase (ca. AD 850 to 1200).

The Organizational Implications of Architecture at Moundville and Cahokia

What practices generated the largest and most complex Mississippian centers? We examine this issue through an analysis of Mississippian public and ritual architecture from Moundville in west-central Alabama and Cahokia in southwestern Illinois. Politico-religious buildings and associated practices or powers constituted the historical development of both places. Cahokians created a wider variety and more complicated distribution of such buildings than did Moundvillians. We argue that the Cahokian architectural order provides evidence of supra-kin movements that help to explain that region's complex ritual-residential precincts, nodal site networks, and farming districts. These relationships operated as part of a more centrally administered and regionally articulated mode of sociopolitical organization than existed at early Moundville.

Wilson, Katherine [365]

The Ceramic Assemblage from Washington Mounds: A Caddo Site in Southwestern Arkansas

The Washington Mounds site is an Early to Middle Caddo period (AD 800–1300) mound site with 11 mounds, some of which contain burials; two village areas are associated with the site surrounding the mounds. It is located in southwest Arkansas between the Red River and Little Missouri River Basins. Some level of ritual activity occurred at the site, but the types or scale was previously unknown. Two excavations have been done at the site: first in the early twentieth century by M. R. Harrington, and a second in 1981 by the Arkansas Archaeological Society and the Arkansas Archaeological Survey. Whole pots and potsherds from both documented excavations are considered in the analysis as well as pipe fragments (Red River long-stem varieties) to determine periods of use as well as ritual themes prevalent at the site. This study is an analysis of the ceramic assemblage through the theoretical perspective of ceramic ecology. As this is the first thorough analysis done at this site, the goals of the research include establishing information on life, status, and ritual activities of the people who occupied this site.

Wilson, Michael (Department of Earth & Envir Sci [Emeritus], Douglas College) [307]

Geochronology and Chronostratigraphy of the Sheep Rock Spring Site, Late Pleistocene to Holocene, Missouri River Headwaters Region, Southwest Montana

The Sheep Rock Spring site (24JF292) lies in a small SW Montana valley between Sheep Rock and a residual tor. A late Quaternary sequence (>5 m) supports a chronostratigraphic model from dates on charred material in the upper two units: 1) basalt rock landslide diamicton; 2) down-valley debris flows; 3) final Pleistocene-early Holocene (FP-EH, >10,200–8700 RCYBP) channel/floodplain alluvium and paleosols; and 4) mid-Holocene (MH, ca. 6000–5430 RCYBP) alluvial/colluvial fan with paleosols. Radiocarbon (N = 26) and stable isotope measurements underpin the age-model, with local events superimposed on regional early Holocene warming and drying. Samples include charred material (n = 11), organic sediments (n = 5), bone “collagen” (n = 7), and wood (n = 3). Residual bone organics from extinct megafauna among the landslide boulders gave a pre-Last Glacial date of ~20,700 RCYBP, doubtful given a 13C/12C ratio of ~33.1‰. Dated contexts provide evidence for introduction of relatively small corner and/or side-notched projectile point types from terminal Paleoindian times onward. Artifacts suggest intermittent, short-term camping and tool production. Artifact redeposition also raises concern for some dating samples. Organic sediment dates agree with the age-model (9060–8200 RCYBP for FP-EH, 5510–4720 RCYBP for MH), while wood and some measurements on acid-insoluble bone fractions do not; water-table fluctuations may be responsible.

Sex-Related Differences in Dental Caries Prevalence in the Prehistoric American Southwest

This research comprises a comprehensive study of oral health from three prehistoric Southwest sites in order to identify sexual differences in the prevalence of dental disease after the onset of agriculture. Dental pathologies, such as dental caries and antemortem tooth loss (AMTL), directly relate to an individual’s diet, therefore indicate disparities in subsistence and dietary patterns. Previous studies have found that females exhibit higher rates of caries compared to males. These differences are considered to be the result of physiological, behavioral, or social variances between or within communities. My research reveals further insight into regional and temporal perspectives among pueblo skeletal samples. Specimens from the Southwest sites of Pottery Mound (LA416), NAN Ranch (LA2465) and Kuaua Pueblo (LA187) were used for this research. I examined 57 male and 56 female dentitions to uncover possible sex-related disparities in dental caries. Males and females from Pottery Mound and Kuaua exhibited similar rates of dental caries and AMTL, suggesting no distinct variation in dietary patterns or behaviors between the sexes. NAN Ranch held the most statistically significant differences between males and females, indicating that the factors associated with the development of dental pathologies are complex and ultimately depend on site-specific dynamics.

Winemiller, Terrance [281] see McKillop, Heather
For decades, archaeologists have used replicative studies to develop a better understanding of prehistoric technology. Many replicative studies have focused on the manufacture and use of stone projectiles, resulting in a detailed understanding of the design of hunting weapons in relation to various features of the environment and, in turn, elegant explanations for technological change over time. Yet if ethnoarchaeological accounts are any indication, lithic technology was only one (perhaps minor) part of many prehistoric technological systems. It is likely, then, that the technological changes we document through a morphometric analysis of stone projectile points occurred against a backdrop of perishable technologies often not represented in the archaeological record. Here, we report on a replicative experiment designed to investigate whether we can “see” perishable projectiles in the archaeological record based on the damage they inflict on animal bones. Specifically, we examine if wood-tipped, fire-hardened, and stone-tipped arrows produce distinctive damage signatures. We use the results of our study to examine explanations offered to account for the transition from the dart to the bow and arrow in North America.

[310]  **Collecting Costa Rican and Nicaraguan Art: On the Case of Enrique Vargas Alfaro, Dealer**

In the mid-twentieth century crates full of Costa Rican antiquities made their way into the United States through the diplomatic immunity of Enrique Vargas Alfaro. Paul Clifford, then a business man in Miami and later donor and curator at the Duke University Museum of Art, purchased works from Vargas in addition to procuring his own pieces from Peru. Clifford’s friend Bill Thibadeau of Atlanta and a few of his neighbors enjoyed “block parties” to open the latest Vargas crate and then to divvy up the goodies inside. The Mayers of Dallas and later Denver also purchased pieces from Vargas. As the laws changed against such collecting efforts, some of these collectors also changed their ways, while others continued to procure new pieces and/or to defend these collecting practices. Through several decades of researching Nicaraguan and Costa Rican art (Nicaraguan pieces were often traded into Costa Rica in ancient times and interred there, coming to light in the twentieth century through looting), I am slowly uncovering more and more details about the story of how these pieces came to the United States and how this case study fits into the greater dilemma of collecting antiquities in the twenty-first century.

[8]  **Estimating Sex from Bones of the Hands and Feet: A Bioarchaeological Study of the Ancient Maya Site of Blue Creek, Belize**

For bioarchaeologists, biological sex estimation based off of skeletal indicators is a crucial element when creating a biological profile for human remains. While there are several ways for estimating sex, primarily involving examining cranial and pelvic morphology, one useful method that remains underutilized is metric analysis of bones from the hands and feet. Since males and females are sexually dimorphic, the ability to discriminate biological sex from hand and foot bones is possible and is shown to be valid. Skeletal metric data drawn from the hands and feet have successfully discriminated between male and female (bio)archaeological remains in Europe and throughout North America. Osteometric data for a Maya population from Nojol Nah in the Blue Creek region of Belize are presented to demonstrate the utility of such metrics in estimating sex. These data are useful to archaeologists or bioarchaeologists working with fragmentary or isolated remains in the field or lab.

Winterhalder, Bruce (Anthropology, UC Davis), Luis Pacheco-Cobos (Ecologia Conductual Humana, Universidad Veracruzana), Carmen Cortez (Graduate Group in Ecology, UC Davis), Estrella Chevez (Biologia, Universidad Veracruzana) and Chloe Atwater (Anthropology, UC Davis)

[162]  **The Effects in a Maya Community of School Enrollment on Young Adult Time Allocation to Activities Dependent on Traditional Ecological Knowledge**

School enrollment in traditional communities potentially compromises young peoples’ participation in agro-ecological subsistence activities that encourage the development and practice of traditional ecological knowledge (TEK). Drawing on data from a Maya community located in Toledo District, Belize, we compared the time allocated to agro-ecological activities for school going (SG) or non-school going (NSG) male and female youth between the ages of 13 and 18 years. We find that SG males spend relatively less time engaged in agro-ecological activities (compared to leisure, eating, personal hygiene, and visiting) than do NSG males. School enrollment, however, does not affect the time females devote to subsistence-related activities. Regular school attendance thus appears to have a greater effect on young men than women. As a remedy, we propose and briefly describe a field-developed, active learning curriculum for Mayan high school students focused on milpa agro-ecology and forest subsistence activities in which traditional and scientific experiences can be shared. While data on age-specific commitment to subsistence activities can help us to understand the effectiveness of the prehistoric milpa economy, we focus here on reducing contemporary conflicts between formal education and traditional ecological practices.

Wise, S. Andrew

[241]  **Midden Muddle**

Archaeologists occasionally find inconstant artifact assemblages between sites that appear similar. These variations in artifact frequency and diversity can hinder efforts to establish a one-to-one correlation between artifacts and cultural behaviors. However, coastal shell middens can provide important information regarding past habitation and social organization. By using shell and artifact distribution data, this research examines how Woodland cultures utilized coastal sites between 1000 BC to AD 1000. A comparative analysis of multiple midden assemblages from the Georgia and South Carolina coast demonstrates that there is considerable divergence at the inter-assemblage level. Close attention was paid to significant artifact patterns in the hopes of confirming a standard midden typology. Priority was given to the presence of burials and features due to their strong association with human activity and social organization. While ultimately sites are variable and cannot be forced into sterile categories, archaeologists can look at all measured variables to identify unique and helpful patterns.

Wisely, Justin (Far Western Anthropological Research Group, Inc.)

[274]  **Starch Grain Analysis of Bedrock Mortars in California: Implications to Our Understanding of California Prehistory**

Starch grain analysis is a growing field in California archaeology, with the potential to significantly add to our understanding of prehistoric peoples. Using a nondestructive extraction method for field sampling bedrock mortars, I was able to extract microscopic plant residues from the mortar surface for analysis. The subsequent identifications were made using my ethnographically-informed comparative collection of modern native plants. The results of this research indicate that the function of bedrock mortars is significantly more varied than currently assumed, and that small seed processing played a much larger role in California subsistence than previously thought.

[181]  Ungulate Bone Fat Exploitation at the Adoption of Horticulture in Western Iowa  

Fat in the form of bone marrow and/or grease is a valued resource among foragers, and is more frequently exploited during times of subsistence stress. Risk-reduction in the face of resource stress is one potential theory for why prehistoric people incorporated horticulture into existing hunting and gathering practices. During the Woodland period (2800–1350 BP), the tallgrass prairie region of western Iowa provided a rich environment where numerous prey species could be found, including bison and deer. This paper examines subsistence stress during the adoption of horticulture by focusing on evidence for the utilization of bone fat within highly ranked ungulate taxa present at a selection of Woodland period sites within western Iowa. This research provides one line of evidence from which to examine the underlying factors involved in the shift toward production economies which occurred in later prehistory.

[7]  Animal Use in Ancient Maya Terminal Deposits: Examining Faunal Remains from Sites in the Belize Valley to Identify Ritual Activities  

Zooarchaeological materials from terminal deposits in the Belize Valley have the potential to assist archaeologists with understanding if terminal deposits represent ritual activities. This poster presents the results of zooarchaeological investigations of terminal deposits at the sites of Lower Dover and Baking Pot. While archaeologists from the Belize Valley Archaeological Reconnaissance Project (BVAR) have focused on the pottery and lithic materials in these deposits a thorough comparative analysis of the faunal remains from both sites has not previously been completed. Our analysis focuses specifically on the skeletal elements and species present, evidence for worked bone or cutmarks, and taphonomic features that may assist with deciphering influences on the deposits through time. Comparing these two sites will assist with understanding if the faunal materials from terminal deposits can provide information on the use of animals in ritual activities by the Maya and to further the understanding of the purpose for terminal deposits in the region.

[192]  Soundscapes in the Past: Interaudibility in the Chacoan Built Landscape  

Sound has been a long disregarded aspect of the cultural landscape, despite being an important factor in how we, as human beings, interact with the wider world. By incorporating a consideration of sound, archaeologists can more fully understand the embodied experience explored through phenomenological approaches. In this poster, we investigate the interaudibility present within the built landscape of Chaco Canyon, using a GIS tool we have developed over the past two years. Focusing on Downtown Chaco, we present a soundscape, illustrating how events at shrines, stone circles, isolated kivas, and great houses may have been heard at other locations.

[181]  Dietary DNA Analysis of Mississippian Dog Coprolites  

Traditional methods for assessing diet of animal coprolite samples include targeted PCR and sequencing of specific genes. While useful for species identification, focusing on a single gene region disregards the plant and animal DNA fragments that are from other parts of the genome. Here we used next-generation sequencing methods to sequence DNA from coprolite samples from Terminal Late Woodland and Mississippian dogs from the Janey B. Goode site in Southern Illinois. BLAST searches were used to compare the sequenced reads to complete mitochondrial and chloroplast genomes of plants and animals. Analysis of the coprolites demonstrates that the dogs at Janey B. Goode ate an animal diet of fish, which correlates with previous zooarchaeological analyses of coprolite contents, and a more varied plant diet that included sunflowers, and, in some of the dogs, maize. The presence of maize in the diet of the dogs is significant because maize was an important part of Mississippian culture, and determining the age of the coprolites can help assess when maize arrived to southern Illinois, the timing of which has not yet been clarified. This research demonstrates that next-generation sequencing of coprolites can yield more diverse dietary information than targeted PCR methods.

[388]  Intensive Use of Wild Chenopodium by Central California Hunter-Gatherers  

Three decades of California paleoethnobotany have shown that Chenopodium is the most common small seed found in central California archaeological sites. Chenopodium is concentrated in sedentary residential communities in lowland areas, where historical population densities rivaled or exceeded those found elsewhere in the world. The most intensive use known for Chenopodium is from wetland areas of the Sacramento and Santa Clara valleys. Despite thousands of years as the preeminent small-seeded plant food and good reason to suspect active wild plant management, initial recent studies reveal no evidence of Chenopodium domestication in California.

[171]  Early Farming Communities in East Africa and the Horn: New Zooarchaeological Evidence from Mezber, Northern Ethiopia  

Animal herding formed a central component of Pre-Aksumite (>800–450 BCE) and Aksumite (450 BCE–800 CE) subsistence economies in the North Ethiopian and Eritrean highlands. Despite this, detailed understanding of animal utilization and diversity of species is lacking for this period. New data on...
species abundance and radiocarbon date from the site of Mezber in the North Ethiopian highland throws a new light on the earliest mixed farming communities in the Horn of Africa over the last 3,000 years. This rural settlement site provides faunal evidence for herd management strategies. Cattle, sheep, and goats are integrated with chickens originating from the Red Sea area. Cattle make up a high proportion of the assemblage through time. This relative high abundance of cattle indicates an environment that was stable and supported stock keeping for at least 1,000 years. The presence of a small percentage of wild animals in the Mezber assemblage shows animal husbandry that was complemented by hunting systems.

Wolf, Marc (GC CUNY)
GIS, Identity, and the Sacred Landscape
GIS techniques are no foreign to Mesoamerican studies though the hybridization of digital analytics and human identity is incomplete. In recent years suites of technologies have allowed for better visualization of data within archaeological projects. Though computer programs and higher profile data-gathering techniques have become widely embraced by the archaeological community, research should be rooted in cultural proclivities as well. By recording the complex shifts in topography via remote sensing, drafting architecture based on satellite derived data, and using excavation data to corroborate and extend data within the paradigms of computer driven analytical techniques, new patterns and questions emerge. This paper will focus on recent GNSS mapping of the archaeological site of Cancuen in the Transversal region of the interface between highlands and lowlands. The site offers a unique application and integration of GIS techniques while acknowledging the importance of the human element behind the constructed landscape.

Wolf, Sara (DOI-NPS-NMSC)
Emergency Response PTSD, Climate Change Denial, and Resiliency: The New World Disorder
Curators and conservators have been wading through water for decades to rescue museum collections after natural and man-made disasters. The urge to “fix” things that have broken seem to be rooted in our DNA. Since 2003, I have had the opportunity not only to be a part of the emergency response community, but to witness the impact of these events on responders and collections. At the same time, there has been the development of an entire museum emergency response profession, a dramatic upick in the commercial response field, and a piling-on of emergency response training. The disaster response culture also has spawned full academic programs, nearly endless analyses of motive, culture class, and emergency psychology that aim to improve our response future. Actual responses, however, appear to polarize around avoidance changes; tied to fears about climate change, or defensive actions founded on denial. In both cases, tending to be focused on “fixing,” we have incorporated the idea of building resiliency into the architecture without considering threats from the wider external environment. This presentation seeks to resolve the natural tendencies of people to express either, “it won’t happen here (again),” versus the Chicken Little Syndrome.

Wolfgang, Jesse (Stony Brook University)
More Than a Source of Data: The Benefits of Active Collaboration between Macrofaunal and Specialist Analyses at Neolithic Çatalhöyük
The faunal remains excavated by the Çatalhöyük Research Project are notoriously voluminous, making them the focus of many specialist analyses over the course of the recent project. Stable isotopic data from zooarchaeological remains have long been used to inform paleoecology and past human dietary patterns. Zooarchaeological isotopic data have increasingly been used to revolutionize our understanding of past herding strategies, particularly in early herding contexts like Neolithic Çatalhöyük. The resulting large datasets from zooarchaeological and isotopic studies at Çatalhöyük have provided crucial data for understanding characterizing past diets, herding systems, and ecologies. However, these datasets have been largely fragmented from one another by the initial structure of the Çatalhöyük Research Project and its faunal database, as well as the logistics of coordinating in-field and off-field research agendas. This paper discusses the potential for more concerted integration between stable isotopic and zooarchaeological data by demonstrating how consideration of an animal’s age and sex can help restructure stable isotopic comparisons of animal diet to reflect past herding systems. The opportunities afforded by this integration are broadly applicable and help reframe the isotopic analysis of zooarchaeological data from a source of background, ecological data toward an avenue for investigating past social dynamics.

[213] Use Wear and Standardization Analysis of Pottery from Dibaping, a Banshan Period Cemetery in Southern Gansu Province, China
Excavated in 1978, the cemetery at the site of Dibaping in southern Gansu Province, China revealed hundreds of Banshan period (2600–2300 BC) ceramic vessels. The elaborately painted geometric motifs on many of the vessels led to them quickly being touted as an example of the pinnacle of artistic achievement in Neolithic northwestern China. Aside from typology, however, no other analyses have been done on these objects. The result is that little is known about how these vessels were created, the role that they played in mortuary practices, or even if they were used before being interred. This paper will present the results of recent use wear and standardization analysis of these vessels and the effect these have on our understanding of their production, use, and deposition. These results will then be framed within our wider understanding of the benefits and limitations of use wear and standardization analysis, and our current knowledge of Banshan period production and consumption practices.

[151] Diet and Mobility in Roman and Byzantine Turkey
Isotope analyses (C, N, Sr) have been conducted on human skeletal remains (n = 150) from the Roman and Byzantine periods (ca. 133 BC–ca. 1453) from the sites of Hierapolis and Ephesos (Turkey) to characterize and compare their diet and mobility. In addition we undertook a large-scale strontium isotope-mapping project in the region, modern plant and snail samples are also used to characterize the local bioavailable strontium values in southwestern Turkey. Hierapolis and Ephesos were both major centers of spiritual and commercial activities during the Roman and Byzantine periods, and were important pilgrimage sites. This study has allowed us to be able to explore the diet and mobility patterns of residents of these sites, and also to look for isotope evidence of migrants and pilgrims. This large-scale study is ongoing and here we will present the initial results.

Woo, Katherine (University of Sydney)  
[374] Paleoeconomies in the East Alligator River Region, Australia
The East Alligator River Region has undergone considerable environmental change throughout the Pleistocene and Holocene, with changing sea levels dramatically altering the ecosystems of this region. Current archaeological models for this region indicate that people adapted their economic activities to successfully exploit these shifting environments. Mollusks have played an important role in the economic activities of these groups and often comprise large portions of the regional assemblages, but they have not been subject to in-depth studies. Detailed analyses of midden material from rockshelter sites will develop a more comprehensive understanding of the changing economic role of mollusks, both in subsistence and as a raw material for tool use. Additionally, this project will use the known biological and ecological information available for these organisms as environmental proxies, in combination with existing data, to reconstruct the past environments at these sites and to examine and build on current models of long-term human behavior and use of coastal resources. These detailed analyses of the molluskan material provides new lines of evidence enabling reexamination of preexisting models for the region.

[281] Inland, Urban vs. Coastal, Rural Salt Production in the Southern Maya Lowlands: The View from Salinas de los Nueve Cerros
Salinas de los Nueve Cerros is the only non-coastal salt source in the Maya lowlands. For over two millennia, Nueve Cerros’ residents produced massive quantities of salt that was commercialized throughout the western Maya world. Unlike the Caribbean salt works, the salt here was contained within a large urban zone. The salt works used a variety of techniques to make the finished product, boiling brine and leaching salt-laden soils as in Paynes Creek but also scraping the salt flats. Each of these activities occurred in contexts that were tightly controlled by the ruling class—the workshops were adjacent to administrative structures containing wealthy tombs and both the salt dome and the brine stream were ringed by palaces, temples, and other elite structures that marked them as restricted, elite space. While the elite did control access to the salt source and the whole production process, the public had access to large quantities of the finished product, which they were able to use to produce a variety of secondary products—salted fish and meats, leather, etc.—without any evidence of elite involvement beyond the salt itself. By focusing their efforts on controlling salt, they inserted themselves into nearly every economic activity there.

[335] The Impact of Changes during the Hohokam Classic Period on Irrigation Agriculture and Irrigation Management in the Middle Gila River Valley, Arizona
This paper examines the impact of changes during the Hohokam Classic period on the social organization of canal irrigation management along the middle Gila River in south-central Arizona. A series of important social, political, and environmental changes occurred during the Hohokam Sedentary to Classic period transition. This study examines this transition to see if it represents a hinge point in how irrigation was organized. The focus is on the irrigation organization which is the social institution that manages and assigns the roles to accomplish the tasks of managing an irrigation system. Another aspect of the study assesses how irrigation organizations are linked with the related political institutions as well as with each other. This helps to evaluate whether political leaders attained control over production or surplus from the canal systems in an effort to achieve higher sociopolitical status. The study is accomplished through an analysis of canal systems and settlement patterns at the village of Snaketown, as well as the neighboring Granite Knob, Santan, and Gila Butte canal systems and settlements. With this study, I return focus to Snaketown where Emil Haury originally defined the Hohokam cultural tradition, and reveal new insights into the prehistoric Southwest.

[85] Cautionary Tales in the Use of Captive Carnivore Tooth Mark Data
Evidence for hominin meat acquisition in the form of butchery marks on fossil animal bones dates back to at least 2.6 million years ago. With this new dietary behavior came competition between hominins and large carnivores for animal carcasses. Identifying which carnivores hominins were interacting with would allow various models of the timing and sequence of hominin and carnivore carcass to be evaluated. However, many studies of carnivore tooth marking and damage patterns are conducted with captive carnivores, without considering if captive samples are actually comparable to wild samples. We analyzed tooth pits created by captive and free-ranging lions in Kenya using a Dino-Lite microscope and found that while tooth pit sizes are similar, frequencies are different—larger groups of carnivores generally inflict more tooth pits. Therefore we advocate caution in using captive samples as models for the frequency of tooth pits inflicted by specific carnivore species. However, as the number of tooth pits may be indicative of the number of carnivores feeding on a prey animal, tooth pit frequencies may be useful for reconstructing whether social (e.g., lion, hyena) or solitary (e.g., leopard, sabertooth) carnivores were most likely responsible for tooth marks in some fossil assemblages.

[190] Ecologies of Settlement of the Community of Svalbárð, Northeast Iceland
The Archaeology of Settlement and Abandonment of Svalbárð research project has reconstructed chronologies of settlement movements on the Svalbárð estate (extreme northeast Iceland), from the ninth to the nineteenth century AD, as well as their environmental and socioecconomic contexts. Settlement expansions occurred in the tenth to thirteenth and the eighteenth to nineteenth centuries AD, interspersed with waves of widespread abandonment after ca. 1300 and 1800. Analyses of amended soils and of soil and air temperature and humidity data from sites across the estate allow assessment of the productive potential and growing season of particular farms during past climate regimes. Thereby, thresholds of viability for particular farms can be projected. Climate-driven environmental changes figure in the first phase of abandonment, but to varying degrees in individual farm sites. Landscape archaeology and zooarchaeological studies suggest that ongoing changes in herding and subsistence economies and land holding institutions were also key motivators of settlement and abandonment trends. Farms differ greatly in productive potential while soil humidity was a key variable limiting their resiliency. The enclosure of favored sites early on argues for a centralized, redistributive, pattern of land management. Finally, the anthropogenic soil “memory” of successful prior settlement favored continued settlement thereafter.

[8] Keeping It in the Family? An Investigation into the Relatedness of Individuals Found in an Ancient Maya Chultún
The ancient Maya site of Blue Creek, located in northern Belize, has revealed archaeological evidence suggesting regional occupation from the Preclassic through Terminal Classic periods. The excavation of one Late Classic group (550–830 CE), Kin Tan, by the Maya Research Project revealed a chultún containing the remains of five commingled individuals of various ages. Examination of the exposed skeletal remains revealed some commonalities in postcranial bone traits among those interred within the chultún. Data were collected on 17 cranial and postcranial nonmetric traits in order to determine whether the individuals within the Kin Tan chultún could be biologically related. Several common traits were observed (septal apertures, marginal tubercles, and suprameatal spines) in the sample, supporting the hypothesis that those individuals entombed within the Kin Tan chultún are potentially biologically related. This research helps to shed light on the mortuary rituals and funerary traditions of the occupants of Blue Creek.

Workinger, Andrew and Stacie King (Indiana University-Bloomington)

[137] Obsidian Blade Production and Husbandry in the Nejapa/Tavela Region of Oaxaca, Mexico
Studies of obsidian tool manufacture in Mesoamerica typically focus on workshops located at source areas or at the major sites controlling them. In this paper, we explore production at the periphery, from the Nejapa/Tavela region of Oaxaca located roughly midway between the sources in Central Mexico and those in the Highlands of Guatemala. Rather than the thousands of artifacts representing the byproducts and errors of a single workshop, we are forced to rely upon the handful that found their way into the general archaeological record, as both surface finds and from excavated contexts. The artifacts analyzed for this study include all 643 pieces of obsidian collected during the Nejapa/Tavela Archaeological Project. This relatively small number reflects the scarcity of the raw material, a problem which was largely overcome through careful husbandry. Local artisans learned to recover from manufacturing errors and also to craft thin and narrow blades to prolong the production life of imported cores. Scarcity is also evidenced by the small size of exhausted cores from the region, a possible indication of a handheld blade removal technique.

Worman, F. Scott (Missouri State University) and Anastasia Steffen (Valles Caldera National Preserve)

[87] Watch Out for Landslides and Gopher Holes! Using Obsidian Hydration to Measure Postdepositional Site Disturbance in the VCNP
Our study examines the potential for using obsidian hydration analyses to quantify postdepositional site disturbance. The Valles Caldera National Preserve (VCNP) in northern New Mexico comprises a diverse and dynamic mountainous landscape that people have visited regularly for millennia to access large obsidian quarries and other resources. The result is a rich archaeological record with abundant obsidian artifacts. However, that record has been altered, sometimes dramatically, by physical, biological, and cultural processes. We used standard excavation techniques along with detailed pedostratigraphic recording and clast size distribution analysis to begin investigating postdepositional processes at two large component sites in the VCNP. We then submitted hundreds of pieces of debitage for obsidian hydration analyses. The combined results provide one way to quantify the stratigraphic integrity of deposits at multiple locations at each site. In addition to illustrating the range of postdepositional alterations present, they demonstrate the effects of large-scale landscape factors such as slope and aspect. Moreover, we suggest that obsidian hydration analyses can contribute to effective resource management. Instead of emphasizing protection and/or further investigation of sites with apparently intact stratigraphy, it is possible to quantify the degree to which different locations may yield detailed information about the human past.

[140] Gomphotheres, Mastodons, and Mammoths: The Fauna from El Fin del Mundo, Sonora
El Fin del Mundo, Sonora is the only known site where Clovis artifacts have been found in association with the remains of gomphotheres (Cuvieronius sp.), dated to 11,550 ± 60 BP. Analysis of the faunal remains from the site confirms the presence of two juvenile/subadult gomphotheres (Cuvieronius sp.) found in close association with Clovis artifacts. A second bone bed located beneath the cultural layer, dated to ≤12,180 ±40 BP, contains the remains of gomphothere, mastodon, mammoth, horse, and tapir. The co-occurrence of gomphothere, mastodon, and mammoth in the same bone bed is
virtually unknown at any paleontological site other than El Fin del Mundo. Here, the implications of this association of “disharmonious” taxa are discussed in the context of terminal Pleistocene environmental change.

Probing the Nexus between Hohokam Demography and Agricultural Productivity across the Preclassic/Classic Transition
The onset of the Hohokam Classic Period witnessed the consolidation of settlements within the major river valleys of southern Arizona, a demographic reorganization that culminated after centuries of regional expansion, population growth, and cultural florescence. In the Salt River Valley, the resultant demographic packing was unprecedented and appears to have promoted environmental degradation, aggravated biological stress, and suppressed birth rates. It has been suggested that communities responded to this increased stress by intensifying their reliance on maize agriculture. We therefore use this paper to explore whether the productivity of farmland was a factor in the demographic processes associated with the Classic Period transition in the Salt River Valley. If so, we suspect populations would have massed in proximity to the most viable farmlands in the valley. To test this, we compare relevant data on soil quality around local platform mounds, the epicenters and hallmarks of Classic Period primary villages across the Hohokam World to those around ball courts, hallmarks of the Preclassic Hohokam World. Because platform mounds were products of considerable labor investment and pillars of community identity, their locations signal places where communities deliberately and strategically chose to either maintain ties or establish new land claims during the Preclassic/Classic transition.

Evolution of Iron Age to Modern Landscapes in the Benoué River Valley, Cameroon
African landscapes have undergone radical ecological transformations since agriculture was introduced and spread across the continent. In some areas, it appears that grassland was encouraged at the expense of forests and woodlands, for agriculture and to provide fodder for livestock. To this point, most of the evidence for such practices has come secondarily from ocean or swamp cores, not directly from archaeological contexts. In this paper, we present a scenario for landscape evolution and ecological conditions during the Iron Age in the Middle Benoué River Valley in northern Cameroon, using data from archaeological sites and surrounding sedimentary and edaphic environments. We evaluate evidence that anthropic mounds were strategically located to simultaneously take advantage of riparian and upland environments. Stable isotope data indicates that portions of the region rapidly transformed from woodland to grassland during the Iron Age, but upland regions were less significantly altered, despite simultaneous archaeological site construction. The introduction of new crops and land management tools over the last 200 years has continued to transform the region’s geomorphology and human ecology.

Wright, Joshua (University of Aberdeen) [25]
Three Cities in the Heartland of the Khitan Liao Empire
A wide range of Medieval settlement has been identified in the watershed of the Shar mörön river, a territory of grassland and narrow river valleys in the heartland of the nomadic Khitan and their Liao state (907–1125 CE). These settlements range from village landscapes to imperial capitals. This paper will introduce three urban settings of the Liao state: 1) A mercantile center, 2) a local administrative hub, and 3) an imperial capital city along with their immediate hinterlands. Through a synthesis of archaeological survey data, historical accounts and remote sensing we will characterize these cities, lay out some of the central questions in the study of these sites, and describe their forms and place in the larger inhabited landscapes of the Eurasian borderlands. Central questions include, to what extent were they immobile anchors in a landscape of mobile habitation? Elements of a system rigid enclosure for citizens of the empire? Monuments to the power of the Liao empire? Or one phase in a long term history of settlement in this culturally dynamic region?

Reconstructing Ancient Maya Nursing Behavior and Children’s Diets at Tikal, Guatemala
We examine the ancient Maya nursing practices and children’s diets at the archaeological metropolis of Tikal, Guatemala, through stable isotopic analysis of permanent teeth in adult skeletons. Stable carbon isotope analysis of tooth enamel permits a measure of the relative amount of carbon from maize foods in the diet, and helps track the introduction of solid foods into the children’s diet. Stable oxygen isotopes in tooth enamel reflect the sources of water that children consumed, and shed light on the duration of breastfeeding. By sampling canines, which form between birth and 4.5 years of age, and by measuring isotope ratios on microsamples of enamel from different stages of canine growth, these data bring into focus the nature of dietary change in the first few years of life. Third molars form in later childhood, between 9 and 12 years of age, giving a measure of older childhood diet in the same individuals. Here, we report on the analysis of mandibular canines from 80 Tikal skeletons, and third molars from 48 skeletons. These data provide a means to test hypotheses about differential access to nutritional resources among social groups at Tikal by examining childhood diets and nursing behavior more directly.

Wright, Rita (New York University) [177]
From Rojdi to Harappa and Beyond: Regional Variation in the Indus Civilization
Steve Weber’s pioneering research on botanical remains and environment has provided foundational studies for subsistence and settlement in the Indus civilization. Results of his field research at Harappa in the Punjab, Rojdi in Gujarat, and Farmana in Haryana focused in three key areas where major Indus centers were established. Differences in archaeobotanical remains provided a firm basis from plant remains and long-term agricultural packages in the three regions. These ranged from multi-cropping strategies that included overlapping plant usage to differences in selection of dominant crops. Although Weber emphasized their environmental differences as selective factors, his emphasis on choice as a major determinant allowed for comparisons between the early remains of the Indus civilization and recent trends in the three regions.

**Modeling Communities: Social Transformation of Early Kaushi, Taiwan**  
[208]

This paper examines the shifting boundaries and social movements within two sites, Saqacengalj and Aumagan, which exemplifies the early developments of the Kaushi people. In the light of Ingold’s “wayfaring theory” (Ingold, 2012), this research argues that interpersonal relationships are not entirely based on social identities, and social relations should also be investigated, regardless of their hierarchical status, but through intimate human interaction. Therefore, this research models human agency from a “meshworked” perspective, and demonstrates how social interactions and relations are influenced through agents walking around a settlement. This bottom-up approach allows the examination of the allocated social relations as opposed to the delegated social identity, and benefits from understanding how different communities interacted. This paper not only highlights the methodological approach of the model, but also presents the changes in settlement pattern as well as the social transformation of early Kaushi people.

**Dating the Bronze Artifacts from the Archaeological Sites along the Hexi Corridor**  
[26]

There are many bronze artifacts found from the sites located along the Hexi Corridor. The radiocarbon dates assigned to the archaeological sites do not always represent the time of the bronze artifacts from the sites. The bronze artifacts can’t be dated directly. To get the precise dates of bronze artifacts needs to understand the formation of archaeological sites and the archaeological context of the bronze artifacts with pottery and other datable remains. The good samples for radiocarbon dating are the short-life plant, bone remains and so on unearthed with clear archaeological context of bronze artifacts. Some sites were well excavated in recent years. These made it possible to get the precise dates for the archaeological sites and bronze artifacts. The ages of the bronze artifacts appeared at different locations along the Hexi Corridor will be discussed in this paper.

**Take a Knap Inside: Evidence for Lithic Activities and Behaviors in Various Pit Structure Types at a Basketmaker III Settlement in Southwest Colorado**  
[89]

Basketmaker III (AD 500–725) was a period of technological and social change for Ancestral Pueblo peoples of the northern Southwest. Along with population expansion, territorial colonization, and the development of original social institutions, Basketmaker III populations invested in a new technological complex that included potted pottery and dry-land agriculture. Lithic reduction activities are an understudied component of this social and technological complex. Our research captures a range of behaviors associated with lithic reduction and utilization at an aggregated Basketmaker III settlement located in southwest Colorado. The Dillard Site (5MT10647), occupied in the sixth century AD, is comprised of 13 pit structures that include temporary and long-term residences and a rare early Ancestral Pueblo great kiva. By examining and comparing macro- and micro-debitage and tool assemblages found on structure floors, this research demonstrates that the site’s occupants patterned their lithic reduction behavior in both public and private spaces. This resulted in specialized production areas, disposal and cleaning behaviors, and a symbolic association with lithic material.

**The Archaeobotany of Ritual: The Role of Palm (Arecaceae) in Ancient Maya Caves**  
[321]

The past several decades of research have identified caves as important loci for pre columbian and historic Maya ritual activity. To the ancient Maya, caves served as portals to the underworld, functioning as sites where ritual practitioners could be in closer contact with important deities and enact rites. The Belize River Valley has been a significant area for cave exploration and excavation, and Stela Cave in particular, located in the Cayo District in western Belize, has provided a rich source of data for understanding this ritual role of caves. The Maya utilized Stela Cave from the Late Preclassic period through the more recent historic period, and excavations yielded numerous archaeobotanical remains. Among this assemblage we have identified substantial amounts of palm wood (Arecaceae). In this presentation we discuss the archaeobotanical assemblage from Stela Cave, focusing on the role of palm and its importance in pre columbian Maya cave ritual.

**Technological Complexities of the Peopling of Eastern Beringia**  
[140]

Alaska archaeologists continue to disagree on a unified culture history. The primary point of contention surrounds the presence or absence of microblade technology in central Alaska and the meaning of the Nenana and Denali complexes. While some interpret the former as a unique manifestation representing a separate migratory population, others disagree; and, the Denali complex has become a catchall category for a variety of artifact types leading to questions over its conceptual validity. This assessment tests specific questions pertinent to the relationship between prehistoric tool use and ecotones in an attempt to explain the presence or absence of particular artifact types and land use strategies through time. It also reflects on issues caused by repeated occupations, palmiest assemblages, and other taphonomic processes that influence archaeological consensus. Results indicate separate phases in the initial colonization of Alaska and form a testable hypothesis based on functional land use properties associated with the Denali complex era in a way that distinguishes it from other early technologies in the region. The approach contributes to a long-standing discussion over subjectivity among archaeological categories and explains assemblage variability in eastern Beringia with widespread implications for interpreting the initial peopling of the Americas.

**The Inca Dogs and Their Ancestors**  
[358]

The goal of this paper is to elucidate the social role of the dog in ancient Peru as an artifact, a physical manifestation of culture, produced by humans, through archaeological and iconographic interpretation. The large numbers of dogs available for study are a neglected archaeological resource, and one
that can provide a wide variety of information on human life and cultures in ancient Peru. Through the examination of archaeological dog remains and dog iconography from differing temporal and geographic contexts, we can track changes in morphology and use to establish a database following these changes in archaeological contexts and functional differences as well. Through this research I will show that the dog in ancient Peru, through differing temporal and geographic contexts, sometimes inhabited a special place in society, conferring special status on their human owners.

Mimesis and Alterity in Classic Veracruz Ceramic Art

The relief-carved fine paste wares, figurines, and ceramic sculptures of south-central Veracruz exhibit stylistic similarities often attributed to mass production. Yet, there are few molds in the archaeological record, suggesting that replication hinges on the artist’s understanding of materials, techniques and canons of representation. Looking beyond the southern Gulf lowlands we see certain affinities between Classic Veracruz ceramic art and that of its Mesoamerican neighbors. Barbara Stark notes that ceramic resemblances can be measured on an ordinal scale distinguishing degrees of copying. Using Stark’s metrics of replication, imitation, and adaptation, this paper examines stylistic standardization and emulation both locally and interregionally.

Investigation of Incising Techniques on Jades from the Fuhao Tomb in Yinxu

During the Shang dynasty the remarkable tradition of working jades extends back to the Neolithic period. However, the duplicate or symmetrical design incised on jades is the major artistic style at that stage. The present study is based on examination of molds of tool marks on several jades unearthed from the Fuhao tomb in Yinxu by scanning electron microscopy. Our observations suggest that rotary incising wheels charged with abrasive (which is called Jieyu sand in ancient China) were used for incising the fine features and handheld tools were still being occasionally used in some details. In addition, no evidence was found for rotary sawing tools on the jades.

People in Construction: Insights from Ethnographic, Historic, and Archaeological Accounts in China

Labor recruitment and management are essential to accomplish massive public construction in ancient times, as in today. Archaeologists across the world have examined ethnographic accounts and conducted experiments to understand labor costs and organizational structure for construction and maintenance of large architectural projects. Common conclusions are that the workforce in monument construction during the pre-Iron age could have been easily recruited by non-state level polities. However, past research has overlooked the time pressure of completing the construction within a given period and the challenges from scheduling conflicts with other important activities such as farming. The research presented here examined historic and ethnographic accounts to understand the seasonal availability of laborers and the allocation strategies for laborers in historic China. In addition, the research examined the time frame of public construction and source of laborers at the Erlitou urban center, 1750–1520 BCE. The results will help archaeologists reexamine the labor management strategies in prehistoric China and worldwide.

Navigating a Shifting Landscape: Tlaxcallan Trade in the Late Postclassic

As the political landscape changed continuously in central Mexico during the Late Postclassic, polities of the region had to constantly adjust and adapt, forging new alliances and dispensing old ones. Faced with an increasingly expansive state in the Basin of Mexico, polities in the Puebla-Tlaxcala Valley likewise had to adjust accordingly. Increasingly isolated, Tlaxcallan found alternate ways to integrate into the greater Mesoamerican market system, while resisting political integration in the Triple Alliance sphere of influence. This paper assesses how Postclassic Tlaxcallan maintained this balancing act through an evaluation of ethnohistoric and archaeological evidence about the polity’s interaction with its neighbors in central Mexico by considering different models and scales of interaction between Tlaxcallan and its neighbors.

Kinship Organization Reflected in Bifurcated Settlements

The bifurcated settlements of prehistoric China indicate that their internal organization is a reflection of a kind of kinship organization akin to the moieties of South America, the phratries of North America, marriage classes of Australia, and the Xing groups of ancient China. With the emergence of clans, the Xing (姓) group system was transformed to the Zhaozu (昭穆) system.

Exotic Beads and Jar Burials: Social Elaboration in the Old Kiyayangan Village, Ifugao, Philippines

Trade and interaction are linked to the development of social ranking among premodern societies, indications for which are seen on mortuary practices, particularly on the existence of exotic burial goods. Our excavations at Old Kiyayangan Village (OKV) in the northern Philippine highlands feature in-utero and infant ceramic jar burials with associated grave goods, primarily beads. The investigations reported in this presentation looks at the relationship between both the quality and quantity of the burial beads and the juveniles they were buried with. The varied amounts per grave could indicate an expression of social ranking in Ifugao society as supported by ethnographic studies of current Ifugao social classes and heirloom beads. The presence of Chinese-style glass beads in a Philippine site suggests a network of trade between Ifugao and other Philippine or Asian polities. A comparison of the Ifugao beads to other styles of Philippine and Chinese beads can provide insight on shared cultural processes, craftsmanship, and traditions. In this study we expect to see a pattern of bead quality, quantity, and style related to juvenile jar burials. This analysis will provide a better understanding of Ifugao social practices and how it compares to other Philippine sites.

Human Adaptation and Natural Resource Usage in Prehistoric Southern Ryukyu Islands, Southwestern Japan

This study aims to discuss about the strategy of prehistoric human adaptation to the island environment, especially focus on the natural resource usage. I introduce the case of southern part of Ryukyu islands—the southwestern part of Japan archipelago, where the first long-term human settlement had occurred about 4,300 years ago. Prehistoric people in southern Ryukyu islands had a unique material culture (absence of pottery, use of giant clam shell adzes), which was dissimilar to the surrounding cultural groups, like the Jomon culture of the Japan archipelago or the Neolithic culture, which spread from Taiwan to Southeast Asia. This suggests that the prehistoric southern Ryukyu islands had been generally isolated. On the other hand, their unique material culture may relate to the geological environment of their islands. I suggest that prehistoric people developed a strategy suitable for surviving in these island environments, and improved their own material culture to adapt to a new ecology.

Ethnoarchaeological Analysis of Prehistoric Baskets from Central Japan and Basketry Techniques found at the Museum of Archaeological Research

Many ancient baskets have been excavated from the wetland sites of the Japan’s prehistoric period in the Hokuriku district, Central Japan. Sixty-five baskets have been excavated from 10 prehistoric sites and date from c. 3600 cal BC to c. cal AD 250. Also 14 impressions of basketry were found on the bottom of deep bowls from eight prehistoric sites. Two points are clear from the analysis of these basketry materials: 1) in terms of construction materials, a Inugaya (in Japanese; Cephalotaxus harringtonia), a Japanese cedar (Cryptomeria japonica), a hiba arborvitae (Thujopsis dolabrata), a silvervine (actinidia), and a tudurafuji (in Japanese; Sinomenium acutum) were used to make basketry. No baskets were made of straw, and 2) regional difference in basket materials plainly existed in prehistoric Japan, bamboo in the Tohoku and Kanto district and plant other than bamboos in the Hokuriku district. We have been using ethnographic basketry to help us understand these ancient basketry examples since these historic baskets were made with Japanese cypress, silvervine, and tudurafuji in the Hokuriku district 30 years ago. Archaeologists, who work at the museum of archaeological research of Komatsu City, have been teaching schoolchildren and the elderly how to make basketry using traditional ancient techniques.

An Archaeological Investigation into the Genetic and Dietary Histories of Dogs at the Bridge River Site, British Columbia

Domesticated dog (Canis lupus familiaris) remains have been recovered from a variety of Northwest Plateau archaeological sites, including Bridge River, a complex hunter-gatherer village on the Fraser River of British Columbia. To gain insight into the genetic continuity and dietary history of these dogs, this study applies ancient DNA techniques to dog bones and coprolites recovered from two pithouses at Bridge River. Dog mitochondrial DNA (mtDNA) is used to inform on genetic relationships between domesticated dogs at Bridge River and other ancient dog populations, both in British Columbia and worldwide. Dog diet information is gleaned from salmon mtDNA sequences recovered from both coprolites and salmon bones within the coprolites. Whole genome analysis, followed by next-generation sequencing on an Illumina MiSeq platform, shed additional light on other dietary components, as well host nuclear DNA from the coprolites.

A Middle Yangshao Cemetery of the Yangguanzhai Settlement

In order to better understand the moated settlement of Yangguanzhai (ca. 5300–4800 BP) in the Wei River Valley of China, the archaeological team surveyed east of the moated area in 2015. A large number of pit burials with side chambers were found. The cemetery is so far the first known adult cemetery of this period (Miaoqigou Phase of Yangshao Culture). Based on C14 dating and funerary goods, the cemetery is contemporaneous with the Yangguanzhai settlement. This discovery provides important data for future research on Miaoqigou settlement pattern, burial custom, social organization, and relatedness of populations at the time. The side chamber burials of Yangguanzhai date to several hundred years earlier than other known burials of this type found in western China. They can therefore provide important archaeological data for further inquiry into this burial type’s origins, as well as possible links between the ancient residents of the Wei River Valley and other groups to the west.

Yang, Miaomiao (Shaanxi Provincial Institute of Archaeology), Songmei Hu (Shaanxi Provincial Institute of Archaeology) and Weilin Wang (Shaanxi Provincial Institute of Archaeology) [279]

Faunal Remains from the Yangguanzhai Site
Over several seasons of excavation, a large quantity of faunal remains have been unearthed from the Yangguanzhai site. These remains were all collected systematically by excavation unit and have been carefully measured and identified by taxon. The analysis of these remains indicates the presence of at least 11 species, including fresh water shellfish (Unio douglasiae), pheasant, crane, dog, domestic pig, roe deer, spotted deer, red deer, and cattle. The presence of some of these species suggests that the climate was warmer and damper than in present times in the Gaoling area. The bones of dogs, pigs, and cattle account for 88.89% of the total specimens, and those of pigs are the most abundant. The presence of wild animal remains also suggests that in addition to raising domestic animals, the residents of Yangguanzhai also engaged in hunting activities.

The Emergence, Development, and Regional Differences of the Mixed Farming of Rice and Millet in the Upper and Middle Huahe River, China

In this research, flotation and starch analyses were conducted on samples from eight archaeological sites in the upper and middle HRV. The results indicate that the mixed farming of rice and millet first appeared in the later phase of the middle Neolithic in the regions of the Peiligang Culture, then developed quite rapidly in the late Neolithic (6.8–5.0 ka BP), finally becoming the main subsistence economy at the end of the Neolithic in the upper HRV. However, there are obvious differences in the emergence and development of agriculture between the middle and upper HRV. Rice farming was the only agricultural system during the middle Neolithic, lasting until the end of the Neolithic, when mixed farming appeared in the middle HRV. Furthermore, although mixed farming appeared in both the upper and middle HRV during the end of the Neolithic, the roles of rice, foxtail millet and broomcorn millet in the subsistence economy were not the same. In general, millet was more widely cultivated than rice in the upper HRV, but rice occupied the same or a slightly more prominent position in the middle HRV at the end of the Neolithic.

Follow the Women: Ceramics and Post-Fremont Ethnogenesis

The Promontory Gray ceramic type is problematic within the narrative of proto-Apacheans at the Promontory Caves: progenitor populations of Subarctic Dene did not make or use pottery. A solution to this dilemma is readily evident in both oral traditions and genetic studies that show large-scale recruitment of women into founding proto-Apachean populations. Ceramics, normally an aspect of women’s craft production, likely arrived with the women who joined them. Early dates for the peak of Promontory Culture occupation, AD 1240–1290, justify a closer comparison of Promontory ceramics to contemporary late Fremont assemblages. Given the potential for culture contact and ensuing processes of ethno genetic change, a model is presented here to distinguish among ceramic assemblages left by groups that engaged in trade or imitation, or that featured the movement of experts themselves. While some indicative learning is evident, the earliest Promontory Gray specimens demonstrate an already refined ceramic tradition. They are a departure from locally made Great Salt Lake Gray at the nearby Fremont settlement of Chournos Springs, but are often indistinguishable from calcite-tempered Uinta Gray and a highly micaceous type known as Knolls Gray. Two areas—the Uinta Basin and Gunnison Bay—are drawn into sharp focus as loci of proto-Apachean social recruitment.

Yao, Alice (University of Chicago)

Land Use and Field Ecologies in Southwest China

This paper complements prevailing studies on prehistoric domestication and agriculture with an eye toward the interrelated problem of land use and food security in south China. In ecologies characterized by monsoonal variability, rugged terrain, and dense vegetation, what are the conditions that challenge or enable the cultivation of a range of staples? Using archaeological, ethnohistorical, and ethnographic data, I examine how extensification of field practices enabled the cultivation of wet/dry crops such as millet, rice, and wheat during the Late Holocene. Management of these inter-cropped fields may have enabled adaptation to climatic variability and addressed long term issues of food security in the tropics.

Microscopic Leftovers: Exploratory Starch Grain Analysis on Ceramic Vessels from the Shangshan Culture, China.

This paper will outline trends observed in pottery technology and dietary practices of the early Holocene Shangshan Culture (11,400 to 8400 cal. BP) in the lower Yangtze Valley, China. The Shangshan people produced some of the earliest known fine ware, and it is hypothesized that communities engaged in the low-level production of rice, which began the process of domesticating this crucial cereal. To date, the nature of pottery use and rice consumption at Shangshan sites remains partially understood, but with the application of residue analysis it is possible to examine the microscopic remains of storage and cooking vessels. Therefore, being currently explored, Shangshan pottery technology through the lens of culinary practices and diet using starch grain analysis has proven particularly useful in subsistence studies of poorly or rarely preserved species. In addition to evidence for rice consumption, we are interested in elaborating on the variety of plant species being processed, and if any patterns exist in the use of particular vessel types.

The Ottoman Rule of Athens and How it Shaped the Topography of the Acropolis

This poster will discuss the topographical changes of the Athenian Acropolis and how it affected the city’s identity. The Acropolis is an iconic monument defining Athens as a city. It was erected in Preclassical times, and has been the center of religious festivals and the city itself ever since. In 1453 the Ottoman Turks conquered Athens and made it their own. Most monuments, including the Acropolis, were altered to fit the Turkish lifestyle, giving the monuments a different function than the glorified Classical period. This was horrific for the Athenians because they viewed the Classical times as a Golden era, and did not want to see it fade. All churches were turned into mosques, Turks became neighbors to Athenians, and most importantly, Christians were not allowed on the Acropolis. Today, tourists can visit the Acropolis and see the changes made during the Turkish rule. The easiest to
spot is the caved-in roof and destroyed wall of the Parthenon. Due to its significant influence on the city, I’ve chosen to focus on the three main monuments on the Acropolis; the Parthenon, the Erechtheion, and the Propylaea. I will discuss the changes made and how the effects were felt throughout Athens.

Yellen, John (National Science Foundation) [70] The Framework for National Science Foundation Funding of Archaeological Research
National Science Foundation funding for archaeological research is driven by several factors some internal and others external to NSF. The Foundation is an agency of the federal government and the amount of money authorized for expenditure and strictures on how it is to be allocated is determined by a multifaceted process which involves the Foundation itself, the President and multiple House and Senate congressional committees. Thus for each annual budget appropriation cycle, uncertainty is involved. The Foundation itself has then considerable leeway in the competitions held and the amounts allocated to individual Programs. While archaeology receives support through multiple sources within NSF the Archaeology Program constitutes the focal point and data indicate a stable funding base over many years. If the past is any predictor of the future, one might expect the pattern to continue. NSF criteria require proposal evaluation to take into account both “intellectual merit” and “broader impacts,” the latter of which is defined as “benefit society or advance desired social outcomes.” The hope is that the current framework is both well enough established and appropriately designed for a stable future.

The Digital Index of North American Archaeology (DINAA) is expanding from its initial proof-of-concept phase, scaling to a truly continental effort. As a linked open data hub for information related to archaeological sites, DINAA interoperates governmental, research, and archival information sets about hundreds of thousands of archaeological sites. Although DINAA links archaeological information at a scale that was not feasible even a decade ago, its greater strengths come from a commitment to open data and open-source ethics, collaboration, and multi-stakeholder partnerships. DINAA’s loose coupling of networked information forms an index through which archaeological researchers as well as the public can communicate and query disciplinary knowledge about the past, making archived data, physical collections, and documentation more readily discoverable through spatial, temporal, and cultural contexts. The project also aims to support the heritage management efforts of sovereign Tribal and other government officials. This poster reports on the current state of DINAA, highlighting current work supported by both the Institute for Museum and Library Services (IMLS) and the National Science Foundation (NSF). The poster illustrates methods to network archaeological data on a continental scale, and highlights some of the successes in building a database “by community” instead of “by committee.”

Yerkes, Richard (Ohio State University), Attila Gyucha (Field Museum, Chicago, USA) and William Parkinson (Field Museum, Chicago, USA) [178] Social Dynamics and Archaeological Sciences at Neolithic Tells: Investigations on the Great Hungarian Plain by the Körös Regional Archaeological Project
Investigation of social dynamics at Neolithic tells, Szeghalom-Kovácshalom and Vésztő-Mágor, Hungary, included surface collection, geophysical and geochemical surveys, targeted excavations, micromorphology, stable isotope studies, compositional analysis, and contextual analysis of 14C dates, cultural materials, and burials. Both sites were established ca. 5200 BC, cal., and they are located on the same branch of the Sebes-Körös River, seven km apart. However, they have different dimensions and settlement layouts. At Szeghalom-Kovácshalom a 60 ha nucleated settlement complex surrounds a small tell. The larger Vésztő-Mágor tell was enclosed by encircling ditches, but there is no adjacent flat settlement. Spatial analysis using GIS documented rapid horizontal settlement expansion ca. 4800 BC, cal., while micromorphological studies and calibrated 14C dates revealed rapid vertical growth at both tells. Archaeometric and contextual analysis provided vital data used to examine the archaeological correlates of social complexity. There was some evidence for social differentiation and for ritual activities led by emerging elites. However, this first occurrence of population nucleation did not lead to institutionalized hereditary inequality and powerful rulers at the tells. On the Great Hungarian Plain, this occurred during the Bronze Age. Nonetheless, population nucleation did contribute to the emergence of new ideas about sociopolitical organization.

Yeshurun, Reuven (University of Haifa) and Melinda Zeder (Smithsonian Institution) [340] Fox Overabundance and Human Response in the Earliest Villages of the Near East
Ethological and ecological studies point to the proliferation of small mammalian carnivores, most notably red fox (Vulpes vulpes), in human-modified environments. Foxes prey on human trash and consequently their populations in and around settlements are denser, their survival rate is improved and their foraging territories contract, centering on refuse dumps. This carnivore overabundance leads to a series of effects on the local ecosystems. The foxes’ strong commensal relationship with humans highlights the unintentional but highly effective alteration of the ecosystem by human communities. Here we investigate archaeologically when and how the impact of human settlement refuse started to significantly affect the local fox populations. We also examine humans’ response to this phenomenon. Fox overabundance and commensalism are evident as early as the first permanent hunter-gatherer settlements appear in the Near East, ca. 15,000 years ago, preceding the appearance of agricultural villages. We demonstrate that subsequently, humans habitually used foxes as resource. Thus, terminal Pleistocene and early Holocene hunter-gatherers unintentionally created an overabundance of foxes and then managed to use this side effect of sedentism to their favor, by including foxes in their broadening subsistence base.

Alaskan Game Drives: An Architectural Assessment
Ethnographic accounts of communal hunting activities in Alaska are abundant, yet archaeological evidence of this practice is scarce. The inuksuit—elaborate stacked rock cairns—that demarcate many game drives in Alaska provide evidence of these important traditional subsistence strategies. Improved documentation of these features will facilitate a better understanding of not only their function but their meaning to the original builders and implementers of game drive systems. Comprehensive investigation of game drive sites and spatial analyses of their features point to patterns that reflect local landscape use and broader regional trends.

[14] Further Defining the Role of the Forensic Archaeologist
As the use of archaeologists in forensic matters grows, it is important to define the role the archaeologist ought to play in such situations. Archaeologists should educate law enforcement personnel as to their utility in investigations. It is important that archaeologists understand their usefulness in criminal matters, and even more importantly, archaeologists should understand their limitations in investigations. There is a need to establish guidelines as to what archaeologists should/should not do while involved in criminal cases. It is also important to attempt to separate the roles of the forensic archaeologist and the forensic anthropologist. It appears that many, including practitioners in both fields, do not know where to limit the roles of each. A discussion of these matters will further the progression of the field of forensic archaeology.

Younie, Angela (Far Western Anthropological Research Group), Jack Meyer (Far Western Anthropological Research Group) and Brian Byrd (Far Western Anthropological Research Group)
[294] Mound-Building, Site Structure, and Land-Use Patterns in the Sacramento-San Joaquin Delta
Mound sites are a notable characteristic of mid- to late-Holocene occupation throughout the Central California. Most recent archaeological research on the region’s mounds has focused on the their dense clustering along the San Francisco Bay margins; in contrast, much less attention has been focused on the mounds of the adjacent Sacramento-San Joaquin River Delta. Although often grouped together, few systematic studies have been undertaken to evaluate differing site patterning, the structure of mortuary practices versus residential activities, and the impact of local landscape features on the distribution and visibility of mounded middens. Mounds along the San Francisco Bay are often considered to occur in clusters complete with densely-deposited shell and earth mounds, non-mounded cemeteries, and petroglyphs. Although of a similar age, mound sites in the productive but otherwise marshy mosaic of streams and wetlands in the Delta region appear to have differing structural signatures. Naturally formed relict sand dunes provided viable dry land for habitation and were repeatedly occupied over time. Though geoarchaeological modeling and exploration of site structure, our research focuses on the Hotchkiss cluster of dune-mounds in the South Delta, and then applies these results to a broader consideration of dune-mound patterning throughout the Delta.

[116] Study on the Subsistence of Neolithic and Early Bronze Age China Using Published Mammal Records
This research is based on all published zooarchaeological study on Chinese Neolithic and Early Neolithic sites and mainly focuses on the animal subsistence economy in the same period. With the advent of quantitative analysis, refined models can now be built and analyzed from all the published data. The application of big data studies on animal remains provided information of range and relative importance of taxa and their possible change through time-scale and region which may reflect an ancient environment around sites, subsistence economy of ancient people as well as consumption patterns within sites which can be used to evaluate the relative importance of animals in the diets obtained through various subsistence strategies. At the same time, animal origins and dispersal can also be traced, which may help to understand the antiquity of changes related to domestication.

Yu, Pei-Lin (Boise State University)
[208] Behavioral Ecology of Neolithic Transformations in Taiwan: Ceramics and Settlements
Six thousand years ago, encounters between Paleolithic Taiwanese foragers and seafaring farmers of Mainland China ushered in a new agricultural lifestyle. Two hallmarks of the early Taiwanese Neolithic are sedentary settlements and red cord-marked ceramic wares. How quickly did foragers adopt these cultural traits? Did they adopt them together or separately? Archaeological data from the Neolithic transition is scarce, but ethnographic information suggests the rate of change is affected by considerations of costs and benefits compared to the existing lifeway. This paper uses projections from Lewis Binford’s Hunter-Gatherer database to offers hypothetical predictions for mobility and subsistence of Taiwan’s Paleolithic foragers, and the tempo and mode of adoption of ceramic technology and sedentized living.

Sounds in Context: Musical Instruments from Teotihuacán

In this paper we present the advances in the organological, acoustic and contextual analysis of musical instruments excavated by Dr. Linda Manzanilla in the sectors of Teopancaczo, Oztoyahualco, Tunnels, and Xalla, all of them located in the archaeological site of Teotihuacán. These instruments were part of a complex system of sound communication that often accompanied the rituals and daily activities. We propose some interpretations on the use of certain instruments and their relationship with other materials excavated in the same context.

Precolumbian Huastec Metallurgy

Although the Huasteca may have had an important role in the emergence and development of metallurgy in Precolumbian Mesoamerica, little has been published, apart from Dorothy Hosler and Guy Stresser-Péan’s short study on Huastec metallurgy (1992). They proposed that the Huasteca was second earliest region in Mesoamerica after West Mexico to produce bronze alloys artifacts during the Postclassic period. Their research positions the Huasteca as an early adopter and innovator of this technology. We follow up on this early important research by reviewing the known corpus of metal artifacts from the Huasteca ranging from copper alloys, silver, and gold objects and by investigating the possible relationship between the Huasteca and mining centers, such as Guadalcazar, and other metal-working regions, such as Guerrero and the American Southeast to identify patterns of technological exchange. We also analyze the representations of Huastec metal objects in precolumbian and Early Colonial artworks to illustrate how metal objects were used and to gain insight into stylistic interchange between the Huasteca and other parts of Mesoamerica. We argue that the analysis of Huastec metal objects confirms that the region was deeply integrated in Mesoamerican exchange networks and that it developed local technical and artistic innovations in metal.

Perceptions of Changing Landscape Mosaics in Southern Belize

What drives human uncertainty when confronting gradual change versus catastrophic, rapid change? Based on longitudinal ethnographic data that includes household behavioral observations, oral histories and structured survey interviews of land use change, and continuous participant observation data, we describe the ways farming families in southern Belize have responded to changing environments over time, within the context of a mosaic of livelihood strategies. Ethnographic interviews with community members focused on their perceptions of environmental change over their lifetimes and responses to agricultural uncertainty from drought, hurricanes, or other events. These are juxtaposed with ongoing political conflict with nation state and other actors over heritage and identity, territory, and misperceptions of land use practices since the 1980s in southern Belize. We consider the following questions in our paper: How did Maya farmers, their institutions, and the landscape itself respond to a changing environment? What does this suggest about future resilience in the face of predicted future climate changes?

Zaro, Gregory (University of Maine), Martina Celhar (University of Zadar), Kenneth Nystrom (State University of New York at New Paltz), Dario Vujevic (University of Zadar) and Karla Gusar (University of Zadar)
ancient cityscapes with long occupational histories have great potential for reconstructing changes in social structure, spatial planning, political governance, identity, economy, environment, and climate. Recovering such information, however, poses many challenges, both human and financial. Archaeological deposits are often deeply buried and palimpsestic, representing a complex mixture of processes including collapse, partial abandonment, repurposing, and reoccupation. Yet, anthropological inquiry into human societal organization and its coevolution with the physical world demands that archaeologists sort out occupational history and changes in the built environment with some degree of chronological precision. Such are the challenges, and opportunities, at the Nadin-Gradina archaeological site in coastal Croatia, where ongoing fieldwork is beginning to define the temporal parameters of its construction and evolution over the course of approximately 2,500 years—from a Liburnian hill fort in the first millennium BCE to an Ottoman frontier settlement in the sixteenth and seventeenth centuries. The results permit a series of more robust anthropological questions related to human response and adaptation to urbanization, landscape change, and climate over a span of centuries to millennia, while also opening the door to questions of cultural identity, colonization, and migration.

Zarrillo, Sonia (University of Calgary)

Genetic studies suggest that cacao (Theobroma cacao L.) domestication occurred in the Upper Amazon of southeastern Ecuador and northeastern Peru and was then transported by humans northward to Central America and Mexico. As such, we should expect to find the earliest archaeological evidence of cacao use in the tropical forests of South America. This paper presents starch granule evidence for the early use of cacao from the Upper Amazon site of Santa Ana-La Florida during the Ecuadorian Early Formative Period.

Zatorski, Jezelle (Stantec Consulting Ltd.) and Keli Watson (Crossroads CRM)

Culturally Modified Trees (CMTs) in the Central Interior of British Columbia are well-known and extensively documented. While there are several types of CMTs, the most common in the interior, by far, are barked stripped Lodgepole Pine for the purpose of cambium collection as a food resource. The majority of the discussion and analysis of CMTs is field-based and primarily focuses on scar identification to determine cultural origin, dating methods, mapping and describing locales where large numbers of CMTs are found in mass quantity. What has been lacking is an attempt to consider these CMT sites as an integral part of the cultural landscape of Central Interior First Nations. In this paper we will explore the potential use of geospatial data to examine CMT sites in terms of regional distribution and land use patterns. The Carrier Nations in the Central Interior of British Columbia are known to have followed a seasonal round, focusing on different resources in different parts of their landscape at different times of the year. Cambium collection is an important, and overlooked, part of their holistic interaction and understanding of their surrounding landscape.

Zavala, Bridget M. (Universidad Juarez del Estado de Durango)

Many archaeologists have recorded plazas, altars, and rock art in Durango’s prehispanic landscapes. These spaces are often characterized as settings for ritual activities. Nevertheless, few researchers have posited the kinds of activities that were carried out in these spaces. In this paper I analyze data from excavation of the sites of Corral de Piedra and Los Berros in the Sextin valley in northern Durango, Mexico. The materials, architecture and spatial distribution suggest a variety of different ritual actions that made these spaces meaningful to the agents that built these locales. I consider recent ethnographic work among contemporary groups in the region to illustrate the modern-day use of analogous spaces in search for meaningful interpretations of specialized features in the precolombian past.

Zavodny, Emily (Penn State University) and Sarah B. McClure (Penn State University)

Here we present results from a preliminary stable isotope and zooarchaeology study of cattle from the Lika region of northern Croatia. During routine investigation of Bronze and Iron Age faunal assemblages, we identified bones belonging to a small unspecified cattle breed. These same specimens also have unexpected stable carbon and nitrogen isotope signatures, and are more similar to both domesticated and wild browsers than grazing cattle in other regions. We argue that these adaptations were exploited and encouraged by local populations, who adopted these cattle as part of a larger economic strategy tailored to the harsh and unpredictable environment of Lika. We conclude with a brief overview of the modern buša cattle, the most likely successor to our specimens and a heritage breed that is still raised in Lika today.

Zawadzka, Dagmara (Université du Québec à Montréal [UQAM])

Perceptions of self and of personhood are fluid within anemic ontologies that tend to stress spiritual similarities between humans and nonhumans. This fluidity is reflected in concepts of bodies. Bodies endow their owners with particular qualities, perceptual skills, behaviors and ultimately, identities. Beings can transform their bodily appearance, therefore what is perceived by an onlooker does not necessarily correspond to the being that is perceived. In the Canadian Shield, depictions of anthropomorphic bodies range from simple schematic stick figures to elaborate idiosyncratic images where clothing and facial features are indicated. Bodies are also evoked in images of heads, hands and probable vulvas. In this paper I will attempt to shed light on how embodiment was enmeshed within rock art by looking at bodily experiences depicted in rock art; at the effects that rock art could have had on living bodies; and at the importance of the kinetic process of creating rock art for upholding relationships with other-than-human persons. The experiences and motivations that led to the creation of rock art, as well as the process itself, ultimately reveal the agency of rock art.

Two Figurines and a Conquest: Toltec and Aztec Warriors in the Sierra Sur of Oaxaca?

In this talk I will present a contextual and iconographic analysis of two unusual, yet almost identical, figurines of lavishly dressed warriors, reported from different sites in the Chontal Highlands of Oaxaca. While variations on mold-made solid figurines of armed individuals were common in Late Classic Oaxaca, the particular attributes of these figurines are more analogous to militaristic iconography emerging from Postclassic Central Mexico. Taking the figurines’ iconography and regional historical documents as a point of departure, I will evaluate possible scenarios for both Toltec and Aztec geopolitical interventions in the region. Finally, I will argue that these new data paint the eastern Sierra Sur not as the geographical obstacle it may have appeared in the recent past, but rather as a highly-traveled and coveted bridge between the Isthmus, the highlands, and the coastal regions of southern Mexico.

Cooperation and Order among Communal Bison Hunters

This paper discusses the trajectories and intersections of cooperative practices and ordering strategies among prehistoric communal bison hunters. Utilizing the vast and ancient record of bison hunting in the region and particularly in Montana, the paper specifically focuses on the rise of large-scale bison harvests in the northwestern Plains of North America, and the effect of hunting technology on social cooperation at various scales (kin, band, supra-band). As well, the paper delves on the institution of strategies for managing the success of surplus production for consumption, storage, and exchange. The equally vast historic and ethnographic records of bison hunters in the region are tapped to unpack the role of gender in the structure of individual, kin, and non-kin cooperative practices and ordering strategies along the economic, ritual, and political realms of social life.

Archaeological Ethnography for a Decolonizing Methodology in the Central Highlands of Peru

Ethnographic research is herein demonstrated to contribute a crucially important initial step in the reconstruction of indigenous histories and to building a praxis of collaborative archaeology. Ethnographic research was conducted during two field seasons in 2015 and 2016 in and around the sprawling ruins of the capital city of the Wari Empire in the central highlands of Peru to reach an understanding of the contemporary cultural idiosyncrasies pertinent to the Peruvian historical context. Collaborative archaeology has made great strides to address issues of the colonial embeddedness of archaeology, the decolonization of our discipline, and the social integration of descendant communities in prehistoric cultural research in the recent past. As a result, the discipline of archaeology has begun to adopt research methods that integrate native populations at every stage of the research in order to address these differences that split history into two parts in settler nations. However, multi-scalar ethnographic research prior to attempting collaborative ventures have not yet been fully adopted by most researchers and it is the purpose of this presentation to demonstrate their validity and relevancy to establishing mutually beneficial, rather than need- or guilt-based, relationships for the protection and preservation of archaeological sites.

Animal Imagery and the Mythic Level of Jama-Coaque Figural Style

The mythological and iconographic analyses of Peter G. Roe have made seminal contributions to our understanding of Amerindian cosmology and religious thought in South America, both in the ethnographic present and in the prehispanic past. His unitary mythic model set forth in the Cosmic Zygote (1982) and explored in subsequent publications has convincingly demonstrated that this quintessentially Amazonian model has “deep-time” attributes that shed interpretive light on iconographic representations expressed in prehispanic Central Andean cultures such as Chavín and Moche. Less certain is its applicability to ceramic figural styles and iconographic representations found in post-Formative coastal Ecuadorian cultures such as Jama-Coaque where a particularly rich assemblage of human, plant, and animal imagery is found, albeit from looted artifacts now curated in national museums. This paper explores the iconographic interpretations of Andrés Gutiérrez Usillos (2011) in his impressive compendium of Jama-Coaque figural sculpture from the Banco Central museum collections entitled El Eje del Universo: Chamanes, sacerdotes y religiosidad en la cultura Jama-Coaque del Ecuador Prehispánico. Roe’s mythic model is then brought to bear on this body of work to determine whether the model can provide an alternative interpretation of these Jama-Coaque “gods and mythic beings” expressed in ceramic sculpture.

A Diachronic Interdisciplinary View of Maya Foodways

This paper reviews archaeological, iconographic, epigraphic, and linguistic evidence for Maya foodways, documenting both the remarkable stability of some traditions and the equally significant changes in others, mostly due to cultural contact, civilizational rupture, and generational shift during some two millennia of Maya history. Although hardly a frequent topic of Maya monumentality, with a few notable exceptions, numerous ceramic vessels, murals, and graffiti depict and/or hieroglyphically reference Classic comestibles and beverages, and modern Mayan languages share numerous terms for these items, suggesting a long antiquity for various foods and drinks. Similarly, archaeologists have long documented the instruments and places of consumption, and have had surprising success in recent years in the direct chemical identification of ancient foodstuffs. Less clear has been the social settings for which various foods were considered appropriate: legacies of several periods of contact with Central Mexican culinary traditions (in the Early Classic and Postclassic periods), and the wholesale transformation of the royal court and its cuisine in the wake of a disastrous early ninth century civilizational collapse. And yet, surprising details about the dynamic social and political roles of food emerge if one takes a diachronic view informed by evidence from several distinct but complementary disciplines.

Zeng, Lingyi (Yale University)
EDXRF Analysis on Ceramics during the Mongol Period in China

In this paper I will present the results from analyzing and comparing ceramics from multiple contexts, including ceramic production centers, burials and residential areas during the Mongol period. I adopted Energy-Dispersive X-ray fluorescence (EDXRF), a very effective and nondestructive way to analyze the chemical compositions of their pastes, glazes and pigments of samples from Jingdezhen, Inner Mongolia, and other areas of the Mongol Empire. Other scientific techniques and statistic methods also applied to analyze the provenances of them and to distinguish the official wares from wares intended for commercial use. My research not only focused on how objects were produced, consumed and exchanged, but also attempted to understand the underlying sociopolitical factors that affected these processes over time and space, which I believe will contribute to the understanding of this multiethnic society.

From a Strategic Passage to a Remote Town: The Status Change of Dunhuang in the History of China and West Communication Reflected from the Beacon Ruins in Dunhuang

Silk Road played an important role in the ancient China and West communication. Dunhuang is located in the most western part of the Hexi Corridor, which is a valley between Qilian Mountain and Beishan Mountain. It connects the countries of the Middle Asia, Europe and Africa in west and the East Asia in East. Beacon ruin is the most important type among the archaeological ruins, and played a key role in protecting the Northwest frontier and the Silk Road accessibility. Among the 182 ruins of Dunhuang found in the third cultural relics general investigation in China, there are 76 beacon ruins (some were used in multi-dynasties), including 44 beacon ruins dated to Han Dynasty, 15 dated to Jin, and 18 dated to Qing. The different beacon ruins number reflects the status change of Dunhuang in the History of China and West communication.

Prehistoric Human Adaptation to Tibetan Plateau Environment Indicated by 151 site in the Qinghai Lake Basin

Current study indicates that Northeastern Tibetan Plateau (NETP) is one of the first widely occupied places by prehistoric people on the Tibetan Plateau. This makes NETP very important to understand the human history on the plateau and human adaptation to high elevation environment. Hence, 151 site, a paleo- to Epi-Paleolithic site in the Qinghai Lake basin on NETP, was chosen to excavate. Thousands pieces of animal bones, hundreds pieces of stone artifacts and several possible hearths were unearthed and obtained during two excavation seasons. Carefully redating of the site shows that it was first occupied shortly around 15 ka BP, then reoccupied from 9000–6000 BP more intensely. Preliminary study of the site suggests that the first appearance of human in Qinghai Lake basin is closely related to the amelioration of the Last Deglaciation and the prevalence of microlithic technology in North China, which may enlighten the study of early human migration on to whole plateau.

Zhang, Guowen (Department of Archaeology and Museology, Nankai University)

Carbon and Nitrogen Isotopic Analysis on Human and Animal Bones of Nanwa Site, Henan Province, China

The Nanwa site (1680 BC) Song Dynasty; located in Dengfeng city, Henan Province, China, provided a valuable opportunity for the Xia Dynasty and the Chinese civilization investigation. We could provide effective evidence for the food resources utilize pattern and agricultural economy development. Stable isotopic carbon, nitrogen analysis of 14 animals and 22 human bone collagen from the Nanwa site indicated that, wild animals (–19.9‰, 4.4‰, n = 1) have a C3-based terrestrial diet. Domesticated pigs (–7.6±0.6‰, 6.2±0.4‰, n = 7) have a diet of predominated C4-based foods, as well as the sheep (–6.9‰, 6.2‰, n = 1), cattle (–9.0‰, 7.8‰, n = 1), and dog (–6.6±0.5‰, 6.9±0.3‰, n = 2), which is likely obtained from human feeding. The δ13C and δ15N value of the human from the Erlitou, Later Shang and to spring and autumn period is –12.1±4.1‰, –11.6±1.3‰, –7.5±4.9‰ and 5.5±1.3‰, 6.8±0.3‰, 6.8±0.9‰, indicated that they mainly relied on C4 foods, probably millet or few animals fed on C4 plants. We also found that the Nanwa of the Erlitou to Late Shang Dynasty had consumed few C3 foods, which indicated a mixed agricultural economy, probably supplied by rice, beans, and wheat. Compared to other archaeological culture people, the Nanwa had a different animal husbandry and agricultural economy pattern.

Zhang, Hua (Simon Fraser University)

Osteoarthritis, Labor Division, and Occupational Specialization of the Late Shang China: Insights from Yinxu (ca. 1250–1046 BC)

This study investigates the prevalence of osteoarthritis of commoners at Yinxu, the last capital of the Late Shang dynasty (ca. 1250–1046 BC), to study lifeways and stress of early urban populations in ancient China. A total of 197 adult skeletal human remains from five sites were analyzed to examine eight joints of upper and lower limbs in addition to three indicators of spinal osseous changes. The clear sex difference of elevated osteoarthritis prevalence in males indicates a strong gender division of labor. In addition, the distinctive osteoarthritis pattern of higher upper limb/body osteoarthritis reveals possible occupational specialization that involves repetitive lifting and carrying heavy-weight objects. When archaeological contexts are incorporated, the skeletal population from the Xiaomintun site with this distinctive pattern can be identified as a bronze-casting artisan group. Relatively higher osteoarthritis of the Xiaomintun females when compared with the specialist females may also suggest that those women might also have participated in bronze-casting workshop activities. Such a family-involved occupation, if it existed, may have contributed to the establishment of lineage-based and occupation-oriented neighborhoods as proposed by many Shang archaeologists.

New Archaeological Evidence of Prehistoric Cultural Interactions in the Middle of Han River Valley, Central China

During 2007–2009, the Gouwan Site in Xichuan County, Henan province, was excavated by archaeologists from Department of Archaeology, Zhengzhou University. Located in the middle of Han River valley, the site represents prehistoric cultural manifestations of Yangshao, Quijialing, Shijiahe and Wangwan III in their four developmental sequences although remains of the earliest Yangshao are the most abundant. While the Yangshao and Wangwan III were part of north cultural system in the Central Plains, Quijialing and Shijiahe Culture were of the South China cultural representations. The important part of this archaeological discovery is to have different cultural elements from both north and south regions at the Gouwan site. Furthermore, trenched settlement of Yangshao in middle Han River valley was identified at the site for the first time. This feature, along data resulted from other relatively clear spatial analyses provided a case study of regional micro settlement patterns and their social changes. Therefore, these new data derived from the Gouwan site provide new archaeological evidence of prehistoric cultural interactions in the middle of Han River valley.

Investigating the Diet and Health of Neolithic Boar in Central Turkey: A Pilot Study from Boncuklu Höyük

Boncuklu Höyük (the ninth millennium to the eighth millennium cal. BC) is an Early Neolithic settlement found in the Konya Plain, Central Anatolia. At this site, wild boar (Sus scrofa) is the most common species found in the mammal remains. This pilot study tries to explore the relationship between Boncuklu boar and the community that inhabited this area. Samples of archaeological boar’s teeth from Boncuklu Höyük are analyzed using three methods: 1) dental morphometrics, 2) dental microwear analysis, and 3) Linear Enamel Hypoplasia, of which dental microwear analysis is the focus in this initial study. These methods allow insights into the diet and health condition of Boncuklu boar. As omnivores, boar have potential to compete with humans for food. Especially, the initial cultivation of crops in Boncuklu probably aggravated this competitive relationship. It is likely that intensive boar hunting aimed to control their population, while no evidence shows they were closely managed by humans. The study of Boncuklu boar potentially reveals the subsistence strategy of the Boncuklu community and the early pig domestication in Central Anatolia.

Zhang, Quan

The Landscape of China’s Participation in the Bronze Age Eurasian Network

In the last decade, much has been learned about the network of interaction between Bronze Age Eurasia, and the importance of the steppe pastoralists in the creation of this network. However, the mechanisms that enabled societies in ancient China (both those bordering on and distant from the steppe) to participate in the Bronze Age Eurasian arena are still poorly understood. Based on the latest archaeological discoveries in China, this article focuses on the participation of four regions of ancient China: the Ejin River Transfer Zone (ERTZ); the western Hexi corridor; central Inner Mongolia; and the middle Yellow River valley. The article analyzed all significant innovations, materials, and technologies transmitted via the Eurasian network and adopted in ancient China, with an emphasis on metallurgy and the variations in the mechanism of its adoption across different societies during the Bronze Age.

The Emergence of Blade Industry in Late Upper Paleolithic Central Plain of China

The lithic remains of blade manufacturing have been found in the Central China Plain dating to roughly 25 ka BP. Based on chaîne opératoire analysis of lithic assemblages from Dongshi and Xishi sites, the blade industry in this region shared many features in common with typical blade industries of Western Eurasia. Such discovery challenges the presumption that the hinterland of East Asia lacked the development of blade industrialization during the Paleolithic age. The emergence of blade crafting reflects a great change in technical tradition in North China and begs the question of whether this change was caused by cultural transmission from the north and west or whether it was stimulated by a shift in local adaptive strategy. By comparing the lithic assemblages in larger temporal and spatial frames, as well as by exploring the technical organization of blade manufacturing in the Central China Plain, it is argued that the emergence of the typical blade industry in this region was influenced more by cultural transmissions from the Eurasian Steppe. Additionally, environment changes of the Central China Plain at 25 ka BP created a positive condition for the local people to accept this new technology and reform it in later periods.

[116] Ancient DNA Studies of Domesticated Cattle in Northern China

This study aims to use ancient DNA techniques to characterize the genetic features of ancient domesticated cattle in order to trace the origin and spread of cattle in ancient China from eight Late Neolithic and Bronze Age sites in Northern China. DNA was successfully extracted from ancient cattle bone or tooth samples in dedicated ancient DNA labs following rigorous protocols for contamination controls. This study was focused on amplifying mitochondrial D-loop using standard PCR techniques. Among the obtained mtDNA sequences, several haplogroups could be identified including haplogroup C, which belongs to Bos primigenius. Our analysis indicated that there were different ways cattle might have been brought into China. In addition, this study also demonstrated the unique contribution that ancient DNA analysis can make, when combined with archaeological contexts, to our understanding of the origin and history of domesticated animals and to the reconstruction of human-animal interactions in the past.

Zhao, Yichao (Shandong Institute of Cultural Relics and Archaeology)

[213] Use-Wear Analysis on Cooking Vessels of the Longshan Culture: Case Studies on the Tonglin Site

Some preliminary research on ceramic vessels of the Longshan culture had indicated li vessels as the most important type of cooking vessels. Vessel’s categories might not exclusively indicate a vessel type. As was observed for the Tonglin site, an important site of Longshan culture at Linzi, li, guan, and pen vessels are the most abundant categories type. However, li vessels of Tonglin site have small rim diameter sizes on average, and it is necessary to collaborate use-wear analysis for defining li, guan, and pen vessel type. It is confined to the double handled guan and the three-legged pen with use-wear marks, which indicate possible specifically used for cooking practices. Moreover, use-wear analysis performed on ceramic vessels shows that the main difference between li, guan, and pen vessels was a mix of dry or wet cooking modes.

Zhao, Yongsheng (Shandong University), Wen Zeng (Shandong University) and Shangwu Jiang (Shandong University)

[115] A Study of Kneeling Facet Observed on Bronze Age Human Skeletons Excavated in North China

The kneeling facet is formed on the metatarsal heads because of perpetual kneeling over a long period of time. It was observed in several sites in China. We analyzed the metatarsals of individuals of the Bronze Age from four sites in Shandong Province, China: 1) Daxinzhuang, 2) Liujiazhai, 3) Chengziya, and 4) Houzhangda. We found that the kneeling facet is ubiquitous in Bronze Age individuals. No significant difference of the frequency is observed either between the sexes or among the owner of different levels of tombs; and the kneeling facet is more obvious within advancement of aging.

[333] The Stone-Construction Tombs of Xiaguanzi in Maxian County, and the Question of Cultural Contact throughout Western China

Xiaguanzi site in Maxian County, located at the junction of the upper reaches of Min and Fu Rivers, is an important node on the channels of culture transmission between North and South China. From 2014 to 2015, Neolithic remains and stone-constructed tombs were excavated. The Neolithic remains include pottery, stone and bone artifacts, leather objects, animal bones, plant seeds, house remains, tombs, and ash pits. Although there no painted pottery occurred at Xiaguanzi, the pottery found here is very similar to Neolithic finds from the upper reaches of the Min River. This is the first time that stone-constructed graves have been found in the upper reaches of the Min River. These stone-constructed graves are larger in size than the typical local stone-cist graves, and they are furthermore influenced by the Han culture. Based on stratigraphic evidence and the object types found in the graves, they can be dated to the early Western and the late Eastern Han, making them much later than previous finds in the region. The discoveries from Xiaguanzi are therefore very important for establishing the local chronology and developmental sequence of stone tombs in the Min River Valley and surrounding areas.

[92] Bioarchaeological Assemblages at Çatalhöyük: A Relational Examination of Porotic Hyperostosis and Cribra Orbitalia Etiologies and Transmissions

Porotic hyperostosis, manifested as pittings on the outer table of the cranial vault, and cribra orbitalia, the analogous porosities that form on orbital roofs, are two commonly observed pathologies used extensively by bioarchaeologists to understand past health and nutritional conditions. Yet the etiologies of porotic hyperostosis and cribra orbitalia are largely varied and not well understood, with proposed explanations ranging from diet and nutrition to chronic infectious diseases. This paper exists to: 1) create a novel theoretical framework to holistically examine porotic hyperostosis and cribra orbitalia etiologies, and 2) apply the theoretical model to bioarchaeological data gathered from Çatalhöyük, Turkey in order to arrive at an extended evolutionary understanding of disease transmission. I draw upon relational theories to reconsider etiologies not as distinct prongs, but as an integrated assemblage of the body, pathology, and environment. Furthermore, I show how a fuller incorporation of social and cultural behaviors into the porotic hyperostosis and cribra orbitalia etiologic models helps explain the static rates of the lesions over time, despite increasing population growth. I conclude by articulating the need for archaeologists to incorporate the wide range of factors influencing inheritance so that more comprehensive models for disease ecology can be constructed.

[115] Health and Stress of Neolithic Yangshao Culture Skeletal Population from Wanggou Site, Zhengzhou

The Wanggou site, located in the Lower Yellow River valley, is a large Yangshao culture cemetery, dating to 7000–5000 BP. Two hundred and eleven skeletons were examined for variations from normal morphology, including nonmetric traits, to characterized pathology of the Neolithic Age residents of Central China. This study aims to use ancient DNA techniques to characterize the genetic features of ancient domesticated cattle in order to trace the origin and spread of cattle in ancient China from eight Late Neolithic and Bronze Age sites in Northern China. DNA was successfully extracted from ancient cattle bone or tooth samples in dedicated ancient DNA labs following rigorous protocols for contamination controls. This study was focused on amplifying mitochondrial D-loop using standard PCR techniques. Among the obtained mtDNA sequences, several haplogroups could be identified including haplogroup C, which belongs to Bos primigenius. Our analysis indicated that there were different ways cattle might have been brought into China. In addition, this study also demonstrated the unique contribution that ancient DNA analysis can make, when combined with archaeological contexts, to our understanding of the origin and history of domesticated animals and to the reconstruction of human-animal interactions in the past.

Interpretation of “Figure with Green Facial Expression” Unearthed in Pit No.2 at Emperor Qinshihuang’s Mausoleum Site Museum

There are various opinions about this kneeling archer which was unearthed in Pit No.2 at Emperor Qinshihuang’s Mausoleum Site Museum known as the “Figure with Green Facial Expression.” This paper holds a view that it should be called the “Figure with Cyan Facial Expression”; and combined with the ideational and cultural backgrounds and perception of colors, so to express the humanity and politics of Chinese color theory under the influence of Yin-Yang and Five-element thoughts. Seen from the original meaning of “cyan,” it gives warriors a sense of youthful vigor. Analyzed from the point of color psychology, “cyan” means humanistic property which shows the inner personality of warriors, such as loyalty, education and cautiousness. In addition, the “figure with cyan facial expression” is a reflection of color diversity used in the art fabrication of terracotta warriors.

Preliminary Investigation of Health and Stress in a Human Skeletal Population of Liangzhu Culture from Jiangzhuang Site, Xinghua, Jiangsu

This present study investigates human skeletal remains (N = 108) of Jiangzhuang site from Xinghua, Jiangsu, China. Jiangzhuang, dated to the Liangzhu Culture (ca. 3400–2250 BC), provides a unique opportunity to explore the stress and lifeways of ancient people from the Neolithic rice agricultural community in East China, since the preservation of human remains is very rare due to the acidic soils of the region. Multiple skeletal indicators of stress were examined including oral pathologies, nonspecific indicators of nutritional and physiological disturbance (cribra orbitalia, linear enamel hypoplasia, osteoperiostitis, and activity-related osseous manifestations (osteoarthritides and enthesal changes). In conjunction with other lines of bioarchaeological evidence (stable isotopic and aDNA analyses), our results suggest that health was adversely affected in several ways, particularly considering the high percentage of pathological indicators indicating physical stress. However, dental health was relatively good overall testifying the low-starch rice agriculture. This study adds to our growing understanding of the ways in which the transition to a rice agriculture changed stress exposure and lifeways of the people of Jiangzhuang in Neolithic East China.

Site Formation Analysis of Middle Stone Age Locality GaJj17 in the Koobi Fora Formation, Northern Kenya

The Koobi Fora Formation (KF Fm.) of the Turkana Basin in Kenya is comprised of a Plio-Pleistocene sedimentary sequence that has produced unprecedented paleoanthropological discoveries. Previous work in the KF Fm. reported an archaeological locality, GaJj17, exhibiting in situ Middle Stone Age (MSA) material eroding from an indurated sandstone. Understanding the depositional context of this locality required further geologic study as few MSA localities are represented in the KF Fm. This is due to the extensive unconformity between the youngest Mbr. of the KF Fm., (Chari Mbr. <1.39 Ma) and the overlying Galana Boi Fm., (<10 ka). Renewed excavations at GaJj17 allowed for sedimentary facies analyses, revealing associated aeolian and fluvial lithofacies. We further evaluate the depositional history of the archaeological horizon using standard fabric analysis of archaeological materials. Geochronological studies were also conducted (e.g., optical stimulated luminescence (OSL) and radiocarbon). Performing the geochemical (XRF) identification of a tuff that underlies the archaeological horizon provides further geochronological control. Mineralogical and petrographic studies of the surrounding sediments provide an understanding of the depositional context and sediment provenance. This research was supported by the NSF International Research Experience for Students (OISE 1358178 and 1358200).

New Approaches to Study Health and Disease in the Pecrolonial Circum-Caribbean

The most frequent pathologies found throughout the circum-Caribbean before arrival of the Europeans are dental and periodontal diseases. To date, ancient oral health has been studied using a variety of techniques, and recently ancient DNA (aDNA) analysis of dental calculus (calcified plaque) has shown great promise in revealing not only (oral) health and disease, but also diet and the composition of the oral microbiome over archaeological timescales. In this paper, we present ancient metagenomic data generated from human dental calculus from multiple archaeological sites in the circum-Caribbean. We compare the phylogenetic and taxonomic composition of precolonial oral microbiomes to modern dental calculus samples and find that the microbial composition of the precolonial Caribbean oral microbiome is similar to that of present-day populations. Our findings also shed light on the oral health and disease of indigenous communities before European contact.

**[177]** *Maya Peasantry: Crop Diversity Past and Present*  
For several years, peasant communities on the Yucatán Peninsula, Mexico, have not produced high enough maize-yields to sustain populations in the area. This is despite the fact that modern-day demographics are considerably lower than population estimates for the heights of Maya cultural development during the precolombian era. Some scholars have argued that maize was not the sole staple for the ancient Maya. Root and tree crops are among the candidates for alternative staples given their productive potential and adaptation to the tropical conditions of the Yucatán Peninsula. A review of ethnographic as well as archaeological and ethnohistoric sources regarding Maya dietary patterns provides a picture of inconsistencies and temporal dissociations. On the other hand, recent advances in paleoenthbotany promise to provide more direct clues on alternative crops that had been successfully cultivated in the past. A better understanding of the role of maize within ancient Maya diet would allow us inform present day policies and decision-making processes. I argue that the archaeological record can contribute to the knowledge upon which a dialogue between scholars, politicians, and Maya farmers will be found to improve the living-conditions of the latter and increase the level of dietary auto-sufficiency in the area.

**[225]** *The Anahuatl Pectorals from the Offerings of the Great Temple of Tenochtitlan*  
The anahuatl pectoral is one of the shell ornaments that have been found in the offerings of the great temple of Tenochtitlan. In paintings and sculptures, it is worn by Tezcatlipoca and deities that are stars and warriors, as Tlahuizcalpantecuhtli and Mixcoatl. Inside the offerings, the anahuatl are associated to items related to the underworld, sacrifice and war. This has led to propose that these pectorals represented the stars, which were the warriors during the night. The presence of the anahuatl pectorals in the tenochca offerings dates back to constructive stage IVb (AD 1469–1489), when a tenochca style of manufacturing shell objects is created. By this time, these pieces were always made of Pinctada maxatlanica shells, which were abraded with basalt stone and cut and decorated with obsidian tools. Nevertheless, in offerings excavated recently that correspond to constructive stage VI (AD 1489–1502), anahuatl pectorals have been found made with different tools and even of fresh water mussels. In this paper some possible explanations to these changes are presented.
The Initial Upper Paleolithic of Northern Mongolia: Site Function, Mobility, and Assemblage Plasticity

In the broadest sense, the term Initial Upper Paleolithic refers to archaeological assemblages that, without being necessarily 'transitional,' combine retained Middle Paleolithic and derived Upper Paleolithic features. Here, we present an assemblage that documents such a phenomenon at the site of Tolbor 16, northern Mongolia. Although we suggest that the layer 7b can be assigned to the northeast Asian variant of the IUP, a detailed analysis and the use of a narrow definition highlights some aspects of the technical systems as being subject to functional plasticity. For example, measured frequencies of MP tool types and blade blanks may not exclusively represent an evolutionary stage, but also reflect patterns of recycling and export. With a lack of well-preserved fauna, the lithic assemblage could then be used as a proxy to address issues of preservation bias, spatial distribution and site function. By comparing our results with other examples from the Tolbor Valley and from Siberia, we discuss how settlement patterns influence our understanding of the IUP phenomenon and its evolution. Our observations suggest that, while plasticity may affect our ability to recognize IUP, the technological structure of lithic assemblages remains surprisingly consistent.

Sculpting a Mississippian Aztalan: A Landscape Perspective

The culmination of over a century of research at the Aztalan site in south-central Wisconsin has highlighted the drastic extent of landscape modification by the site's inhabitants. Notably, with the arrival of Middle Mississippian by the end of the eleventh century AD these modifications included construction of earthen platform mounds, formal plazas, and landscape reclamation. Utilizing publicly available lidar derived surface data for Jefferson County, Wisconsin, this poster presents a summary of the terrain and morphometric analyses of the site and its surrounding environs. The analysis of the landscape along the Crawfish River Valley adjacent to the site aims to further underscore the scale of landscape modifications associated with the socioreligious practices of Middle Mississippian populations in the Eastern Woodlands.
